- Power supply monitoring with redundant low-voltage detectors, single high-voltage detectors, and internal ADC connection to check the internal voltages during application
- Robust clock monitoring, including PLL loss of lock detection
- Embedded flash memory with ECC (single-bit data correction, double-bit data detection) and address encoding (parallel address path check)
- System RAM with ECC
  - Single-bit data correction
  - Double-bit data detection

  - Address detection
- Cortex-M7 cache memories with ECC (single-bit data correction, double-bit data detection)
- Peripherals memories (EMAC, FlexCAN) with ECC (single-bit data correction, double-bit data detection)
- End-to-End EDC (E2E EDC), with address encoding and monitoring of the control signals done by a dedicated module (XBIC). This ensures the safety of storage and of the data path to the internal storage (RAM, flash memory, core cache) and peripherals across the crossbar switch. See the XBIC chapter for details.
- Hardware CRC module that supports end-to-end data check integrity for any data transfer in the system (SRAM to peripherals via DMA transfer, external interfaces to SRAM/peripherals, and so on)
- Cortex-M7 MPUs
- XRDC for memory and peripheral protection
- AIPS_Lite peripheral protection with trusted master-slave connection
- Register protection mechanism for safety-critical registers
- On-chip temperature sensor for temperature monitoring
- Self-test:
  - LBIST to detect latent faults in functional logic as well as in safety integrity mechanisms

NOTE

LBIST is not supported in MWCT2016S and MWCT2015S.

  - MBIST to ensure integrity of the memories in the chip (SRAM, ITCM, DTCM, peripheral memories, and so on)
  - Check-the-checker software library
  - ADC self-test
- FCCU for error collection and reaction, including reporting error status to system; FCCU supports these programmable reaction types:
  - Interrupt
  - Functional reset
- Error pads indicate the chip's internal state to the external chip interface or SBC.
- EIM to inject errors into the memories and interface gaskets to verify the error-detection features of the memory controllers and the interface gaskets
- ERM to collect diagnostic information from memory controllers in case of an error event

46.3 I/O peripherals

The arrangement of I/O peripherals across peripheral bridges allows redundant use of peripherals while limiting possible causes of CCF. Redundant use includes using equivalent peripherals in a replicated way as well as using functionally different peripherals in, for example, feedback measurement loops. Comparison of redundant operation is the responsibility of the application software, not the safety hardware mechanism.

The peripherals are distributed evenly across the peripheral bridges (AIPS*n*), except for singular modules like EMAC, QuadSPI, and so on.

NOTE

EMAC and QuadSPI are not present in MWCT2016S and MWCT2015S.

46.4 Self-test

The chip supports a self-test operation. Your safety software must initiate self-test by configuring STCU2; the chip does not initiate it. STCU2 then controls the self-test operation. Self-test supports both MBIST and LBIST. After the self-test operation completes, the chip enters a reset sequence. Self-test results are stored in STCU2 and your safety software can read the results after the reset sequence.

Figure 178 depicts the processing steps related to the self-test operation, and its linkage to the chip reset and an application start. You decide whether to run a self-test or to skip it before starting an application. You must also specify the self-test configuration before relinquishing control to STCU2 for performing the self-test operation. This processing finishes by reentering the chip reset sequence, depending on whether the chip encountered an unrecoverable fault during the self-test operation. When an unrecoverable fault is encountered during the self-test operation, the chip enters a reset sequence by performing a destructive reset. When no such fault is encountered, the self-test operation completes by entering the chip sequence with a functional reset sequence. You can prevent reset cycling by limiting the amount of resets permitted; the chip shuts down when this limit has been reached. See the "Functional reset escalation" and "Destructive reset escalation" sections in the MC_RGM chapter.

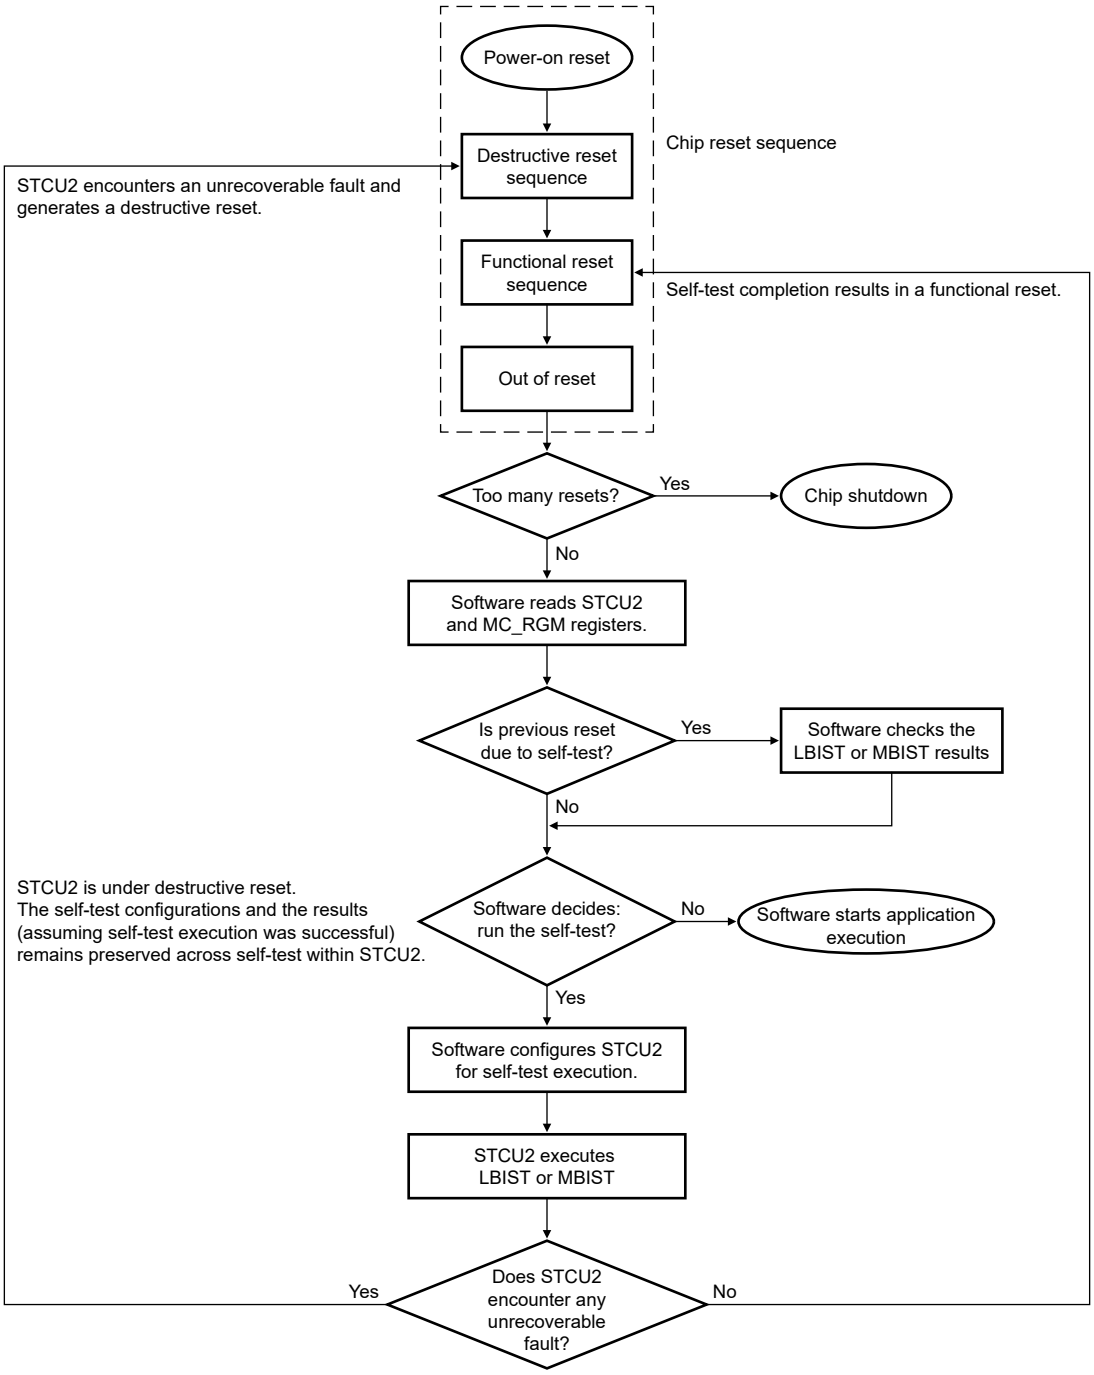

Figure 178. LBIST/MBIST execution

Figure 179 visualizes the top-level partitioning of the chip. The chip consists of two partitions, Run and Standby.

- Run: This partition consists of logic which is present in switchable domain and is shut off (has no supply) while the chip operates in low-power (Standby) mode.
- Standby: This partition consists of always-on logic which is functional even while the chip operates In low-power (Standby) mode.

The Run partition also contains the control logic that is essential for the chip self-test operation, as well as blocks that undergo self-test. The chip consists of a single LBIST partition, which is a subpartition within the Run partition. The LBIST subpartition

contains the logic over which self-test is executed. The logic outside the LBIST subpartition and within the Run partition consists of the LBIST control logic as well as logic which does not undergo LBIST.

The components within these different partitions are listed below the figure (they are not indicated in the figure for clarity).

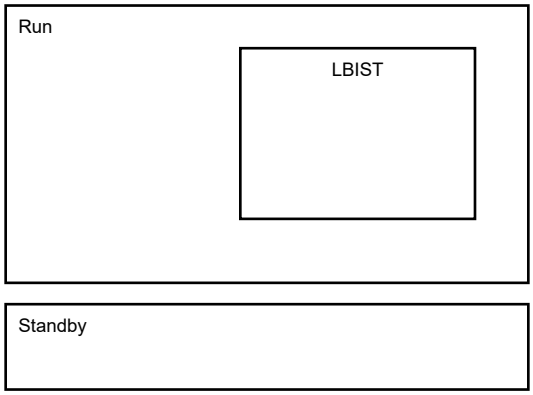

Figure 179. MWCT2D17S chip top-level partition view

The following list specifies the content of the LBIST partition and both power domains related to their participation in the self-test operation:

- Modules participating in the LBIST operation:

  NOTE

  LBIST is not supported in MWCT2016S and MWCT2015S. The modules participating in the LBIST operation are out of LBIST in MWCT2016S and MWCT2015S.

  — eDMA
  — EIM
  — ERM
  — XRDC
    - MDAC0 (Cortex-M7_0)
    - MDAC1 (eDMA)
    - MDAC2 (reserved)
    - MDAC3 (HSE_B)
    - MDAC4 (Cortex-M7_1)
    - MDAC5 (EMAC)
    - MRC0 (flash memory)
    - MRC1 (PRAM)
    - MRC2 (QuadSPI)

      NOTE

      Cortex-M7, EMAC, and QuadSPI are not present in MWCT2016S and MWCT2015S.

    - PDAC1
    - PDAC2
  — CRC
  — FCCU

- FOSU
- PFLASH_CTL
- PRAM_C0
- PRAM_C1
- SWT_1
- CMU
  - CMU_FC_0
  - CMU_FM_1
  - CMU_FM_2
  - CMU_FC_3
  - CMU_FC_4
  - CMU_FC_5
- IAHB gaskets

NOTE

An IAHB gasket is a frequency translation gasket in the system. These gaskets are used to add register walls and synchronize the timing domain across different operating frequencies. See the configurable gaskets in the 'Block diagram' in 'Introduction' chapter for the locations of the IAHB_GASKETs in the chip.

  - DMA_GSKT
  - HSE_GSKT
  - AIPS1_GSKT
  - AIPS2_GSKT
  - QSPI_GSKT

NOTE

AIPS2_GSKT and QSPI_GSKT are not present in MWCT2016S and MWCT2015S.

  - TCM_GSKT
  - EMAC_GSKT
  - EDC master checker gaskets (See block diagram in Introduction chapter for details)
  - EDC slave checker gasket (See block diagram in Introduction chapter for details)
- Crossbar switches and bridges
  - AXBS_0 (main)
  - AXBS_1 (peripheral)
  - AXBS_2 (eDMA)
  - AXBS_3 (Cortex-M7 TCM)
  - AXBS_4 (HSE)
  - AIPS_Lite_1
  - AIPS_Lite_2

NOTE

AIPS2_Lite_ is not present in MWCT2016S and MWCT2015S.

- Modules within the Standby domain (not participating in the LBIST operation):
  - 32 KB standby SRAM
  - LPCMP_0–LPCMP_2
  - Reset generation
    - MC_RGM
    - POR_WDG
  - Power management
    - PMC
    - MC_PCU
    - WKPU
    - Chip standby pins
  - Clock sources
    - FIRC
    - SIRC
    - FXOSC
    - SXOSC

NOTE

SXOSC is not present in MWCT2015S.

  - Timers
    - PIT_0
    - RTC
    - SWT_0
- Modules not participating in the LBIST operation (in the Run domain):
  - HSE subsystem
    - Engine
    - Memories
  - Cortex-M7_0
    - Core
    - I-cache
    - D-cache
    - ITCM
    - DTCM
  - Cortex-M7_1

NOTE

Cortex-M7_1 is not present in MWCT2016S and MWCT2015S.

    - Core
    - I-cache

- D-cache
- ITCM
- DTCM

— CMUs
- CMU0
- CMU3

— Analog blocks
- ADC_0–ADC_2
- TempSense

NOTE

ADC_2 is not present in MWCT2D16S, MWCT2016S, and MWCT2015S.

— Communication modules
- LPSPI_0–LPSPI_5
- LPI2C_0
- LPI2C_1
- LPUART_0–LPUART_15
- FlexCAN_0–FlexCAN_5
- SAI_0
- SAI_1

NOTE

SAI_0 and SAI_1 are not present in MWCT2016S and MWCT2015S.

— Timers
- PIT_1
- PIT_2
- eMIOS
- BCTU
- STM_0
- STM_1

NOTE

PIT_2 and STM_1 are not present in MWCT2016S and MWCT2015S.

— TRGMUX

— PLLDIG

— SIUL2

— LCU_0

— LCU_1

— STCU2

— DMAMUX

— MCM

— MCSM

— INTM

— SEMA42

— MU

NOTE

SEMA42 and chip MU are not present in MWCT2016S and MWCT2015S.

— TSPC

NOTE

REG_PROT of an IP undergoes (or does not undergo) LBIST in conjunction with the protected module that undergoes (or does not undergo) LBIST.

The modules that are vital to the self-test operation are excluded from LBIST regions to allow LBIST to execute successfully.

You must run self-test with PLLDIG configured as the system clock. The LBIST clock controller controls the clock during serial shift, but returns clock control to the functional nodes during the self-test.

46.5 Glossary

ASIL Automotive safety integrity level. This is a risk classification scheme as defined by ISO 26262 for automotive standard.

CCF Common cause failure

DTCM Data tightly coupled memory

ECC Error correction code

ITCM Instruction tightly coupled memory

LBIST Logic built-in self-test

MBIST Memory built-in self-test

PLL Phase-locked loop oscillator

PMIC Power management integrated chip

SBC System basis chip

Chapter 47
Error Injection Module (EIM)

47.1 Chip-specific EIM information

47.1.1 EIM instances

This chip supports up to four instances of EIM:

- EIM_0
- EIM_1
- EIM_2
- EIM_3

Table 219. EIM instances

Instances	MWCT2D16S/MWCT2D17S/MWCT2016S/MWCT2015S/MWCT2014S
EIM_0	Yes
EIM_1	No
EIM_2	No
EIM_3	No

47.1.2 EIM channel mapping

EIM integrates with the memory controller and memory array to enable error injection in a controlled way. Each memory controller has its own EIM channel.

Cortex-M7_1, EMAC, AIPS2 gasket, Cortex-M7 lockstep, and QuadSPI gasket are not available in the MWCT2016S and MWCT2015S product variants of the MWCT family.

Table 220. EIM channel mapping - MWCT2015S, MWCT2x16S, MWCT2D17S

Channel #	Target	Data bits [1]	Check bits[1]	# of data bits	# of check bits
0	SRAM0	Word1[31:0] – SRAM0 read data[63:32]	Word0[31:24] – SRAM0 read data ECC[7:0]	64	8
		Word2[31:0] – SRAM0 read data[31:0]			
1	SRAM1[2]	Word1[31:0] – SRAM1 read data[63:32]	Word0[31:24] SRAM1 read data ECC[7:0]	64	8
		Word2[31:0] – SRAM1 read data[31:0]			
2	DMA TCD	Word1[31:0] – DMA TCD RAM read data[63:32]	Word0[31:24] DMA TCD RAM read data checkbits[7:0]	64	8
		Word2[31:0] – DMA TCD RAM read data[31:0]

1. You must write to EICHDi_WORDj registers to inject errors in the desired data and check bits. For details, see tables "Error injection channel descriptor: DATA_MASK details" and "DATA_MASK bit: Channel-word mapping" in this chapter.
2. SRAM1 is not available for the MWCT2D16S, MWCT2016S, and MWCT2015S variants.
3. Applicable for MWCT2D16S only.

The two enables, GEIEN and EICHEN*n*, enable the error injection functionality. The former enables it globally and the latter does it for a particular channel. This double-layer enable provides protection against accidental enabling and reconfiguration of the error injection function for each channel.

EIM provides support for inducing single-bit and multi-bit inversions on read data when accessing peripheral RAMs through its data mask registers.

NOTE

For enabling error injection on EDC gaskets (corresponding to channel 28, channel 29, and channel 30), you must also enable the fields corresponding to the required EDC gasket in the MSCM_ENEDC register before enabling the EIM channel.

EIM_EICHD1_CH01, EIM_EICHD1_CH08, EIM_EICHD1_CH09, EIM_EICHD1_CH10, EIM_EICHD1_CH11, EIM_EICHD1_CH12, EIM_EICHD1_CH16, EIM_EICHD1_CH17, EIM_EICHD1_CH18, EIM_EICHD1_CH19, EIM_EICHD1_CH21, EIM_EICHD1_CH22, EIM_EICHD1_CH24, EIM_EICHD1_CH26, EIM_EICHD1_CH27 are not present in MWCT2016S, hence the registers corresponding to these channels are also not present in MWCT2016S.

47.1.3 Behavior of EIM error injection on gaskets

The error injection on gaskets don't impact the actual data flow. The gasket read data, write data and the monitor error don't get changed when EIM error injection is done. The gasket compares the actual data with the modified data (with error injection) and flags the gasket alarm. In case of single-bit error also, the alarm is flagged.

The channels which depict such behavior are the gasket channels listed below:

- Channel 19: GMAC/EMAC gasket
- Channel 20: Cortex-M7 TCM gasket
- Channel 21: DMA AXBS S0 gasket
- Channel 22: DMA AXBS S1 gasket
- Channel 23: HSE gasket
- Channel 24: QuadSPI gasket

- Channel 25: AIPS1 gasket
- Channel 26: AIPS2 gasket

47.2 Overview

The Error Injection Module (EIM) is mainly used for diagnostic purposes. It provides a method for diagnostic coverage of internal memories (for example, system RAM, cache RAMs, and peripheral memories). See the chip-specific EIM information to determine which functional safety features are supported by this method.

EIM enables you to induce artificial errors on error-checking mechanisms of a system, such as ECC for RAM read data and parity bits. For each such mechanism that EIM supports on the chip, EIM can inject single-bit and multi-bit inversions on data in the applicable target bus. Injecting faults on memory accesses can be used to exercise the SEC-DED ECC function of the related system.

47.2.1 Features

The EIM includes these features:

- Supports 31 error injection channels. See the chip-specific EIM information for channel assignment details.
- Protection against accidental enable and reconfiguration error injection function via two-stage enable mechanism

47.2.2 Block diagram

The following diagram shows an example of EIM implementation with a 64-bit read data bus and an 8-bit checkbit bus.

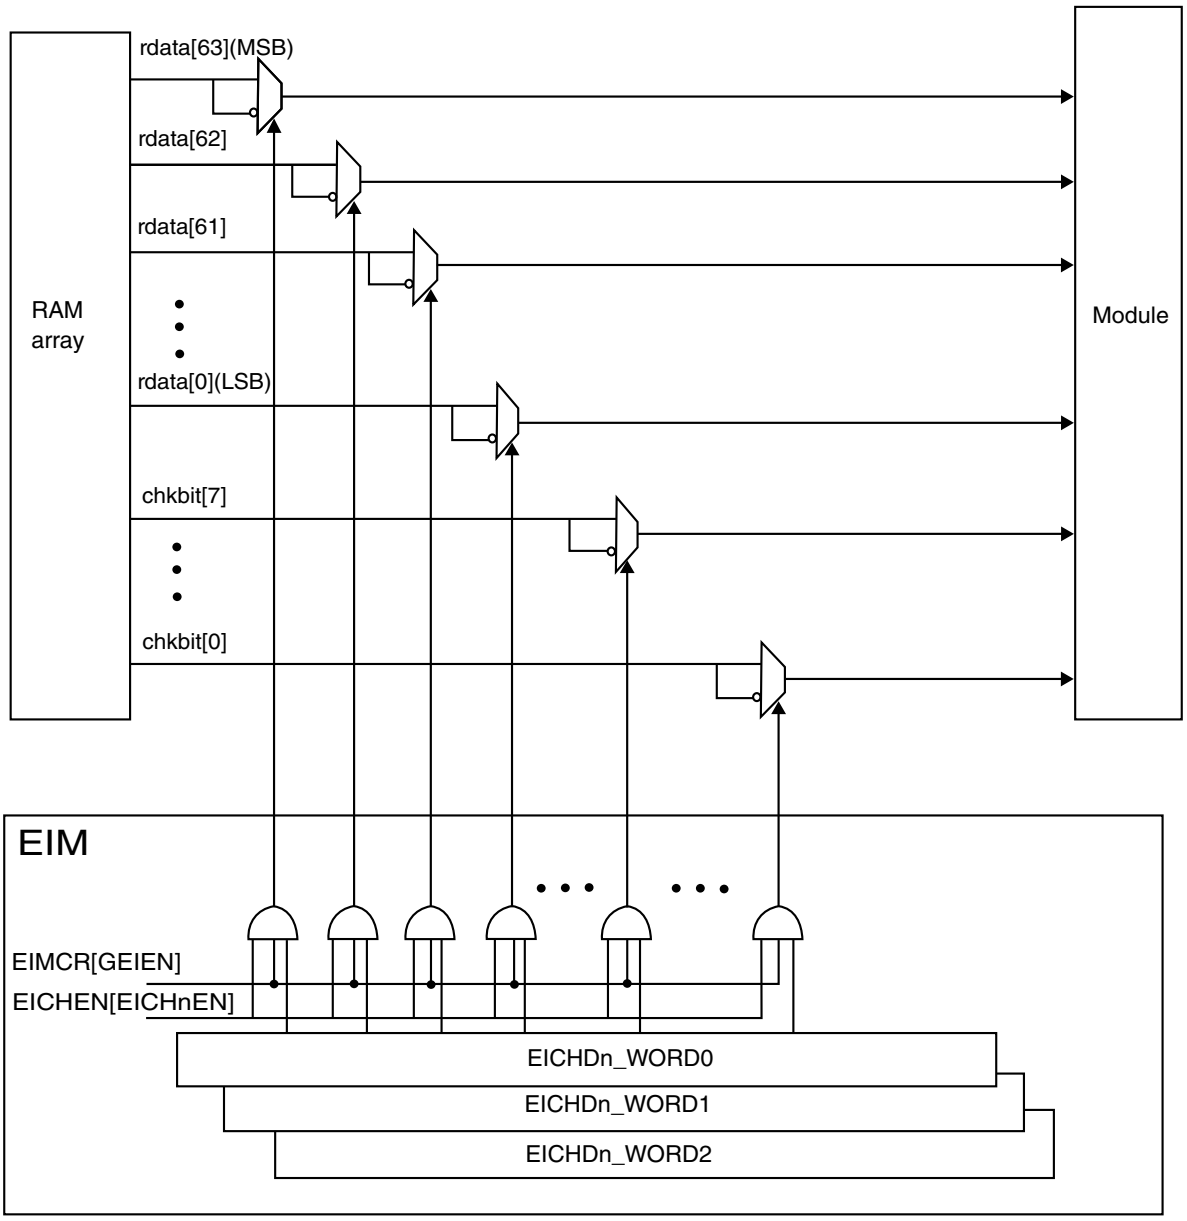

Figure 180. EIM functional block diagram (64-bit read data bus and 8-bit check bit bus)

Several memory elements are implemented within a device, which may not only be the large memory blocks (Flash and SRAM) but also smaller memories like caches, the TCD blocks, and the embedded peripheral memories. Some larger memories may actually be built from multiple memory elements, dependent on their size or function. Each of these memory elements implements its own control logic, the memory controller, that performs the accesses to the actual memory, the memory array. An EIM channel is associated with a memory controller and provides the capability to alter one or multiple signals in the read access path from the corresponding memory array(s). Only memory controllers controlling a safety related memory may be associated with an EIM channel.

47.3 Functional description

The EIM provides protection against accidental enabling and reconfiguration of the error injection function by enforcing a two-stage enablement mechanism. To properly enable the error injection mechanism for a channel:

- Write 1 to the EICHEN[EICH*n*EN] field, where *n* denotes the channel number.

- Write 1 to EIMCR[GEIEN].

NOTE

When the use case for a channel requires writing any EICHD*n*_WORD register, write the EICHD*n*_WORD register before executing the two-stage enablement mechanism. A successful write to any EICHD*n*_WORD register clears the corresponding EICHEN[EICH*n*EN] field.

The EIM supports 31 error injection channels. See the chip-specific EIM information for channel assignment details. Each channel:

- Can be assigned to a single memory array interface by intercepting the assigned memory read data bus and checkbit bus, and injects errors by inverting the value transmitted for selected bits on each bus line.
- Can be assigned to a redundant comparison unit by intercepting the signals being compared, and injecting errors by inverting the value transmitted for selected bits on each bus line.

On a memory read access, the applicable EICHD*n*_WORD registers define which bits of the read data and/or checkbit bus to invert.

Figure 180 depicts the interception and override of a 64-bit read data bus and an 8-bit checkbit data bus for an example memory array.

Error injection scenarios

The EIM supports these cases of error injection:

- To generate a single-bit error, invert only 1 bit of the CHKBIT_MASK or DATA_MASK in the EICHD*n*_WORD registers.
- To generate a multi-bit error, invert only 2 bits of the CHKBIT_MASK or DATA_MASK in the EICHD*n*_WORD registers.

NOTE

An attempt to invert more than 2 bits in one operation might result in undefined behavior.

47.4 EIM register descriptions

The EIM provides a programming model mapped to an on-platform peripheral slot.

Programming model access

All system bus masters can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes
- To undefined (reserved) addresses

Attempted updates to the programming model while the EIM is in the midst of an operation result in non-deterministic behavior.

Error injection channel descriptor: function and structure

Each error injection channel descriptor:

- Specifies a mask that defines which bits of the read data and/or checkbit bus from target RAM are inverted on a read access.
- Consists of a 288-bit (36-byte) structure, composed of nine 32-bit words, in the EIM programming model. Unused words are not documented.
  - Word0 (EICHD*n*_WORD0), if present, defines the checkbit mask.

— Word1 (EICHD*n*_WORD1) and additional words, if present, define the data mask. Word registers subsequent to Word1 are present only when required by the total width of the channel's data mask. Error injection channel descriptor: DATA_MASK details.

The multiple channel descriptors are organized sequentially.

Error injection channel descriptor: DATA_MASK details

For each channel: The following tables show the distribution of DATA_MASK's bits across the WORD registers. The first table shows the total width of DATA_MASK and the distribution of its bits across WORD1, WORD2, and WORD3. The second table shows the distribution of DATA_MASK's bits across WORD4 and subsequent registers.

Table 221. Error injection channel descriptor: DATA_MASK details

Channel	DATA_MASK total width (bits)	Specific bits of DATA_MASK in

47.4.3 Error Injection Channel Enable register (EICHEN)

Offset

Register	Offset
EICHEN	4h

Function

Each field of the Error Injection Channel Enable register (EICHEN) is used to enable or disable the corresponding error injection channel.

NOTE

To enable an error injection channel, the Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted.

Fields

Field	Function
31 EICH0EN	Error Injection Channel 0 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 0 1b - Error injection is enabled on Error Injection Channel 0
30 EICH1EN	Error Injection Channel 1 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 1 1b - Error injection is enabled on Error Injection Channel 1
29 EICH2EN	Error Injection Channel 2 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 2 1b - Error injection is enabled on Error Injection Channel 2
28 EICH3EN	Error Injection Channel 3 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. 0 —	Reserved

47.4.4 Error Injection Channel Descriptor n, Word0 (EICHD0_WORD0 - EICHD2_WORD0)

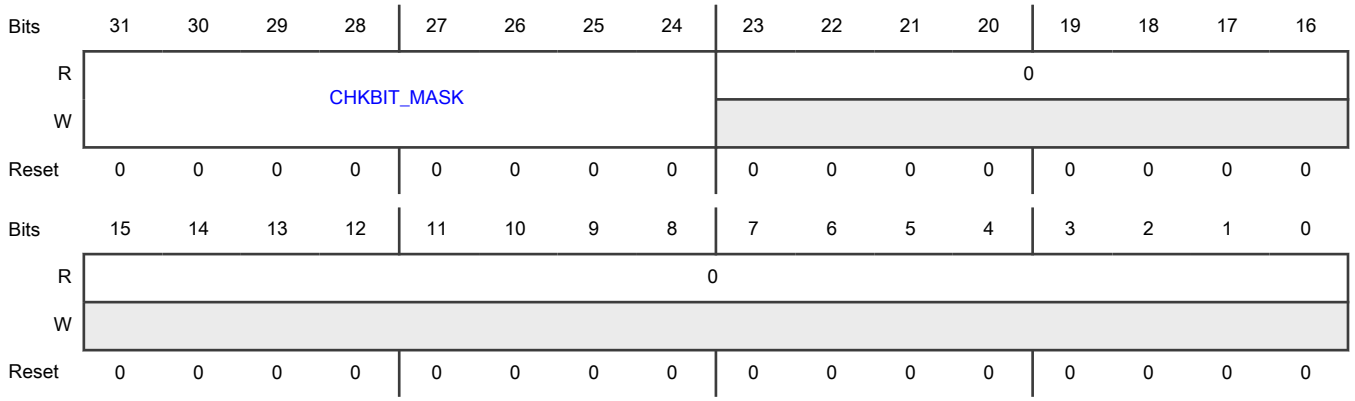
Offset

Register	Offset
EICHD0_WORD0	100h
EICHD1_WORD0	140h
EICHD2_WORD0	180h

Function

The first word of the Error Injection Channel Descriptor defines a left-justified mask field: CHKBIT_MASK. Each bit of CHKBIT_MASK specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified on read accesses. Successful write to this field clears the corresponding error injection channel valid bit, EICHEN[EICH*n*EN].

Diagram



Fields

Field	Function
31-24 CHKBIT_MASK	Checkbit Mask This field defines a bit-mapped mask that specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. For any unique details about the mapping of CHKBIT_MASK's bits to a channel's target RAM, see the chip-specific EIM information. **NOTE** Because CHKBIT_MASK is left-justified, the highest bit in the bit range is always in the position of the most significant bit. For CHKBIT_MASK[7:0] (8 bits wide), CHKBIT_MASK[7] is in the position of the most significant bit. 0b - The corresponding bit of the checkbit bus remains unmodified. 1b - The corresponding bit of the checkbit bus is inverted.
23-0 —	Reserved

47.4.5 Error Injection Channel Descriptor n, Word1 (EICHD0_WORD1 - EICHD2_WORD1)

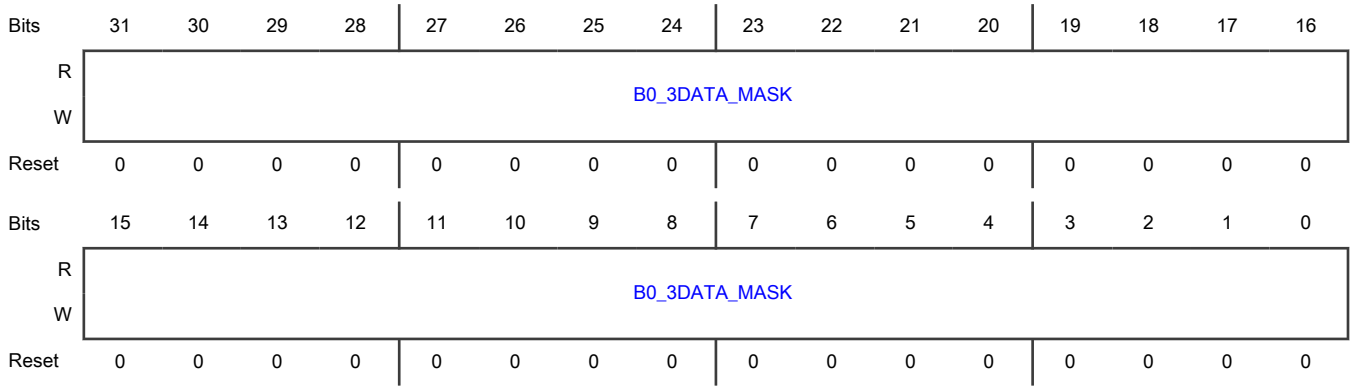
Offset

Register	Offset
EICHD0_WORD1	104h
EICHD1_WORD1	144h
EICHD2_WORD1	184h

Function

The second word of the Error Injection Channel Descriptor defines a right-justified mask field. The bits in B0_3DATA_MASK correspond to bytes 0–3 of the target bus. Each bit specifies whether the corresponding bit of the target bus should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

Diagram



Fields

Field	Function
31-0 B0_3DATA_MASK	Data Mask Bytes 0-3 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. **NOTE** For the specific DATA_MASK bits to which B0_3DATA_MASK corresponds, See Error injection channel descriptor: DATA_MASK details. 0b - The corresponding bit of bytes 0-3 on the read data bus remains unmodified. 1b - The corresponding bit of bytes 0-3 on the read data bus is inverted.

Fields

Field	Function
31-12 —	Reserved
11-0 B0_3DATA_MASK	Data Mask Bytes 0-3 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. **NOTE** For the specific DATA_MASK bits to which B0_3DATA_MASK corresponds, See Error injection channel descriptor: DATA_MASK details. 0b - The corresponding bit of bytes 0-3 on the read data bus remains unmodified. 1b - The corresponding bit of bytes 0-3 on the read data bus is inverted.

47.4.9 Error Injection Channel Descriptor 4, Word0 (EICHD4_WORD0)

Offset

Register	Offset
EICHD4_WORD0	200h

Function

The first word of the Error Injection Channel Descriptor defines a left-justified mask field: CHKBIT_MASK. Each bit of CHKBIT_MASK specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified on read accesses. Successful write to this field clears the corresponding error injection channel valid bit, EICHEN[EICH*n*EN].

23-0 B0_3DATA_MASK	Data Mask Bytes 0-3 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. **NOTE** For the specific DATA_MASK bits to which B0_3DATA_MASK corresponds, See Error injection channel descriptor: DATA_MASK details. 0b - The corresponding bit of bytes 0-3 on the read data bus remains unmodified. 1b - The corresponding bit of bytes 0-3 on the read data bus is inverted.

47.4.29 Error Injection Channel Descriptor n, Word1 (EICHD29_WORD1 - EICHD30_WORD1)

Offset

Register	Offset
EICHD29_WORD1	844h
EICHD30_WORD1	884h

Function

The second word of the Error Injection Channel Descriptor defines a right-justified mask field. The bits in B0_3DATA_MASK correspond to bytes 0–3 of the target bus. Each bit specifies whether the corresponding bit of the target bus should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

Chapter 48
Error Reporting Module (ERM)

48.1 Chip-specific ERM information

48.1.1 ERM instances

This chip supports up to two instances of ERM:

- ERM_0
- ERM_1

Table 223. ERM instances

Instances	MWCT2D16S/MWCT2D17S/MWCT2016S/MWCT2015S
ERM_0	Yes
ERM_1	No

48.1.2 ERM channel mapping

ERM provides information on memory events associated with ECC and parity. It also provides you an option to enable interrupt notification for these events.

Table 224. ERM_0 channel mapping

Channel #	Module	Captured status
00	SRAM0	Single-bit error, multi-bit error, syndrome, absolute error address aligned to double-word (64-bit) boundary
01	SRAM1 [1]	Single-bit error, multi-bit error, syndrome, absolute error address+18000h aligned to double-word (64-bit) boundary[2]
02	Cortex-M7_0 I-cache tag RAM	Single-bit error, multi-bit error[3]
03	Cortex-M7_0 I-cache data RAM	Single-bit error, multi-bit error[3]
04	Cortex-M7_0 D-cache tag RAM	Single-bit error, multi-bit error[3]
05	Cortex-M7_0 D-cache data RAM	Single-bit error, multi-bit error[3]
06	Cortex-M7_1 I-cache tag RAM [4]	Single-bit error, multi-bit error[3]
07	Cortex-M7_1 I-cache data RAM	Single-bit error, multi-bit error[3]
08	Cortex-M7_1 D-cache tag RAM	Single-bit error, multi-bit error[3]
09	Cortex-M7_1 D-cache data RAM	Single-bit error, multi-bit error[3]
10	Cortex-M7_0 ITCM	Single-bit error, multi-bit error, syndrome, offset error address
11	Cortex-M7_0 D0TCM	Single-bit error, multi-bit error, syndrome, offset error address
12	Cortex-M7_0 D1TCM	Single-bit error, multi-bit error, syndrome, offset error address[5]
13	Cortex-M7_1 ITCM	Single-bit error, multi-bit error, syndrome, offset error address
14	Cortex-M7_1 D0TCM	Single-bit error, multi-bit error, syndrome, offset error address

Table continues on the next page...

Table 224. ERM_0 channel mapping (continued)

Channel #	Module	Captured status
15	Cortex-M7_1 D1TCM	Single-bit error, multi-bit error, syndrome, offset error address[5]
16	DMA TCD	Single-bit error, multi-bit error, syndrome, offset error address[6]
17	Flash memory port p0	Single-bit error, multi-bit error, absolute error address
18	Flash memory port p1	Single-bit error, multi-bit error, absolute error address
19	Flash memory port p2 [7]	Single-bit error, multi-bit error, absolute error address

1. SRAM1 is not available for the MWCT2D16S, MWCT2016S, and MWCT2015S product variants.
2. The size of SRAM0 is 160 KB, and therefore, to align addresses to the next power of 2, an address space of 256 KB is reserved for error reporting. However, SRAM0 and SRAM1 are in contiguous locations in the memory map. So, you must subtract 18000h (256 KB-160 KB = 96 KB that corresponds to 18000h) from the reported address to get an absolute address. See the "Memory and Memory Interfaces" chapter for SRAM details on different MWCT2xxxS variants.
3. The cache controller does not report error addresses and syndrome.
4. Cortex-M7_1 and its associated RAM and caches are not available in the MWCT2016S and MWCT2015S product variants.
5. For address reporting, bit 2 of the address is masked because this bit decides whether the access (read or write) is for D0TCM or D1TCM. For example, if the offset address is 0h or 8h, it is routed to D0TCM, but if the offset address is 4h or Ch, it is routed to D1TCM. The errors that are latched for these offset addresses are as follows:
   - Offset 0h : Address 0h is latched into the ERM channel corresponding to D0TCM.
   - Offset 4h : Address 0h is latched into the ERM channel corresponding to D1TCM.
   - Offset 8h : Address 8h is latched into the ERM channel corresponding to D0TCM.
   - Offset Ch : Address 8h is latched into the ERM channel corresponding to D1TCM.
6. Bits [31:10] and [2:0] are always 0 because they are not connected.

   Bits [9:5] indicate the corresponding TCD out of all the 32 implemented TCDs.

   Bits [4:3] indicate an offset of TCDs with respect to a 64-bit aligned boundary.
   - If [4:3] is 00, it indicates that an error is on offset address 20h.
   - If [4:3] is 01, it indicates that an error is on offset address 28h.
   - If [4:3] is 10, it indicates that an error is on offset address 30h.
   - If [4:3] is 11, it indicates that an error is on offset address 38h.
7. Flash memory port p2 is not applicable for the MWCT2016S and MWCT2015S product variants.

Table 225. ERM_1 channel mapping

Channel #	Module	Captured status
0	SRAM2	Single-bit error, multi-bit error, syndrome, absolute error address aligned to double, word (64-bit) boundary

48.2 Overview

The Error Reporting Module (ERM) provides information and optional interrupt notification on memory error events associated with ECC and parity. The ERM collects error events on memory accesses for memory arrays, such as flash memory, system RAM, or peripheral RAMs. ERM supports various channels for memory sources where each ERM channel is associated with a different memory module. See the chip-specific ERM information for details about supported memory sources and specific memory channel assignments. If memory supports ECC then ERM syndrome and error address information is captured along with error event. ERM does not receive this information in case of cache or memory with parity along with error event.

48.2.1 Features

The ERM includes these features:

- Optional interrupt notification on captured error events
- Capturing of address and syndrome information on single-bit correction and non-correctable ECC events
- Support for error event capturing for memory sources, with individual reporting fields and interrupt configuration per memory channel
- Recording the count value of the number of corrected error events

48.3 Functional description

48.3.1 Single-bit correction events

When a single-bit correction event on Memory *n* is detected, the ERM:

- Records the event by changing the value of the applicable Status Register bit SR*x*[SBC*n*] to 1.

- Increments the correctable error count value (until the counter reaches its maximum value): CORR_ERR_CNT*n*[COUNT].
- Records the corresponding access address that initiated the event in the Memory *n* Error Address Register: EAR*n* (if this register is present for the channel).
- Stores the corresponding ECC syndrome in the Memory *n* Error Syndrome Register: SYN*n* (if this register is present for the channel). This register identifies the bit position of the corrected data on single-bit data inversion.

The ERM holds event information only for the last reported event.

To clear the record of an event, write 1 to SR*x*[SBC*n*] to change its value to 0.

To reset the correctable error count value, write all zeros to CORR_ERR_CNT*n*[COUNT].

Optional interrupt notification for single-bit correction events

The ERM provides an option to generate an interrupt notification upon the report of a single-bit correction event. This sequence describes how to use the option:

1. To enable interrupt notification for single-bit correction events on Memory *n*, set CR*x*[ESCIE*n*] to 1.
2. Subsequently, when a single-bit correction event on Memory *n* is detected, the ERM:
   - Records the event and address, and stores the ECC syndrome as usual.
   - Additionally sends an interrupt notification corresponding to the event.
3. To clear both the record of an event and the corresponding interrupt notification, write 1 to SR*x*[SBC*n*] to change its value to 0.

48.3.2 Non-correctable error events

When a non-correctable ECC error event on Memory *n* is detected, the ERM:

- Records the event by changing the value of the applicable Status Register bit: SR*x*[NCE*n*] to 1.
- Records the corresponding access address that initiated the event in the Memory *n* Error Address Register: EAR*n* (if this register is present for the channel).
- Stores the corresponding ECC syndrome in the Memory *n* Error Syndrome Register: SYN*n* (if this register is present for the channel).
  - In the event of a non-correctable address bit inversion, SYN*n* identifies the pertinent address bit position.
  - In the event of a non-correctable, multi-bit data inversion, the syndrome value does not provide any additional diagnostic information.

The ERM holds event information only for the last reported event.

To clear the record of an event, write 1 to SR*x*[NCE*n*] to change its value to 0.

Optional interrupt notification for non-correctable error events

The ERM provides an option to generate an interrupt notification upon the report of a non-correctable ECC event. This sequence describes how to use the option:

1. To enable interrupt notifications for non-correctable error events on Memory *n*, set CR*x*[ENCIE*n*] to 1.
2. Subsequently, when a non-correctable error event on Memory *n* is detected, the ERM:
   - Records the event and address and stores the ECC syndrome as usual.
   - Additionally sends an interrupt notification corresponding to the event.
3. To clear both the record of an event and the corresponding interrupt notification, write 1 to SR*x*[NCE*n*] to change its value to 0.

48.4 Initialization

For each ERM channel supporting memory with ECC, prepare the corresponding memory array before enabling ERM interrupts about errors for that memory.

1. Initialize the memory to a known value so that the correct corresponding ECC codeword is stored.
2. During the memory's initialization, if the ERM captures information about any ECC error event, clear the corresponding SR*x*[SBC*n*] or SR*x*[NCE*n*] field that stores the record of the event.
3. Program the applicable CR*x*[ESCIE*n*] and CR*x*[ENCIE*n*] fields to enable ERM interrupts as desired.

48.5 ERM register descriptions

You can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes

NOTE

See the chip-specific ERM information for details on Memory channel mapping.

48.5.8 ERM Memory a Error Address Register (EAR0 - EAR19)

Offset

Register	Offset
EAR0	100h

Table continues on the next page...

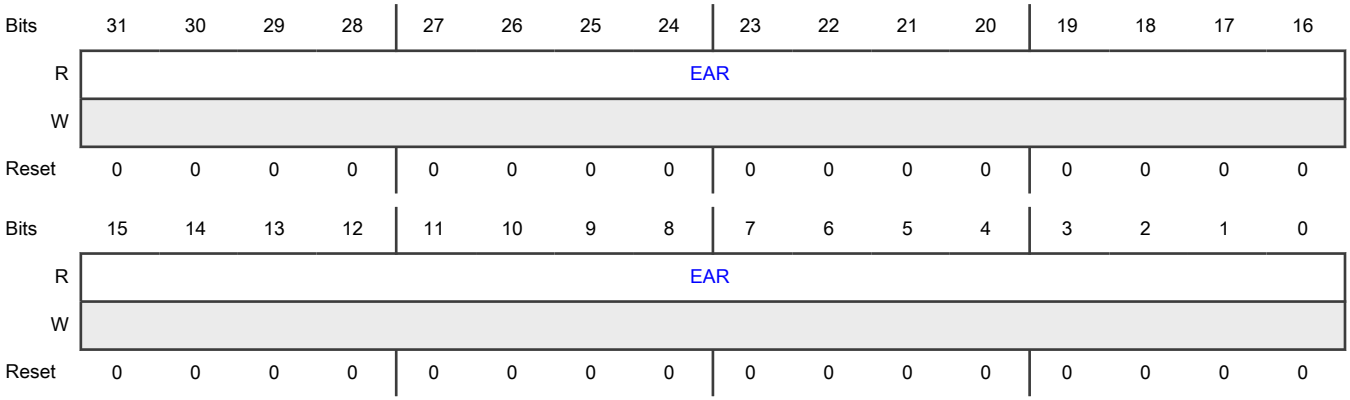
Table continued from the previous page...

Register	Offset
EAR1	110h
EAR10	1A0h
EAR11	1B0h
EAR12	1C0h
EAR13	1D0h
EAR14	1E0h
EAR15	1F0h
EAR16	200h
EAR17	210h
EAR18	220h
EAR19	230h

Function

Each ERM Memory n Error Address Register is a 32-bit register for capturing the address of the last ECC event in Memory *n*, where *n* denotes the memory channel. Any attempted write to EAR*n* is ignored.

Diagram



Fields

Field	Function
31-0 EAR	EAR Memory *n* Error Address — This field contains the faulting system address of the last recorded ECC event on Memory *n*.

48.5.9 ERM Memory a Syndrome Register (SYN0 - SYN16)

Offset

Register	Offset
SYN0	104h
SYN1	114h
SYN10	1A4h
SYN11	1B4h
SYN12	1C4h
SYN13	1D4h
SYN14	1E4h
SYN15	1F4h
SYN16	204h

Function

The ERM Memory n Syndrome Register is a 32-bit register for capturing the calculated syndrome of the last ECC event on Memory *n*, where *n* denotes the memory channel. Any attempted write to SYN*n* is ignored. The syndrome value identifies the pertinent bit position on a correctable, single-bit data inversion or a non-correctable, single-bit address inversion. The syndrome value does not provide any additional diagnostic information on non-correctable, multi-bit inversions.

Field	Function
31-24 SYNDROME	SYNDROME Memory *n* Syndrome — This field contains the ECC syndrome associated with the last recorded ECC event on Memory *n*.
23-0 —	Reserved

48.5.10 ERM Memory a Correctable Error Count Register (CORR_ERR_CNT0 - CORR_ERR_CNT19)

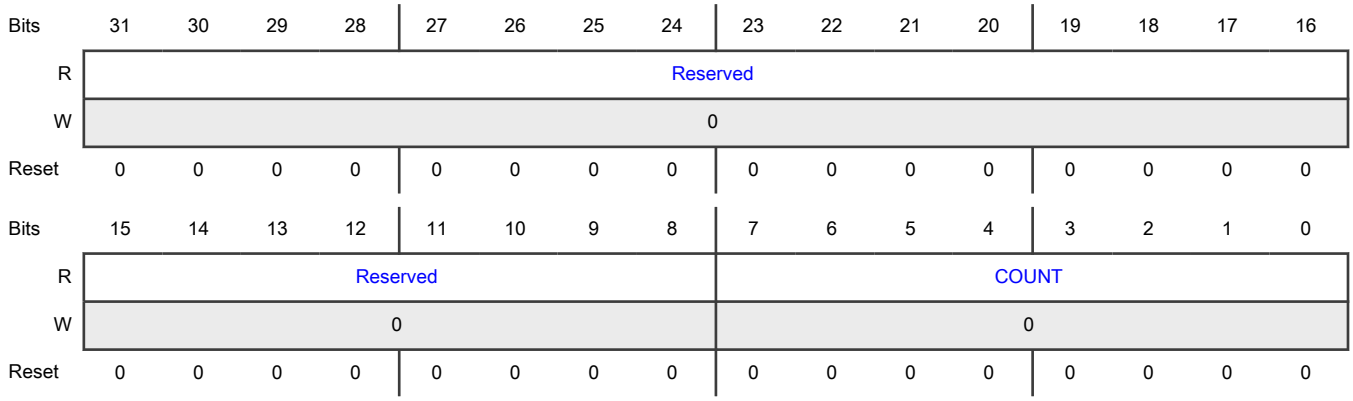
Offset

Register	Offset
CORR_ERR_CNT0	108h
CORR_ERR_CNT1	118h
CORR_ERR_CNT2	128h
CORR_ERR_CNT3	138h
CORR_ERR_CNT4	148h
CORR_ERR_CNT5	158h
CORR_ERR_CNT6	168h
CORR_ERR_CNT7	178h
CORR_ERR_CNT8	188h
CORR_ERR_CNT9	198h
CORR_ERR_CNT10	1A8h
CORR_ERR_CNT11	1B8h
CORR_ERR_CNT12	1C8h
CORR_ERR_CNT13	1D8h
CORR_ERR_CNT14	1E8h
CORR_ERR_CNT15	1F8h
CORR_ERR_CNT16	208h
CORR_ERR_CNT17	218h
CORR_ERR_CNT18	228h
CORR_ERR_CNT19	238h

Function

Each 32-bit ERM Memory n Correctable Error Count Register records the count value of the number of correctable ECC error events for Memory *n*, where *n* denotes the memory channel.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 COUNT	Memory n Correctable Error Count For each correctable error event, the ERM increments this field's error count value until the counter reaches its maximum value FFh. COUNT field description can be updated as required. COUNT value will stop once it reaches maximum value FFh and will not wrap even if error occurs. Read this field to determine the correctable error count value so far. Write all zeros to this field to reset the counter. Writing non-zero (or partial zero) values has no effect.

48.6 Glossary

ECC Error correction code

Chapter 49
Fault Collection and Control Unit (FCCU)

49.1 Chip-specific FCCU information

49.1.1 FCCU NCF slots

Table 226. FCCU NCF slots

Slot number	Source module (error type)
NCF[0]	• Cortex-M7 LS and core lockup • HSE_B lockup
NCF[1]	Interconnect: • All EDC bus gaskets • XBIC monitors and platform gaskets
NCF[2]	ECC errors: • PRAMC • TCMs • Caches • eDMA • EDC after ECC • HSE_B RAM errors
NCF[3]	All flash memory errors: • FMU • PFLASH • DCM flash memory
NCF[4]	Voltage-related errors: • PMC 1.1 V and 2.5 V GNG • Pad overvoltage
NCF[5]	Debug and test monitoring
NCF[6]	INTM
NCF[7]	Software notification

49.1.2 Chip-boundary FCCU signals

Table 227. Chip-boundary FCCU signals

FCCU signal	Chip signal
EOUT0	FCCU_ERR0
EOUT1	FCCU_ERR1

49.1.3 FCCU clocking

Table 228. FCCU clocking

FCCU clock signal	Chip clock signal
CLKSAFE	FIRC_CLK
CLKPRIM	AIPS_PLAT_CLK

49.1.4 FOSU timer interval

The FOSU_COUNT value determines the FOSU timer interval. On this chip, FOSU_COUNT is 69780h.

49.1.5 Supported internal chip reactions

The short functional reset discussed in this chapter is equivalent to the chip functional reset. See the interrupt map file attached to this document for interrupts from FCCU to NVIC.

NOTE

After STCU2 completes the self-testing procedure, the chip reboots and FCCU resets.

49.1.6 Supported FCCU EOUT fault output modes (protocols)

This chip supports only the Bistable protocol of FCCU EOUT, and does not support the other protocols discussed in this chapter, Dual-Rail and Time-Switching.

49.1.7 Recommended reaction programming for faults

You can upgrade or downgrade the reaction of the faults according to the recommended reaction discussed in the fault map file attached to this document.

In case you upgrade a reaction, no issues are expected in the behavior. If you downgrade the reaction, the functionality is not guaranteed.

This is the recommendation for faults caused by lockstep errors:

1. The recommended reaction for the lockstep error fault is a functional reset.
2. Program the core to perform the following steps after rebooting:
    a. Initialize TCM (because TCMs can become corrupted)
    b. Invalidate the cache (because caches can become corrupted)
3. Write 1 to the corresponding bit in FCCU.NCF_S0 register to clear the non-critical fault status.
4. If the FCCU fault gets cleared, you have nothing else to do for fault handling (this means, the FCCU lockstep error is recovered).
5. If the error persists, it indicates that the internal registers of the two cores have different values. To bring them to the same value, you could perform any of these steps:
    a. Initialize destructive reset through software by using MC_ME.MODE_CONF[DEST_RST] to recover from lockstep. This initializes the FCCU with no pending faults.
    b. Reconfigure the Cortex-M7 debug configurations (which would have been lost in previous step due to destructive reset in the system).

49.1.8 FCCU NCF handling architecture

This chip supports eight NCFs. Therefore, multiple faults of similar nature are ORed together and then connected as a single NCF to FCCU. To control individual fault, there are enable/disable controls provided within DCM in registers DCMRWD3, DCMRWD4 and DCMRWD5.

Similarly, the FCCU.NCF_S0 captures the status of fault within FCCU. This fault might have resulted due to any fault mapped on the corresponding FCCU NCF channel. The DCM status registers, DCMROD3, DCMROD4 and DCMROD5 capture the status of individual faults which are mapped onto FCCU NCFs. Figure 181 shows this arrangement.

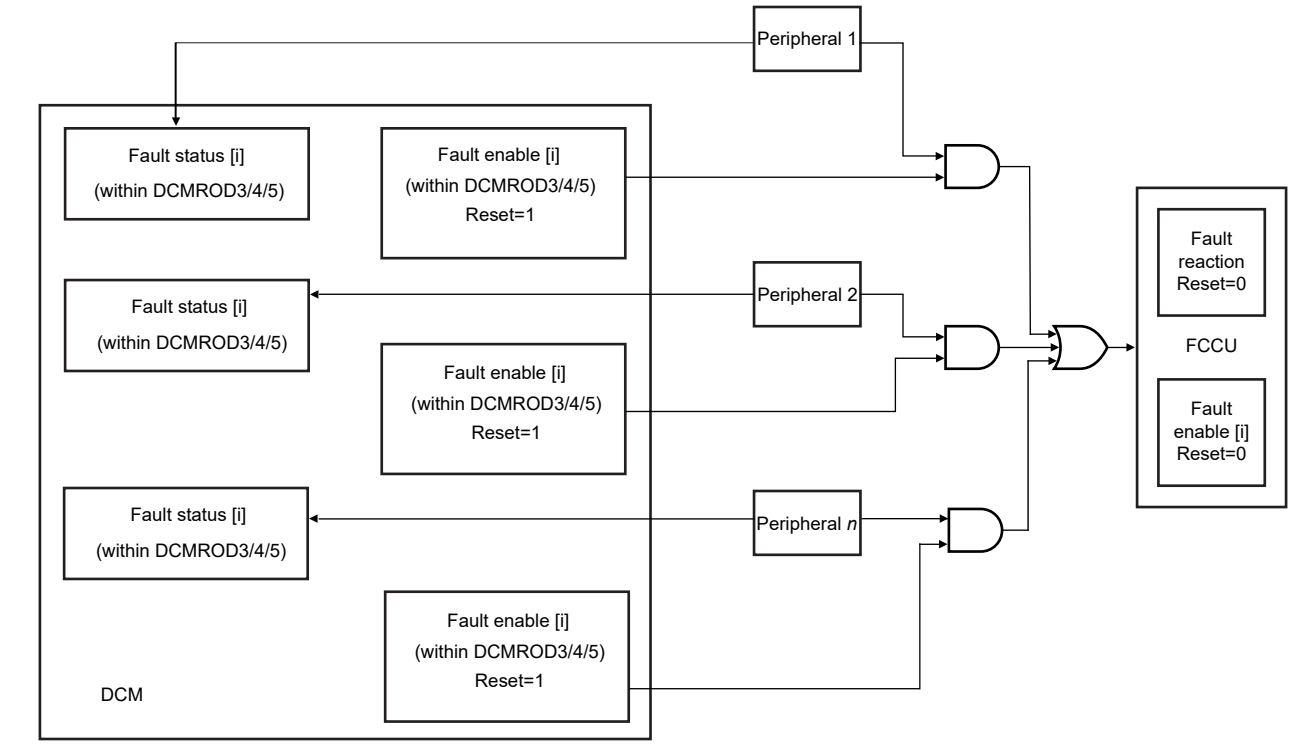


Figure 181. FCCU NCF handling architecture

49.2 Introduction

The FCCU provides a hardware interface to collect faults and to place the device into a safe state when a failure is detected in the device. No CPU intervention is requested for collection and control operations. FCCU offers a systematic approach to fault collection and control.

49.3 Features

The key features of the FCCU module are these:

- Management of non-critical faults
- HW or SW fault recovery management
- Fault collection from safety relevant modules on the device
- Fault injection (fake faults)
- Collection of test results
- Lockable configuration
  - Changes are only possible after entering the CONFIG state

  - Supports a transient and a permanent lock
  - Configuration changes observed by a watchdog timer
- Configurable fault control
- External reaction (FAULT state): EOUT signaling. Error indication via the pin(s) is controlled by FCCU.
- Internal chip reactions (ALARM state): interrupt request
- Configurable internal chip reactions for each NCF (FAULT state):
  - Short functional reset request pulse
  - NMI
  - No reaction
  - IRQ
- In Bi-Stable operational mode, one of the EOUT signals is high to indicate an OK operational state of FCCU.
- After power on, the EOUT signals have high impedance.[6] They indicate an operational state only after the software configures them.
- In case of a failure event or on software request for error pin indication, the pin(s) are set to faulty state for a minimum time T_{min} (see DELTA_T[DELTA_T]), even if the software tries to release it before (for the case of error pin configured in Bi-Stable mode only).

The self-checking procedure checks the FCCU circuitry at the start up. The FCCU is operational with the default configuration immediately after the completion of the self-checking procedure. Internal (short functional reset request pulse, interrupt request) and external (EOUT signaling) reactions are statically defined or programmable. The default configuration can be modified only in the Configuration (CONFIG) state. FCCU is designed to function when CLKPRIM is faster than the CLKSAFE clocks.

49.4 Block diagram

The following figure represents a top-level diagram of the FCCU module.

[6] Actual value depends on device-specific setting at pad level.

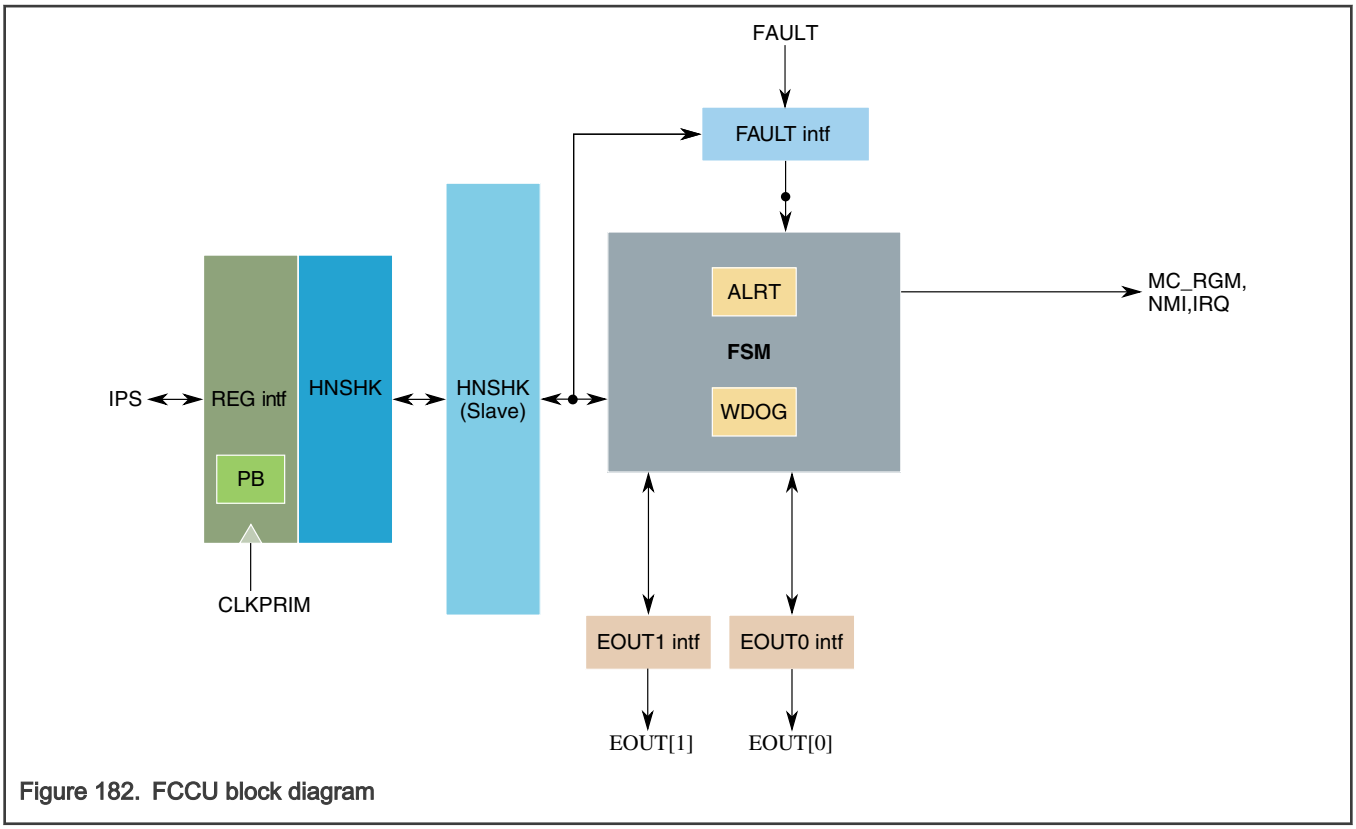

Figure 182. FCCU block diagram

This table describes the FCCU submodules.

Table 229. FCCU submodules

Submodule	Description
REG intf	Includes the register file, the IPS bus interface, the IRQ interface and the parity block (PB) for the configuration registers
HNSHK blocks (master and slave blocks)	Includes the FSM ability to support the handshake between the REG interface and the FSM unit because of the usage of two asynchronous clocks [CLKPRIM(module clock) and CLKSAFE(RC oscillator clock)]
FSM unit	Implements the main functions of FCCU. The FSM also includes the: • Watchdog timer (WDG) • Alarm timer (ALRT)
FAULT intf	Implements the interface for fault conditioning and management
EOUTx units	Implement the output stage to manage the EOUT interfaces

49.5 Signal description

49.5.1 Signals

This table describes the signals on the boundary of FCCU.

Signal	Direction	Function	Sensitivity	Clock
Clock and reset				
CLKPRIM	Input	Primary Clock—supplies the primary clock.	Rising edge	—
CLKSAFE0	Input	Safe Clock 0—supplies one of two 48 MHz clocks for use by various redundant submodules. This clock and CLKSAFE1 are often referred to as the same clock (CLKSAFE).	Rising edge	—
CLKSAFE1	Input	Safe Clock 1—supplies one of two 48 MHz clocks for use by various redundant submodules. This clock and CLKSAFE0 are often referred to as the same clock (CLKSAFE).	Rising edge	—
Fault interface				
NCF[7:0]	Input	Non-critical Fault Channels—receive indications of non-critical faults from various sources. See the fault map file attached to this document.	Programmable	Asynchronous
EOUT interface				
EIN[1:0]	Input	Error Inputs—provide the mechanism for FCCU to capture the states that off-chip logic drives on the associated EOUT[1:0] signals. FCCU captures the states in the EINOUT[EIN1] and EINOUT[EIN0] fields.	—	Asynchronous
EOUT[1:0]	Output	Error Outputs—indicate FCCU's condition (faulty, nonfaulty, or configuration) to off-chip logic.	Programmable	CLKSAFE0, CLKSAFE1
FOSU interface				
FIF	Output	FCCU In Fault—indicates to the FOSU module, if present, that FCCU is recognizing a fault. FCCU asserts and then deasserts this signal in two cases: *Case 1* When the EOUT signals are programmed to be always low (CFG[FCCU_SET_CLEAR]), FCCU	High	CLKSAFE0, CLKSAFE1

Table continues on the next page...

Table continued from the previous page...

Signal	Direction	Function	Sensitivity	Clock
		asserts this signal until the EOUT signals are programmed not to be always low. *Case 2* When the EOUT signals are programmed not to be always low (CFG[FCCU_SET_CLEAR]), FCCU asserts this signal when all of the following are true: • FCCU enters the FAULT state as the result of a fault. • If the fault is a non-critical fault, the associated EOUT_SIG_ENa[EOUTENn] field is set to enabled. FCCU deasserts this signal when FCCU leaves the FAULT state.		
Interrupt interface				
NMIOUT	Output	Non-maskable Interrupt Output—Sends a non-maskable interrupt request to the processor core or cores when FCCU enters the FAULT state as the result of a non-critical fault for which NMI is enabled as the reaction (NMI_ENa[NMIENn]).	Low	CLKPRIM

49.6 Functional description

49.6.1 Definitions

In general, the following definitions are applicable for fault management:

- HW recoverable fault: The fault indication is a level-sensitive signal that remains asserted until the fault cause is deasserted. That is, if logical 0 on the fault signal indicates fault, then the status flags are valid as long as the fault line stays at 0. The status is automatically cleared when the fault signal goes to 1. Typically the fault signal is latched external to the FCCU in the module where the fault occurred. The FCCU state transitions are consequently executed on the state changes of the input fault signal. No SW intervention in the FCCU is required to recover the fault condition.
- SW recoverable fault: The fault indication is a signal asserted without a defined time duration. The fault signal is latched in the FCCU. The fault recovery is executed following a SW recovery procedure (status/flag register clearing).

HW recoverable is an option to exclude the handling of error source/s by FCCU management SW, in case it is known that the fault is recoverable by itself when the fault condition is corrected.

These type of chip resets reset the FCCU:

- Power-on
- Destructive

A short functional reset of the chip do not reset the FCCU.

For more information on each type of reset, see the Reset Generation Module (MC_RGM) and reset chapters.

49.6.2 FSM description

The functionality of FCCU is depicted by the FSM state diagram (see Figure 183).

FCCU has four states that are identified with the following meaning:

- CONFIG: Used only to modify the configuration of FCCU from its default. A subset of the FCCU registers, dedicated to define the FCCU configuration (global configuration, reactions to fault, timeout, non-critical fault masking) can be accessed in write mode only in the CONFIG state.

  The CONFIG state is accessible only in the NORMAL state and if the configuration is not locked. A permanent configuration lock can be disabled by a reset that also resets the FCCU. The transient lock register is unlocked by writing BCh into it. FCCU gets transiently locked again if an invalid key is written into TRANS_LOCK[TRANSKEY] (that is, other than BCh). To lock FCCU for configuration, write FFh to PERMNT_LOCK[PERMNTKEY].

  After the release of reset, the state of the transient lock is locked, and the state of the permanent lock is unlocked.

  The locking feature only restricts the FSM movement into CONFIG state. After the user enters the CONFIG state and then tries to lock the configuration, the locking of configuration is effective only after FCCU moves to the NORMAL state; it will not be effective in the current CONFIG state.

  The CONFIG to NORMAL state transition can be executed by SW or automatically following a timeout condition of the watchdog. In case the timeout information and the SW request for state change to NORMAL appears at the same time, watchdog timeout has the priority and hence the configuration registers (those that are writable only in the CONFIG state) are reset to their default values. The movement to the NORMAL state is made.

  The incoming faults, occurring during the configuration phase (CONFIG state) are latched in order to process them when FCCU is moved to the NORMAL state, according to the new configuration.

  All pending faults that occur during the CONFIG state result in both of the following:

  — Highest-priority state transition

  — Interrupt generation (NMI or alarm IRQ)

  If the state transition occurs, it gives the reset reaction corresponding to the worst case based on all the faults (pending or non-pending faults) that occurred during the CONFIG state.

- NORMAL: This is FCCU's operating state when no faults are occurring. It is also the default state on the reset exit. Following state transitions occur on one of the following events:

  — Unmasked non-critical faults with the timeout disabled: FCCU moves to the FAULT state.

  — Unmasked non-critical faults with the timeout enabled: FCCU moves to the ALARM state.

  — Masked non-critical faults: FCCU stays in the NORMAL state.

- ALARM: FCCU moves into the ALARM state when an unmasked non-critical fault occurs and the timeout is enabled. Transition to the ALARM state goes along with an interrupt alarm, if enabled. By definition, this fault may be recovered within a programmable timeout period, before it generates a transition to the FAULT state. The timeout is reinitialized if FCCU enters the NORMAL state. The timeout restarts following the recovery from the FAULT state.

- FAULT: FCCU moves into the FAULT state when one of the following condition occurs:

  — Timeout related to a non-critical fault when FCCU is in the ALARM state

  — Unmasked non-critical faults with the timeout disabled

The transition from the NORMAL or ALARM to the FAULT state goes along with the generation of:

- Internal chip reaction—NMI interrupt (optional)
- External reaction—EOUT signaling (optional)

- Internal chip reaction—SW option: Soft reaction (Short functional reset request pulse if configured)
- Non Maskable Interrupt (NMI) is routed to all cores.

After moving to the FAULT state, if there is either a previous pending fault or a new fault for which NMI is enabled, NMI generation takes place.

Multiple faults can occur at the same time.

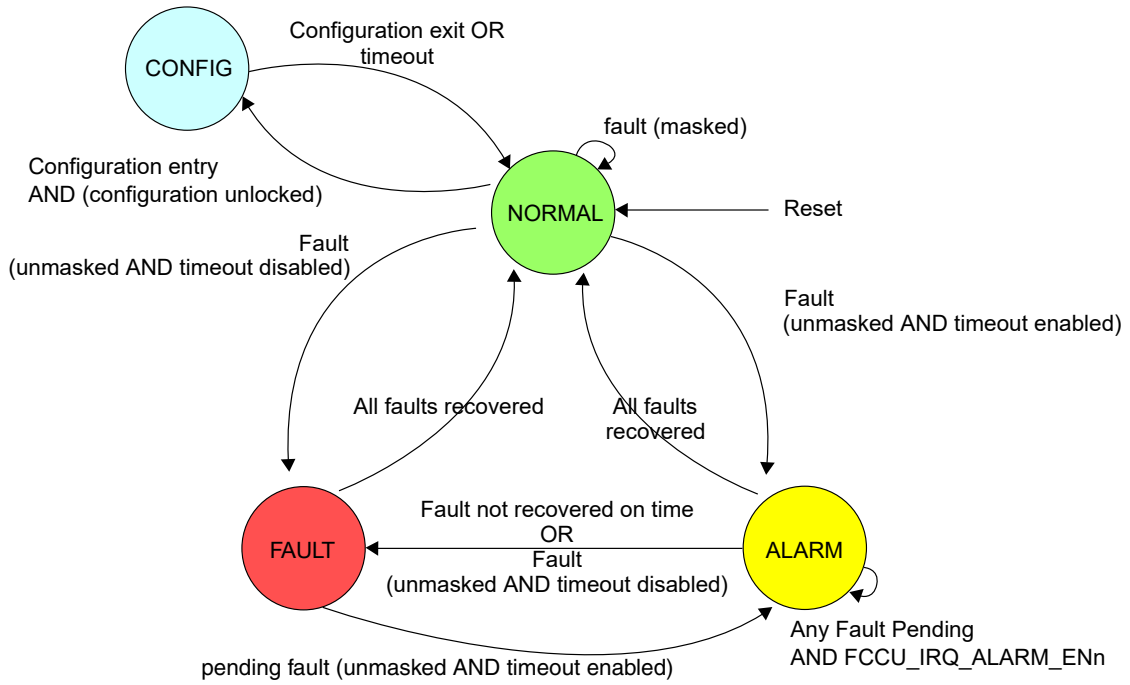

Figure 183. FCCU state diagram

49.6.3 Fault priority scheme and nesting

The FAULT state has a higher priority than the ALARM state in case of concurrent fault events (non-critical) that occur in the NORMAL state.

The ALARM to FAULT state transition occurs if a non-critical fault (unmasked and with timeout disabled) is asserted in the ALARM state.

The ALARM to NORMAL state transition occurs only if all the non-critical faults (including the faults that have been collected after the entry in the ALARM state) have been cleared (SW or HW recovery); otherwise the FCCU remains in the ALARM state.

The FAULT to NORMAL state transition occurs only if all the non-critical faults (including the faults that have been collected after the entry in the FAULT/ALARM state) have been cleared (SW or HW recovery); otherwise the FCCU moves to the ALARM state (if any non-critical fault is still pending and the timeout is not elapsed).

In general, no fault nesting is supported except for the non-critical faults that cause an ALARM to FAULT state transition. In this case, the NCF timer is stopped until the FAULT state is recovered. If FCCU is in the ALARM state and another fault occurs, which has its alarm timeout enabled, then the alarm timer shall not reload and shall not start again.

49.6.4 Fault recovery

The following timing diagrams describe the main use cases of FCCU in terms of fault events and related recovery.

A typical sequence related to non-critical fault management (ALARM state), see Figure 184 and Figure 185, is as follows:

1. Non-critical fault assertion

2. FCCU state transition (automatic): NORMAL to ALARM
   - Alarm interrupt request (if enabled)
   - Timeout running
3. System state: RUN
4. Alarm interrupt management: fault recovery
   - FCCU state transition: ALARM to NORMAL

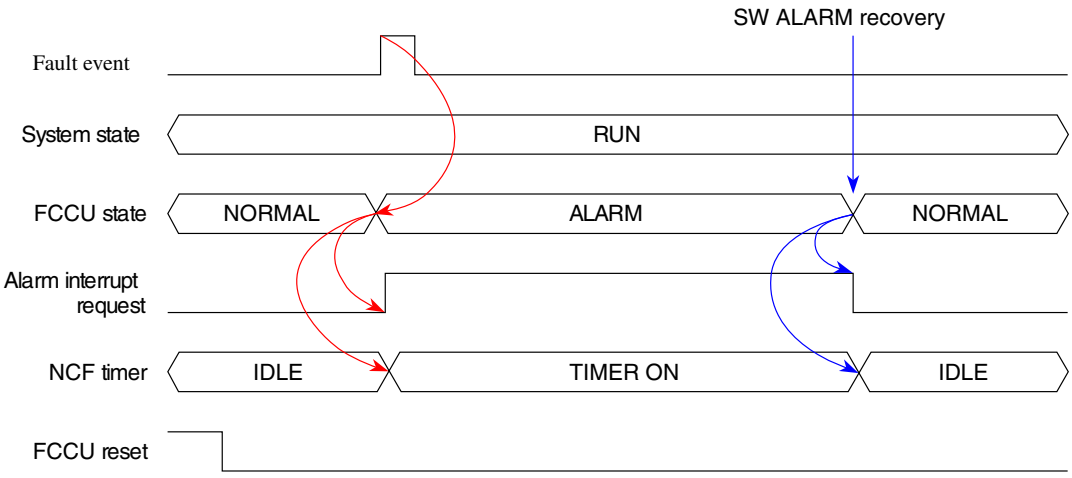

Figure 184. Non-critical fault (ALARM state) SW recovery

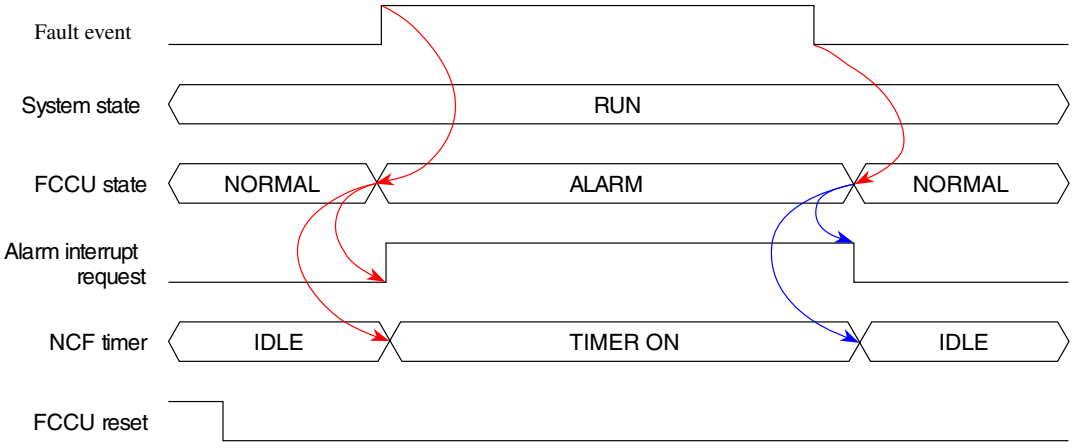

Figure 185. Non-critical fault (ALARM state) HW recovery

A typical sequence related to non-critical fault management (ALARM to FAULT state), see Figure 186, is as follows:

1. Non-critical fault assertion
2. FCCU state transition (automatic): NORMAL to ALARM
   - Alarm interrupt request (if enabled)
   - Timeout running
3. FCCU state transition (following the timeout trigger): ALARM to FAULT
   - NMI assertion (if enabled)
4. NMI interrupt management (if enabled)

- Fault recovery (by software): FCCU state transition: FAULT to NORMAL

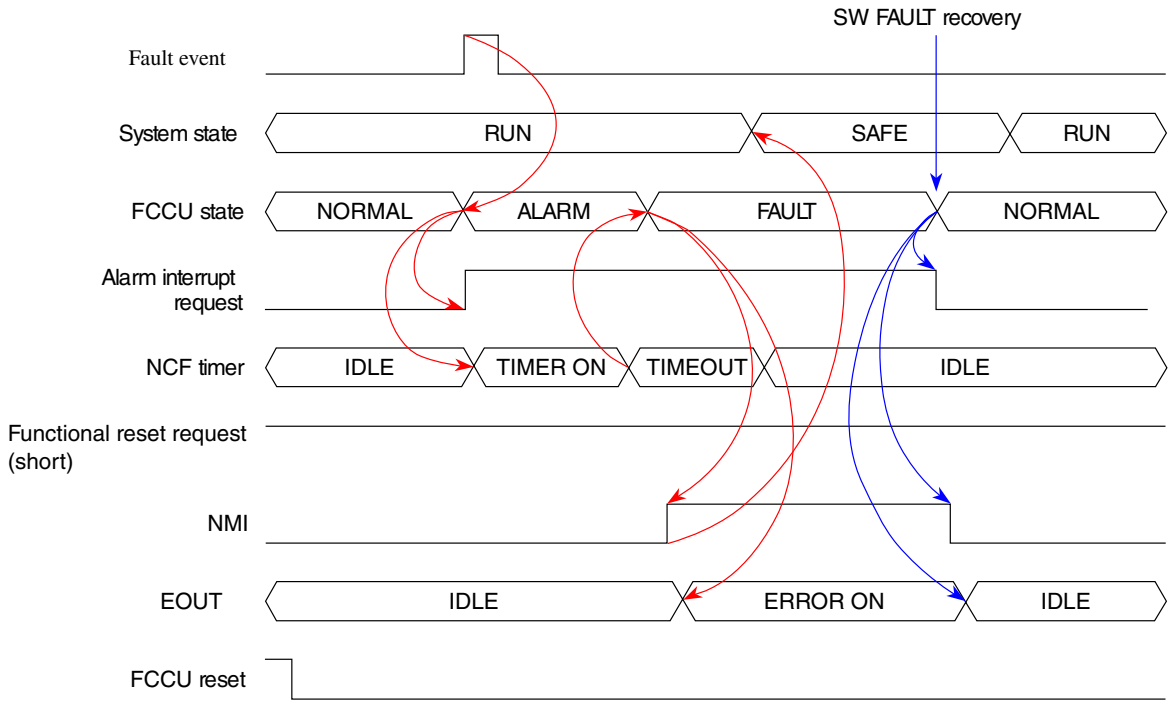

Figure 186. Non-critical fault (ALARM to FAULT state) recovery

49.6.5 EOUT interface

Introduction

You use the EOUT[1:0] signals to indicate FCCU's condition to off-chip logic.

NOTE

For information on the availability and names of these FCCU signals on the boundary of this chip, see the chip-specific FCCU information.

The FCCU conditions

There are three FCCU conditions:

Condition	Description
Faulty	All of the following are true: • The fault-output (EOUT) timer is running (see How the fault-output (EOUT) timer works in Bi-Stable fault-output mode). • FCCU is in FAULT state.
Nonfaulty	All of the following are true:

Table continues on the next page...

Table continued from the previous page...

Condition	Description
	• The fault-output (EOUT) timer is not running. • FCCU is in ALARM or NORMAL state.
Configuration	All of the following are true: • The fault-output (EOUT) timer is not running. • FCCU is in CONFIG state.

How the fault-output (EOUT) timer works in Bi-Stable fault-output mode

In Bi-Stable fault-output mode (FOM), FCCU starts the fault-output (EOUT) timer when all of the following are true:

- If the EOUT signals are in Bi-Stable FOM, and the EOUT signals are not programmed to be always low (CFG[FCCU_SET_CLEAR]).
- The EOUT timer is not already running.
- FCCU enters the FAULT state as the result of a fault.

When the fault-output (EOUT) timer is already running and a new fault occurs:

- If FCCU is in the CONFIG state: FCCU does not restart the EOUT timer.
- If FCCU is in the NORMAL or ALARM state:
  - And ALARM state is enabled for the fault (non-critical): FCCU enters (or remains in) the ALARM state but does not restart the EOUT timer.
  - And ALARM state is disabled for the fault (non-critical): FCCU enters the FAULT state and restarts the EOUT timer.
- If FCCU is in the FAULT state: FCCU restarts the fault-output (EOUT) timer.

FCCU stops and reinitializes the fault-output (EOUT) timer when all of the following are true:

- If the EOUT signals are in Bi-Stable fault-output mode (CFG[FOM]), and T_{min} (see DELTA_T[DELTA_T]) has expired.
- All faults that caused FCCU to enter or remain in the FAULT state since FCCU started the fault-output (EOUT) timer have been cleared, causing FCCU to return to the NORMAL state.

Prepare the EOUT signals to indicate FCCU's condition

- If the EOUT signals are in Bi-Stable fault-output mode (CFG[FOM]), ensure that the EOUT signals are controlled by FCCU's FSM (CFG[FCCU_SET_CLEAR]).
- Ensure that the EOUT signals are active (CFG[FCCU_SET_AFTER_RESET]).

NOTE

If the EOUT signals are in Bi-Stable fault-output mode, you must deactivate and then reactivate the EOUT signals (CFG[FCCU_SET_AFTER_RESET]) to correctly initialize them so they have opposite states.

More about the EOUT interface

Different fault-output modes (protocols) for the fault-output (EOUT) interface are supported (CFG[FOM]):

- Bi-Stable

NOTE

See the chip-specific FCCU information for the fault-output modes supported by this chip.

You can further configure the fault-output modes using the following attributes:

Attribute	Field	Setting used in the example diagrams and tables that follow
Configuration mode	CFG[CM]	Different
Polarity selection	CFG[PS]	For the faulty indication, EOUT1 is high, and EOUT0 is low.

EOUT frequency: This frequency is generated by dividing the CLKSAFE frequency by a fixed factor of 2^{18}.

$$EOUT_{freq} = \frac{CLKSAFE_{freq}}{2^{18}}$$

For example, with a CLKSAFE frequency of 16 MHz, this drives a signal of 61 Hz on EOUT.

In case of a failure event or on software request for EOUT indication, the signal(s) are set to the faulty state for a minimum time (T_{min}), even if software tries to release it before. If software configures the error pins to OK(1), and if a fault comes trying to drive the pin to NOK(0), then priority is given to the fault indication and the error signals indicate NOK, such as an incoming fault is not masked even when software has set the error signal to high. Also, if the error signals are forced to low by software by writing to CFG[FCCU_SET_CLEAR], then the signals shall remain low (or high) for the entire duration of T_{min}. During the T_{min} by a non-software fault, the FCCU FSM moves independently of this signal state (low), and as soon as the timer expires, the pin behavior is dictated by the state in which the FSM finds itself in, and it is not possible to set the signals to OK by software moving FCCU to the CONFIG state, as long as this timer is running. No software intervention is needed to bring the signal from the low state.

Software can bring the pin back to OK state by clearing the faults and waiting for the T_{min} interval to expire, after which the FCCU automatically enters the NORMAL state and the error signal indicates OK.

In case another failure event happens within T_{min} after a first one, the T_{min} counter is restarted.

49.6.5.1 Bi-Stable protocol

The encoding scheme is provided in Table 230 and the related timing diagram is shown in Figure 187.

Table 230. Bi-Stable encoding

Condition	EOUT[1:0] (CFG[PS] is 0)	EOUT[1:0] (CFG[PS] is 1)
Nonfaulty	Static 01	Static 10
Faulty	Static 10	Static 01
Reset	High-impedance (no toggling)[1]	High-impedance (no toggling)
Configuration (CFG[CM] is 1 and CFG[FCCU_SET_AFTER_RESET] is 0)	High-impedance (no toggling)[2]	High-impedance (no toggling)
Configuration (When CFG[CM] is 1 and CFG[FCCU_SET_AFTER_RESET] is 1)	Static 01	Static 10

1. Final value depends on device specific settings at pad level.
2. Ensure that the EOUT signals are active (CFG[FCCU_SET_AFTER_RESET]); otherwise, the EOUT signals stay in a high-impedance state after reset lifts.

NOTE

Figure 187 is formatted to display the behavior in all four conditions (reset, nonfaulty, faulty, and configuration), not to imply transitions between one condition and another. In particular, a transition from the faulty condition to the configuration condition is not possible.

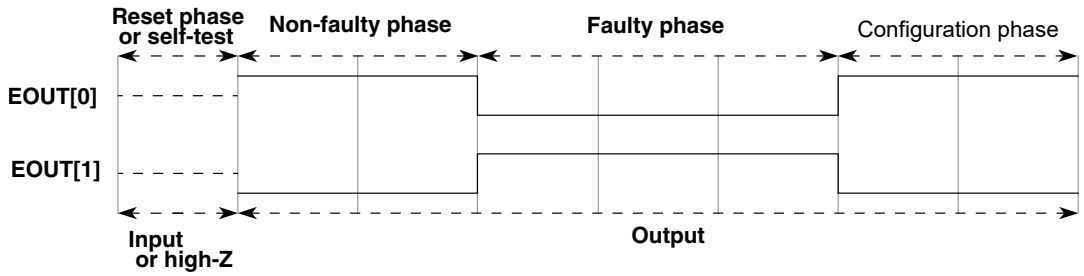

Figure 187. Bi-Stable protocol

49.7 Prepare FCCU for configuration

49.7.1 Introduction

You prepare FCCU for configuration by first configuring the CONFIG state and then putting FCCU in that state.

49.7.2 About preparing FCCU for configuration

When preparing FCCU for configuration, keep the following in mind:

- To put FCCU in CONFIG state, FCCU must be in NORMAL state.
- After FCCU is reset, the configuration is temporarily locked. You must temporarily unlock the configuration before you can put FCCU in the CONFIG state.
- When FCCU is in the CONFIG state, FCCU does not actually save the changes you make to the configuration. To save changes to the configuration, you must manually put FCCU in the NORMAL state. If FCCU automatically leaves the CONFIG state and enters the NORMAL state because the Configuration-state timeout interval (CFG_TO[TO]) expires (called a Configuration-state timeout), FCCU changes the value of the Configuration (CFG) register to its Configuration-state-timeout value and the value of each of the other configuration registers to its reset value. FCCU also changes the value of the Configuration-State Timeout Interval (CFG_TO) register to its reset value. For information on the Configuration-state timeout value, see CFG register bit value at different events. For a list of configuration registers, see Configuration registers.

49.7.3 Configure the CONFIG state

1. Set the Configuration-state timeout interval (CFG_TO[TO]).
2. Enable the Configuration-state-timeout interrupt signal (IRQ_EN[CFG_TO_IEN]), if you want FCCU to request an interrupt when a Configuration-state timeout occurs.

49.7.4 Put FCCU in the CONFIG state

1. Unlock the configuration temporarily (TRANS_LOCK[TRANSKEY]) in Supervisor mode.
2. Check the FCCU status (STAT[STATUS]).
   - If the FCCU status is CONFIG, FCCU is in the CONFIG state. Stop.
   - If the FCCU status is NORMAL, go to step 3.

- If the FCCU status is ALARM or FAULT, go to step 5.

3. Run the OP1 operation (see Run an operation).
4. Check the operation status (CTRL[OPS]).
   - If the operation status is Successful, FCCU is in the CONFIG state. Stop.
   - If the operation status is Aborted, the configuration is probably permanently locked. Go to step 7.
5. Recover all faults (see Fault recovery).
6. Go to step 2.
7. Reset FCCU.

49.8 Configure FCCU

49.8.1 Introduction

You configure FCCU so it functions according to the needs of your particular application.

49.8.2 About configuring FCCU

When configuring FCCU:

- If you enable a non-critical fault channel but disable all reactions for that channel, FCCU changes state when necessary but does not perform any reaction because reactions are disabled. If you enable reactions for a non-critical fault channel but disable that channel, and FCCU is in the NORMAL state when a fault occurs on the channel, FCCU does not enter the ALARM or FAULT state and therefore does not perform any reaction.

49.8.3 Configure the non-critical fault channels

For each non-critical fault channel that you want FCCU to monitor:

1. Set the recovery type (NCF_CFGa[NCFCn]).
2. Enable at least one type of Fault-state reaction:
   - Chip functional reset (NCFS_CFGa[NCFSCn])
   - Non-maskable interrupt (NMI_ENa[NMIENn])
   - EOUT signaling (EOUT_SIG_ENa[EOUTENn])

   NOTE

   If you enable the chip functional reset as the type of Fault-state reaction for a channel, enable at least one other type of Fault-state reaction for the channel or enable the ALARM state (step 4) for the channel.

3. Set the Alarm-state timeout interval (NCF_TO[TO]), if you plan to enable the ALARM state for any non-critical fault channel.

   NOTE

   Ensure that the Alarm-state timeout interval is less than the FOSU module's timeout interval; otherwise, FOSU generates a chip reset every time a fault occurs on the channel. The FOSU timeout interval (FOSU_COUNT) is a chip-specific value. See the chip-specific FCCU information.

4. Enable the ALARM state (NCF_TOEa[NCFTOEn]) for any non-critical fault channel for which you want FCCU to enter the ALARM state before entering the FAULT state.
5. Enable the Alarm-state reaction (IRQ_ALARM_ENa[IRQENn]) for each non-critical fault channel for which you enabled the ALARM state.
6. Enable the corresponding NCF_Ea[NCFEn] field for each non-critical fault channel that you want FCCU to monitor.

49.9 Put FCCU in the NORMAL state

49.9.1 Introduction

You put FCCU in the NORMAL state to save changes to the configuration, and to allow FCCU to enter the ALARM or FAULT state when a fault occurs on an enabled fault channel.

49.9.2 About putting FCCU in NORMAL state

When putting FCCU in the NORMAL state:

- If you attempt to lock the configuration while FCCU is in CONFIG state, FCCU does not actually lock the configuration until FCCU leaves CONFIG state—that is, either you put FCCU in the NORMAL state, or FCCU puts itself in the NORMAL state because the Configuration-state timeout interval (CFG_TO[TO]) expires.
- After you permanently lock the configuration, you must reset FCCU before you can put FCCU in the CONFIG state.

49.9.3 Put FCCU in the NORMAL state

1. Check the FCCU status (STAT[STATUS]).
   - If the FCCU status is NORMAL, go to step 6.
   - If the FCCU status is CONFIG, go to step 2.
   - If the FCCU status is ALARM or FAULT, go to step 4.
2. Run the OP2 operation (see Run an operation).
3. Check the operation status (CTRL[OPS]).
   - If the operation status is Successful, FCCU is in the NORMAL state. Go to step 6.
   - If the operation status is Aborted, go to step 2.
4. Recover all faults (see Fault recovery).
5. Go to step 1.
6. Lock the configuration if you want to prevent any changes to it:
   - To require a key to unlock the configuration, from Supervisor mode, temporarily lock the configuration (TRANS_LOCK[TRANSKEY]).
   - To require a reset of FCCU to unlock the configuration, from Supervisor mode, permanently lock the configuration (PERMNT_LOCK[PERMNTKEY]).

     The configuration is permanently locked until FCCU is reset.

49.10 Manage faults

49.10.1 Introduction

After saving changes to the configuration, you are ready to use FCCU to manage faults.

49.10.2 Determine if there are any unrecovered non-critical faults

Check the unrecovered-fault indicators for the non-critical faults (NCF_Sa[NCFSn]).

49.10.3 Recover a software-recoverable non-critical fault

1. Resolve the source of the software-recoverable non-critical fault.
2. Unlock the NCF_Sa registers (NCFK[NCFK]) using a 32-bit write.

3. Initiate clearing of the unrecovered-fault indicator for the software-recoverable non-critical fault (NCF_Sa[NCFSn]) using a 32-bit write.

   FCCU initiates the OP12 operation.

   NOTE

   If you want to clear multiple unrecovered-fault indicators and those indicators reside in different NCF_Sa registers, you must perform steps 2 and 3 for each individual register.

4. Check the operation status (CTRL[OPS]).
   - If the operation status is In Progress, go to step 4.
   - If the operation status is Successful, go to step 5.
   - If the operation status is Aborted, go to step 2.
5. Check the unrecovered-fault indicator for the software-recoverable non-critical fault (NCF_Sa[NCFSn]).
   - If the indicator indicates no unrecovered fault, the fault has been recovered. Stop.
   - If the indicator still indicates an unrecovered fault, go to step 2.

49.10.4 Clear the freeze-status indicators

1. Run the OP13 operation (see Run an operation).
2. Check the operation status (CTRL[OPS]).
   - If the operation status is Successful, stop .
   - If the operation status is Aborted, go to step 1.

49.11 Run operations

49.11.1 Introduction

You run operations to perform actions such as putting FCCU in the CONFIG state or setting the operation status to Idle. For a complete list of operations you can run, see CTRL[OPR].

49.11.2 About running operations

When running operations:

- FCCU ignores any operations initiated while the operation status is In Progress.
- Certain operations must be unlocked before you can initiate them. After you initiate them, they are locked again.

49.11.3 Run an operation

1. Check the operation status (CTRL[OPS]).
2. Go to step 1 if the operation status is In Progress.
3. Unlock the operation (CTRLK[CTRLK]) using a 32-bit write, if the operation must be unlocked before you can initiate it.

   NOTE

   The Control Key (CTRLK) register used in this step and the Control (CTRL) register used in the next step must be written with consecutive instructions. Do not use read-modify-write instructions, such as bit-field instructions, to modify these registers.

4. Initiate the operation (CTRL[OPR]) using a 32-bit write.
5. Check the operation status (CTRL[OPS]).

6. Go to step 5 if the operation status is In Progress.

The operation status is now Idle (OP15 only), Aborted, or Successful.

49.12 FOSU

The FOSU provides a supervision of the primary fault notification path by analyzing FCCU's behavior for correctness. It waits for any reaction of the FCCU in a fixed time window after a fault is signaled.

The intention of the FOSU is to provide a secondary fault reaction path in most cases when the FCCU fails but not to needlessly propagate a fault which is already handled by the FCCU in a full chip reset. Only a failed primary fault reaction (that is, FCCU's failure) is a reason for the secondary reaction to take over (and generate a destructive reset request).

There is a 'do nothing' input coming from FCCU which indicates that the FCCU is programmed for no reaction for ALL FAULTS. It is a "static" input in the sense that it does not change after FCCU configuration. The FOSU masks the incoming faults with the 'do nothing' control from the FCCU, meaning that a fault is not captured by the FOSU if the 'do nothing' signal is asserted (that is, a disabled fault). There is no minimum pulse width requirement on the fault indication other than what is required by the technology, which is the same as that of the FCCU. FOSU does not monitor FCCU for the case of faults occurring during the CONFIG state.

The FOSU contains a timer with a duration of FOSU_COUNT, driven by CLKSAFE. The timer is initialized and started on any captured, enabled fault. While the timer is running, any subsequent captured fault will neither restart nor reinitialize the timer. The timer is stopped when the FCCU shows any of the following reactions (the FOSU does not check whether the reaction is the configured one for the faults which occurred):

- Reset: short functional reset
- IRQ (triggered by ALARM state)
- NMI
- Error out triggered (by FCCU or by SW)

When the timer is stopped, the fault capture logic is cleared to ensure that the timer is not restarted because of faults still 'stuck' in the capture logic. The timer is then restarted by the next new failure indication. When the timer expires, the FOSU's failure indicator output is asserted after it ensures that the fault is enabled and the static "fccu program to do nothing" signal is deasserted. This is because FCCU uses settings after it exits CONFIG state, even if fault captured before the exit.

The FOSU's failure indicator output is connected to one of the MC_RGM's 'destructive' reset inputs, so its assertion will cause a reset sequence to be initiated starting at DEST0. The FOSU module is reset with the same reset as is used by the FCCU. When this reset is asserted, the FOSU's capture logic is cleared, its timer is kept stopped and in a non-expired state, and its failure indicator output is deasserted.

NOTE

FOSU is triggered on assertion of enabled fault. In case the triggering fault is disabled, FOSU times out without reaction.

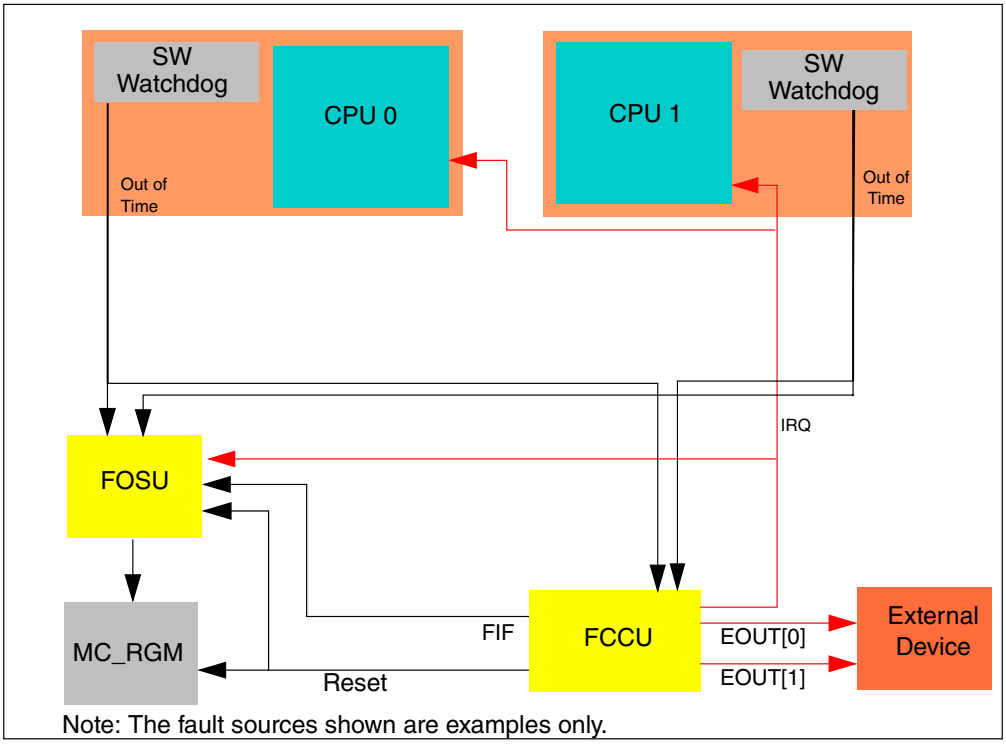

Figure 188. FOSU connections to the FCCU and MC_RGM

49.13 Use cases and limitations

Configuration guidelines

Follow these guidelines to configure FCCU:

- If you want FCCU to react to a fault on a non-critical fault channel:
  - Enable the channel (Non-critical Fault Enable (NCF_E0)).
  - Enable at least one type of Fault-state reaction for the channel: chip reset (Non-critical Fault-State Configuration (NCFS_CFG0)), fault-output (EOUT) signaling (Non-critical Fault-State EOUT Signaling Enable (EOUT_SIG_EN0)), or non-maskable interrupt (Non-critical Fault-State Non-maskable-Interrupt-Request Enable (NMI_EN0)).
  - If you enable chip reset as the type of Fault-state reaction for the channel (Non-critical Fault-State Configuration (NCFS_CFG0)), enable either ALARM state (Non-critical-Fault Alarm-State Timeout Enable (NCF_TOE0)) or at least one other type of Fault-state reaction for the channel: fault-output (EOUT) signaling (Non-critical Fault-State EOUT Signaling Enable (EOUT_SIG_EN0)) or non-maskable interrupt (Non-critical Fault-State Non-maskable-Interrupt-Request Enable (NMI_EN0)).
  - If you enable ALARM state for the channel (Non-critical-Fault Alarm-State Timeout Enable (NCF_TOE0)), enable the Alarm-state reaction (Non-critical Alarm-State Interrupt-Request Enable (IRQ_ALARM_EN0)).
  - If you enable ALARM state for the channel (Non-critical-Fault Alarm-State Timeout Enable (NCF_TOE0)), make sure the Alarm-state timer interval (Non-critical-Fault Alarm-State Timeout Interval (NCF_TO)) is less than the FOSU module's timer interval; otherwise, FOSU generates a chip reset every time a fault occurs on the channel. The FOSU timer interval (FOSU_COUNT) is chip-specific. See the chip-specific FCCU information.

NOTE

If you enable a non-critical fault channel but disable all reactions for that channel, FCCU changes state if necessary but doesn't perform any reaction because reactions are disabled. If you enable reactions for a non-critical fault channel but disable that channel, and FCCU is in NORMAL state when a fault occurs on the channel, FCCU doesn't enter ALARM or FAULT state and therefore doesn't perform any reaction.

Recommendations to configure FCCU

1. After a power on, or 'destructive' reset (when initiated by the assertion of the chip reset pin, RESET_B), where both system and FCCU are reset, the following steps could be followed to configure FCCU:
    a. Check and clear any pending fault status
    b. Verify FCCU is in NORMAL state, else repeat step(a) above
    c. Configure FCCU
2. After any 'functional' reset of the system, arising out of a reset request from FCCU or other sources, the following steps could be followed to reconfigure FCCU:
    a. If active, wait for the Error out T_{min} to expire
    b. Check and clear fault status
    c. Error pin moves to "non faulty" state, once fault status is cleared and T_{min} expires
    d. Verify FCCU is in NORMAL state, else repeat step(a) above
    e. Read and verify value in NCF_En
    f. Reconfigure FCCU, if necessary

49.14 Register descriptions

49.14.1 FCCU register descriptions

The FCCU registers are listed in the table below. Any address offset not explicitly mentioned in this table is reserved.

The FCCU supports word (32-bit), half-word (16-bit), and byte (8-bit) read and write accesses.

Follow these register-access guidelines:

- Do not read from or write to any addresses that are not shown in the following table. Doing so may or may not result in a transfer error.
- Do not write to any of the configuration registers unless FCCU is in the CONFIG state. Doing so results in a transfer error.
- Do not write to the Transient Configuration Lock (TRANS_LOCK) or Permanent Configuration Lock (PERMNT_LOCK) registers unless your code runs in the Supervisor mode. Doing so results in a transfer error.

For each possible NCF failure source, a different reaction—including no reaction—is configurable through the use of NMI, IRQ, and short reset selection registers. It is not possible for a single event upset to switch off all reactions on failures as implementation is per fault source (but it will be possible to switch them all off by SW if intended). Failures themselves are not able to disable all reactions and indications.

The FCCU is not reset by short functional resets.

Fields

Field	Function
31-0 CTRLK	Locked-Operation Control Key Writable only with a 32-bit write. Unlocks locked operations (CTRL[OPR]) so you can initiate them. For information on how to unlock locked operations before you initiate them, see Run an operation. **NOTE** • You must initiate an operation in the FCCU register access that immediately follows the one that unlocks it; otherwise, the operation is again locked. • Reading from this register always returns the value 0000_0000h. Operations not listed here are not locked and do not need to be unlocked. 9137_56AFh: Unlock OP1. 825A_132Bh: Unlock OP2. Any other value: Do nothing.

49.14.1.4 Configuration (CFG)

Offset

Register	Offset
CFG	8h

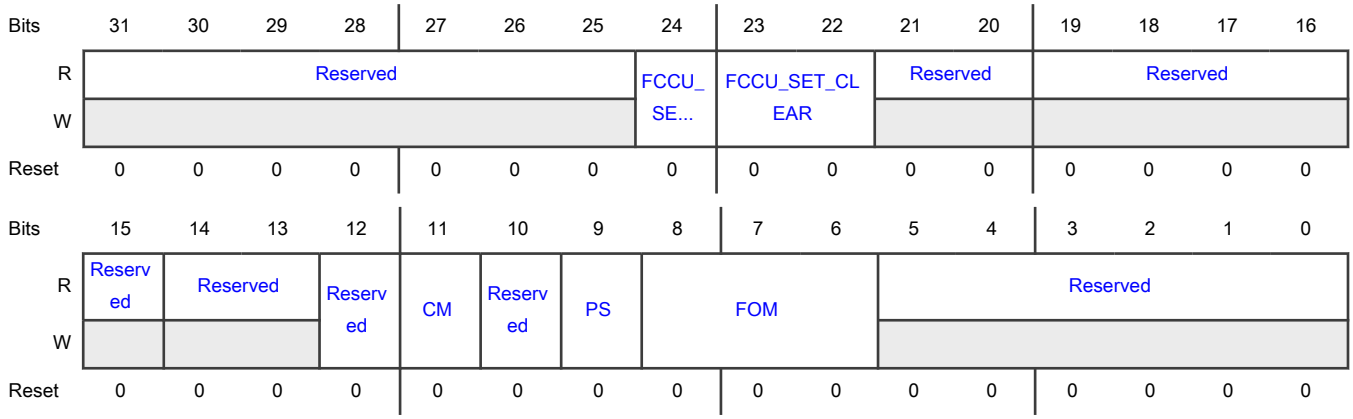
Function

Writable only when FCCU is in the CONFIG state. Changed by FCCU to another value when the chip resets FCCU, a Configuration-state timeout occurs, or you run an OP31 operation. See CFG register bit value at different events for more information. Specifies the global configuration for FCCU.

NOTE

If you specify a new value for any of the fields in this register that affect the EOUT signals while the fault-output (EOUT) timer is running (FCCU is indicating a fault on the EOUT signals), FCCU does not use the new settings you specified until after the fault-output (EOUT) timer expires (FCCU stops indicating a fault on the EOUT signals).

Diagram



Fields

Field	Function
31-25 —	Reserved
24 FCCU_SET_AFTER_RESET	Fault-Output (EOUT) Activate For fault-output (EOUT) signaling, controls whether the EOUT signals are active. 0b - Inactive (the EOUT signals are in a high-impedance state) 1b - Active (the EOUT signals indicate FCCU's condition)
23-22 FCCU_SET_CLEAR	Fault-Output (EOUT) Control Applies only to Bi-Stable fault-output mode (CFG[FOM]) and when the EOUT signals are active (CFG[FCCU_SET_AFTER_RESET]). Controls whether the fault-output (EOUT) signals are managed by FCCU's FSM. 00b - Controlled by the FSM 01b - Always low 10b - Controlled by the FSM 11b - High until a fault occurs on a channel, regardless of whether that fault is disabled; thereafter, controlled by the FSM. Note: FCCU ignores an attempt to write this value if the fault-output (EOUT) timer is already running.

Fields

Field	Function
31-0 NCFK	Non-critical Fault Key Writable only with a 32-bit write. Unlocks the NCF_Sa registers so you can write to them while recovering a software-recoverable non-critical fault. For information on how to unlock the NCF_Sa registers before writing to them, see Recover a software-recoverable non-critical fault. **NOTE** • You must write to one of the NCF_Sa registers immediately after unlocking it (that is, in the FCCU register access that immediately follows the one that unlocks them); otherwise the registers are again locked. If you want to write to multiple NCF_Sa registers, you must unlock each register immediately before you write to it. • Reading from this register always returns the value 0000_0000h. AB34_98FEh: Unlock. Any other value: Do nothing.

49.14.1.9 Non-critical Fault Enable (NCF_E0)

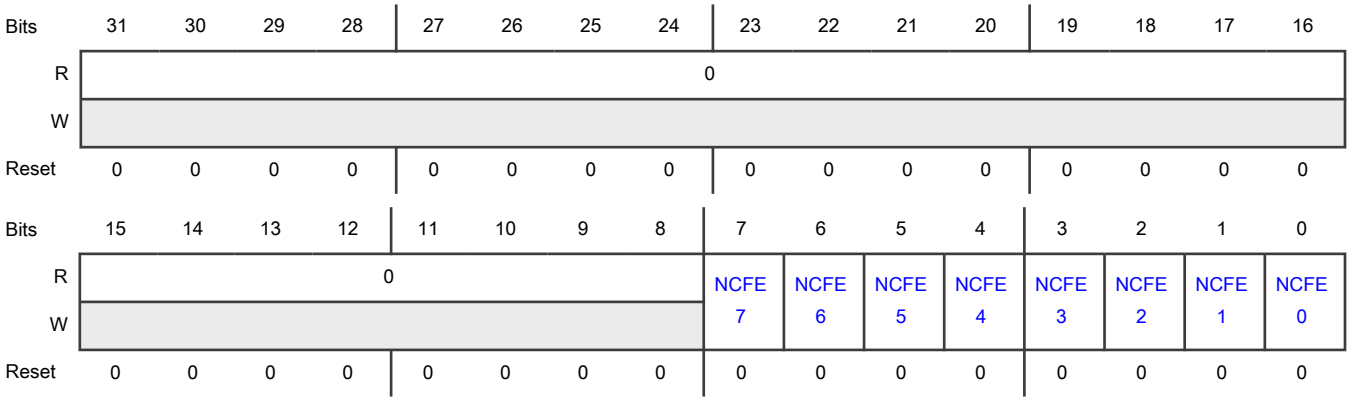
Offset

Register	Offset
NCF_E0	94h

Function

See NCF_Ea[NCFEn].

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 NCFEn	Non-critical Fault Enable n Writable only when FCCU is in the CONFIG state. Changed by FCCU to its reset value when a Configuration-state timeout occurs. Controls whether the associated non-critical fault channel (n) is enabled. When a non-critical fault channel is enabled, a fault on that channel causes FCCU to leave the NORMAL state and enter the FAULT state (or ALARM state if enabled for the channel). For information on how to configure the non-critical fault channels, see Configure the non-critical fault channels. 0b - Disabled 1b - Enabled

49.14.1.10 Non-critical-Fault Alarm-State Timeout Enable (NCF_TOE0)

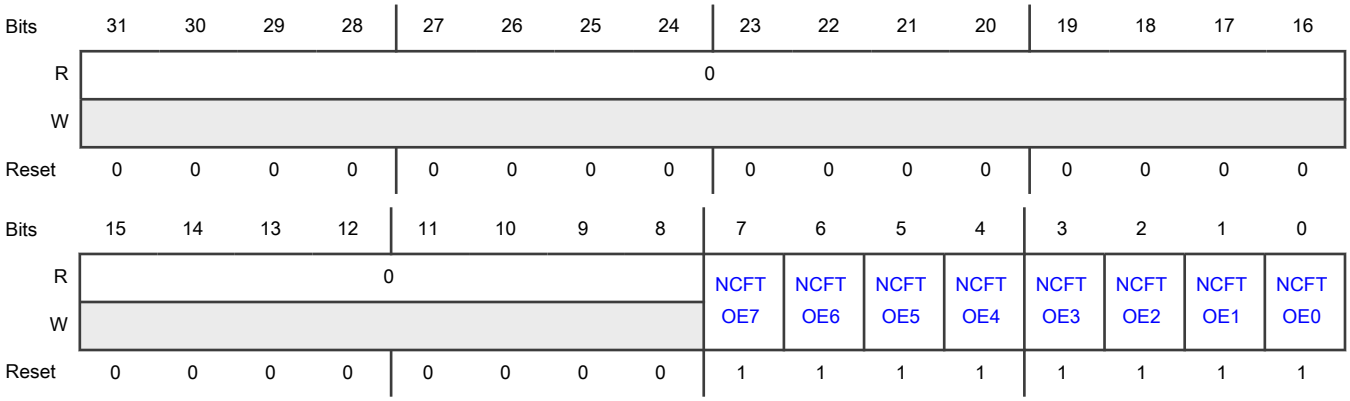
Offset

Register	Offset
NCF_TOE0	A4h

Function

See NCF_TOEa[NCFTOEn].

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 NCFTOEn	Non-critical-Fault Alarm-State Timeout Enable n Writable only when FCCU is in the CONFIG state. Changed by FCCU to its reset value when a Configuration-state timeout occurs. Controls whether the ALARM state is enabled for the associated non-critical fault channel (n). When the ALARM state is enabled for an enabled non-critical fault channel, a fault on that channel causes FCCU to leave the NORMAL state and enter the ALARM state instead of FAULT state. If the fault is not recovered within the Alarm-state timeout interval, then FCCU leaves the ALARM state and enters the FAULT state. For information on how to configure the non-critical fault channels, see Configure the non-critical fault channels. 0b - Disabled 1b - Enabled

49.14.1.11 Non-critical-Fault Alarm-State Timeout Interval (NCF_TO)

Fields

Field	Function
31-0 TO	Non-critical-Fault Alarm-State Timeout Interval Writable only when FCCU is in the CONFIG state. Changed by FCCU to its reset value when a Configuration-state timeout occurs. Controls the maximum amount of time that FCCU can be in the ALARM state ($T_{Max\ Alarm}$) according to this equation: $T_{Max\ Alarm} = TO \times T_{CLKSAFE}$ where $T_{CLKSAFE}$ is the safe-clock period. If FCCU enters the ALARM state (because a fault occurs on an enabled non-critical fault channel for which the ALARM state is enabled) and this timeout interval expires (called an Alarm-state timeout), then FCCU leaves the ALARM state and enters the FAULT state. **NOTE** Make sure the Alarm-state timeout interval is less than the FOSU module's timeout interval; otherwise, a fault that occurs while FCCU is in the ALARM state can cause FOSU to generate a chip reset. The FOSU timeout interval (FOSU_COUNT) is chip-specific. See the chip-specific FCCU information.

49.14.1.12 Configuration-State Timeout Interval (CFG_TO)

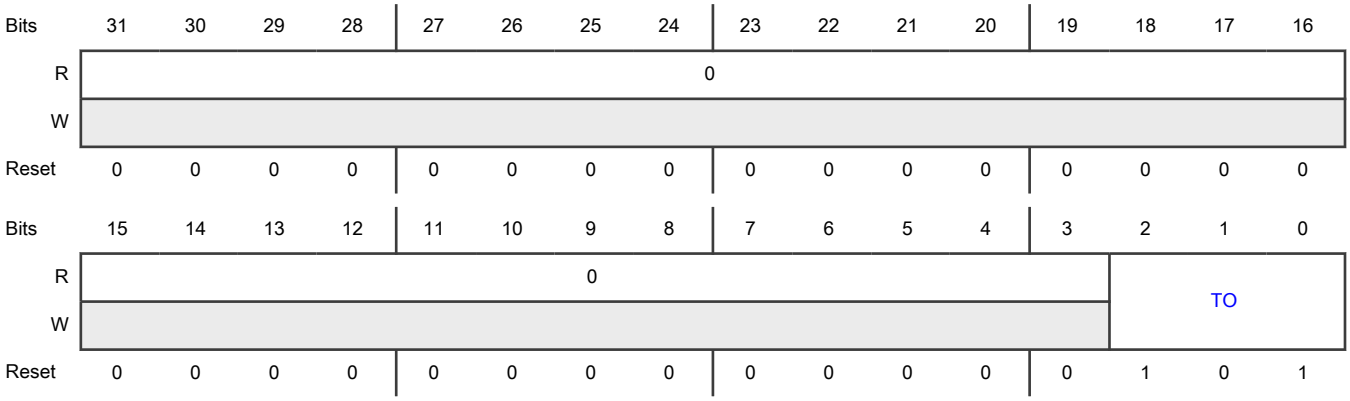
Offset

Register	Offset
CFG_TO	B8h

Function

See CFG_TO[TO]

Diagram



Fields

Field	Function
31-3 —	Reserved
2-0 TO	Configuration-State Timeout Interval Writable only when FCCU is in the NORMAL, ALARM, or FAULT state (not in the CONFIG state). Changed by FCCU to its reset value when a Configuration-state timeout occurs. Not accessible while a Configuration-state timeout (OP14 operation) is in progress. Controls the maximum amount of time that FCCU can be in the CONFIG state ($T_{\text{Max configuration}}$) according to this equation: $T_{\text{Max configuration}} = T_{\text{CLKSAFE}} \times 2^{(\text{TO} + 13)}$ where T_{CLKSAFE} is the safe-clock period. If you put FCCU in the CONFIG state and this timeout interval expires (called a Configuration-state timeout), then FCCU: • Automatically leaves the CONFIG state and enters the NORMAL state • Changes the value of the Configuration (CFG) register to its Configuration-state-timeout value and the value of each of the other configuration registers to its reset value. For information on the Configuration (CFG) register's Configuration-state-timeout value, see CFG register bit value at different events. For a list of configuration registers, see Configuration registers.

49.14.1.13 IO Control (EINOUT)

Offset

Register	Offset
EINOUT	BCh

Function

The EINOUT register allows the following operations typically in the NORMAL state:

- To control the EOUT[1] output level when the FCCU is configured in "Test1" or "Test0" fault output mode (CFG[FOM])

- To control the EOUT[0] output level when the FCCU is configured in "Test1" or "Test2" fault output mode (CFG[FOM])
- to observe the state of signals at EIN[1:0] pins

The following table shows Bi-Stable encoding.

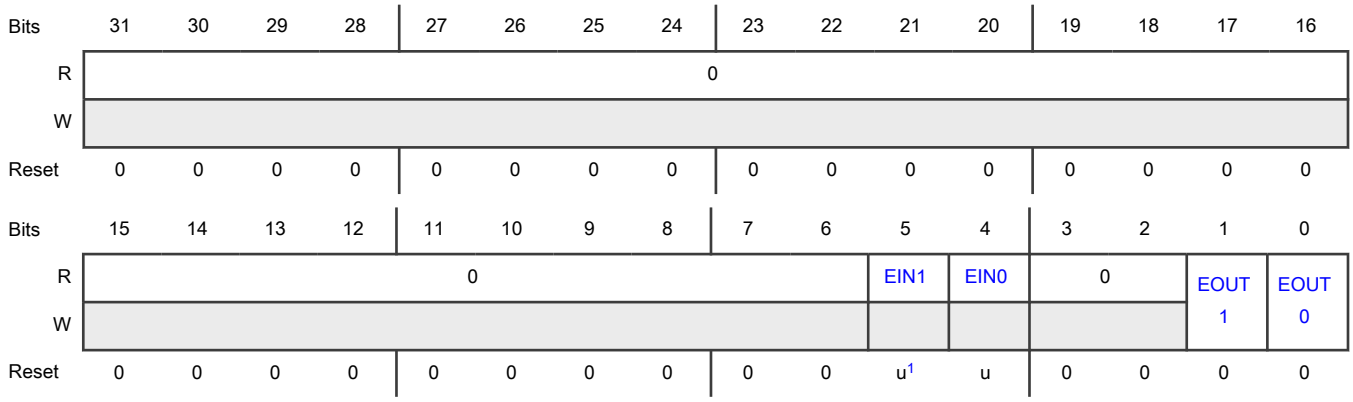
Table 231. Bi-Stable encoding

Mode = CFG[FOM]	EOUT[0]	EOUT[1]
Test1	output	output
Test2	output	input
Test0	input	output

NOTE

Because of the resynchronization stage of the EOUT interface, there is a latency of a few CLKSAFE cycles following a write/read operation of the EINOUT register.

Diagram



1. Reset value varies as per the corresponding EIN signal.

Fields

Field	Function
31-6 —	Reserved
5 EIN1	Error Input 1 Applies only when the EOUT signals are active (FCCU_SET_AFTER_RESET). Indicates the state of the EIN1 signal. 0b - Low 1b - High
4 EIN0	Error Input 0

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Applies only when the EOUT signals are active (FCCU_SET_AFTER_RESET). Indicates the state of the EIN0 signal. 0b - Low 1b - High
3-2 —	Reserved
1 EOUT1	EOUT1 Error out 1 (significant only if the CFG.FOM = Test1 or Test0 => EOUT[1] configured in output mode). The EOUT1 set/clear the respective EOUT[1] output signal if CFG.FOM = 110 or 101, otherwise it is a "don't-care" value. **NOTE** When the configuration watchdog timer expires, FCCU changes the value of this field to its reset value. 0b - force EOUT[1] = 0 1b - force EOUT[1] = 1
0 EOUT0	EOUT0 Error out 0 (significative only if the CFG.FOM = Test1 or Test2 => EOUT[0] configured in output mode). The EOUT0 set/clear the respective EOUT[0] output signal if CFG.FOM = 110 or 111, otherwise it is a "don't care" value. **NOTE** When the configuration watchdog timer expires, FCCU changes the value of this field to its reset value. 0b - force EOUT[0] = 0 1b - force EOUT[0] = 1

49.14.1.14 Status (STAT)

Offset

Register	Offset
STAT	C0h

Function

This register indicates the following:

- States that FCCU is driving on the EOUT signals
- Whether FCCU is in a faulty condition

- Current state of FCCU

FFh: Multiple Fault-to-Alarm-state transitions

49.14.1.19 Non-critical Fault Fake (NCFF)

Offset

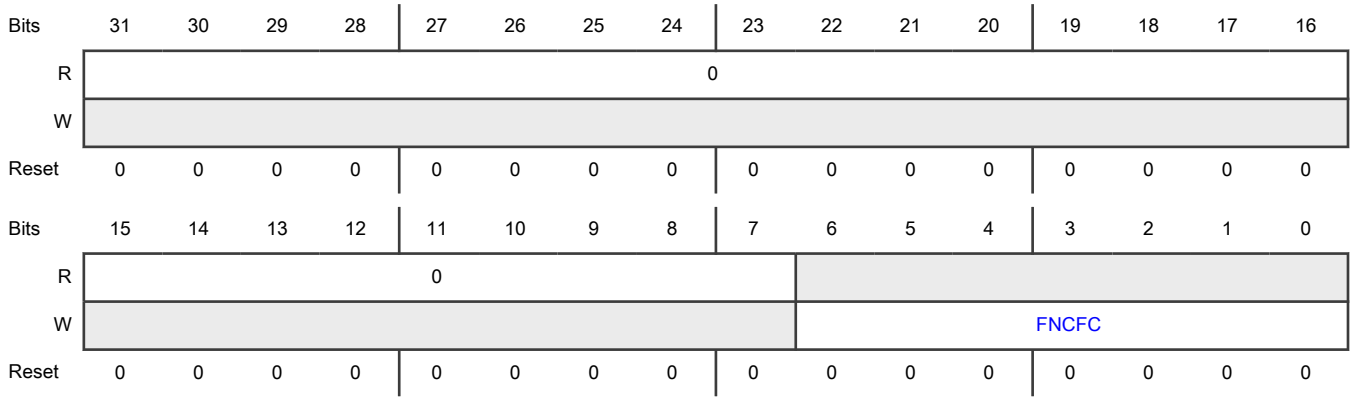
Register	Offset
NCFF	DCh

Function

This register contains a unique code to set a non-critical fault in mutually exclusive mode by the external FAULT interface (signal setting). It allows the SW emulation of the non-critical faults, by injecting the fault directly in the FAULT root, to verify the entire path and reaction. The reaction following a fake non-critical fault cannot be masked.

This is a write-only register with a set of codes corresponding to each non-critical fault injection.

Diagram



Fields

49.14.1.20 IRQ Status (IRQ_STAT)

Offset

Register	Offset
IRQ_STAT	E0h

Function

This register provides the FCCU interrupt status related to the following events:

- Configuration-state timeout error
- Alarm interrupt
- NMI interrupt

The configuration-state timeout interrupt is asserted if both IRQ_STAT[CFG_TO_STAT] and IRQ_EN[CFG_TO_IEN] bits are asserted. It is cleared when a 1 is written to the IRQ_STAT[CFG_TO_STAT] bit.

The NMI and ALARM interrupts are asserted and cleared according to the FCCU state. The status bits of the IRQ_STAT trace the status of the related interrupt lines.

Fields

Field	Function
31-8 —	Reserved
7-0 NMIENn	Non-critical Fault-State Non-maskable-Interrupt-Request Enable n

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Writable only when FCCU is in the CONFIG state. Changed by FCCU to its reset value when a Configuration-state timeout occurs. Controls whether the non-maskable interrupt request is enabled as a Fault-state reaction for the associated non-critical fault channel (n). When the non-maskable interrupt request is enabled for an enabled non-critical fault channel, a fault on that channel causes FCCU to assert the NMIOUT signal when FCCU enters the FAULT state; NMIOUT remains asserted until FCCU exits FAULT state. For information on how to configure the non-critical fault channels, see Configure the non-critical fault channels. 0b - Disabled 1b - Enabled

49.14.1.27 Non-critical Fault-State EOUT Signaling Enable (EOUT_SIG_EN0)

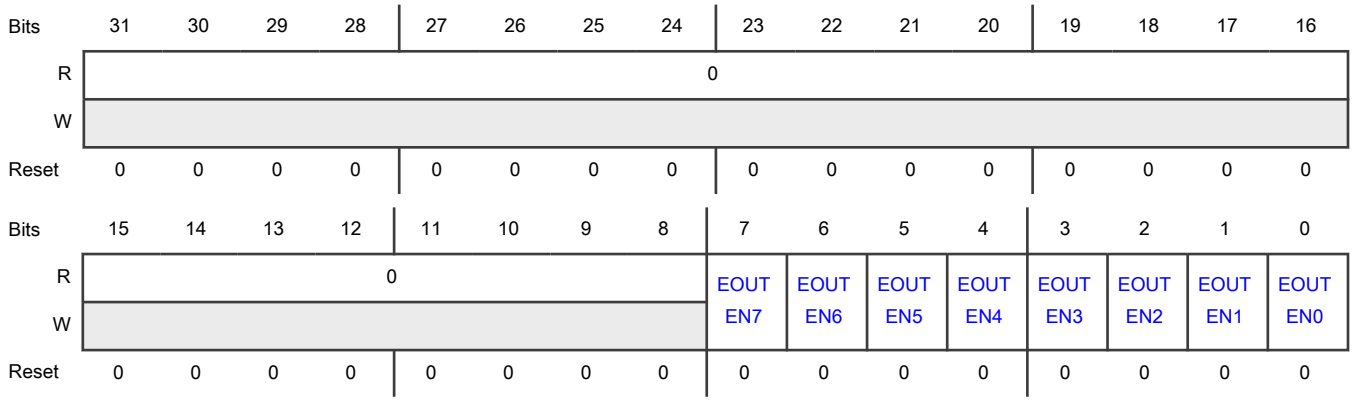
Offset

Register	Offset
EOUT_SIG_EN0	11Ch

Function

See EOUT_SIG_ENa[EOUTENn].

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0	Non-critical Fault-State EOUT Signaling Enable n

Table continues on the next page...

Table continued from the previous page...

Field	Function
EOUTENn	Writable only when FCCU is in the CONFIG state. Changed by FCCU to its reset value when a Configuration-state timeout occurs. Applies only when the EOUT signals are active (CFG[FCCU_SET_AFTER_RESET]). When FCCU is configured for Bi-Stable fault-output mode (CFG[FOM]), controls whether EOUT signaling is enabled as a Fault-state reaction for the associated non-critical fault channel (n). (For other fault-output modes, EOUT signaling is always enabled, regardless of the value of this field.) When EOUT signaling is enabled for an enabled non-critical fault channel, a fault on that channel causes FCCU to indicate the faulty condition on the EOUT[1:0] signals when FCCU enters the FAULT state. For information on how to configure the non-critical fault channels, see Configure the non-critical fault channels. For all fault-output modes, also controls whether FCCU asserts the FIF signal when a fault on the associated non-critical fault channel (n) causes FCCU to enter the FAULT state. **NOTE** For all fault-output modes, you must set this field to enabled to ensure that FCCU asserts the FIF signal when FCCU enters FAULT state as the result of a fault on the associated non-critical fault channel (n) so the FOSU module does not mistakenly generate a destructive chip reset. 0b - In Bi-Stable fault-output mode, both EOUT signaling and FIF assertion are disabled; in other fault-output modes, EOUT signaling is enabled and FIF assertion is disabled. 1b - Both EOUT signaling and FIF assertion are enabled in all fault-output modes.

49.14.1.28 Alarm-State Timer (TMR_ALARM)

Offset

Register	Offset
TMR_ALARM	12Ch

Function

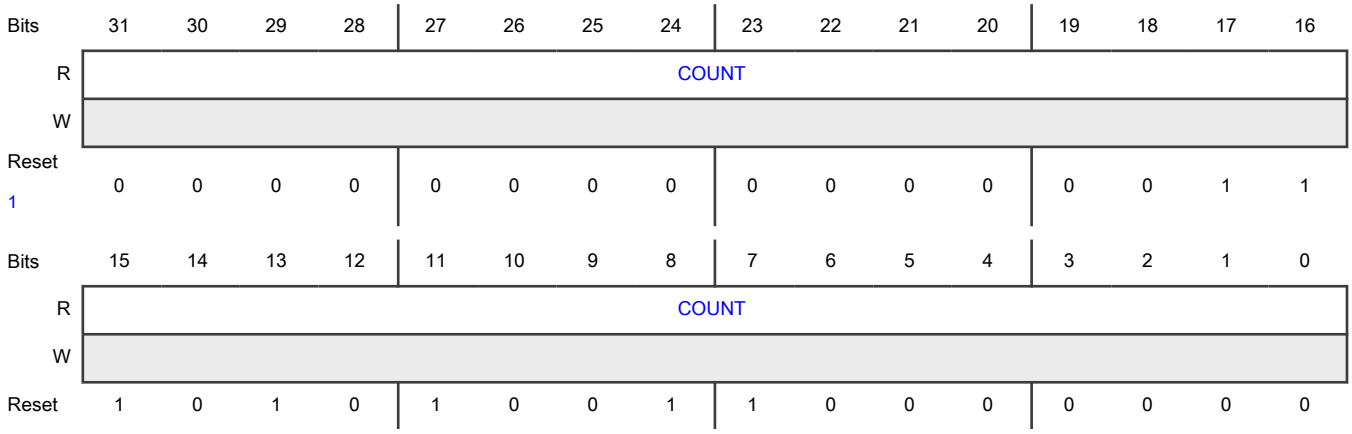
See TMR_ALARM[COUNT].

This table shows how the Alarm-state timer's state and value vary by FCCU state:

Table 232. TMR_ALARM reset value

FCCU state	Timer state	Timer value
CONFIG	Idle	0000_0000h
NORMAL	Idle	Initial value: NCF_TO[TO]
ALARM	Running	Value when read
FAULT	Idle	End of count

Diagram



1. The default reset value is provided by NCF_TO[TO]. See Table 232 for the reset value at different FCCU states.

Fields

Field	Function
31-0 COUNT	Alarm-State Timer Count Specifies the value of the Alarm-state timer in CLKSAFE periods.

49.14.1.29 Configuration-State Timer (TMR_CFG)

Offset

Register	Offset
TMR_CFG	134h

Function

See TMR_CFG[COUNT].

This table shows how the Configuration-state timer's state and value vary by FCCU state:

FCCU state	Timer state	Timer value
CONFIG	Running	Value when read
NORMAL	Idle	000F_FFFFh
ALARM	Idle	000F_FFFFh
FAULT	Idle	000F_FFFFh

Diagram

Field	Function
31-0 COUNT	Configuration-State Timer Count Specifies the value of the Configuration-state timer in CLKSAFE periods.

49.14.1.30 Fault-Output Timer (TMR_ETMR)

Offset

Register	Offset
TMR_ETMR	138h

Function

See TMR_ETMR[COUNT].

This table shows how the fault-output timer's state and value vary by FCCU state:

FCCU state	Timer state (value)
CONFIG	Idle (0000_0000h)
NORMAL	Idle (0000_0000h)
ALARM	Idle (0000_0000h)
FAULT	Running (value when read)

Diagram

Fields

Field	Function
31-0 COUNT	Fault-Output Timer Count Specifies the value of the fault-output timer in CLKSAFE periods.

49.14.2 Configuration registers

49.14.2.1 Definition

Configuration registers are registers that:

- Let you configure FCCU's Alarm-state timer interval, fault channels, and fault-output (EOUT) signals.
- You can write to only when the configuration is not locked and FCCU is in CONFIG state (see Put FCCU in the CONFIG state).
- Save the values you write to them while FCCU is in CONFIG state only after you manually put FCCU in NORMAL state. If FCCU automatically leaves CONFIG state and enters NORMAL state because the configuration-timer interval (CFG_TO[TO]) expires (called a Configuration-state timeout), FCCU changes the value of the Configuration (CFG) register to its Configuration-state-timeout value and the value of each of the other configuration registers to its reset value; FCCU also changes the value of the Configuration-State Timeout Interval (CFG_TO) register to its reset value. For information on the Configuration-state timeout value, see CFG register bit value at different events.

49.14.2.2 Configuration registers

Following is the list of configuration registers in this module. They are listed in an offset order from lowest to highest.

- Configuration (CFG)
- Non-critical Fault Configuration (NCF_CFGa)
- Non-critical Fault-State Configuration (NCFS_CFG0)
- Non-critical Fault Enable (NCF_E0)
- Non-critical-Fault Alarm-State Timeout Enable (NCF_TOE0)
- Non-critical-Fault Alarm-State Timeout Interval (NCF_TO)
- Delta T (DELTA_T)
- Non-critical Alarm-State Interrupt-Request Enable (IRQ_ALARM_EN0)
- Non-critical Fault-State Non-maskable-Interrupt-Request Enable (NMI_EN0)

- Non-critical Fault-State EOUT Signaling Enable (EOUT_SIG_EN0)

49.14.3 CFG register bit value at different events

In this chip, there are no events that affect the bits in the configuration register.

49.15 Glossary

CF	Critical fault
EOUT	Error out
FOSU	FCCU output supervision unit
FSM	Finite state machine
intf	Interface
IRQ	Interrupt request
NCF	Non-critical fault
NMI	Non-maskable interrupt

Chapter 50
Self-test General-Purpose Registers (SELFTEST_GPR)

50.1 Introduction

SELFTEST_GPR configures the STCU2 LBIST shift cycles. Programming self-test GPRs is a part of the self-test programming sequence. See the "Self-test programming sequence" section in the STCU2 chapter.

NXP supports only STCU2 Built-In Self-Test (BIST) sequences that have been validated by NXP for in-field testing usage.

The detailed programming sequences for supported configurations are available in a separate application note (contact your NXP sales representative).

The values for SELFTEST_GPR registers must be aligned with the NXP supported configurations only.

NOTE

SELFTEST_GPR is not present in MWCT2016S and MWCT2015S.

NOTE

While accessing SELFTEST_GPR space, software must ensure that the STCU2 block has its clock enabled, i.e., MC_ME.PRTN1_COFB3_CLKEN[REQ104] configured as 1'b1. Not ensuring this might result in unpredictable device behaviour.

50.2 Peripheral shift clock switching (PCS)

The PCS feature is used to avoid current surges at the start and/or end of LBIST. Since LBIST can cause sudden current surges which might lead to chip malfunction.

With PCS enabled, there are additional (SELFTEST_GPR.CONFIG_GPR[PCS_STEP_SIZE] + 1)*16 patterns beyond the configured count. If enabled at the start of LBIST (using SELFTEST_GPR.CONFIG_GPR[PCS_ENABLE_START]), it would cause the shift clock to scale up in this duration from divide by 16 to the original frequency (by changing divider in each step).

Similarly, if configured at the end of LBIST (using SELFTEST_GPR.CONFIG_GPR[PCS_ENABLE_END]), the shift clock frequency will be scaled down from original frequency to divide by 16.

50.3 SELFTEST_GPR register descriptions

50.3.1 SELFTEST_GPR memory map

SELFTEST_GPR base address: 403B_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Configuration register (CONFIG_REG)	32	RW	0000_ADD5h
14h	LBIST Program (LBIST_PROG_REG)	32	RW	0003_0050h

50.3.2 Configuration register (CONFIG_REG)

Offset

Fields

Field	Function
31-8 —	Reserved
7-0 LBIST_SHIFT_COUNT	LBIST Shift Count Specifies the number of shift cycles in a scan chain in one pattern count for the LBIST partition.

50.4 Glossary

BIST clock	The BIST clock refers to the BIST operational clock which is the clock source used while LBIST is operational by the LBIST controller, which is the MC_CGM clock node LBIST_CLK for the chip. See the system block diagram for details.
LBIST	Logic built-in self-test
Pattern count	The pattern count refers to an empirically determined value of shift patterns run in LBIST on a scan chain to result in predetermined fault coverage, based on device safety integrity level. Since the LBIST scheme is Pseudo Random Testing, a sufficiently good value of pattern count is used which provides the required fault coverage.
Scan chain	A sequential chain of flops in scan mode over which one scan pattern (generated by PRPG, that is, Pseudo Random Pattern Generator) in LBIST will be shifted and the output MISR (Multi Input Signature Register) will be matched with earlier known value to determine pass or fail criterion of that particular chain.

Chapter 51
Self-Test Control Unit (STCU2)

51.1 Chip-specific STCU2 information

51.1.1 Supported BIST sequences

This chip supports only STCU2 BIST sequences that NXP has validated for in-field testing usage. The detailed programming sequences for supported configurations are available in a separate application note (contact your NXP sales representative for this information).

51.1.2 Self-test overview

STCU2 provides the overall control of both LBIST and MBIST, in serial or parallel, depending on the power, timing, or coverage constraints.

NOTE

LBIST is not available for MWCT2016S and MWCT2015S.

The application software initiates the self-test sequence or procedure (please use whichever term is correct), and has provisions to bypass the self-test configuration to directly move to normal Run mode.

There is a programmable BIST-sequence-execution watchdog timer that specifies the maximum time allowed for the execution of a BIST sequence. In case the selected LBISTs or MBISTs are not complete during the assigned time, the current LBISTs or MBISTs execution is interrupted and a failure is flagged into ERR_STAT[WDTOSW] and MBESWx or LBESW.

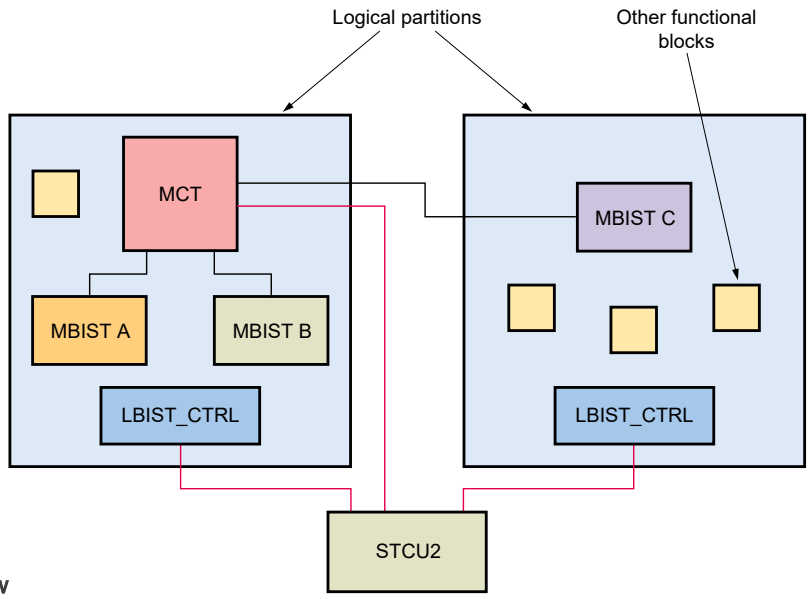
The STCU2 execution includes three phases:

- Software configuration. Load or program the test configuration parameters to be executed, depending on ASIL target and performance requirements. The self-test configuration parameters allow the self-test sequence to run with different times depending on pattern numbers and types, achieving different levels of coverage.
- Start of BIST execution. This involves software register configuration in STCU2. The BIST completion is followed by a functional reset.
- End of BIST execution. After BIST execution and functional reset are complete, the BIST results are made available and you decide how to continue (trigger a new reset or start a safety application). The BIST execution completion is signalized in an internal STCU2 register (LBESWn) bit which is not affected by the functional reset. The BIST test results are also not affected by the functional reset.

The following figure shows a pictorial representation of two LBIST partitions having two and one MBIST groups, respectively. STCU2 interacts with LBIST_CTRL for the respective partitions to configure and control the LBIST sequence and compare results.

It also interacts with MTR controller (MCT) for MBIST. Each LBIST partition has its corresponding controller whereas a single MCT can cater to multiple MBIST groups.

Figure 189.



Self-test overview

NOTE

LBIST_CTRL is not available for MWCT2016S and MWCT2015S.

Each LBIST partition also includes a block called Self-test GPR involving a set of registers that provide miscellaneous configuration and parameter details for an LBIST operation.

When you trigger a self-test sequence, the chip becomes unavailable for software application during the self-test run.

51.1.3 STCU2 LBIST/MBIST mapping

This topic covers STCU2 LBIST/MBIST mapping.

LBIST mapping

The below table lists the LBIST mapping of the chip. The NLBIST value is 1.

Table 233. LBIST mapping

BIST ID (NLBIST)	BIST instance name	Modules
0	LBIST	DMA: • DMA controller
		EIM
		ERM
		XRDC • MDAC0 • MDAC1

Table continues on the next page...

Table 235. MWCT2016S MBIST mapping (continued)

BIST index (NMCUT)	BIST name	Memory index	Memory instance name
4	FLEX_CAN_RAMS	5	FLEXCAN5 MB memory

There are different number of MBIST indices (NMCUT) across different parts. The below table shows the variation across different chips.

Table 236. NMCUT

Chip	NMCUT
MWCT2D17S	12
MWCT2016S	5

51.1.4 Clock connectivity

STCU2 works on the system clock domain. The scan operations while LBIST are done on TCK clock.

Table 237. Clock connectivity

STCU2 clock	Clock connected to the chip	Remarks
STCU2 CORE_CLK	AIPS_SLOW_CLK	System clock divider output clock node for STCU2 operations and register interface accesses
REG_INTF_CLK		
SHIFT_CLK	JTAG_TCK	JTAG_TCK used for shift operations when self-test is in progress

51.1.5 Memory map for self-test GPRs

See the memory map file attached to this document and 'SELFTEST_GPR' chapter for details.

51.1.6 Handling unrecoverable faults

Only recoverable and non-critical faults from STCU2 are mapped to FCCU. The unrecoverable and critical faults are mapped to MC_RGM. Therefore, ignore any references to mapping of unrecoverable and critical faults with FCCU in this chapter.

51.1.7 Indicating fault state during the main reset domain Self-Test

FCCU EOUT indicates the fault state during the Self-Test as soon as the UTEST_MISC[FCCU_EOUT_ DEDICATED] is enabled and DCMRWD2[EOUT_STAT_DUR_STEST] is enabled at the time of Self-Test setup steps.

The fault state remains asserted until the bit DCMRWD2[EOUT_STAT_DUR_STEST] is cleared post Self-Test reset sequence.

In case it is not required to indicate the fault state during the Self-Test, then the bit DCMRWD2[EOUT_STAT_DUR_STEST] should not be programmed.

51.1.8 Error events management in main reset domain Self-Test

Error events should be mapped to unrecoverable faults in STCU2_ERR_FM register for main reset domain Self-Test.

51.1.9 AUTOLOCK_VALUE for register write access via STCU2_SKC

Register write-access watchdog timer explains that access to STCU2 registers via the STCU2_SKC security-key mechanism times out after a number of STCU2 clock cycles equal to AUTOLOCK_VALUE. On this chip, AUTOLOCK_VALUE is 32'hFFFF_FFFF.

51.1.10 PLL loss of lock during Self-Test

Detection of PLL loss of lock during LBIST or MBIST causes a destructive reset in the system.

CMU0 programming is required before the Self-Test programming begins.

All the registers present in LBIST domains do not retain their content after Self-Test reset.

51.1.11 STCU2 BIST start (BSTART) register description

Attempted accesses with the undefined reserved values in the BSTART register can result in undefined behavior. The following table defines the BSTART field on this chip.

Table 238. BSTART description

Field value	Description
000b	NOP (reset value)
001b	RUN_ONLY: Run BISTs. MTR controller (MCT) runs the selected BISTs without programming them first.
010b	Reserved
011b	Reserved
100b	PROG_ONLY: Program BISTs only. MCT only programs BISTs and does not start them. This enables different BISTs to be programmed with different algorithms before all the selected BISTs are started using the RUN_ONLY command.
101b	PROG_RUN: Program BISTs and start them.
110b	Reserved
111b	Reserved

51.1.12 STCU2 algorithm select (ALGOSEL) register description

This register selects any one of the predefined algorithms. The value used in this register is mapped to a predefined algorithm register in BIST. After MCT has programmed information on this register and starts some BIST operation, this value is transferred to the predefined algorithm register in every BIST that is selected.

If multiple predefined algorithms are selected, the order of execution is from LSB to MSB.

Any field that does not have a predefined algorithm associated with it is a reserved bit. No data is written to reserved bits and when you read these bits, they always return 0. These predefined algorithms include:

- Backgrounds
- Address modes and other register programming that may be necessary
- The number of BIST runs needed to perform the exact coverage requested.

MCT decodes this information through a series of look-up tables. The following table describes the high-level BIST algorithms that can be invoked through the MCT. The columns in that table have the following meaning:

- Index: The position in this MCT register enables this algorithm.
- Name: The symbolic name for this algorithm.
- Description: The intent and use model for this algorithm.
- BIST runs: The sequence of BIST invocations comprising this algorithm.
- Sequences: The ordered list of march elements to run. Each march element consists of a direction indicator (for increasing addresses and for decreasing addresses) and a set of march phases. A march phase consists of reading (R) or writing (W), the non-inverted (0) or inverted (1) background pattern.
- Used by default: Whether this algorithm is selected in the post-reset state of this register.

Table 239. ALGOSEL description

Index	Name	Description	BIST runs	Sequences	Used by default
3	March C+ single	March C+ with column fast and solid background	MarchC+ column fast 1x (#4)	W0, R0W1, R1W0R0W1, R1W0, R0W1R1W0, R0	Yes
13	BasicChk	Basic selfcontained checkerboard, using column fast	BasicChk (#18)	R0W1R1	-

51.1.13 Self-Test programming sequence

This section describes a high level programming sequence for executing Self-Test. The detailed programming sequences for supported configurations are available in a separate application note (contact your NXP sales representative).

- Program clock sources and MC_CGMs as per the clock configuration.

  NOTE

  While running MBIST on EMAC timestamp memory, MC_CGM.MUX_9_DC_0[DIV] should be appropriately configured to ensure EMAC_CLK_TS should be atleast 1.5 times the AIPS_SLOW_CLK frequency.

- Program SELFTEST_GPR[CONFIG_REG] and SELFTEST_GPR[LBIST_PROG_REG] as per the LBIST configurations.

  NOTE

  This is not applicable for MWCT2016S and MWCT2015S wherein LBIST is not supported.

- Program STCU2 as per NXP recommended.
- Program dcf_client_utest_misc[FCCU_EOUT_DEDICATED] and DCMRWD2[EOUT_STAT_DUR_STEST] to configure EOUT pins as dedicated and to indicate FCCU error states on EOUT pins during Self-Test respectively.
- Configure ERCTRL[ERASSERT] register bit in MC_RGM to achieve desired behaviour of Reset Pin as documented in Reset Section and Pad States Section.
- Disable functional reset sources to avoid false Self-Test abort scenarios. For example, software watchdog timers cannot be serviced while Self-Test because the software is not accessible and can cause invalid timeout reset. See Reset events and configurations while Self-Test.
- Program the PCS_ENABLE[8:7] fields of the CONFIG_REG register (SELFTEST_GPR) to 0 to disable PCS.
- Trigger Self-Test execution by programming RUNSW register in STCU2.
- At the end of the Self-Test run, a functional reset is generated. Out of reset, the software can check the status registers inside STCU2 and take actions accordingly.

51.1.14 Modules operation during/post Self-Test

The clock, reset, power generation modules, such as RGM, PMC, CGM, FIRC, PLL, and SIRC will be available during and post Self-Test. However, because the chip undergoes the reset sequence, PLL and CGM will be reset.

CMU0 and CMU3 will be available during Self-Test if enabled prior to Self-Test, but will be Reset post Self-Test.

STCU2 will also be available during Self-Test and the results can be read post Self-Test.

51.1.15 Reset events and configurations while Self-Test

As Self-Test is a software initiated Self-Test, it is expected by software to ensure all the peripherals are disabled as documented in Software considerations before Self-Test.

The functional reset sources should be appropriately configured to avoid any functional reset while Self-Test is running (disable SWT_RST and HSE_SWT_RST. JTAGC should not be in EXTEST, HIGHZ or CLAMP instructions). This ensures no selftest abort while running selftest due to functional reset source. The below table specifies the state of functional reset sources for Self-Test.

Table 240. Reset events and configurations while self-test

Reset source	Reset description	Configurations/remarks for selftest
FCCU_RST	FCCU reset reaction	The FCCU is a part of logic which is under Self-Test and thus it would be disabled during the Self-Test
ST_DONE	Self-Test done reset	The selftest done indication resets the device post selftest. While Self-Test is running, the Self-Test done indication will be in disabled state
SWT_RST	SWT reset request	SWT should be disabled in Self-Test configuration sequence.
JTAG_RST	JTAG Reset	JTAG communication should be inactive while Self-Test and JTAGC state machine should not be in EXTEST, HIGHZ or CLAMP instructions
HSE_SWT_RST	HSE SWT timeout	HSE_SWT should be disabled in Self-Test configuration sequence.
SW_FUNC	software 'functional' reset	The software is inactive during Self-Test and hence software functional reset will not arrive while the chip is under Self-Test.
DEBUG_FUNC	debug 'functional' reset	MDM DAP should not be configured for debug functional reset generation while Self-Test is running.

The destructive reset sources are available while in Self-Test. In case of any destructive reset event, the device undergoes a destructive reset sequence, thereby resetting the STCU2 and Self-Test logic itself.

After completion of Self-Test (LBIST or MBIST), a functional reset sequence is executed by MC_RGM.

51.1.16 Software considerations before Self-Test

1. As all the communication peripherals are not in LBIST partitions; hence, it is required by SW to stop all communications and disable all the PCTLs of the communication peripherals before initiating Self-Test as the device will be unusable in Self-Test. This is needed so that there is graceful safe stating of inputs of non-lbisted peripheral modules.
2. Configure RGM functional reset sources as interrupts before Self-Test as per the considerations mentioned in Reset events and configurations while Self-Test, i.e., the SWTs should be disabled, the JTAGC should not be in states which can cause a JTAG reset event (EXTEST, HIGHZ, CLAMP instructions) and the software should not trigger a functional reset event via MC_ME or MDM_AP while the selftest is ongoing. This is to avoid any abort scenario due to any functional reset source as Self-Test is initiated by SW.

There is no issue with Reset pin as Reset pin is a source of destructive reset and will reset STCU2 and Self-Test related logic etc.

51.1.17 End of Self-Test

The Self-Test completion is a source of functional reset to the device, by which the device executes a functional reset sequence. The logic which is LBISTed additionally undergoes a complete POR sequence to ensure that the random content shifted during BIST sequence get cleared.

At the end of MBIST, the software should execute below steps:

1. Software reads the MBIST end flag to identify that the MBIST sequence had ended properly without any interruption or abort, by reading STCU2.MBESWn.
2. Software reads the MBIST status to identify whether the MBIST was successful or not, by reading STCU2.MBSSWn.

NOTE

The MBIST status should always be read in accordance with MBIST end flag. The STCU2.MBSSWn status is irrelevant if STCU2.MBESWn indicates that MBIST execution is incomplete.

At the end of LBIST, the software should execute below steps:

1. Software reads the LBIST end flag to identify that the LBIST sequence had ended properly without any interruption or abort, by reading STCU2.LBESWn.
2. Software reads the LBIST status to identify whether the LBIST was successful or not, by reading STCU2.LBSSWn.

NOTE

The LBIST status should always be read in accordance with LBIST end flag. The STCU2.LBSSWn status is irrelevant if STCU2.LBESWn indicates that LBIST execution is incomplete.

51.2 Introduction

STCU2 is a comprehensive programmable hardware module that:

- Manages the execution of BISTs
- Indicates whether each BIST passed
- Manages the chip's LBIST and the MBIST blocks

51.3 Main features

STCU2 includes:

- System interface for reading from and writing to the STCU2 registers during runtime (online) via the CPU
- Programmable scheduler for BIST execution
- Control over LBIST concurrent or sequential execution
- Control over MBIST concurrent or sequential execution
- Programmable LBIST delayed concurrent start
- Programmable internal clock prescaler to reduce internal and BIST clocks
- PLL lock signal monitoring during BIST sequences
- Programmable BIST-sequence-execution watchdog timer that specifies the maximum time allowed for the execution of a BIST sequence
- Fixed register-write-access watchdog timer that specifies the maximum amount of time that STCU2 allows you to write to its registers after you unlock them
- Fields that indicate the execution status of each BIST, see Types of BIST sequences and Types of BIST partitions
- Fields that indicate the status of each type of online STCU2 internal error condition

- Programmable fault mapping of each BIST for controlling the type of fault that STCU2 reports (recoverable or unrecoverable) when the BIST fails to execute
- Programmable fault mapping of each STCU2 internal error condition for controlling the type of fault that STCU2 reports (recoverable or unrecoverable) when the condition occurs
- Signals to report recoverable and unrecoverable faults to the FCCU module
- Redundant recoverable and unrecoverable fault-generation logic to improve reliability
- FCCU recoverable and unrecoverable fault-injection mechanism
- Global register write-protection mechanism that requires two security key codes
- Global automatic power saving after a BIST sequence is completed when watchdog timer time-out is detected
- Watchdog automatic clock wake-up mechanism when software unlocks the STCU2 registers for write access
- Watchdog automatic power saving when the fixed register-write-access watchdog timer times out

51.4 Block diagram

This diagram shows the parts of STCU2:

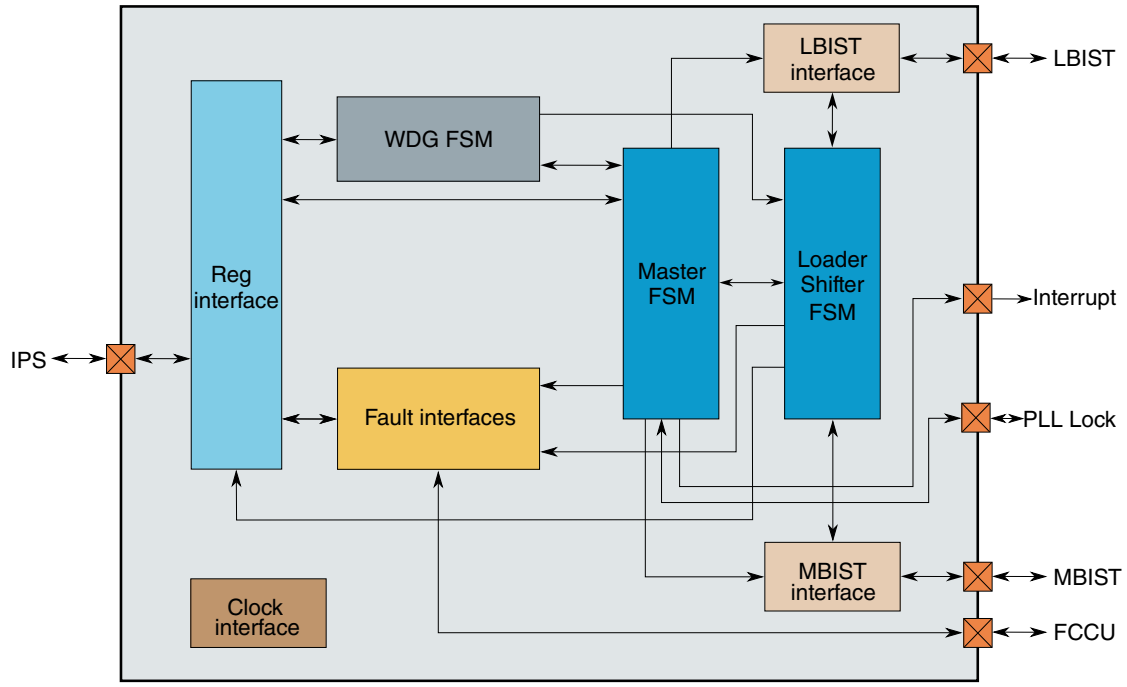

Figure 190. STCU2 block diagram

This table describes the parts of STCU2:

Table 241. STCU2 parts

Part	Function
Reg interface	Provides access to: • Registers

Table continues on the next page...

Table 241. STCU2 parts (continued)

Part	Function
	• The security key logic • The IPS interface
Fault interface	Performs the following tasks: • Collects the fault conditions caused by STCU2 internal error conditions and each BIST executed in a sequence • Sets the global recoverable or unrecoverable status flag, depending on the fault mapping for a given BIST • Manages the recoverable and unrecoverable fault lines to and from the FCCU module • Manages the set/clear injection mechanism provided by the FCCU module To improve the intrinsic reliability of this critical logic, the generation logic is duplicated.
Clock interface	Manages the internal and the BIST clock prescaler, the internal clock-gating power saving, and the wake-up clock feature
WDG FSM	Provides the following: • A programmable BIST-sequence-execution watchdog timer that specifies the maximum time allowed for the execution of a BIST sequence • A fixed register-write-access watchdog timer that specifies the maximum amount of time that STCU2 allows you to write to its registers after you unlock them
Master FSM	Coordinates and schedules all of the operations performed during a BIST sequence
Loader Shifter FSM	Programs the BIST registers and reads back the data to be checked at the end of each test operation
LBIST interface	Provides the interface between the chip's LBIST engines and the STCU2 controllers
MBIST interface	Provides the interface between the MBIST controller (MTR) and the STCU2 controllers

51.5 Peripheral bus interface

The peripheral bus interface is a slave bus used for configuration purposes via CPU. The module supports the following bus read operations:

- Word (32 bits) data read operations to any registers
- Any other operation is not supported.

Word, low and high half-words, byte operations are supported in write mode only:

- Write access is allowed by software only when CFG[WRP] is cleared. The default value of CFG[WRP] is cleared.
- Exceptions are the following read/write fields: CFG[WRP], ERR_STAT[UFSF] and ERR_STAT[RFSF].
- In all the other conditions, the write operations are not supported and all the STCU2 registers can be only read.

- STCU2 Configuration (CFG) should only be accessed in 32 bit (partial access not allowed).

The STCU2 module generates a transfer error in the following cases:

- Any read access to the registers after writing Key1 and before writing Key2 (in online) and before register write-access watchdog timer expires.
- Any write/read access to the register addresses not mapped on the peripheral but included in the address space of the peripheral
- Any write/read operation different from byte/halfword/word (free byte enables or other operations) on each register
- Any write operation on Double Security Key register applying a wrong sequence of keys (the two write operations cannot be interleaved with other access to STCU2 registers)
- Any write operation performed on a register when the Double Security keys have not been applied
- Any write operation performed on registers when CFG[WRP] is set and the access is performed through software (internal peripheral interface). The exceptions are SKC register (for valid keys value and sequence) and INT_FLG register(interrupt flag) in which STCU2 does not assert transfer error.
- Any write operation performed on Read Only registers

The registers of the STCU2 module are accessible (read/write) in each access mode: user, supervisor, or test.

In case there are write operations on bits marked as reserved, the transfer error is not generated.

NOTE

See the chip-specific STCU2 information for the wait time necessary to write to the online registers.

51.6 BISTs and BIST partitions

51.6.1 Definition: BIST

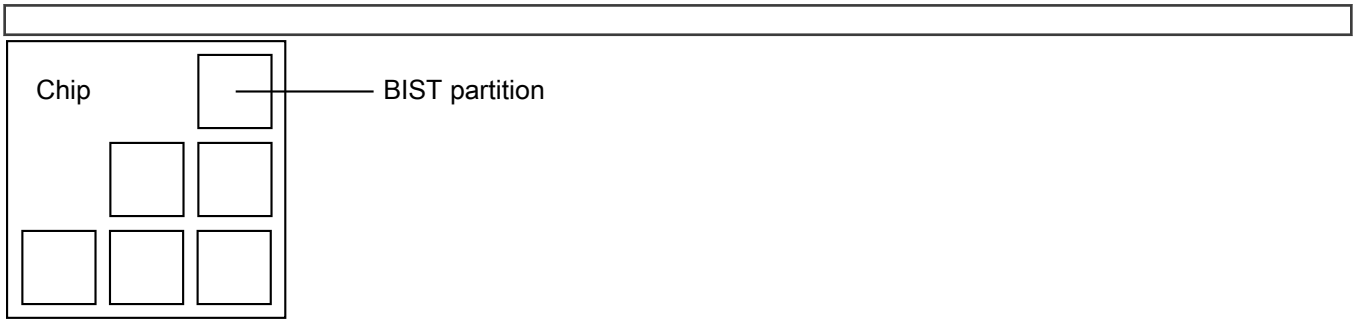
A BIST is a test that the chip can execute to verify the functional integrity of a part of itself. The chip uses STCU2 and other on-chip hardware to execute a BIST.

51.6.2 Definition: BIST partition

A BIST partition is a part of a chip for which a BIST has been defined. The hardware that is included in a given BIST partition is chip-specific. For a list of the hardware included in each of the BIST partitions on this chip, see the chip-specific STCU2 information.

51.6.3 Example: BIST partitions on a chip

This is an example of a chip with six BIST partitions:



51.6.4 Types of BIST partitions

The STCU2 module on this chip supports the following type or types of BIST partitions:

Table 242. Types of BIST partitions

BIST partition type	Description
MBIST partition	An SRAM or ROM block
LBIST partition	One or more digital modules

51.7 BIST sequences

51.7.1 Definition: BIST sequence

A BIST sequence is a programmable series of one or more phases, each of which executes one or more individual BISTs.

51.7.2 STCU2 executes MBISTs before LBISTs

If a BIST sequence includes both MBISTs and LBISTs; STCU2 executes the MBISTs first.

51.7.3 Example: Single-phase BIST sequence

This is an example of a single-phase BIST sequence in which STCU2 executes only one BIST:

Table 243. Example: Single-phase BIST sequence

Phase	BIST executed
0	MBIST 16

51.7.4 Example: Multi-phase BIST sequence

This is an example of a multiphase BIST sequence in which STCU2 executes more than one BIST in parallel in some phases:

Table 244. Example: Multi-phase BIST sequence

Phase	BISTs executed
0	MBISTs 7, 38
1	MBIST 23
2	MBISTs 6, 16, 29, 23
3	LBIST 12
4	LBISTs 13, 8, 11
5	LBISTs 19, 6

51.7.5 Types of BIST sequences

The STCU2 module on this chip supports these types of BIST sequences:

Table 245. Example: Types of BIST sequences

BIST sequence type	Description
Online BIST sequence	A BIST sequence that STCU2 executes during runtime at the request of software. Application software configures and initiates execution of the BIST sequence by loading values into STCU2 registers.

51.7.6 Supported BIST sequences

NXP supports only a specific set of BIST sequences for this chip. For the list of supported BIST sequences, see the chip-specific STCU2 information.

51.8 Functional description

51.8.1 FSM description

The module has three state machines that work together: Master State Machine, Loader/Shifter State Machine, and the Watchdog State Machine. Basically the Master State Machine is the core unit of the STCU2 module. It coordinates all the self-test operations and the other state machines. The Loader/Shifter State Machine is used to program the MBIST and the LBIST parameters and to retrieve the related results depending on the parameters stored into the STCU2 registers and under the control of the Master State Machine. The Watchdog State Machine evaluates all the schedule time for MBIST and LBIST and the time-out in case of wrong STCU2 programming.

51.8.2 BIST scheduling

STCU2 is designed to program the parallel/serial execution of the MBIST or LBIST depending on the power, timing, and coverage constraints.

The mechanism used to provide this flexibility is a linked list of BIST descriptors where the starting pointer is defined in CFG[PTR]. The first LBIST is mapped on 0, the second on 1, and so on. A BIST descriptor identifies a LBIST or MBIST via an index that is associated with its control register (STCU2 LBIST Control (LB_CTRL0) or STCU2 MBIST Control (MB_CTRL0 - MB_CTRL11)). The first MBIST is mapped on (00000080h + 0), the second on (00000080h + 1), and so on. The additional pointers of the linked list are in LB_CTRL*n*[PTR] for LBIST *n* (where *n* is the selected LBIST) and MB_CTRL*m*[PTR] for MBIST *m* (where *m* is the selected MBIST) and must be populated depending on the selected run sequence. The additional fields LB_CTRL[CSM] and MB_CTRL[CSM] provide the flexibility to run concurrently or sequentially the chosen set of the LBIST or MBIST or to close the linked list by setting the NIL pointer.

51.8.3 FCCU interface

The FCCU interface is the hardware flag mechanism towards the system, to indicate the occurrence of an Unrecoverable fault and/or a Recoverable fault failure during the Self Test sequence.

To diagnose physical defects on the two fault signals, a fault injection mechanism is also provided. In this case, the FCCU interface allows the user application to check the integrity of the UF and RF connection lines between the STCU2 and the FCCU. Refer to the description of FCCU fault injection mechanism to understand how the UF/RF set/clear mechanism works.

51.8.4 Watchdogs

The STCU2 implements different watchdogs to ensure that operations are finished in time.

51.8.4.1 BIST watchdog timer

The LBIST and MBIST execution time has to be configured as described in STCU2 Watchdog Granularity (WDG), to account for the overall execution time of the self test sequence. In case the selected LBISTs or MBISTs are not yet completed during assigned

time, the current LBISTs or MBISTs execution is interrupted and a failure is flagged into ERR_STAT[WDTOSW] and MBESWx or LBESW.

In case of multiple sequential run in the same online session and the time-out happens in the middle of a sequential run, the next sequential run will be skipped and the execution ends with the current updated status of the registers reported above.

51.8.4.2 Register write-access watchdog timer

As explained in the STCU2 SK Code (SKC):

- A key mechanism protects STCU2 registers during the self-test configuration phase by preventing any unwanted access.
- A hardware watchdog timer locks register-write access after a number of STCU2 clock cycles. To refresh the hardware watchdog timer before it times out, write Key1 and Key2 sequences.

AUTOLOCK_VALUE is the number of STCU2 clock cycles after which the hardware watchdog timer locks register-write access. See the chip-specific STCU2 information for the value of AUTOLOCK_VALUE.

The hardware watchdog timer is particularly useful in case CFG[WRP] is 0 during the software self-test configuration. In this case, the software application might enable write access to the STCU2 registers.

51.9 Use cases and limitations

For details on use cases and limitations, contact NXP sales representative.

51.10 STCU2 register descriptions

The STCU2 registers are listed in this section.

NOTE

Always write the reset value for the Reserved fields.

During online self-test, after the STCU2 registers are configured, they must not be overridden via internal peripheral system until the self-test is complete.

51.10.1 STCU2 memory map

STCU base address: 403A_0000h

Offset	Register	Width (In bits)	Access	Reset value

51.10.2 STCU2 Run Software (RUNSW)

Offset

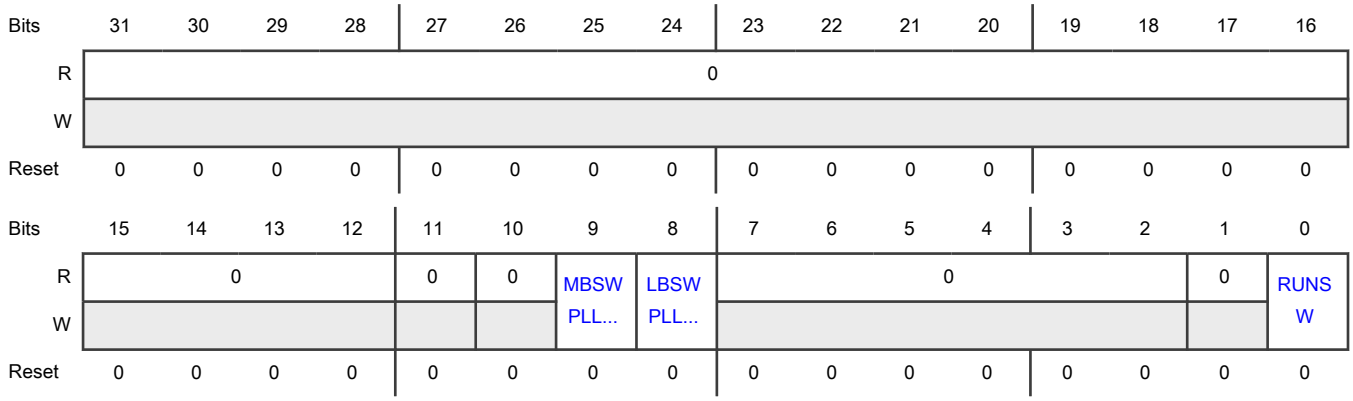
Register	Offset
RUNSW	4h

Function

The RUNSW register defines the RUN bit to start the online self-testing procedure.

The R/W fields in this register are readable at any time. However, you can write to these fields only when CFG[WRP] = 0.

Diagram



Fields

Field	Function

51.10.3 STCU2 SK Code (SKC)

Offset

Register	Offset
SKC	8h

Function

The SKC register implements the security key code mechanism needed to access in write mode to the other STCU2 registers.

To unlock STCU2 access after the STCU2 asynchronous reset and at the end of the STCU2 run, the software (IPS bus) need to apply the following sequence:

- write the key1 into the SKC register
- write the key2 into the SKC register

Depending on the online test step, the two keys are different. Byte write operation is not allowed because the full key has to be recognized as one unit.

In case of invalid access or sequence (Key1/2 have to be applied consecutively), a transfer error on the IPS is asserted. The STCU2 write access is locked and to unlock the access, the sequence has to be applied again.

In case the STCU2 register access lasts more cycles than the one defined in the hard-coded WDG timeout, the STCU2 write access is locked and the WDG and register interface clocks are switched off. Also, in this case, to enable the write access to the STCU2 again and the WDG and register interface clocks, it is required to apply the sequence again. This hard-coded WDG counter starts decrementing its value right after POR is deasserted.

In case it is required to extend the STCU2 register access cycles before the hard-coded WDG timeout expires, Key1 and Key2 sequences need to be applied. The effect of this write operation is to re-initialize the WDG timeout counter. The STCU2 write access is locked and to unlock the access, the sequence has to be applied again.

The SKC register is not readable. The value 00000000h is always returned in case of read operation.

51.10.4 STCU2 Configuration (CFG)

Offset

Register	Offset
CFG	Ch

Function

The CFG register includes the global configuration of the STCU2 and can be updated in the online test steps.

The access to this register is described in the following figure. It further depends on the state of the WRP bit as follows:

- When WRP = 0: The register can be written during the online self-test case without restrictions.
- When WRP = 1:
  - The only bit that can be written without any restriction is WRP.
  - In case there are software operations that write all the register's bits, a transfer error is raised only if the value of the selected byte written differs from the current status of the register. This functionality has been implemented to prevent potential compilation behavior that might invalidate this single bit clean capability.

3 —	Reserved
2-0 CLK_CFG	Logic, Memory BIST, and STCU2 CORE_CLK configuration CLK_CFG defines the ratio between the sys_clk and the internal clock used to program both the LBIST and the MBIST and the STCU2 CORE_CLK. The punch-out mechanism is used to generate the derived clocks. The following configurations are allowed: **NOTE** You can write to this field only when WRP = 0. 000b - sys_clk/1 001b - sys_clk/2 010b - sys_clk/3 011b - sys_clk/4 100b - sys_clk/5 101b - sys_clk/6 110b - sys_clk/7 111b - sys_clk/8

51.10.5 STCU2 Watchdog Granularity (WDG)

Offset

Register	Offset
WDG	14h

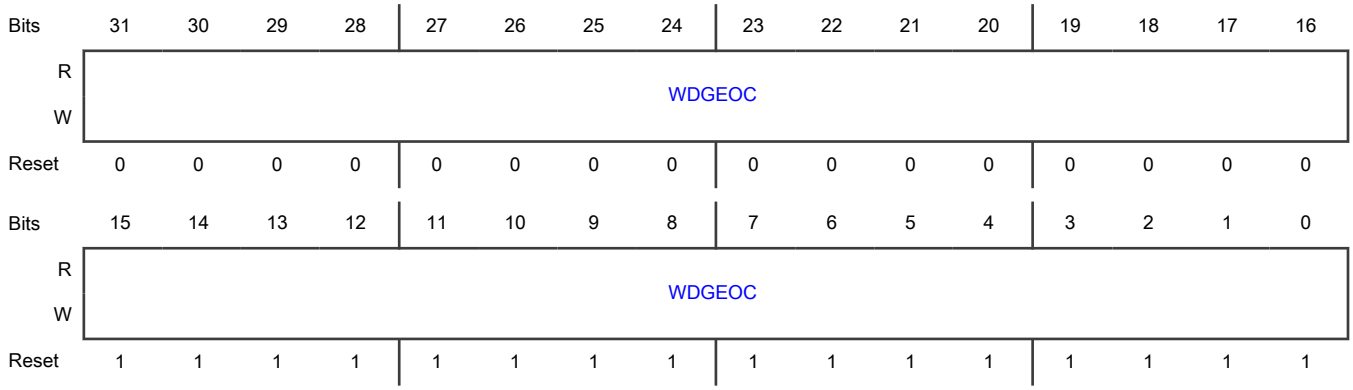
Function

The WDG register defines the time budget of LBIST and MBIST execution providing a protection mechanism in case of dead-lock or endless conditions during the self-test procedure.

In case online self-test sequence is run, it defines the timeout of the execution run.

The R/W fields in this register are readable at any time. You can write to these fields when online self-test phase is active and CFG[WRP] = 0.

Diagram



Fields

Field	Function
31-0 WDGEOC	Watchdog End of Count Timer This value has to be set to define the time budget related to the online self-test execution and check that everything is correctly working within this slot of time. The delay time slots that are allowed are as follows: 0000 0000h: 1 x 16 STCU2 CORE_CLK cycles 0000 0001h: 2 x 16 STCU2 CORE_CLK cycles 0000 0002h: 3 x 16 STCU2 CORE_CLK cycles ... FFFF FFFDh: 4294967294 x 16 STCU2 CORE_CLK cycles FFFF FFFEh: 4294967295 x 16 STCU2 CORE_CLK cycles FFFF FFFFh: 4294967296 x 16 STCU2 CORE_CLK cycles

51.10.6 STCU2 Error (ERR_STAT)

Offset

Register	Offset
ERR_STAT	24h

Function

The ERR_STAT register includes the status flags related to the STCU2 internal error conditions occurred during the configuration or the online self-testing execution.

The UFSF and RFSF can be set/cleared using the FCCU dedicated channels.

The access to this register is described in the following figure and as follows:

- If you select the byte write capability to write only UFSF and RFSF, then there is no restriction in writing these bits.
- If your software performs the write operations on other bits besides UFSF/RFSF, then a transfer error is generated only if the value you are writing to the other bits differs from their value currently stored in the register. This functionality has been implemented to prevent potential compilation behavior that might invalidate the UFSF/RFSF single bit set/clean capability.

23-21 —	Reserved
20 LOCKESW	Online LOCK error You can always read this field. The content of this field is initialized to its reset value when RUNSW[RUNSW] is set to 1. 0b - In case PLL is enabled, it is correctly locked during the self-test sequence 1b - When the PLL is enabled, this flag highlights that there has been an unexpected PLL unlock(loss-of-lock) event during the online self-test sequence execution. The online self-test run is stopped and the status of the currently running LBISTs or MBISTs is saved in the related registers. The LOCK signal is monitored during the LBIST run when RUNSW[LBSWPLLEN] is set and/or during the MBIST run when RUNSW[MBSWPLLEN] = 1.
19 WDTOSW	Online watchdog timeout You can always read this field. The content of this field is initialized to its reset value when RUNSW[RUNSW] is set to 1. 0b - LBIST and MBIST time slots completed within the assigned watchdog time. 1b - LBIST and MBIST time slots not completed within the assigned watchdog time or there are internal mismatches among End of Execution signals.

Table continues on the next page...

Table continued from the previous page...

Field	Function
18 —	Reserved
17 ENGESW	Online engine error You can always read this field. The content of this field is initialized to its reset value when RUNSW[RUNSW] is set to 1. 0b - Valid engine execution 1b - Invalid engine execution. The error conditions that set this bit are FSM, protocol error, and so on.
16 INVPSW	Online invalid pointer You can always read this field. The content of this field is initialized to its reset value when RUNSW[RUNSW] is set to 1. 0b - Valid linked pointer list 1b - Invalid linked pointer list. The following conditions set this bit: Initial LBIST orMBIST pointer is out of range; LBIST is selected when MBIST is concurrently running or vice versa; Error in the LBIST/MBIST linking (execution generates an infinite loop).
15-10 —	Reserved
9 UFSF	Unrecoverable Faults Status Flag This flag reports the global status of the Unrecoverable Faults(UF). This field can be set or cleared using the FCCU dedicated channel, and can also be set or cleared by software. 0b - No errors that trigger the UF condition. 1b - There are errors that trigger the UF condition.
8 RFSF	Recoverable Faults Status Flag This flag reports the global status of the Recoverable Fault (RF). This field can be set or cleared using the FCCU dedicated channel, and can also be set or cleared by software. 0b - No errors that trigger the Recoverable Faults condition 1b - There are errors that trigger the Recoverable Faults condition
7-5 —	Reserved
4-0 —	Reserved Write may occur on these fields but writes have no effect.

51.10.7 STCU2 Error FM (ERR_FM)

Offset

Register	Offset
ERR_FM	28h

Function

The ERR_FM register defines the fault mapping of the STCU2 faults described in the register ERR_STAT in terms of UF or RF. All sources of internal faults can be routed to UF and RF.

The R/W fields in this register are readable at any time. You can write to these fields when online self-test phase is active and CFG[WRP] = 0.

LBIST	Logic BIST
MBIST	Memory BIST
NLBIST	Number of logic built-in self-test controller
NMCUT	Number of memory checked using memory built-in self-test controller
RF	Recoverable faults
UF	Unrecoverable faults
WDG FSM	Watchdog finite state machine

Chapter 52
Register Protection (REG_PROT)

52.1 Chip-specific REG_PROT information

52.1.1 REG_PROT configuration

The MCU safety relevant configuration registers are protected against unauthorized HW/S changes during read/write/clear access by implementing them with register protection module. See the REG_PROT details file attached to this document.

52.1.1.1 CMU_BRIDGE register protection

The CMUs in the device reside on a common peripheral slot as CMU_BRIDGE in the system memory map. Figure 191 indicates the locations of the CMUs alongwith the memory map.

Based on the CMU location in system peripheral memory map, the below locations in the CMU 16KB space are reserved and any access on these locations results in a bus transfer error.

402B_C018 – 402B_C01F

402B_C030 – 402B_C03F

402B_C050 – 402B_C05F

402B_C078 – 402B_C07F

402B_C098 – 402B_C09F

402B_C0B8 – 402B_CFFF

Since the register protection is available in the device for CMU_BRIDGE, the 4KB offset locations (refers as the Area 2 in register protection) are also reserved and accesses over these regions also result in bus transfer error.

402B_D018 – 402B_D01F

402B_D030 – 402B_D03F

402B_D050 – 402B_D05F

402B_D078 – 402B_D07F

402B_D098 – 402B_D09F

402B_D0B8 – 402B_DFFF

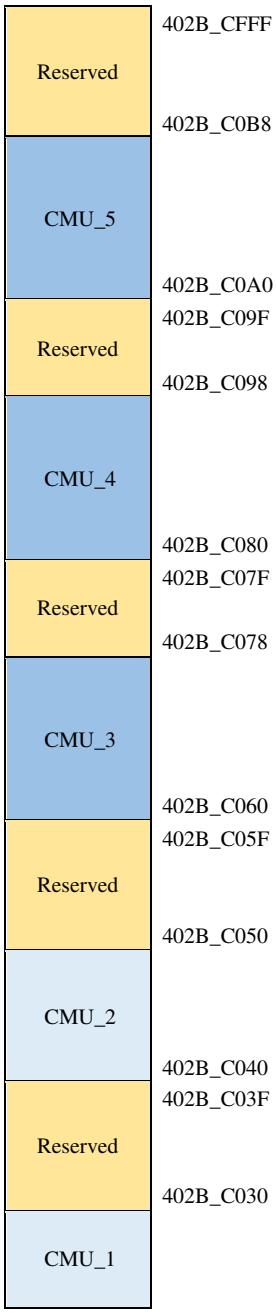

Figure 191. Location of CMUs

52.2 Overview

REG_PROT offers a mechanism to protect defined memory-mapped address locations, in a module under protection, from being written.

REG_PROT is a protection module that is located between the module under protection and the peripheral interface. The address locations to be protected exist in the module under protection and the address locations that can be protected are module specific. Writes to these protected address locations are locked using a Soft Lock Bit Register (SLBR*n*). Any access to address locations in the module under protection is restricted if their corresponding Soft lock fields in a Soft Lock Bit Register (SLBR*n*) are 1.

The configured soft-lock fields can also be write-restricted by using GCR[HLB]. When GCR[HLB]=1, you cannot write to the soft-lock fields. The address locations in the module under protection can be restricted to Supervisor mode access using GCR[UAA].

52.2.1 Block Diagram

The following figure shows the block diagram of this module.

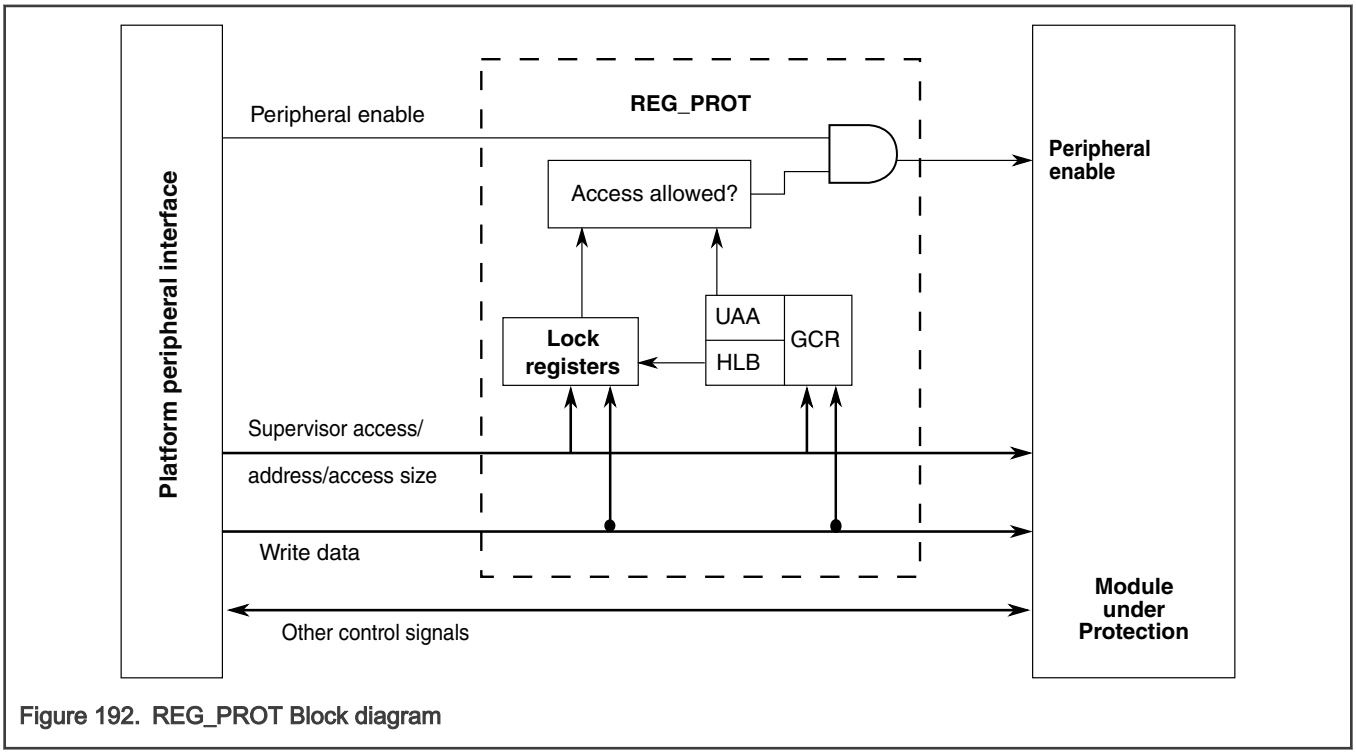

Figure 192. REG_PROT Block diagram

52.2.2 Features

REG_PROT includes these distinctive features:

- Write accesses for the module under protection can be restricted to the supervisor mode only.
- Registers of modules with their register slot size occupying 1 KB to 32 KB of memory-mapped address space, depending on the PROT_MEM parameter, can be dynamically locked. See Memory space and Protection size.
- Multiple ways are present to set the lock bits.
- After the lock bits are configured, they can be protected from changes.

52.3 Functional description

The following sections describe the functional characteristics of the REG_PROT module.

52.3.1 Modes of operation

The mode of REG_PROT depends on the Module Under Protection (MUP). The REG_PROT is operable when the MUP is operable.

The below table shows the write operations in user mode.

Table 246. User mode access table

GCR[UAA]	SLBRn[SLBm]	Write Operation on MUP	Write Operation on REG_PROT
0	0	Transfer error generated, write operation unsuccessful.	Transfer error generated, write operation unsuccessful.
0	1	Transfer error generated, write operation unsuccessful.	Transfer error generated, write operation unsuccessful.
1	0	• If register is implemented and write operation allowed on accessed address location then write operation is successful. • If register is not implemented or write operation is not allowed on accessed address location then transfer error is generated, write operation is unsuccessful.	• If register is implemented and write operation allowed on accessed address location then write operation is successful. • If register is not implemented or write operation is not allowed on accessed address location then transfer error is generated, write operation is unsuccessful.
1	1	Transfer error generated, write operation unsuccessful.	• If register is implemented and write operation allowed on accessed address location then write operation is successful. • If register is not implemented or write operation is not allowed on accessed address location then transfer error is generated.

Note:

- Read operation is always allowed
- n >= 0, m = [0,3]

52.3.2 Memory space and Protection size

This section provides a detailed description of the memory space and protection size of a module using REG_PROT.

The PROT_MEM size varies per chips. It can be:

- 1 KB
- 2 KB
- 4 KB
- 8 KB
- 16 KB
- 32 KB

The resulting memory space is divided into four areas. Memory locations within area #1 and area #2 are a part of the module under protection. Area #3 and area #4 are a part of REG_PROT.

The proper register slot size for each protected module is mentioned in the REG_PROT details file attached to this document.

Following is the memory space for a module that is protected by the REG_PROT module. Reserved registers in area #1 are handled as specified in the protected module's documentation. There is a single register in configuration space that corresponds

to area #4 while the size mentioned in Area size column is to turn the whole area multiple of 4 KB. See the Offset column to know the exact location of the GCR register.

Table 247. Area offset based on protection size

PROT_MEM	Area	Area size	Use	Offset
1 KB	Area 1	1 KB	Module Register(MR0—MR1023)	0000h—03FFh
	Area 2	1 KB	Module Register and Set Soft Lock Bit (LMR0—LMR1023)	0400h—07FFh
	Area 3	256 B	Soft Lock Bit Register (SLBR0—255)	0800h—08FFh
	Area 4	256 B	Global Configuration Register (GCR)	0900h—09FFh
		1.5 KB	Reserved	0A00h— 0FFFh
2 KB	Area 1	2 KB	Module Register (MR0—MR2047)	0000h—07FFh
	Area 2	2KB	Module Register and Set Soft Lock Bit (LMR0—LMR2047)	0800h—0FFFh
	Area 3	512 B	Soft Lock Bit Register (SLBR0—511)	1000h—11FFh
	Area 4	256 B	Global Configuration Register (GCR)	1200h—12FFh
		3.25 KB	Reserved	1300h—1FFFh
4 KB	Area 1	4 KB	Module Register (MR0—MR4095)	0000h—0FFFh
	Area 2	4 KB	Module Register and Set Soft Lock Bit (LMR0—LMR4095)	1000h—1FFFh
	Area 3	1 KB	Soft Lock Bit Register (SLBR0—1023)	2000h—23FFh
	Area 4	256 B	Global Configuration Register (GCR)	2400h—24FFh
		6.75 KB	Reserved	2500h—3FFFh
8 KB	Area 1	8 KB	Module Register (MR0—MR8191)	0000h—1FFFh
	Area 2	8 KB	Module Register and Set Soft Lock Bit (LMR0—LMR8191)	2000h—3FFFh
	Area 3	2 KB	Soft Lock Bit Register (SLBR0—2047)	4000h—47FFh
	Area 4	256 B	Global Configuration Register (GCR)	4800h—48FFh
		1.75 KB	Reserved	4900h—4FFFh
16 KB	Area 1	16 KB	Module Register (MR0—MR16383)	0000h—3FFFh
	Area 2	16 KB	Module Register and Set Soft Lock Bit (LMR0—LMR16383)	4000h—7FFFh
	Area 3	4 KB	Soft Lock Bit Register (SLBR0—4095)	8000h—8FFFh
	Area 4	4 KB	Global Configuration Register (GCR)	9000h—9FFFh
32 KB	Area 1	32 KB	Module Register (MR0—MR32767)	0000h—7FFFh
	Area 2	32 KB	Module Register and Set Soft Lock Bit (LMR0—LMR32767)	8000h—FFFFh
	Area 3	8 KB	Soft Lock Bit Register (SLBR0—8191)	10000h—11FFFh
	Area 4	4 KB	Global Configuration Register (GCR)	12000h—12FFFh

- Area #1 can take the memory space of 1 KB/2 KB/4 KB/8 KB/16 KB/32 KB, which holds the normal functional module registers and is transparent for all read/write operations.
- Area #2 can take the memory space of 1 KB/2 KB/4 KB/8 KB/16 KB/32 KB and is a mirror of area #1. For an example, if area #1 takes 8 KB of memory space, then read/write access to an offset 2000+X reads/writes the register at offset X. However, a write access to offset 2000+X additionally sets the optional soft lock bits for this offset X in the same cycle

as the register at offset X is written. This provides for an automatic write and lock operation. Not all registers in area #1 need to have protection defined by the associated soft lock bits. For unprotected registers at offset Y, accesses to offset 2000+Y are identical to accesses at offset Y.

- Area #3 can take the memory space of 256 B/512 B/1 KB/2 KB/4 KB/8 KB and hold soft lock bits, one bit per byte in area #1. The four soft lock bits associated with one module register word are arranged at byte boundaries in the memory map. The Soft Lock Bit registers can be directly written using a bit mask.
- Area #4 can take the memory space of 1.75 KB/3.5 KB/7 KB/2 KB/4 KB/4 KB and holds the configuration bits of the protection mode. There is one configuration Hard lock bit per module that prevents all further modifications to the soft lock bits and can only be cleared by a system reset after it is set. When user access allowed bit is set, it allows user access to the protected module.

If you access a locked byte with a write transaction, a bus error is issued to the system and the write transaction is not executed. This is true even if not all accessed bytes are locked.

Accessing unimplemented 32—bit registers in area #3 results in a bus transfer error. In area #4, there will not be any transfer error for the address range mentioned in the table above because these address spaces of area #4 are mapped to the GCR register. Accesses in area #4, beyond the address range mentioned in the Module memory map table, are prohibited and might or might not result into a bus abort.

52.3.2.1 Module register (MR)

Each functional module has its own unique set of registers. This chapter refers to these registers generically as module registers (MR), which exist in the lower module memory space (memory area 1), and receive protection from the REG_PROT module.

52.3.2.2 Module Register and Set Soft Lock Bit (LMR)

This is memory area #2 that provides mirrored access to module registers with the side-effect of setting soft lock bits in case of a write access to a register that is defined as protectable by the locking mechanism. Each MR byte is protectable by one associated bit in SLBR*n* [SLB*m*], according to the mapping described in Soft Lock Bit Register (SLBR*n*).

52.3.3 General

This module provides a generic register (address) write-protection mechanism. The register protection size can be:

- 32 bits (address == multiples of 4)
- 16 bits (address == multiples of 2)
- 8 bits (address == multiples of 1)

The addresses that are protected and the register protection size depends on the chip and/or module.

For all addresses that are protected, there are SLBR*n*[SLB*m*] bits that specify whether the address is locked. When an address is locked, it can only be read but not written in any mode (supervisor/normal). If an address is unprotected, the corresponding SLBR*n*[SLB*m*] bit is always 0, regardless of what the software writes to that field.

NOTE

For more information on register protection specification, see the REG_PROT details file attached to this document.

52.3.4 Change lock settings

To change the setting whether an address is locked or unlocked, the corresponding SLBR*n*[SLB*m*] bit needs to be changed. This can be done using the following methods:

- Set the SLBR*n*[SLB*m*] bit(s) by writing to area #2
- Modify the SLBR*n*[SLB*m*] directly by writing to area #3

Both methods are explained in the following sections.

52.3.4.1 Change lock settings via area #2

You can lock a register after writing to it. Note that reading area #2 does not affect soft lock bits. To do so, you must use area # 2.

The following shows an example with PROT_MEM = 8 KB where SLBs are modified using area #2.

When writing 16-bit to address 0008h, MR9 and MR8 in the protected module are updated. The corresponding lock fields remain unchanged (see the left part of Figure 193).

When writing 16-bit to address 2008h, MR9 and MR8 in the protected module are updated. The corresponding lock fields SLBR2[SLB0:1] become 1, and the lock fields SLBR2[SLB2:3] remain unchanged (see the right part of Figure 193).

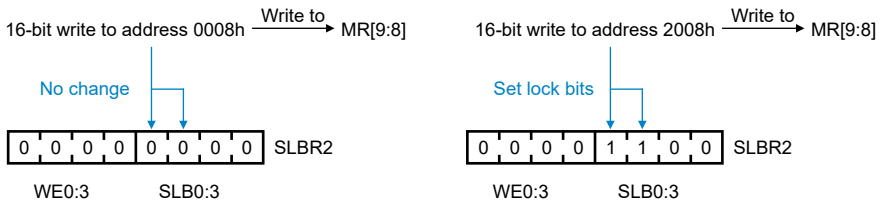

Figure 193. Enable locking via area #2

The following figure shows an example where some addresses are protected and some are not.

In Figure 194, addresses 000Ch and 000Dh are unprotected. Therefore, their corresponding lock fields SLBR3[SLB0:1] are always 0 (shown in bold). During a 32-bit write access to address 200Ch, the lock fields in SLBR3 change as follows:

- SLBR3[SLB2:3] become 1.
- SLBR3[SLB0:1] remain 0.

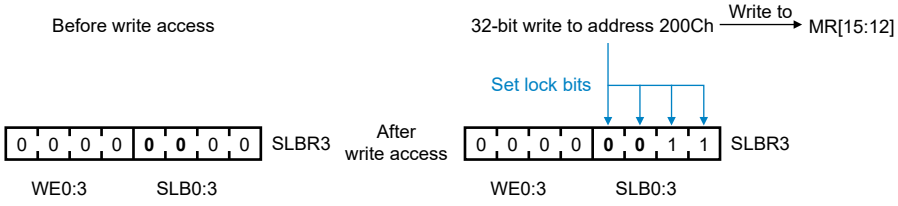

Figure 194. Enable locking for protected and unprotected addresses

52.3.4.2 Change lock settings via area #3

The lock bits are located in area #3 (see Table 247). You can modify them by writing to them. Each SLB*m* field in Soft Lock Bit Register (SLBR*n*) has a mask field, WE*m*, that protects SLB*m* from modification. This masking makes read-modify-write operations unnecessary.

Figure 195 shows two modification examples for registers with 8-bit protection. In part A, a write access to SLBR*n* specifies a mask value that allows modification of all SLBR*n*[SLB0:3] fields. Part B specifies a mask that allows modification only to SLBR*n*[SLB1:3].

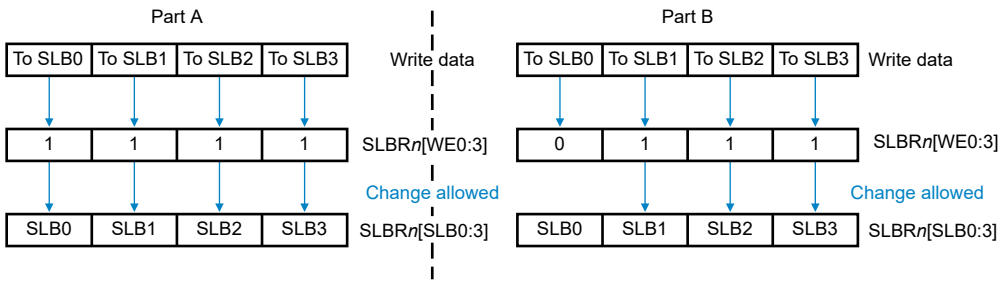

Figure 195. Change lock settings directly via area #3

Figure 196 shows examples for registers with 16-bit protection.

Part A of Figure 196 shows that for SLBR*n*:

- The data written to SLBR*n*[SLB0] is automatically written to SLBR*n*[SLB1].
- The data written to SLBR*n*[SLB2] is automatically written to SLBR*n*[SLB3].

This is because the address reflected by SLBR*n*[SLB0] and SLBR*n*[SLB2] are protected 16-bit wise. Note that in this case, the write enable SLBR*n*[WE0] and SLBR*n*[WE2] must be set while SLBR*n*[WE1] and SLBR*n*[WE3] don't matter.

Part B of Figure 196 shows that the data written to SLBR*n*[SLB0] is automatically written to SLBR*n*[SLB1]. This is done because the address reflected by SLBR*n*[SLB0] has 16-bit protection. In this case, SLBR*n*[WE0] must be 1 and SLBR*n*[WE1] does not matter. SLBR*n*[SLB2] and SLBR*n*[SLB3] remain unchanged because SLBR*n*[WE2] and SLBR*n*[WE3] are 0.

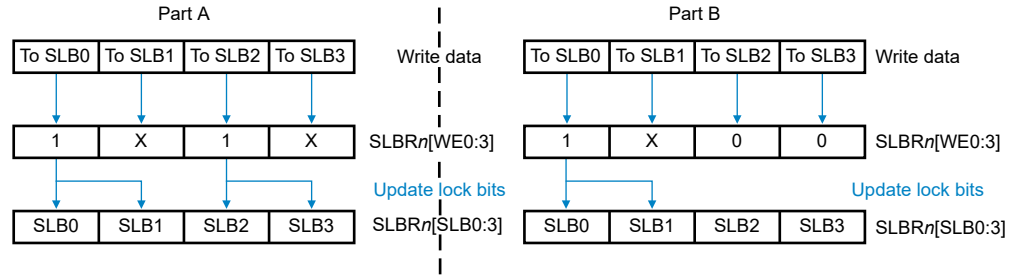

Figure 196. Change lock settings for addresses with 16-bit protection

Figure 197 shows a register with 32-bit protection. In SLBR*n*:

- When SLBR*n*[WE0]=1, the data written to SLBR*n*[SLB0] is automatically written to SLBR*n*[SLB1:3] as well.
- When SLBR*n*[WE0]=0, then SLBR*n*[SLB0:3] remain unchanged. Note that in this case, the write enable SLBR*n*[WE0] must be set while SLBR*n*[WE1:3] does not matter.

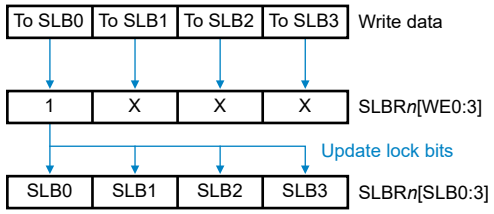

Figure 197. Change lock settings for addresses with 32-bit protection

The following figure shows a mixed protection size configuration.

In SLBR*n*:

- The data written to SLBR*n*[SLB0] is mirrored to SLBR*n*[SLB1] because the corresponding register has 16-bit protection.
- The data written to SLBR*n*[SLB2] is blocked because the corresponding register is unprotected.
- The data written to SLBR*n*[SLB3] is successfully written to SLBR*n*[SLB3] because the corresponding register has 8-bit protection.

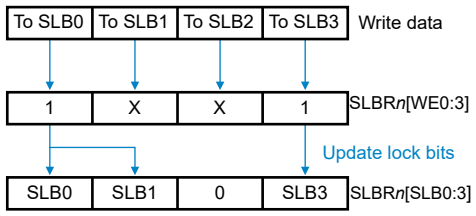

Figure 198. Change lock settings for mixed protection

52.3.4.3 Write protection for locking bits

Changing the locking bits through any of the procedures mentioned in Change lock settings via area #3 and Change lock settings via area #2 is only possible as long as the field GCR.HLB is cleared. After you write 1 to this field, the locking bits cannot be modified until there is a system reset.

52.3.5 Access errors

REG_PROT generates transfer errors under several circumstances, as described below. For the area definition, see Memory space and Protection size.

- If accessing area #1 or area #2, REG_PROT sends any access error from the underlying module under protection.
- If User mode is not allowed, the attempted User mode writes to all areas cause a transfer error, and the writes are blocked.
- If accessing the reserved area, a transfer error is asserted.
- If accessing unimplemented 32-bit registers in areas #3 and #4, a transfer error is asserted.
- If writing to a register in areas #1 and #2, and an SLB field is 1 for any of the affected bytes, then:
  - A transfer error is asserted.
  - The write is blocked.
  - The complete write operation to non-protected bytes in this word is ignored.
- If writing to an SLBR in area #3 with GCR[HLB]=1, a transfer error is asserted.
- Any write operation in any access mode to area #2, when GCR[HLB]=1, is not allowed.

NOTE

The transfer error generated by REG_PROT can only be observed on the CPU that initiates the target register write and has defined the strongly ordered memory region (through its MPU or MMU) covering the target register address.

52.4 External Signals

There are no external signals.

52.5 Initialization

The following sections contain information related to initialization of the Register Protection module.

52.5.1 Sequence

You must configure the REG_PROT first. And then, you need to write 1 to the HLB field in REG_PROT. This ensures that registers under protection are not updated in the user access mode. You need to follow these steps:

1. Enable XRDC protection for the module to enable writes in the supervisor mode only. This step is mandatory, if protected registers of the module are expected to be configured multiple times.
2. Configure REG_PROT to enable write on registers of module under protection.
3. Configure the registers of module under protection.
4. Configure the REG_PROT for the required SLB fields.
5. Set the HLB field in REG_PROT. This step is mandatory, if protected registers of module are expected to be configured only once.

52.5.2 Reset

It is a single clock IP, with single reset.

52.6 REG_PROT register descriptions

This register information documents memory area #3 and area #4.

52.6.1 REG_PROT memory map

REG_PROT base address: base address of protected module instance

Table 248. REG_PROT memory map

PROT_MEM	Offset	Register	Width (In bits)	Access	Reset value
1kB	0x800 – 0x8FF	Soft Lock Bit Register (SLBR0-255)	8	RW	00h
	0x900 – 0x9FF	Global Configuration Register (GCR)	32	RW	0000_0000h
2kB	0x1000 – 0x11FF	Soft Lock Bit Register (SLBR0-511)	8	RW	00h
	0x1200 – 0x12FF	Global Configuration Register (GCR)	32	RW	0000_0000h
4kB	0x2000 – 0x23FF	Soft Lock Bit Register (SLBR0-1023)	8	RW	00h
	0x2400 – 0x24FF	Global Configuration Register (GCR)	32	RW	0000_0000h
8kB	0x4000 – 0x47FF	Soft Lock Bit Register (SLBR0-2047)	8	RW	00h
	0x4800 – 0x48FF	Global Configuration Register (GCR)	32	RW	0000_0000h
16kB	0x8000 – 0x8FFF	Soft Lock Bit Register (SLBR0-4095)	8	RW	00h
	0x9000-0x9FFF	Global Configuration Register (GCR)	32	RW	0000_0000h
32kB	0x10000-0x11FFF	Soft Lock Bit Register (SLBR0-8191)	8	RW	00h
	0x12000 – 0x12FFF	Global Configuration Register (GCR)	32	RW	0000_0000h

52.6.2 Soft Lock Bit Register (SLBR*n*)

Offset

See REG_PROT memory map for SLBR*n* offset ranges. For SLBR*n* addresses, see the REG_PROT details file attached to this document.

Function

These registers hold the Soft Lock Bits (SLBs) for the protected registers in memory area #1, which is the normal register address space of the protected module. Multiple Soft Lock Bit Registers (SLBR*n*) can be implemented, depending on the number of protected module register bytes. Each SLBR*n* has four soft lock fields (SLB0-SLB3), each of which controls write access to a byte in memory area #1. Each soft lock field also has a corresponding write enable field in the same register that controls whether the soft lock field can be written. The following table shows the mapping between the soft lock fields to the bytes in memory area #1.

Table 249. SLBs vs. protected address

SLB	Protected address
SLBR0[SLB0]	MR0
SLBR0[SLB1]	MR1
SLBR0[SLB2]	MR2
SLBR0[SLB3]	MR3
SLBR1[SLB0]	MR4
SLBR1[SLB1]	MR5
SLBR1[SLB2]	MR6
SLBR1[SLB3]	MR7
SLBR2[SLB0]	MR8
...	...

Diagram

Fields

Field	Function
7 WE0	Write enable fields for SLB WE0 enables writing to SLB0. 0b - SLB is not modified. 1b - Value is written to SLB.
6 WE1	Write enable fields for SLB WE1 enables writing to SLB1. 0b - SLB is not modified. 1b - Value is written to SLB.
5	Write enable fields for SLB

Table continues on the next page...

Table continued from the previous page...

Field	Function
WE2	WE2 enables writing to SLB2. 0b - SLB is not modified. 1b - Value is written to SLB.
4 WE3	Write enable bits for SLB WE3 enables writing to SLB3. 0b - SLB is not modified. 1b - Value is written to SLB.
3 SLB0	Soft lock fields for one MRn register SLB0 can block accesses to MR[n *4 + 0]. 0b - Associated MRn byte is unprotected and writable. 1b - Associated MRn byte is locked against write accesses.
2 SLB1	Soft lock bits for one MRn register SLB1 can block accesses to MR[n *4 + 1]. 0b - Associated MRn byte is unprotected and writable. 1b - Associated MRn byte is locked against write accesses.
1 SLB2	Soft lock fields for one MRn register SLB2 can block accesses to MR[n *4 + 2]. 0b - Associated MRn byte is unprotected and writable. 1b - Associated MRn byte is locked against write accesses.
0 SLB3	Soft lock fields for one MRn register SLB3 can block accesses to MR[n *4 + 3]. 0b - Associated MRn byte is unprotected and writable. 1b - Associated MRn byte is locked against write accesses.

52.6.3 Global Configuration Register (GCR)

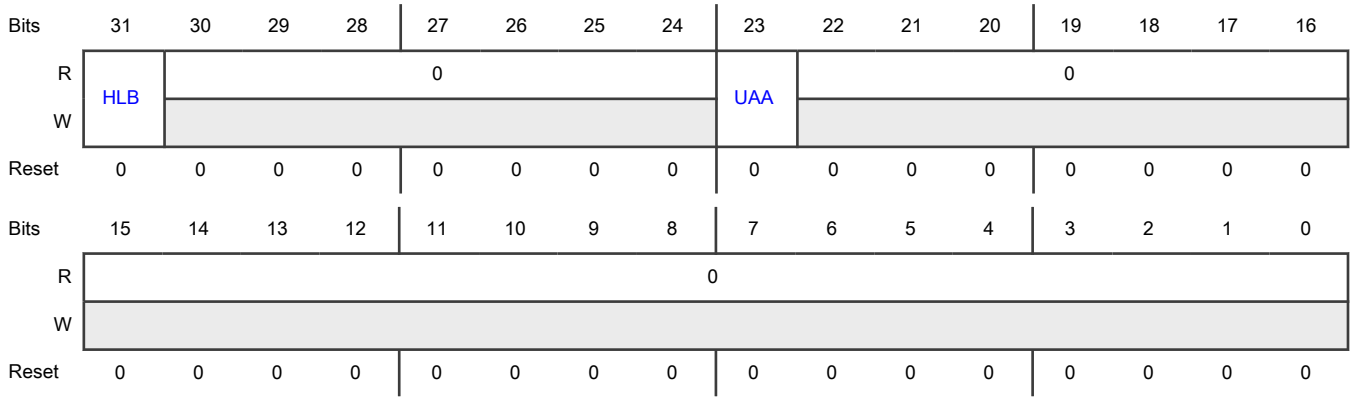
Offset

See REG_PROT memory map for GCR offset.

Function

This register controls module level configurations.

Diagram



Fields

Field	Function
31 HLB	Hard Lock Bit This field cannot be cleared after it is set by the software. It can only be cleared by a system reset. 0b - All SLB fields are accessible and can be modified. 1b - All SLB fields are write protected and cannot be modified.
30-24 —	Reserved
23 UAA	User Access Allowed Controls the user and supervisor mode access to registers of the module under protection. 0b - The registers in the module under protection can only be written in the supervisor mode (user access is not allowed). All the write accesses in user (non-supervisor) mode are not executed and a transfer error is issued. This access restriction is in addition to any access restrictions imposed by the protected IP module. 1b - The registers in the module under protection can be accessed in the mode defined for the module registers without any additional restrictions. It can be modified in both user (non-supervisor) and supervisory mode.
22-0 —	Reserved

52.7 Glossary

PROT_MEM Integration parameter that specifies the size of the module register slot protected. The PROT_MEM size depends on the chip or module.

Hard lock A lock that restricts access to any register bit. You can unlock or clear this lock through the hardware reset.

Soft lock A lock that restricts access to any register bit. You can unlock or clear this lock through the software.

Chapter 53
Clock Monitoring Unit – Frequency Check (CMU_FC)

53.1 Chip-specific CMU_FC information

53.1.1 CMU_FC configuration

The device consists of a robust clock monitoring architecture targeted to monitor various clock nodes to ensure device clock robustness. There are upto seven clock monitoring units present in the device out of which 4 are of type CMU_FC. See 'Clock monitoring' section in Clocking chapter for details on device clock monitoring architecture.

NOTE

CMU_5 is accessible by Cortex-M0+ core only.

CMU_FC combined spec variation: The combined spec variation for CMU (used for configuring CMU_FCx.HTCR[HFREF] and CMU_FCx.HTCR[LFREF]) is the absolute sum of frequency variations of the clock sources. Refer device datasheet for frequency variations for the corresponding clock sources.

53.2 Introduction

CMU_FC ensures the clock integrity of selected clocks and allows continuous clock integrity verification.

CMU_FC checks if the frequency of a monitored clock (*monitored_clock*) is within a programmable frequency range specified by the user. If the frequency is outside the specified limits, it could lead to performance, protocol, and timing failures. CMU_FC requires a clock used as a base reference for the frequency check operation. This reference clock (*reference_clock*) must be within documented limits for correct CMU_FC operation.

53.2.1 Basic operation

CMU_FC counts clock cycles of the monitored clock during a user programmable time duration of *n* clock cycles of the reference clock. There is a comparison between the final count of the monitored clock and the user programmable upper and lower threshold count limits. The control logic determines whether the cycle count is within the programmed limits. If not it sets the Frequency Higher than High frequency reference threshold event status (FHH) field or the Frequency Lower than Low frequency reference threshold event status (FLL) field in the Status Register (SR). If you enable interrupts, an interrupt asserts when the status flag sets.

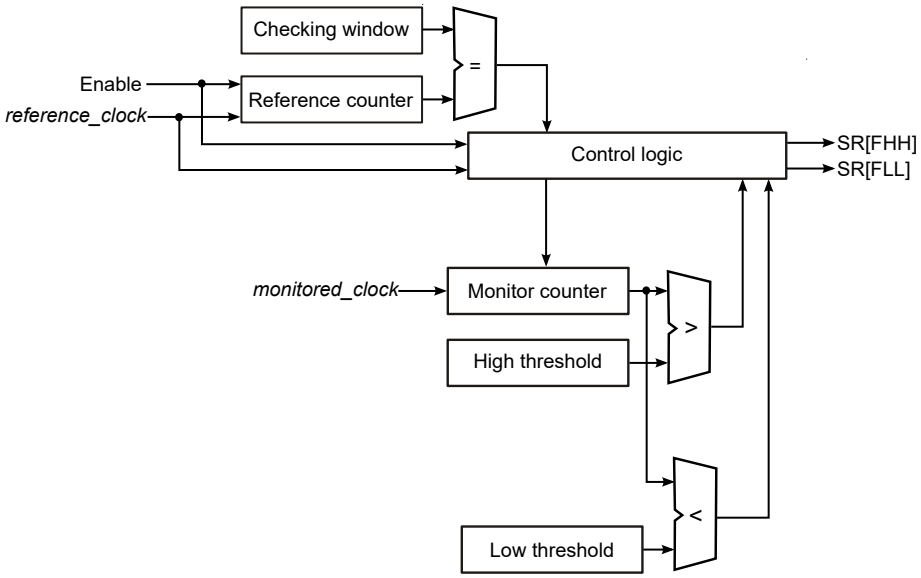


Figure 199. CMU_FC block diagram

CMU_FC cannot detect the following:

- Monitored clock duty cycle variations
- Instantaneous monitored clock frequency variations that do not cross upper or lower threshold limits

53.2.2 Features

The CMU_FC features are:

- Programmable duration of reference clock cycles
- Initiates an event if a monitored clock frequency is higher than high frequency reference (FHH)
- Initiates an event if a monitored clock frequency is lower than low frequency reference (FLL)
- Timeout functionality generates an FLL event if a monitored clock stops functioning
- Masking of FHH event interrupt
- Masking of FLL event interrupt

Table 250. Clock description

Clock	I/O	Description
reference_clock	I	Clock signal that the module uses as a reference to evaluate *monitored_clock*
monitored_clock	I	Clock signal on which frequency check is performed
bus_clock	I	Clock signal on which register read/write operation is performed

NOTE

See the Clocking chapter for details of monitored and reference clocks used on this chip.

53.3 Functional description

53.3.1 Frequency checking

Frequency checking starts when software writes GCR[FCE] = 1. The Run Status field SR[RS] shows 1 after frequency check operation starts.

CMU_FC performs continuous periodic clock checking of the monitored clock. Each checking window involves the following operations:

- Stage 1 – Reference clock counter runs for RCCR[REF_CNT] reference clock cycles. Monitored clock counter runs in parallel for the same time duration as reference clock counter.
- Stage 2 – After stage 1, the module compares the final monitored clock count against the programmed thresholds.

If the monitored clock count is greater than the high threshold value in HTCR[HFREF], an FHH event occurs.

If the monitored clock count is lower than the low threshold value in LTCR[LFREF], an FLL event occurs.

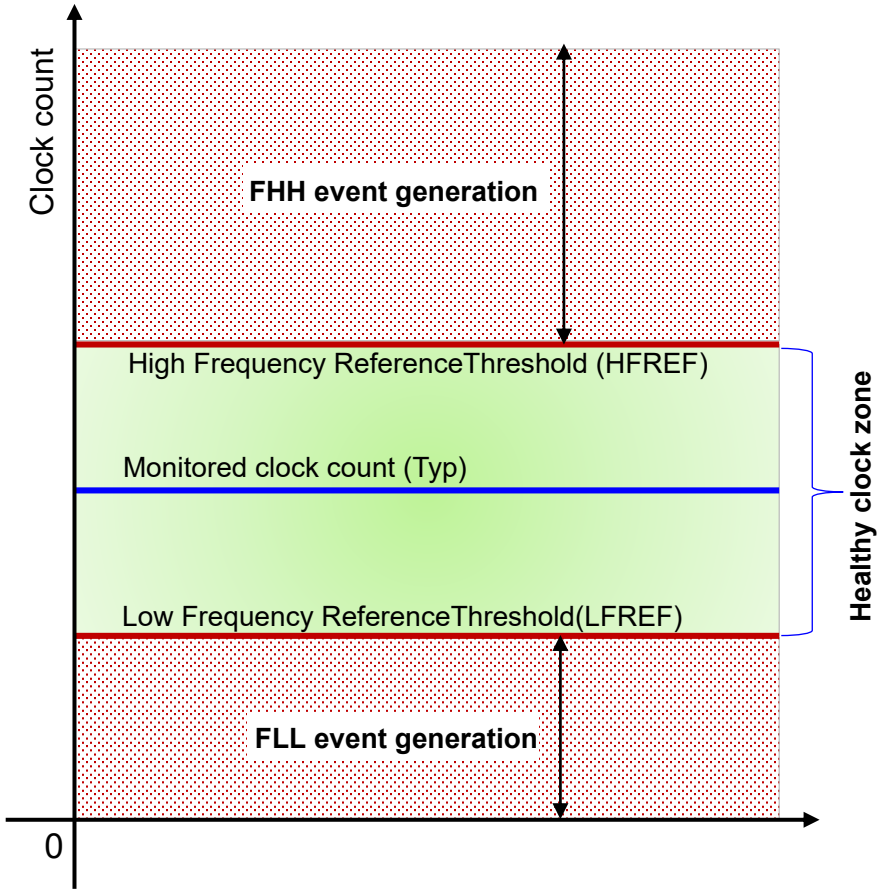

Figure 200. Frequency checking HFREF and LFREF thresholds

53.3.1.1 Monitored clock lost

If a monitored clock ceases operation before evaluation of that clock (Stage 2, see Frequency checking), CMU_FC waits for RCCR[REF_CNT] reference clock periods by extending Stage 2 before triggering an FLL event.

- If *monitored_clock* is not running when enabling CMU_FC:

Worst case FLL response time = (2 × RCCR[REF_CNT] + 12) *reference_clock* cycles + 15 *bus_clock* cycles

- If *monitored_clock* stops when the CMU_FC is running:

Worst case FLL response time = (2 × RCCR[REF_CNT] + 2) *reference_clock* cycles + 3 *bus_clock* cycles

53.4 Programming guidelines

53.4.1 Programming RCCR[REF_CNT]

RCCR[REF_CNT] defines the duration of the checking operation in number of *reference_clock* cycles. The minimum RCCR[REF_CNT] value can be calculated using the following formula:

Minimum RCCR [REF_CNT] = CEILING value of MAX $\left(3 \text{ X } \left(\frac{f_{reference\_clock}}{f_{bus\_clock}}\right), 8 + 5 \text{ X } \left(\frac{f_{reference\_clock}}{f_{monitored\_clock}}\right)\right)$

...where:

- $f_{reference\_clock}$ is the frequency of the reference clock
- f_{bus_clock} is the frequency of the bus clock
- $f_{monitored\_clock}$ is the frequency of the monitored clock

Example to determine RCCR[REF_CNT]:

- f_{bus_clock} = 16 MHz
- $f_{reference\_clock}$ = 8 MHz
- $f_{monitored\_clock}$ = 48 MHz

Formula #1: $3 \text{ X } \left(\frac{f_{reference\_clock}}{f_{bus\_clock}}\right)$

Inserting the values: 3 × (8 / 16) = 1.5

Formula #2: $8 + 5 \text{ X } \left(\frac{f_{reference\_clock}}{f_{monitored\_clock}}\right)$

Inserting the values: 8 + 5 × (8 / 48) ≈ 8.83

MAX (1.5, 8.83): 8.83

CEILING value of MAX: 9

Therefore, minimum RCCR[REF_CNT]: 9

Programmed RCCR[REF_CNT] value must be greater than or equal to the calculated minimum value and should be decided after considering application requirements of frequency check completion response time and overall accuracy required from CMU_FC.

- Higher values of RCCR[REF_CNT] results in longer measurement window, leading to better accuracy in monitored clock check.
- Lower values of RCCR[REF_CNT] results in shorter measurement window, leading to faster FHH and FLL event response, but higher inaccuracy in reported result.

For measurement window calculation, see step 8 in Programming HFREF and LFREF

53.4.2 Programming HFREF and LFREF

You must consider the following when programming HFREF/LFREF:

- Tolerable monitored clock frequency variation
- Maximum reference clock frequency variation
- Inherent module inaccuracy

CMU_FC has an expected maximum deviation of ± 3 *monitored_clock* cycles (CMU_FC_{VAR+} = 3, CMU_FC_{VAR-} = –3).

The following procedure shows how to calculate optimum values for HTCR[HFREF] and LTCR[LFREF] (numbers shown are from example in table):

1. Determine the ideal *monitored_clock* frequency ($f_{monitored\_clock}$ (ideal), 48 MHz).
2. Determine the specified variation of the *monitored_clock* (1.1%).
3. Calculate *monitored_clock* frequency variation: .

$$f_{monitored\_clock}\ (ideal)\ \text{x}\ (1 \pm variation\ (\text{step 2}))$$

   - $f_{monitored\_clock}$ (max) = 48 MHz × (1 + (1.1 ÷ 100)) = 48.53 MHz
   - $f_{monitored\_clock}$ (min)= 48 MHz × (1 – (1.1 ÷ 100)) = 47.47 MHz
4. Determine the ideal *reference_clock* frequency ($f_{reference\_clock}$ (ideal), 8 MHz).
5. Determine the specified variation of the *reference_clock* (3.3%).
6. Calculate ideal *reference_clock* frequency variation:

$$f_{reference\_clock}\ (ideal)\ \text{x}\ (1 \pm variation\ (\text{step 5}))$$

   - $f_{reference\_clock}$ (max) = 8 MHz × (1 + (3.3 ÷ 100)) = 8.26 MHz
   - $f_{reference\_clock}$ (min) = 8 MHz × (1 – (3.3 ÷ 100)) = 7.74 MHz
7. Select the value of RCCR[REF_CNT] needed (80). See Programming RCCR[REF_CNT].
8. Calculate ideal measurement window:

$$\frac{RCCR\ [REF\_CNT]}{f_{reference\_clock}\ (ideal)}$$

   - 80 ÷ 8 MHz = 10000 ns
9. Calculate ideal *monitored_clock* count:

$$\frac{RCCR[REF\_CNT]}{f_{reference\_clock}(ideal)} \times f_{monitored\_clock}\ (ideal)$$

   - 80 ÷ 8 MHz × 48 MHz = 480.00 (round off this value, 480 in this case)
10. Calculate high threshold value (HTCR[HFREF]):

$$\text{Ceiling value of } \left(\frac{f_{monitored\_clock}\,(max)}{f_{reference\_clock}\,(min)} \times RCCR[REF\_CNT] \right) + CMU\_FC_{VAR+}$$

- HTCR[HFREF] = Ceiling(48.53 MHz ÷ 7.74 MHz × 80 + 3) = 505

11. Calculate low threshold value (LTCR[LFREF]):

$$\text{Floor value of } \left(\frac{f_{monitored\_clock}\,(min)}{f_{reference\_clock}\,(max)} \times RCCR[REF\_CNT] \right) - CMU\_FC_{VAR-}$$

- LTCR[LFREF] = Floor(47.47 MHz ÷ 8.26 MHz × 80 – 3) = 456

Table 251. HTCR[HFREF] and LTCR[LFREF] calculation example

Property	Value	Unit
Bus clock frequency (f_{bus_clock})	16	MHz
Monitored clock frequency ($f_{monitored\_clock}$ (ideal))	48	MHz
Specified variation of monitored clock	1.1	%
Monitored clock frequency (maximum after specified variation, $f_{monitored\_clock}$ (max))	48.53	MHz
Monitored clock frequency (minimum after specified variation, $f_{monitored\_clock}$ (min))	47.47	MHz
Reference clock frequency ($f_{reference\_clock}$ (ideal))	8	MHz
Specified variation of reference clock	3.3	%
Reference clock frequency (maximum after specified variation, $f_{reference\_clock}$ (max))	8.26	MHz
Reference clock frequency (minimum after specified variation, $f_{reference\_clock}$ (min))	7.74	MHz
Minimum reference count (RCCR[REF_CNT])	9	—
Programmed reference count (RCCR[REF_CNT]) (must be ≥ minimum RCCR[REF_CNT])	80	—
Measurement window	10000.00	ns
Calculated monitored clock count	480.00	—
Calculated monitored clock Count (rounded)	480	—
Module positive variation (CMU_FC_{VAR+})	3	—
Module negative variation (CMU_FC_{VAR-})	-3	—

Property	Value	Unit
Programmed lower threshold (LTCR[LFREF])	456	—

53.4.3 Module programming sequence

The recommended programming sequence for CMU_FCfrequency checking is:

1. In any order, complete the following:
   - Program RCCR[REF_CNT] to define the frequency measuring window duration in *reference_clock* cycles.
   - Program LTCR[LFREF] and HTCR[HFREF] to set the permissible frequency range of the *monitored_clock*.
   - Program IER to enable interrupt.
2. Write GCR[FCE] = 1 to start the frequency check operation.

   NOTE

   When GCR[FCE] = 1, you must not write to RCCR, HTCR, LTCR, or IER. Attempting to do so generates a bus transfer error.
3. To reconfigure RCCR, LTCR, HTCR , and IER or to stop frequency check operation, wait for SR[RS] = 1, then write GCR[FCE] = 0.

53.5 CMU_FC register descriptions

53.5.1 CMU_FC memory map

This section describes the address order of all the CMU_FC registers. Each description includes a standard register diagram and associated field descriptions.

CMU_0 base address: 402B_C000h

CMU_3 base address: 402B_C060h

CMU_4 base address: 402B_C080h

CMU_5 base address: 402B_C0A0h

Offset	Register	Width (In bits)	Access	Reset value
0h	Global Configuration Register (GCR)	32	RW	0000_0000h
4h	Reference Count Configuration Register (RCCR)	32	RW	0000_0000h
8h	High Threshold Configuration Register (HTCR)	32	RW	00FF_FFFFh
Ch	Low Threshold Configuration Register (LTCR)	32	RW	0000_0000h
10h	Status Register (SR)	32	W1C	0000_0000h
14h	Interrupt Enable Register (IER)	32	RW	0000_0000h

53.5.2 Global Configuration Register (GCR)

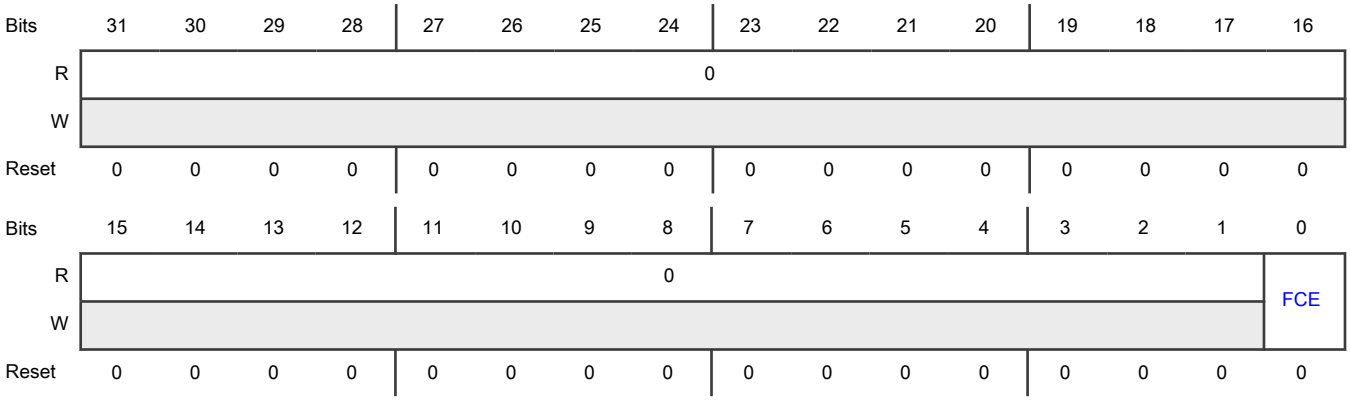
Offset

Register	Offset
GCR	0h

Function

Controls module level configurations such as enabling frequency check.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 FCE	Frequency Check Enable Starts or stops frequency checking. FCE is disabled by default. Software can enable FCE at any time. To stop the ongoing operation, write 0 to FCE only when SR[RS] = 1. 0b - Stops frequency checking 1b - Starts frequency checking

53.5.3 Reference Count Configuration Register (RCCR)

Offset

Register	Offset
RCCR	4h

Function

Programs reference count duration of the frequency check window.

NOTE

Write to RCCR only when GCR[FCE] = 0. A bus transfer error results if software writes RCCR when GCR[FCE] = 1.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-16 —	Reserved
15-0 REF_CNT	Reference clock count Total number of counts of *reference_clock* for which frequency check runs. This field defines the duration of one frequency check window. See Programming RCCR[REF_CNT] for RCCR calculation.

53.5.4 High Threshold Configuration Register (HTCR)

Offset

Register	Offset
HTCR	8h

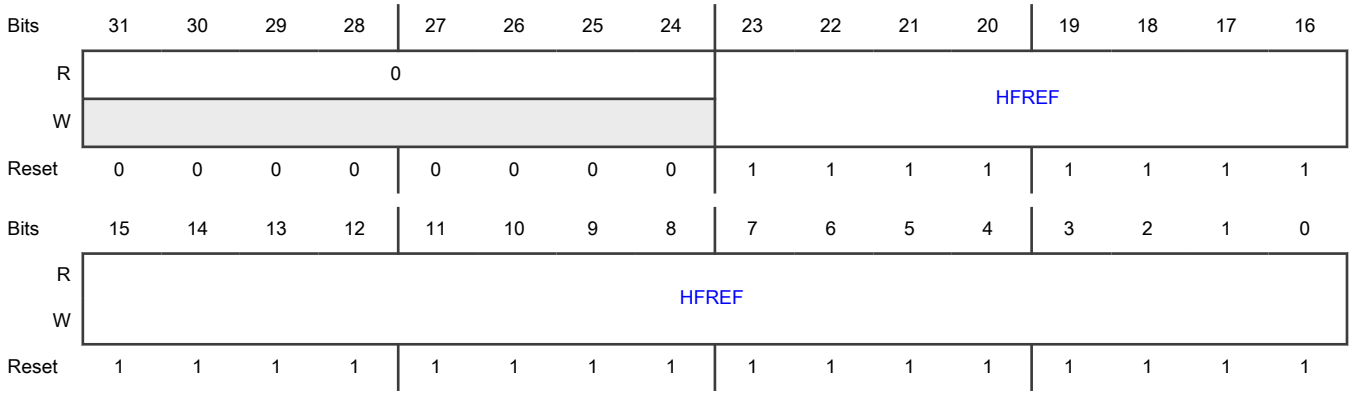
Function

Determines the high threshold limit of the monitored clock counter.

NOTE

Write HTCR only when GCR[FCE] = 0. A bus transfer error results if software writes HTCR when GCR[FCE] = 1.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-0 HFREF	High frequency reference threshold HFREF determines the high reference value for the monitored clock frequency. See Programming HFREF and LFREF for HFREF calculation. **NOTE** Do not program HFREF to a value greater than 0x00FFFFFC.

53.5.5 Low Threshold Configuration Register (LTCR)

Offset

Register	Offset
LTCR	Ch

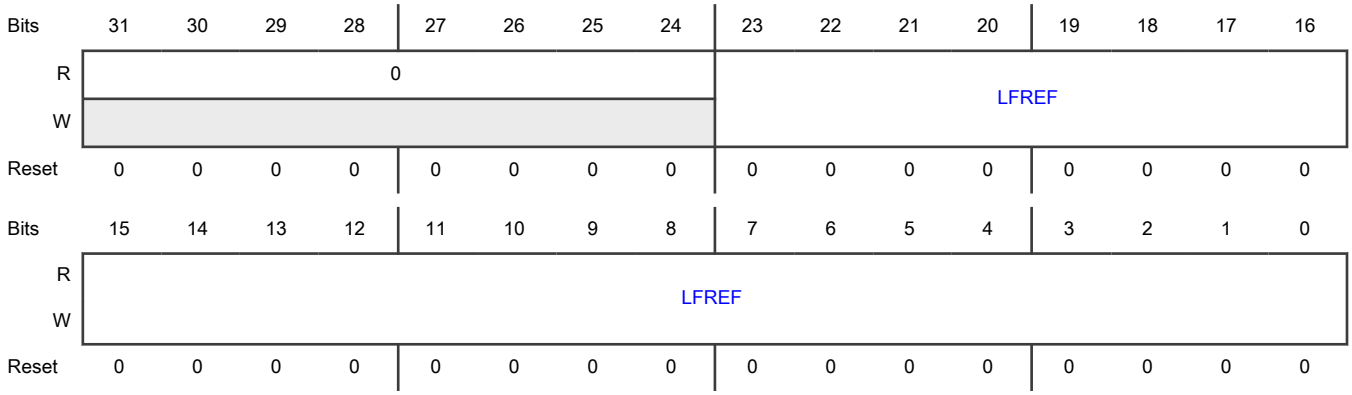
Function

Determines the low threshold limit of the monitored clock counter.

NOTE

Write LTCR only when GCR[FCE] = 0. A bus transfer error results if software writes LTCR when GCR[FCE] = 1.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-0 LFREF	Low Frequency Reference Threshold LFREF determines the low reference value for the monitored clock frequency. See Programming HFREF and LFREF for LFREF calculation. **NOTE** Do not program LFREF to a value less than 0x00000003.

53.5.6 Status Register (SR)

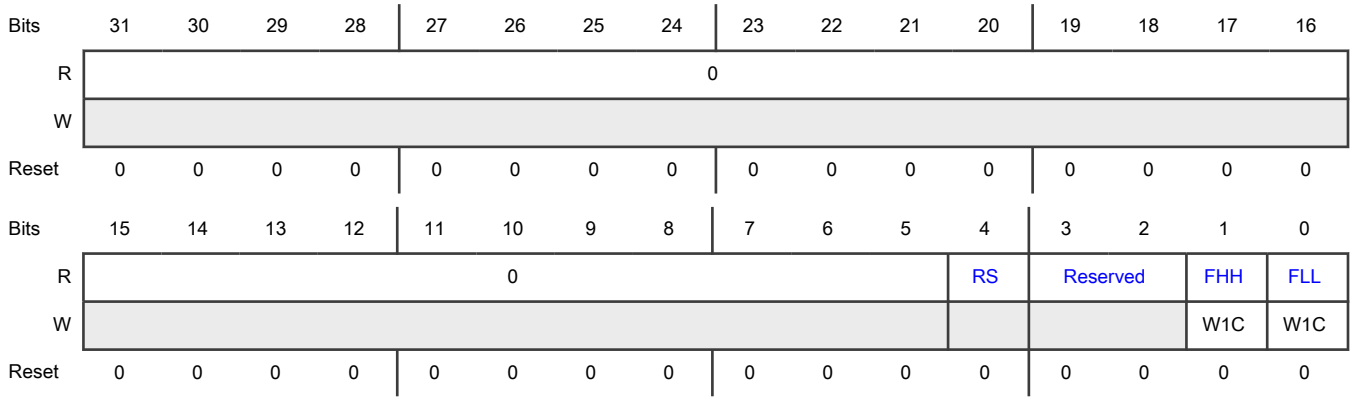
Offset

Register	Offset
SR	10h

Function

Provides the internal status of the module.

Diagram



Fields

Field	Function
31-5 —	Reserved
4 RS	Run Status Shows the running status of module internal operation. After enabling the frequency check operation (GCR[FCE] = 1), there is a fixed delay before this field shows running status. If the system wants to disable the frequency check operation, then the software should read this register and write GCR[FCE] = 0 only when this field is 1. 0b - Frequency check stopped 1b - Frequency check running
3-2 —	Reserved
1 FHH	Frequency higher than high frequency reference threshold event status Hardware writes 1 to FHH when the monitored clock frequency becomes higher than the high threshold value in HTCR[HFREF]. FHH clears when software writes 1. 0b - No FHH event 1b - FHH event occurred
0 FLL	Frequency lower than low frequency reference threshold event status Hardware writes 1 to FLL when the monitored clock frequency becomes lower than the low threshold value in LTCR[LFREF]. FLL clears when software writes 1. 0b - No FLL event 1b - FLL event occurred

53.5.7 Interrupt Enable Register (IER)

Offset

Register	Offset
IER	14h

Function

Enables CMU_FC interrupts.

NOTE

Write IER only when GCR[FCE] = 0. A bus transfer error results if software writes IER when GCR[FCE] = 1.

Enable only either asynchronous FHH event interrupt or synchronous FHH event interrupt at a time.

For example:

- If IER[FHHIE] is set to 1 then set IER[FHHAIE] to 0.
- If IER[FHHAIE] is set to 1 then set IER[FHHIE] to 0.

Enable only either asynchronous FLL event interrupt or synchronous FLL event interrupt at a time.

For example:

- If IER[FLLIE] is set to 1 then set IER[FLLAIE] to 0.
- If IER[FLLAIE] is set to 1 then set IER[FLLIE] to 0.

See Clocking chapter for interrupt usage information based on CMU_FC instances.

53.6 Glossary

FHH The state that the monitored clock frequency is higher than the high frequency reference. FHH is also the name of the register field that indicates this state.

FHH event The event that the module triggers when it detects FHH.

FLL The state that the monitored clock frequency is lower than the lower frequency reference. FLL is also the name of the register field that indicates this state.

FLL event The event that the module triggers when it detects FLL.

Chapter 54
Clock Monitoring Unit – Frequency Meter (CMU_FM)

54.1 Chip-specific CMU_FM information

54.1.1 CMU_FM configuration

The device consists of a robust clock monitoring architecture targeted to monitor various clock nodes to ensure device clock robustness. There are upto seven clock monitoring units present in the device out of which 2 are of type CMU_FM. See 'Clock monitoring' section in Clocking chapter for details on device clock monitoring architecture.

NOTE

CMU metering interrupt is not generated if the clock which is being metered is lost. A timeout status flag, CMU.SR[FMTO] is updated in this case.

NOTE

Software must ensure that CMU1 interrupt is serviced within POR_WDG timeout. In absence of CMU1 interrupt servicing, the POR_WDG detects this as an FIRC failure and initiates a POR recovery.

54.2 Introduction

CMU_FM measures the frequency of the metered clock (*metered_clock*) using another clock as reference. This reference clock (*reference_clock*) must be within documented limits for correct CMU_FM operation. CMU_FM operation is only guaranteed if a reference clock is within normal operating parameters.

54.2.1 Basic operation

The CMU_FM counts the clock cycles of a metered clock in the user programmable time duration *n* number of clock cycles of the reference clock. After completion of a metered clock operation, a register field sets, indicating the operation has completed. The count of the metered clock also updates in the Status Register (SR) after completion of a metered clock operation.

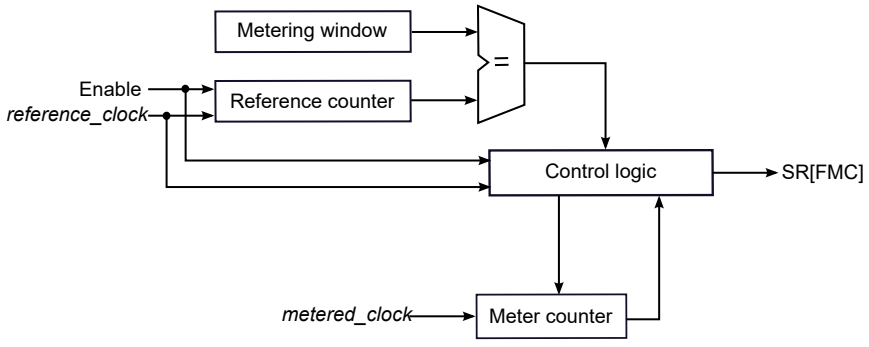

Figure 201. Block diagram

54.2.2 Features

Features of the CMU_FM are:

- Programmable duration of *reference_clock* cycles
- Maskable interrupt generation when frequency metering completes
- Timeout feature indicates loss of *metered_clock*

Table 252. Clock description

Clock	I/O	Description
reference_clock	I	Clock signal that the module uses as a reference to evaluate *metered_clock*
metered_clock	I	Clock signal on which frequency metering is performed
bus_clock	I	Clock signal on which register read/write operation is performed

NOTE

See the Clocking chapter for details of metered and reference clocks used on this chip.

54.3 Functional description

The frequency meter operation initiates when software writes GCR[FME] = 1. When the operation starts, hardware writes SR[RS] = 1. Safety critical applications must poll SR[RS] to determine when metering operation starts.

Frequency metering window involves these operations:

1. Stage 1 — The reference clock counter runs for RCCR[REF_CNT] cycles of *reference_clock*. The metered clock counter runs in parallel for the same time duration as the *reference_clock* counter.
2. Stage 2 — At the end of stage 1, SR[FMC] = 1, SR[MET_CNT] updates with the *metered_clock* count, and CMU_FM writes GCR[FME] = 0.

54.4 Programming guidelines

54.4.1 Programming RCCR[REF_CNT]

RCCR[REF_CNT] defines the duration of the metering operation in number of *reference_clock* cycles. The minimum RCCR[REF_CNT] value can be calculated using the following formula:

$$\textbf{Minimum RCCR [REF\_CNT]} = \text{CEILING value of MAX}\left(3 \text{ X } \left(\frac{f_{reference\_clock}}{f_{bus\_clock}}\right), 8 + 5 \text{ X } \left(\frac{f_{reference\_clock}}{f_{monitored\_clock}}\right)\right)$$

...where:

- $f_{reference\_clock}$ is the frequency of the reference clock
- f_{bus_clock} is the frequency of the bus clock
- $f_{metering\_clock}$ is the frequency of the metered clock

Example to determine RCCR[REF_CNT]:

- f_{bus_clock} = 16 MHz
- $f_{reference\_clock}$ = 8 MHz
- $f_{metered\_clock}$ = 48 MHz

Formula #1:

$$3 \text{ X } \left(\frac{f_{reference\_clock}}{f_{bus\_clock}} \right)$$

Inserting the values: 3 × (8 / 16) = 1.5

Formula #2:

$$6 + 4 \text{ X } \left(\frac{f_{reference\_clock}}{f_{metered\_clock}} \right)$$

Inserting the values: 6 + 4 × (8 / 48) ≈ 6.67

MAX (1.5, 6.67): 6.67

CEILING value of MAX: 7

Therefore, minimum RCCR[REF_CNT]: 7

Programmed RCCR[REF_CNT] value must be greater than or equal to the calculated minimum value and should be decided after considering application requirements of frequency metering completion response time and overall accuracy required from CMU_FM.

- Higher values of RCCR[REF_CNT] results in longer metering window, leading to better accuracy in metered clock measurement.
- Lower values of RCCR[REF_CNT] results in shorter metering window, leading to faster FMC response, but higher inaccuracy in reported result.

54.4.2 Module programming sequence

The recommended programming sequence of CMU_FM is:

1. In any order, complete the following:
   - Program RCCR[REF_CNT] to define the frequency metering window duration in *reference_clock* cycles.
   - Program IER[FMCIE] to enable interrupt.
2. Write GCR[FME] = 1 to start frequency metering operation. Writes to RCCR and IER are disabled after GCR[FME] = 1. Attempting a write to any of them after GCR[FME] = 1 generates a bus transfer error.
3. To reconfigure RCCR and IER or to stop frequency metering operation, wait for SR[RS] = 1, then write GCR[FME] = 0.

Upon completion of metering operations:

- Hardware writes SR[FMC] = 1
- SR[MET_CNT] updates with metered count value
- Hardware writes GCR[FME] = 0

54.5 CMU_FM register descriptions

54.5.1 CMU_FM memory map

Chapter 55
Cyclic Redundancy Check (CRC)

55.1 Chip-specific CRC information

This chip supports one instance of CRC module.

55.2 Introduction

The Cyclic Redundancy Check (CRC) module generates 16/32-bit CRC code for error detection.

The CRC module provides a programmable polynomial and other parameters required to implement a 16-bit or 32-bit CRC standard.

The 16/32-bit code is calculated for 32 bits of data at a time.

55.2.1 Features

Following are the features of the CRC module.

- Hardware CRC generator circuit using a 16-bit or 32-bit programmable shift register
- Programmable initial seed value and polynomial
- Option to transpose input data or output data (the CRC result) bitwise or bytewise. This option is required for certain CRC standards. A bytewise transpose operation is not possible when accessing the CRC data register via 8-bit accesses. In this case, the user's software must perform the bytewise transpose function.
- Option for inversion of final CRC result
- 32-bit CPU register programming interface

55.2.2 Block diagram

The following is a block diagram of the CRC.

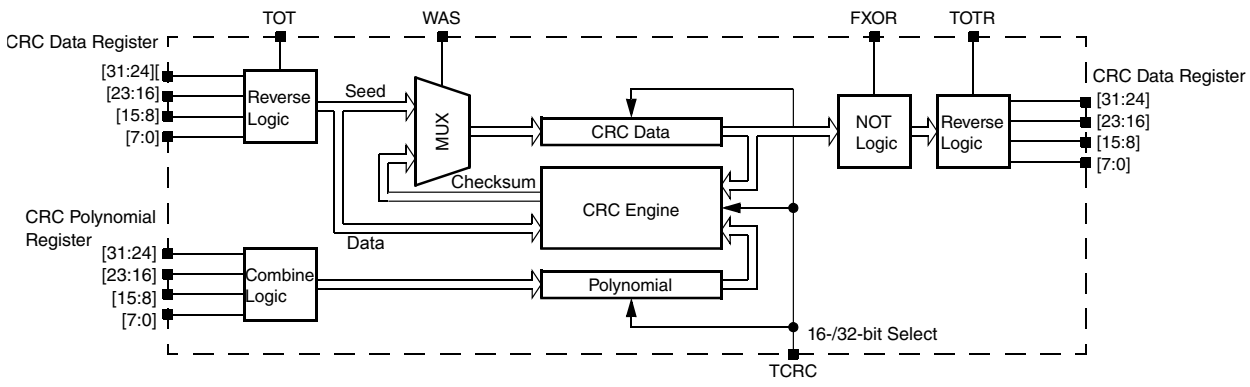

Figure 202. Programmable cyclic redundancy check (CRC) block diagram

55.2.3 Modes of operation

Following sections provide a brief description of various modes which affect the functionality of the CRC module.

55.2.3.1 Run mode

This is the basic mode of operation.

55.2.3.2 Low-power modes

Any CRC calculation in progress stops when the device enters a low-power mode that disables the module clock. It resumes after the clock is enabled or via the system reset for exiting the low-power mode. Clock gating for this module is dependent on the device.

55.3 Functional description

55.3.1 CRC initialization/reinitialization

To enable the CRC calculation, the user must program CRC_CTRL[WAS], CRC_GPOLY, necessary parameters for transposition and CRC result inversion in the applicable registers. Asserting CRC_CTRL[WAS] enables the programming of the seed value into the CRC_DATA register.

After a completed CRC calculation, the module can be reinitialized for a new CRC computation by reasserting CRC_CTRL[WAS] and programming a new, or previously used, seed value. All other parameters must be set before programming the seed value and subsequent data values.

55.3.2 CRC calculations

In 16-bit and 32-bit CRC modes, data values can be programmed 8 bits, 16 bits, or 32 bits at a time, provided all bytes are contiguous. Noncontiguous bytes can lead to an incorrect CRC computation.

55.3.2.1 16-bit CRC

The steps to compute a 16-bit CRC are listed as follows.

1. Clear CRC_CTRL[TCRC] to enable 16-bit CRC mode.
2. Program the transpose and complement options in the CTRL register as required for the CRC calculation. See Transpose feature and CRC result complement for details.
3. Write a 16-bit polynomial to the CRC_GPOLY[LOW] field. The CRC_GPOLY[HIGH] field is not usable in 16-bit CRC mode.
4. Set CRC_CTRL[WAS] to program the seed value.
5. Write a 16-bit seed to CRC_DATA[LU:LL]. CRC_DATA[HU:HL] are not used.
6. Clear CRC_CTRL[WAS] to start writing data values.
7. Write data values into CRC_DATA[HU:HL:LU:LL]. A CRC is computed on every data value write, and the intermediate CRC result is stored back into CRC_DATA[LU:LL].
8. When all values have been written, read the final CRC result from CRC_DATA[LU:LL].

Transpose and complement operations are performed on-the-fly while reading or writing values. See Transpose feature and CRC result complement for details.

55.3.2.2 32-bit CRC

The steps to compute a 32-bit CRC are listed as follows.

1. Set CRC_CTRL[TCRC] to enable 32-bit CRC mode.
2. Program the transpose and complement options in the CTRL register as required for the CRC calculation. See Transpose feature and CRC result complement for details.
3. Write a 32-bit polynomial to CRC_GPOLY[HIGH:LOW].
4. Set CRC_CTRL[WAS] to program the seed value.
5. Write a 32-bit seed to CRC_DATA[HU:HL:LU:LL].
6. Clear CRC_CTRL[WAS] to start writing data values.

7. Write data values into CRC_DATA[HU:HL:LU:LL]. A CRC is computed on every data value write, and the intermediate CRC result is stored back into CRC_DATA[HU:HL:LU:LL].
8. When all values have been written, read the final CRC result from CRC_DATA[HU:HL:LU:LL]. The CRC is calculated bytewise, and two clocks are required to complete one CRC calculation.

Transpose and complement operations are performed on-the-fly while reading or writing values. See Transpose feature and CRC result complement for details.

55.3.3 Transpose feature

By default, the transpose feature is not enabled. However, some CRC standards require the input data and/or the final checksum to be transposed. The user software has the option to configure each transpose operation separately, as desired by the CRC standard. The data is transposed on-the-fly while being read or written.

Some protocols use little-endian format for the data stream to calculate a CRC. In this case, the transpose feature usefully flips the bits. This transpose option is one of the types supported by the CRC module.

55.3.3.1 Types of transpose

The CRC module provides several types of transpose functions to flip the bits and/or bytes, for both writing input data and reading the CRC result, separately using the CTRL[TOT] or CTRL[TOTR] fields, according to the CRC calculation being used.

The following types of transpose functions are available for writing to and reading from the CRC Data register.

1. CTRL[TOT] or CTRL[TOTR] is 0b00.

   No transposition occurs.

2. CTRL[TOT] or CTRL[TOTR] is 0b01

   Bits in a byte are transposed, while bytes are not transposed.

   reg[31:0] becomes {reg[24:31], reg[16:23], reg[8:15], reg[0:7]}. See the following figure.

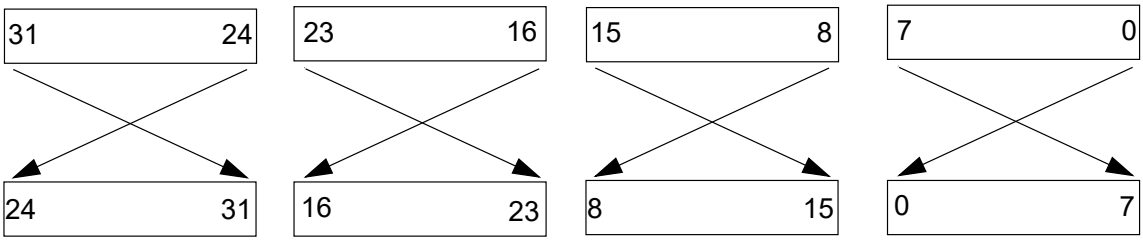

Figure 203. Transpose type 0b01

3. CTRL[TOT] or CTRL[TOTR] is 0b10.

   Both bits in bytes and bytes are transposed.

   reg[31:0] becomes = {reg[0:7], reg[8:15],reg[16:23], reg[24:31]}. See the following figure.

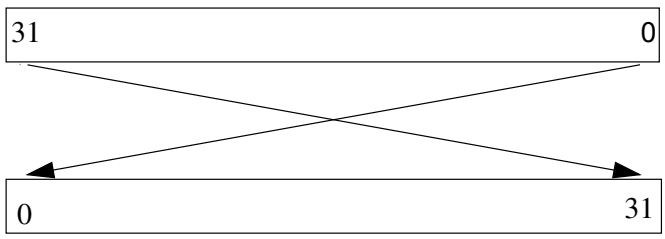

Figure 204. Transpose type 0b10

4. CTRL[TOT] or CTRL[TOTR] is 0b11.

Bytes are transposed, but bits are not transposed.

reg[31:0] becomes {reg[7:0], reg[15:8], reg[23:16], reg[31:24]}. See the following figure.

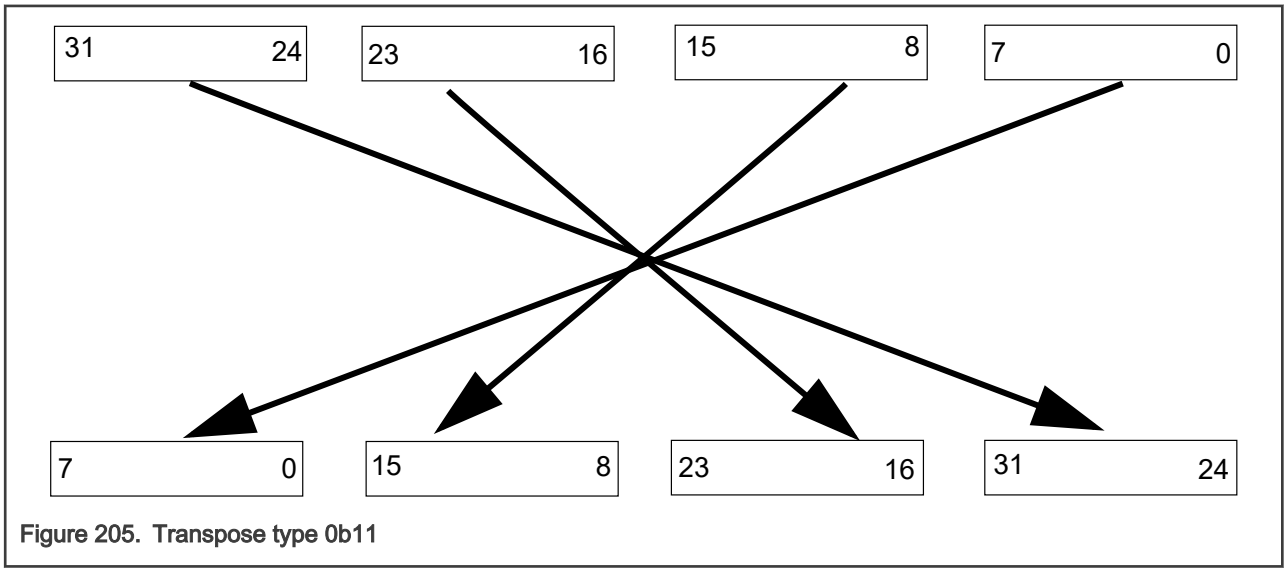

Figure 205. Transpose type 0b11

NOTE

For 8-bit and 16-bit write accesses to the CRC data register, the data is transposed with zeros on the unused byte or bytes (taking 32 bits as a whole), but the CRC is calculated on the valid byte(s) only. When reading the CRC data register for a 16-bit CRC result and using transpose options 10 and 11, the resulting value after transposition resides in the CRC[HU:HL] fields. The user software must account for this situation when reading the 16-bit CRC result, so reading 32 bits is preferred.

55.3.4 CRC result complement

When CTRL[FXOR] is set, the checksum is complemented. The CRC result complement function outputs the complement of the checksum value stored in the CRC Data (DATA) Register every time the CRC Data (DATA) register is read. When CTRL[FXOR] is cleared, reading the CRC Data (DATA) Register accesses the raw checksum value.

55.4 Use cases

NOTE

The following tables apply to little-endian format.

55.4.1 CRC Control Register programming

The following table shows the CRC Control Register programming for 16-bit CRC.

Table 253. Control Register (CTRL) programming for 16-bit CRC

55.5 Memory map and register descriptions

NOTE

Write access to the register addresses not mapped to the peripheral but included in the address space of the peripheral may result in unpredictable functionality. The CRC module should be reconfigured if a transfer error occurs.

55.5.1 CRC register descriptions

55.5.1.1 CRC memory map

CRC base address: 4038_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	CRC DATA register (DATA)	32	RW	FFFF_FFFFh
4h	CRC Polynomial register (GPOLY)	32	RW	0000_1021h
8h	CRC Control register (CTRL)	32	RW	0000_0000h

55.5.1.2 CRC DATA register (DATA)

Offset

Register	Offset
DATA	0h

Function

The CRC DATA register contains the value of the seed, data, and checksum. When CTRL[WAS] is set, any write to the data register is regarded as the seed value. When CTRL[WAS] is cleared, any write to the data register is regarded as data for general CRC computation.

In 16-bit CRC mode, the HU and HL fields are not used for programming the seed value, and reads of these fields return an indeterminate value. In 32-bit CRC mode, all fields are used for programming the seed value.

When programming data values, the values can be written 8 bits, 16 bits, or 32 bits at a time, provided all bytes are contiguous; with MSB of data value written first.

After all data values are written, the CRC result can be read from this data register. In 16-bit CRC mode, the CRC result is available in the LU and LL fields. In 32-bit CRC mode, all fields contain the result. Reads of this register at any time return the intermediate CRC value, provided the CRC module is configured.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	HU								HL							
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	LU								LL							
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Fields

Field	Function
31-24 HU	CRC High Upper Byte In 16-bit CRC mode (CTRL[TCRC] is 0), this field is not used for programming a seed value. In 32-bit CRC mode (CTRL[TCRC] is 1), values written to this field are part of the seed value when CTRL[WAS] is 1. When CTRL[WAS] is 0, data written to this field is used for CRC checksum generation in both 16-bit and 32-bit CRC modes.
23-16 HL	CRC High Lower Byte In 16-bit CRC mode (CTRL[TCRC] is 0), this field is not used for programming a seed value. In 32-bit CRC mode (CTRL[TCRC] is 1), values written to this field are part of the seed value when CTRL[WAS] is 1. When CTRL[WAS] is 0, data written to this field is used for CRC checksum generation in both 16-bit and 32-bit CRC modes.
15-8 LU	CRC Low Upper Byte When CTRL[WAS] is 1, values written to this field are part of the seed value. When CTRL[WAS] is 0, data written to this field is used for CRC checksum generation.
7-0 LL	CRC Low Lower Byte When CTRL[WAS] is 1, values written to this field are part of the seed value. When CTRL[WAS] is 0, data written to this field is used for CRC checksum generation.

55.5.1.3 CRC Polynomial register (GPOLY)

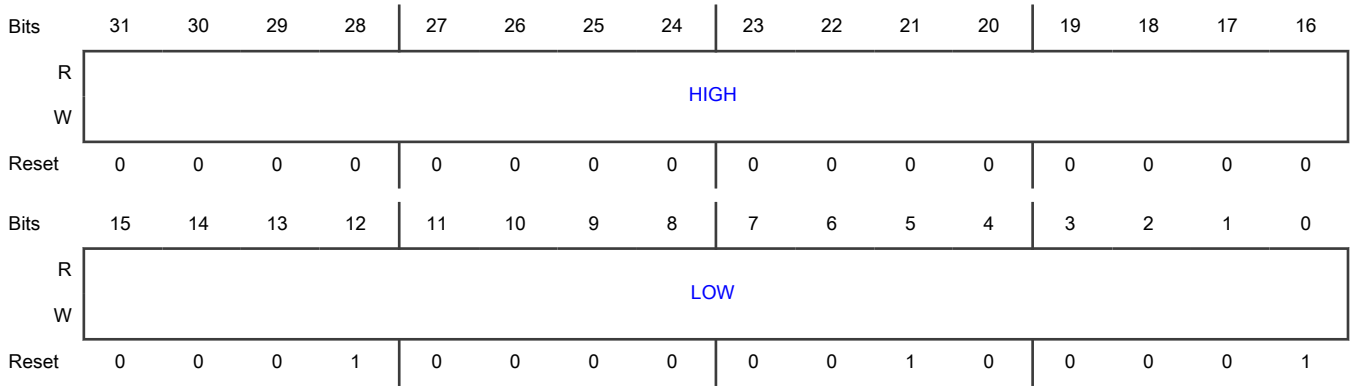
Offset

Register	Offset
GPOLY	4h

Function

This register contains the value of the polynomial for the CRC calculation. The HIGH field contains the upper 16 bits of the CRC polynomial, which are used only in 32-bit CRC mode. Writes to the HIGH field are ignored in 16-bit CRC mode. The LOW field contains the lower 16 bits of the CRC polynomial, which are used in both 16- and 32-bit CRC modes.

Diagram



Fields

Field	Function
31-16 HIGH	High Polynominal Half-word Writable and readable in 32-bit CRC mode (CTRL[TCRC] is 1). This field is not writable in 16-bit CRC mode (CTRL[TCRC] is 0).
15-0 LOW	Low Polynominal Half-word Writable and readable in both 32-bit and 16-bit CRC modes.

55.5.1.4 CRC Control register (CTRL)

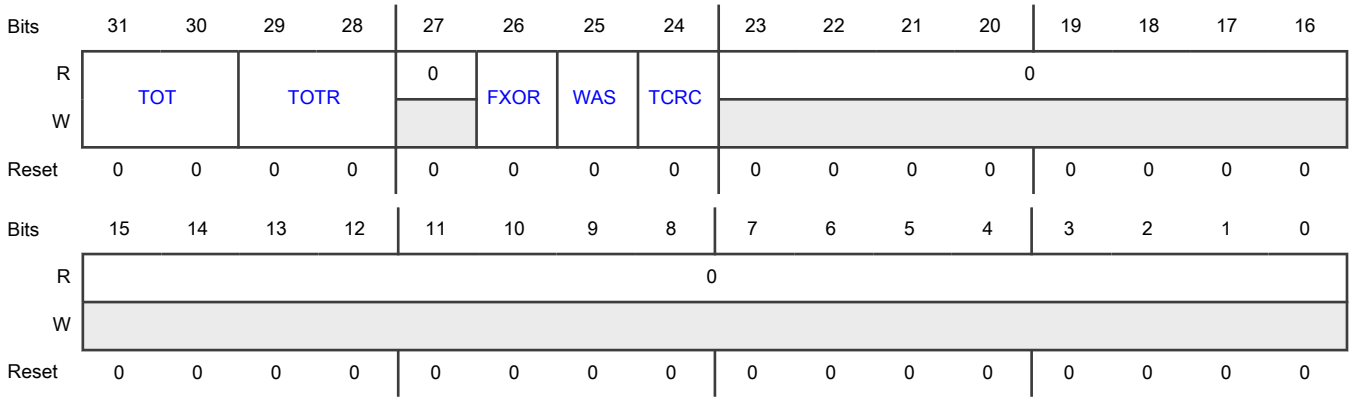
Offset

Register	Offset
CTRL	8h

Function

This register controls the configuration and working of the CRC module. Appropriate bits must be set before starting a new CRC calculation. A new CRC calculation is initialized by asserting CTRL[WAS] and then writing the seed into the CRC DATA register.

Diagram



Fields

Field	Function
31-30 TOT	Type Of Transpose For Writes Defines the transpose configuration of the data written to the CRC DATA register. See Transpose feature for the available transpose options. 00b - No transposition.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	01b - Bits in bytes are transposed; bytes are not transposed. 10b - Both bits in bytes and bytes are transposed. 11b - Only bytes are transposed; no bits in a byte are transposed.
29-28 TOTR	Type Of Transpose For Read Identifies the transpose configuration of the value read from the CRC DATA register. See Transpose feature for the available transpose options. 00b - No transposition. 01b - Bits in bytes are transposed; bytes are not transposed. 10b - Both bits in bytes and bytes are transposed. 11b - Only bytes are transposed; no bits in a byte are transposed.
27 —	Reserved
26 FXOR	Complement Read Of CRC DATA register Some CRC protocols require the final checksum to be XORed with 0xFFFFFFFF or 0xFFFF. Asserting this bit enables on-the-fly complementing of read data. 0b - No XOR on reading. 1b - Invert or complement the read value of the CRC DATA register.
25 WAS	Write CRC DATA register As Seed When asserted, a value written to the CRC DATA register is considered a seed value. When deasserted, a value written to the CRC DATA register is taken as data for CRC computation. 0b - Writes to the CRC DATA register are data values. 1b - Writes to the CRC DATA register are seed values.
24 TCRC	TCRC Width of CRC protocol. 0b - 16-bit CRC protocol. 1b - 32-bit CRC protocol.
23-0 —	Reserved

55.6 Glossary

Transpose	Flipping input or output data bits (or bytes)
Seed value	Initial value of CRC calculation

Chapter 56
Power Conversion and Motor Control (PCMC)

56.1 Introduction

The PCMC subsystem is a group of modules that can be interconnected to perform a variety of real-time tasks, such as:

- Motor control
- Power conversion
- Advanced PWM generation
- Lighting control

The modules that make up PCMC are:

- ADC
- BCTU
- eMIOS
- LCU
- LPCMP
- TRGMUX

See Feature comparison for the number of instances of each module in your chip.

56.2 Block diagram

The figure and table below show a typical configuration.

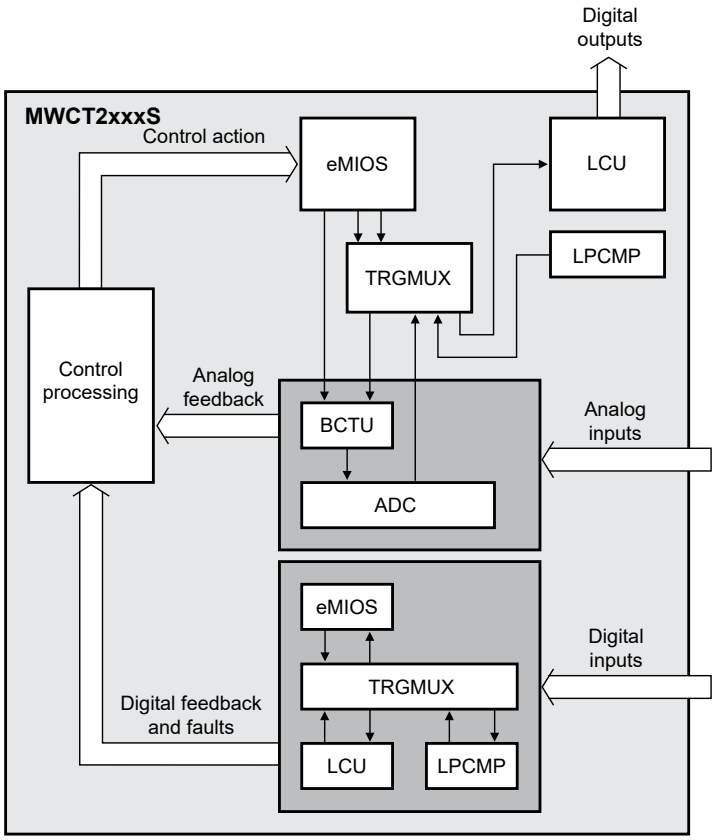


Figure 206. Block diagram

Table 257. Block diagram components

Component	Description
ADC	Measures external analog signals
BCTU	Performs advanced ADC triggering
Control processing	Arm Cortex-M7 core: • Processes digital and analog inputs to generate control outputs • Writes control outputs to peripherals
eMIOS	• Generates high-resolution PWM outputs • Measures time-based digital inputs
LCU	Performs programmable logic functions and fault control
LPCMP	Compares analog values to detect faults
TRGMUX	• Routes signals between internal peripherals • Routes external signals to internal peripherals

56.3 Functional overview

56.3.1 Analog signal measurement

ADC measures the voltage of external analog signals and converts that voltage to a digital value. Each ADC instance operates independently of other instances. Software or hardware can trigger conversions. Together with BCTU and eMIOS, ADC can preempt normal measurements by injecting high-priority measurements when needed.

See Analog-to-Digital Converter.

56.3.2 Advanced ADC triggering

BCTU works with ADC to initiate conversions triggered by outputs from other modules in the PCMC subsystem, such as PWM signals from eMIOS or LCU sequential logic outputs.

With BCTU, you can group measurements into configuration lists containing up to 32 items. Each item contains information such as:

- ADC instance to use for the conversion
- The ADC channel
- The trigger event for initiating the next conversion
- The conversion list address

BCTU can store conversion results by routing them through DMA or putting them in FIFO queues. The FIFO queues enable conversions to occur seamlessly by storing conversion results without software intervention.

BCTU has 72 trigger inputs, 69 of which come from the eMIOS channel outputs. The three remaining trigger inputs come from other on-chip modules via TRGMUX. You can also trigger conversions by software through the BCTU register interface.

BCTU can issue a single conversion or a list of conversions based on a single trigger occurrence. BCTU signals the eMIOS timers when ADC receives a single command or a list of commands. ADC sends conversion data back to BCTU, which loads it in the ADC*n* Result Data (ADC*n*DR) register for the CPU to read.

BCTU-to-ADC interface illustrates the connections between BCTU and an ADC.

56.3.3 BCTU-to-ADC interface

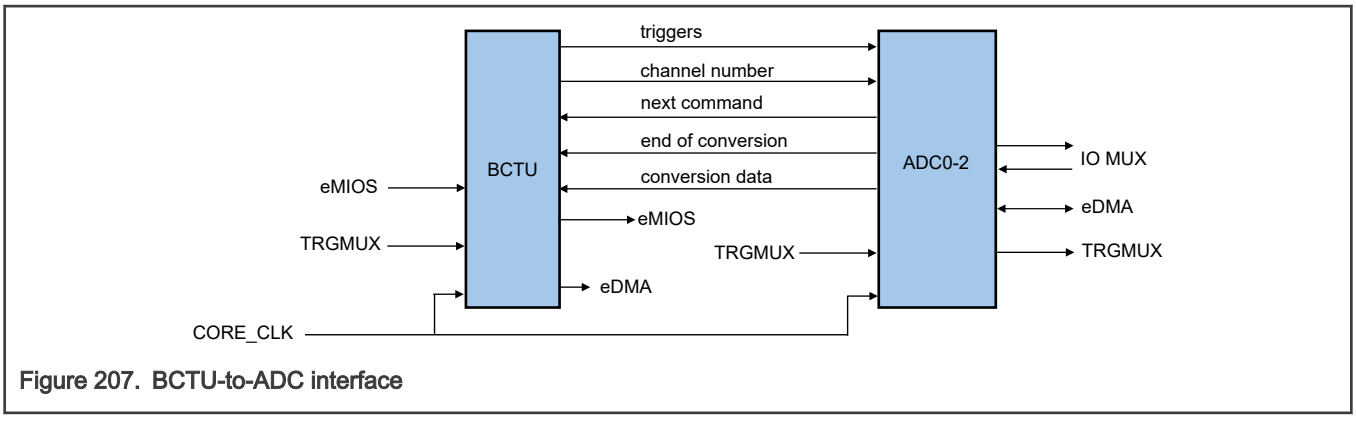

Figure 207. BCTU-to-ADC interface

56.3.4 Generate PWM outputs and measure digital inputs

eMIOS generates high-resolution PWM outputs. Each eMIOS instance has 23 dedicated channel outputs. You can configure each channel to operate in a different mode. Depending on the mode, eMIOS channels can:

- Measure the period of an input signal
- Measure the width of an input pulse
- Function as general-purpose I/O
- Count pulses or edges
- Capture input values
- Compare outputs

For example, eMIOS can generate periodic ADC triggers. Using TRGMUX, you can route eMIOS triggers to other on-chip peripherals such as LCU, another eMIOS instance, external chip I/O, and so on.

eMIOS connections illustrates the input and output connections for eMIOS.

- Enhanced Modular IO Subsystem (eMIOS)
- Body cross-triggering unit (BCTU)
- Trigger Mux (TRGMUX)

56.3.5 eMIOS connections

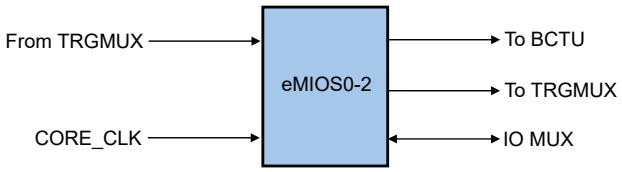

Figure 208. eMIOS connections

56.3.6 Create combinatorial and sequential logic functions

LCU enables you to implement hardware-based combinatorial and sequential logic on the chip. This capability reduces cost and decreases application size.

Each LCU instance has 12 dedicated inputs and 12 outputs. You can use LCU to implement a variety of combinatorial and sequential logic functions with no CPU intervention, including a simple OR gate, flip flops, and motor control logic. As detailed in Fault detection, LCU also plays a significant role in fault management.

LCU connections shows the input and output connections for LCU.

See also:

- Logic Control Unit (LCU)
- LCU use case examples
- Trigger MUX (TRGMUX)
- TRGMUX connectivity file attached to this document

56.3.7 LCU connections

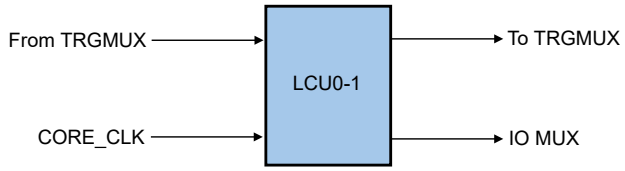

Figure 209. LCU connections

56.3.8 Fault detection

The PCMC subsystem uses LPCMP and LCU to implement fault detection.

LPCMP can detect fault conditions (such as short circuits, over-voltages, and excessive temperature) by comparing an external input voltage to a programmable reference voltage. It produces a digital output that indicates whether the input voltage is higher or lower than the reference voltage.

The chip can detect faults via external digital or analog signals. TRGMUX routes digital signals from SIUL to a peripheral to trigger the appropriate behavior.

LCU has four force inputs that you can use to manage fault assertion via its own internal logic mechanism.

The typical reaction to the presence of fault is to put the system in a safe state by:

- Deasserting output signals such as PWM outputs controlling a power stage.
- Disconnecting an entire circuit by switching off a relay.

See also Low Power Comparator (LPCMP).

56.3.9 Programmable module interconnections

TRGMUX enables you to interconnect on-chip peripherals to create application-specific configurations. TRGMUX has 128 inputs and 111 outputs, which you can interconnect in hundreds of combinations through software during runtime.

You can also route on-chip peripheral outputs to chip I/O pins to enable signal debugging. Similarly, you can route external signals to on-chip peripheral inputs.

NOTE

There is a two-cycle AIPS_SLOW_CLK delay through TRGMUX.

For details of PCMC interconnections, see PCMC connections diagram.

The attached TRGMUX connectivity file, a portion of which appears below, shows the interconnections possible between module instances. Column B in the spreadsheet lists TRGMUX inputs. Row 3 lists TRGMUX outputs. A connection between an input and an output is possible if the intersecting cell of the input row and the output column is blank. "NA" indicates that a connection is not possible.

	A	B	C	D	E	F	G	H	I	J	K	L	M	N

56.4 Reset, clocking, and other considerations

56.4.1 Reset

ADC, BCTU, eMIOS, LCU, and TRGMUX fully reset during a POR, destructive reset, or functional reset.

See also:

- Module reset status
- Software reset

56.4.2 Clocking

Detailed clocking information is given in the links below. In summary:

- CORE_CLK clocks ADC, BCTU, eMIOS, and LCU.
- AIPS_SLOW_CLK clocks TRGMUX.
- In general, you must set AIPS_SLOW_CLK to one-fourth or one-half the frequency of CORE_CLK.

See also:

- ADC and motor control modules
- Clocking use case examples
- System clock frequency limitations
- Clock frequency

56.4.3 Power modes

All ADC, BCTU, eMIOS, LCU, and TRGMUX instances operate only in Run mode. None of the instances operate in Standby mode.

See also:

- Module reset status
- ADC modes of operation
- LCU modes of operation

56.5 Use case examples

56.5.1 Motor control use case

The following sections show:

- A PMSM control system
- A BLDC control system

Both PMSM and BLDC use a rotating magnetic stator field to turn the stator consisting of permanent magnets. The stator is driven by 3-phase AC voltage. The difference between PMSM and BLDC is in how stator position is calculated.

- PMSM calculates stator position by measuring back EMF from the motor.
- BLDC calculates stator position based on feedback from motor sensors.

56.5.1.1 PMSM motor control use case

56.5.1.1.1 Generic PMSM motor control

The following figure and table illustrate a generic PMSM motor control system. The feedback loops in the system create a motor control loop.

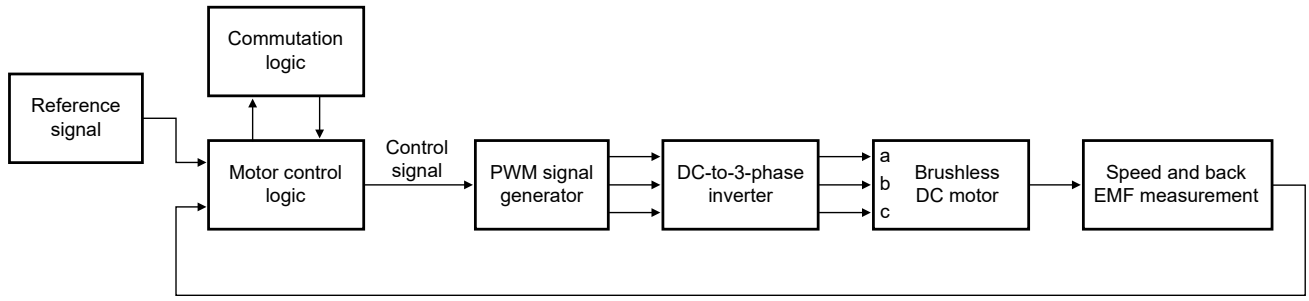

Figure 212. Generic PMSM motor control

Table 258. Block diagram components

Block	Description
Angular position sensor	Generates data that enables commutation logic to calculate rotor position.
Brushless DC motor	Electronically commutated electric motor.
Commutation logic	Compares values from the rotor angular position sensors to entries in a lookup table, and applies voltage to stator winding corresponding to same set of values in lookup table.

Table continues on the next page...

Table 258. Block diagram components (continued)

Block	Description
DC-to-3-phase inverter	Switching network that transmits power to the motor stator windings according to a control signal.
Motor control logic	• Compares speed measurement to required speed and adjusts the PWM signal generator. • Generates the assertions for the PWM signal generator according to commutation logic input.
PWM signal generator	Generates PWM signal voltage source.
Reference signal	Signal that indicates required motor speed.
Speed and back EMF measurement	An ADC is linked to a shunt resistor to perform measurements and detect over-current conditions. If one is found, then hardware generates a fault interrupt.

56.5.1.1.2 PMSM motor control

The PCMC subsystem consists of a group of modules that enable you to implement PMSM motor control loops in a variety of ways. The following figure and table illustrate one possible implementation.

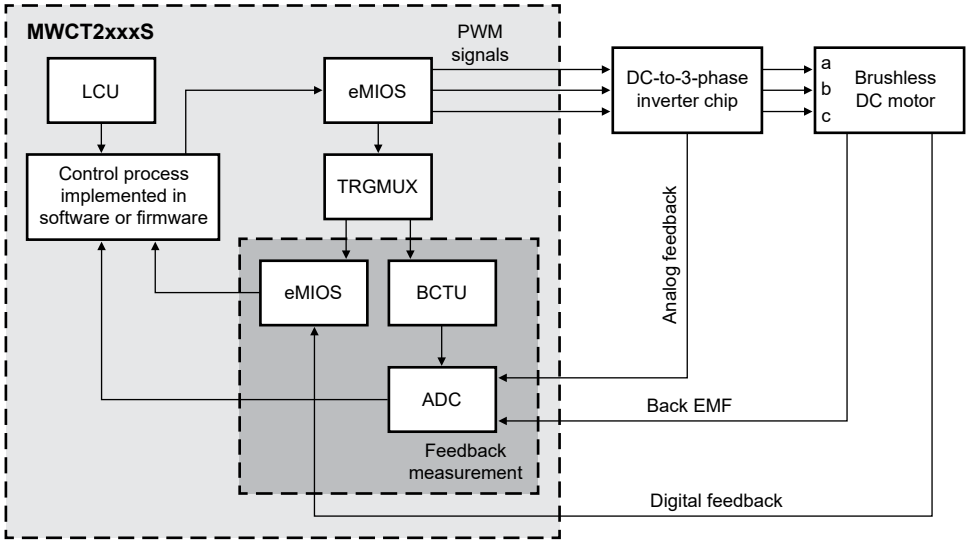

Figure 213. PMSM motor control

Table 259. Block diagram components

Block	Description
ADC	Measures analog inputs (currents and/or voltages) and converts to digital values. Typically, it measures currents and can be configured to generate a fault interrupt when a measured input is outside a pre-defined acceptable range.
BCTU	Triggers conversions by ADC.
Control process	Provides top-level system control functions for FOC or another feasible control algorithm:

Table continues on the next page...

Table 259. Block diagram components (continued)

Block	Description
	• Compares speed measurement to required speed and adjusts the PWM signal generator. • Generates the assertions for the PWM signal generator according to commutation logic input.
DC-to-3-phase inverter	Switching network that transmits power to the motor stator windings according to a control signal.
eMIOS	• Generates PWM input for DC to 3-phase inverter. • Measures digital feedback inputs—BLDC position sensors, for example.
LCU	Implements commutation lookup table. Control Process compares values from the angular position sensors to entries in the lookup table. It then applies voltage to stator winding corresponding to same set of values in lookup table.
TRGMUX	• Enables interconnect to the required set of on-chip peripherals. • Indirectly triggers ADC sampling via BCTU. • Triggers eMIOS to measure digital feedback signals.

56.5.1.2 Sensored BLDC motor control use case

56.5.1.2.1 Generic sensored BLDC motor control

The following figure and table illustrate a generic sensored BLDC motor control system. The feedback loops in the system create a motor control loop.

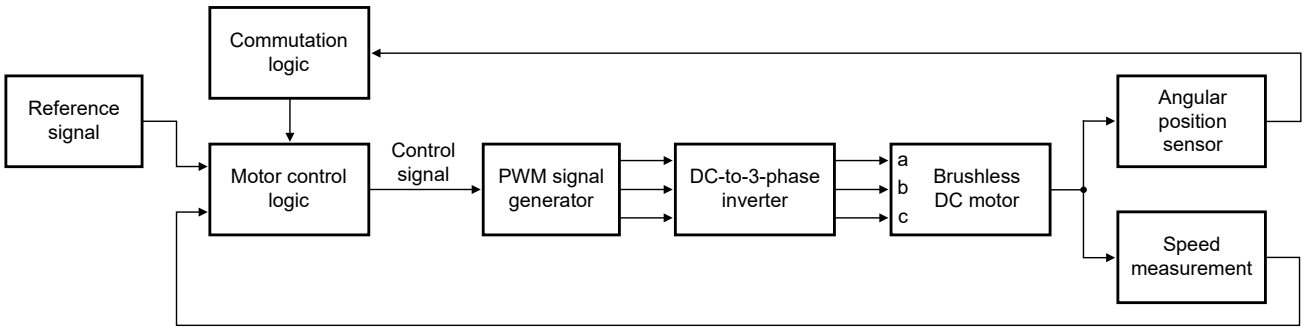

Figure 214. Generic sensored BLDC motor control

Table 260. Block diagram components

Block	Description
Angular position sensor	Hall effect sensors or optical decoders detect rotor position
Commutation logic	Compares values from the angular position sensors to entries in a lookup table and applies voltage to stator winding corresponding to same set of values in lookup table
Reference signal	Signal that indicates required motor speed

Table continues on the next page...

Table 260. Block diagram components (continued)

Block	Description
DC-to-3-phase inverter	Switching network that transmits power to the stator windings according to a control signal
Motor control logic	• Compares speed measurement to required speed and adjusts the PWM signal generator • Generates the assertions for the PWM signal generator according to commutation logic input
Speed measurement	Uses an ADC linked to a shunt resistor to perform measurements and detect over-current conditions, in which case hardware generates an interrupt.

56.5.1.2.2 PCMC sensored field-oriented control (FOC) of 3-phase BLDC motor

FOC is a VFD control method in which the stator currents of a 3-phase AC electric motor (such as BLDC, PMCM, reluctance motor, or other spinning electrical machine) is identified as a vector.

The PCMC subsystem consists of a group of modules that enable you to implement sensored FOC BLDC motor control loops in a variety of ways. The following figure and table show one possible implementation.

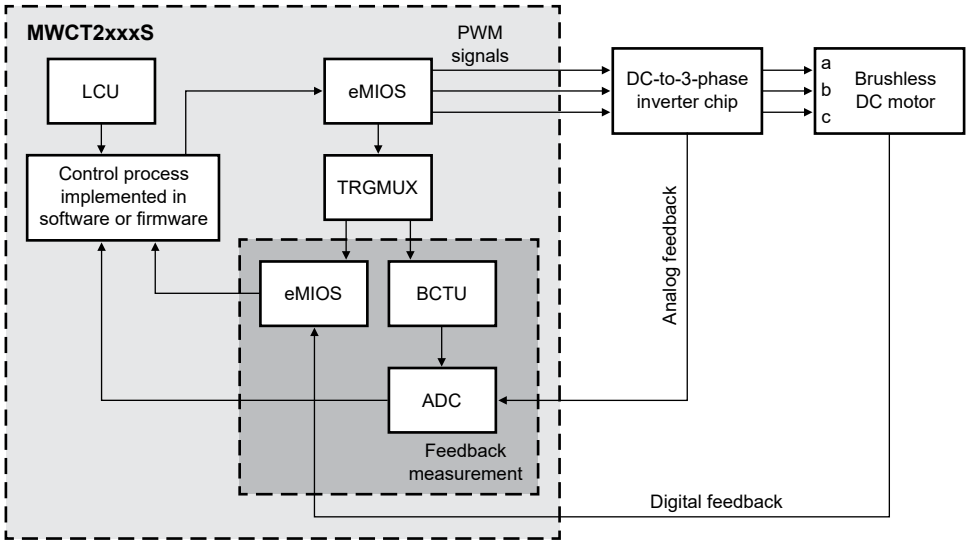

Figure 215. PCMC sensored BLDC motor control

Table 261. Block diagram components

Block	Description
ADC	Measures analog inputs (currents and/or voltages) and converts to digital values. Typically, it measures currents, and can be configured to generate a fault interrupt when a measured input is outside a pre-defined acceptable range.
BCTU	Triggers conversions by ADC.
Control process	Provides top-level system control functions for FOC control:

Table continues on the next page...

Table 261. Block diagram components (continued)

Block	Description
	• Compares speed measurement to required speed and adjusts the PWM signal generator. • Generates the assertions for the PWM signal generator according to commutation logic input.
DC-to-3-phase inverter	Switching network that transmits power to the motor stator windings according to a control signal.
eMIOS	• Generates PWM input for DC to 3-phase inverter. • Measures digital feedback inputs—BLDC position sensors, for example.
LCU	Implements commutation lookup table. Control process compares values from the angular position sensors to entries in the lookup table. It then applies voltage to stator winding corresponding to same set of values in lookup table.
TRGMUX	• Enables interconnect of the required set on on-chip peripherals. • Indirectly triggers ADC sampling via BCTU. • Triggers eMIOS to measure digital feedback signals.

56.6 Design considerations

56.6.1 ADC design considerations

The following topics discuss factors that affect ADC function in applications.

56.6.1.1 ADC measurement accuracy

The FOC motor control algorithm requires a high degree of confidence in the reliability of conversion data. Here are some best practices that contribute to ADC precision.

- Use precision channels (see ADC precision channels).
- Minimize input noise (see ADC input noise).
- Use BCTU triggering (see ADC triggering).

56.6.1.1.1 ADC precision channels

See the chip-specific ADC configuration information for the number of precision channels for each ADC instance.

See the channel mapping table for the channel numbers for the precision channels.

56.6.1.1.2 ADC input noise

Regardless of the application, ADCs are inherently sensitive to input noise. The following best practices help minimize input noise.

- Avoid simultaneous conversions.
- Consider using a low-pass filter on input pins.

All variants of this chip include multiple, independent ADC instances, so it is easily possible to have simultaneous sampling by different ADC instances. This should be avoided, though, because ADC sampling can cause noise on adjacent device ADC inputs. Avoidance of simultaneous sampling should be ensured by software design. This is important for implementations of the FOC algorithm.

Additionally, an RC low-pass filter on ADC input pins can help reduce noise and enhance accuracy.

56.6.1.1.3 ADC triggering

Some applications, including FOC motor control, must use BCTU for precise triggering of ADC measurement. This is because the FOC algorithm requires sampling at specific times to implement the “observer/predictor”. BCTU makes it possible to perform precisely-timed ADC measurement.

For less exigent algorithms or non-closed-loop controlled motors, BCTU triggering and precision ADC channels are not necessarily required.

56.6.1.2 Example ADC configurations

Following are some ADC configurations that might be used for FOC motor control.

Table 262. Example ADC configurations

Description	Settings
Single-shot mode	• Enable Overwrite (OWREN=1) • Disable Write Left-Aligned (WLSIDE=0) • Select single shot (MODE=0) • Disable External Trigger (TRGEN=0) • Disable Injection Trigger (JTRGEN=0) • Disable BCTU triggering (BCTUEN=0) • Disable averaging (AVGEN=0) • Select conversion clock = 1/2 module clock (ADCCLKSEL=01)
Normal conversion scan mode	• Enable Overwrite (OWREN=1) • Disable Write Left-Aligned (WLSIDE=0) • Select looped conversions (MODE=1) • Disable External Trigger (TRGEN=0) • Disable Injection Trigger (JTRGEN=0) • Disable BCTU triggering (BCTUEN=0) • Disable averaging (AVGEN=0) • Select conversion clock = 1/2 module clock (ADCCLKSEL=01)
BCTU control mode	• Enable Overwrite (OWREN=1) • Disable Write Left-Aligned (WLSIDE=0) • Select single shot (MODE=0) • Disable External Trigger (TRGEN=0) • Disable Injection Trigger (JTRGEN=0) • Enable BCTU triggering (BCTUEN=1) • Disable averaging (AVGEN=0) • Select conversion clock = 1/2 module clock (ADCCLKSEL=01)

Table continues on the next page...

Table 262. Example ADC configurations (continued)

Description	Settings
BCTU trigger mode	• Enable Overwrite (OWREN=1) • Disable Write Left-Aligned (WLSIDE=0) • Select single shot (MODE=0) • Disable External Trigger (TRGEN=0) • Disable Injection Trigger (JTRGEN=0) • Enable BCTU triggering (BCTUEN=1) • Enable all trigger sources (BCTU_MODE=1) • Disable averaging (AVGEN=0) • Select conversion clock = 1/2 module clock (ADCCLKSEL=01)

56.6.2 BCTU design considerations

For reasons discussed in ADC triggering, some applications require precise ADC triggering and BCTU provides that capability. The following topics discuss some design considerations when using BCTU.

56.6.2.1 BCTU or ADC data retrieval

Although the primary function of BCTU is to provide precisely timed triggers for ADC conversions, there is some overlap in BCTU and ADC function in that conversion data can be retrieved from either module. For applications in which frequent conversions are performed, such as real-time motor control, BCTU offers a distinct advantage over ADC, because BCTU trigger sources can be configured to route conversion results to a BCTU internal FIFO. Doing so prevents subsequent conversion data from overwriting previous data, making it available for either direct access or DMA transfer to system RAM.

56.6.2.2 Disabling BCTU triggers

There are fault scenarios in which an application must disable BCTU triggers as part of putting the system into a safe state. Examples include:

- Over-voltage condition
- Under-voltage condition
- Calibration parameter mismatch between the embedded motor control system and the motor

Application fault reaction design must include the disabling of BCTU triggers in scenarios in which either system conditions indicate an impending failure, or ADC conversion data is outside control boundaries.

56.6.3 eMIOS design considerations

In a BLDC motor control application, eMIOS plays a central role, providing the driving PWM signal as well as performing feedback signal measurements. The following topics discuss eMIOS considerations in the application design.

56.6.3.1 PWM considerations

In a BLDC motor control application, PWM/power signal requirements are affected by a number of parameters, including:

- Displacement Power Factor
- DF
- THD
- DVA

- CF
- FF

Ensure that the above parameters are included when choosing the timebase and prescaler combination for eMIOS channels producing PWM signals.

56.6.3.2 Input measurement

In a BLDC motor control application, eMIOS measures feedback signals for the motor and provides critical information to the control system. Selecting a timebase and prescaler for eMIOS channels performing input measurement tasks is usually a tradeoff between application requirements for precision and the computational cost in relation to the selected clock speed.

For example, some applications like electric steering demand an extremely precise control for position and torque. This is different from a compressor e-motor, where speed and torque do not demand rigid precision requirements.

Other considerations are related to control of:

- THD
- FF
- GM
- pf correction

The above considerations are significant from the perspective of the PWM reaction speed for the output signal for BLDC applications. These parameters must be considered in the design.

56.6.3.3 eMIOS channel modes useful in motor control

Table 263. eMIOS channel modes useful in motor control

Mode	Description	Use in motor control
MCB	Modulus Counter Buffered (Up/Down)	Time base • PWM frequency • Reload
IPWM	Input Pulse Width Measurement	Capture modes: • Speed measurement • Position measurement • Voltage (duty cycle)
IPM	Input Period Measurement	Speed measurement
PEC	Pulse Edge Counting	Position measurement
OPWMCB	Center aligned Output PWM Buffered with dead time	PWM duty cycle
OPWMB	Output Pulse Width Modulation Buffered	Trigger placement within the period
OPWMT	Output Pulse Width Modulation Trigger	Trigger placement within the period

56.6.3.3.1 MCB PWM and trigger generation

The following figure shows one option for PWM and trigger generation.

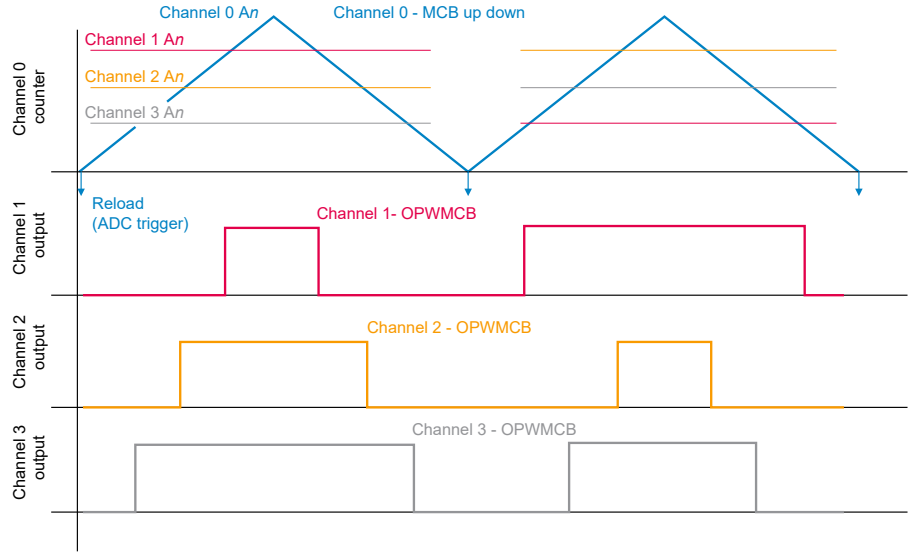

Figure 216. MCB PWM trigger generation

56.6.3.3.2 OPWMCB PWM and trigger generation

The following figure shows another option for PWM and trigger generation.

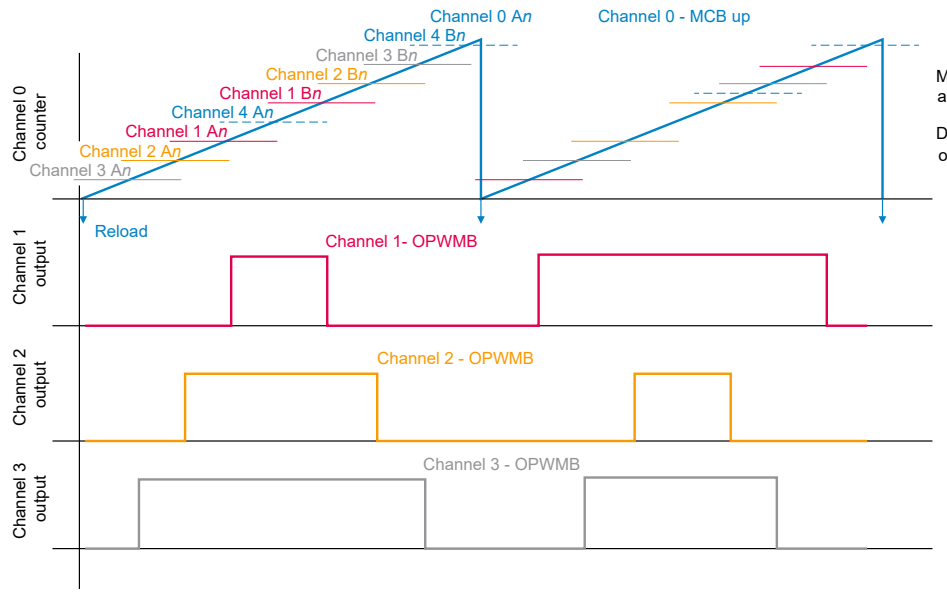

Figure 217. OPWMCB PWM trigger generation

56.7 Glossary

BLDC	Brushless DC. An electronically commutated DC motor.
CF	Crest Factor. A waveform parameter that is the ratio of peak values to its RMS value.
DF	Distortion Factor.

Displacement Power Factor	In power electronics, the phase relationship between voltage and current: $\cos(\theta_v - \theta_i)$, where θ_v is the phase of the voltage and θ_i is the phase of the current.
DVA	Distortion Volt-Amps.
FF	Form Factor.
FOC	Field-Oriented Control.
GM	Gain Margin.
pf	Power factor. In power electronics, it is the ratio of average power to RMS power.
PMSM	Permanent Magnet Synchronous Motor.
THD	Total Harmonic Distortion.
VFD	Variable-Frequency Drive.

Chapter 57
Analog-to-Digital Converter (ADC)

57.1 Chip-specific ADC information

57.1.1 ADC Configuration

This chip has up to 3 instances of ADC. ADC channels are divided into 3 groups - Precision, Standard and External (each with independent configuration settings and different accuracy/performance level). The following table shows the ADC configuration:

Table 264. ADC instances

Instance	MWCT2D17S	MWCT2D16S/MWCT2016S/MWCT2015S
ADC_0	Yes	Yes
ADC_1	Yes	Yes
ADC_2	Yes	No

Table 265. ADC configuration

Feature	ADC_0	ADC_1	ADC_2
No. of precision channels	8	8	8
No. of standard channels	16	16	16
No. of special internal channels	1[1]	0	0
No. of external channels	32	32	0
BCTU trigger support	Yes	Yes	Yes
DMA support	Yes	Yes	Yes
Hardware interleaving	Yes	Yes	Yes
No. of watchdogs	4	4	4
No. of Hardware trigger	3	3	3

1. CHAN_INT0 - channel 50(S)

Table 266. ADC maximum clock frequency

Feature	MWCT2D17S/ MWCT2D16S	MWCT2016S	MWCT2015S
ADC module clock frequency (f_mc)	160/120 MHz	120 MHz	120 MHz

NOTE

For register configurations need for different frequencies, see 'Functional description' section in this chapter.

1. Channels marked with “-“ means they are reserved and access to any reserved channel may result in inappropriate data.

NOTE

The decoding signals for the selection of external ADC channels (ADC_X) are gray-encoded.

NOTE

Value of ANAMUX_OUT is selected by DCMRWF1[SUPPLY_MON_SEL] field.

NOTE

The module clock mentioned in this chapter is CORE_CLK for this chip.

57.1.2 ANAMUX for internal supply monitoring

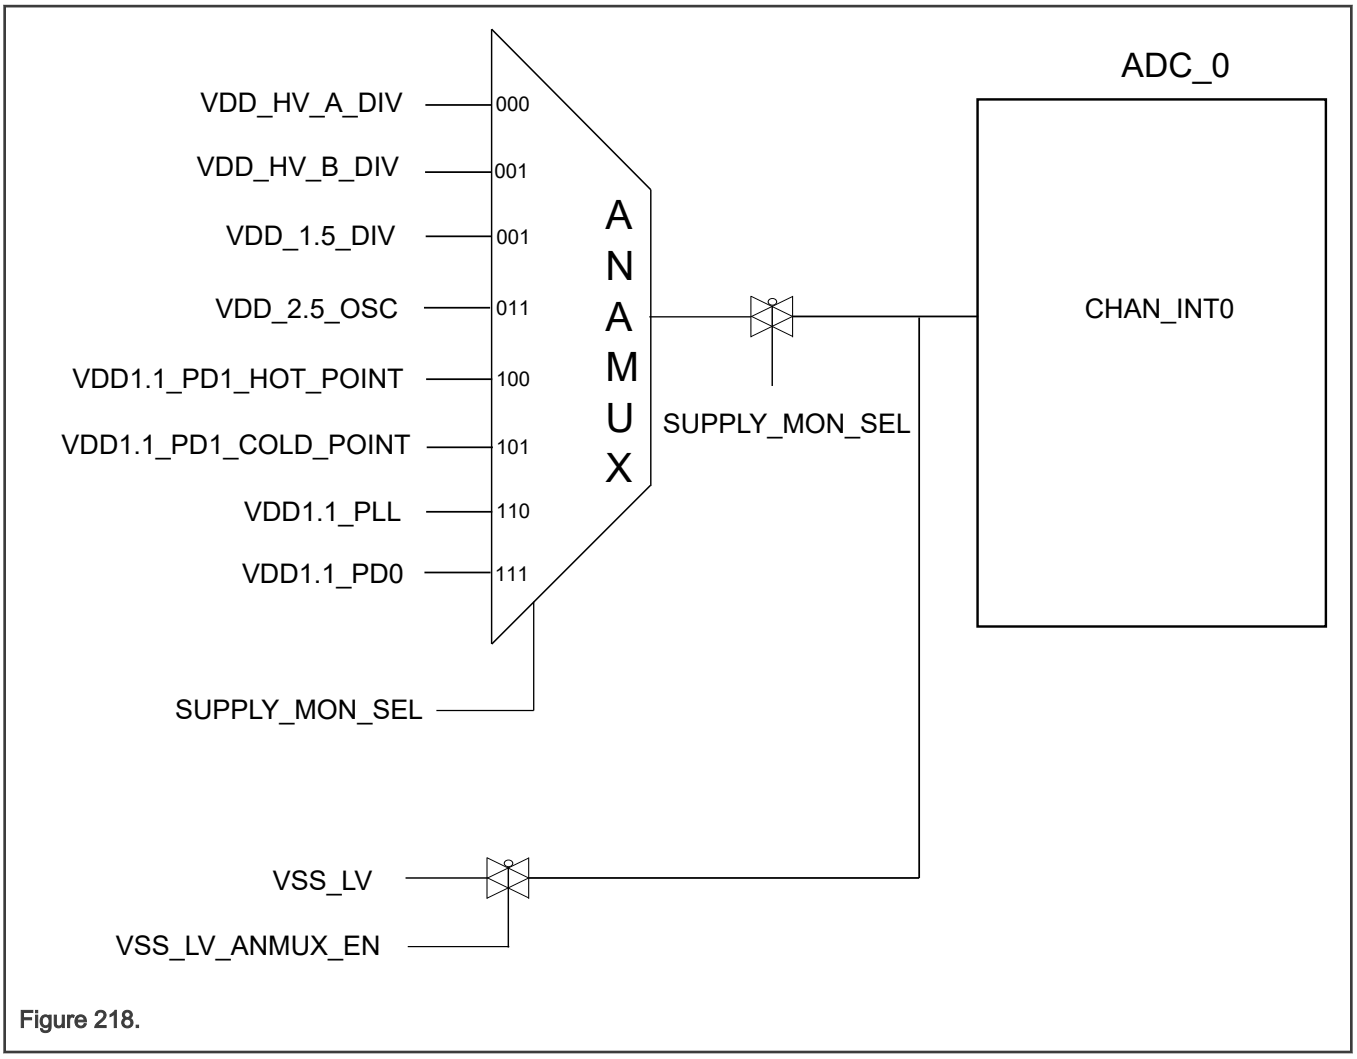

Figure 218.

NOTE

VDD_HV_B_DIV, VDD_1.5_DIV are not available in MWCT2016S and MWCT2015S.

57.1.3 BCTU Interface

All 3 instances of ADC are triggered from the BCTU. The BCTU provides channel conversion commands to the ADC (includes channel number information). In addition, the ADC provides the conversion result back to the BCTU.

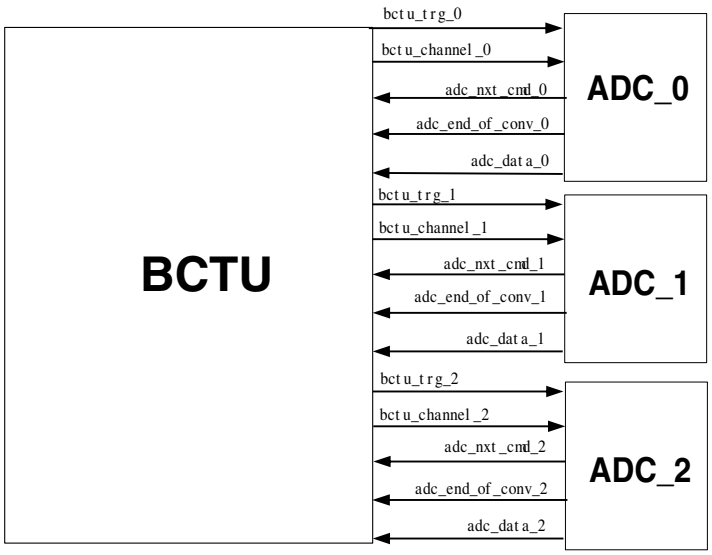

Figure 219. ADC Cross-triggering Unit

BCTU gives trigger pulse to all the 72 channels of ADC to initiate a conversion based on BCTU channel number.

BCTU-ADC result register

ADC result registers (ADCx_PCDRn[CDATA], ADCx_ICDRn[CDATA] and ADCx_ECDRn[CDATA]) store 15 bit conversion data. The BCTU ADC registers store 15-bit conversion data (BCTU_ADC0DR[ADC0_DATA], BCTU_ADC1DR[ADC1_DATA] and BCTU_ADC2DR[ADC2_DATA]).

57.1.4 DMA interface

Each ADC supports a single DMA request that can be requested after the conversion of every channel. The conversion result is stored into a register DMAR and is transferred via DMA or host access.

NOTE

The last ongoing conversion will be aborted as soon as ADC gets STOP request from the software and it will move to STOP mode.

57.1.5 Hardware triggers

In this chip, hardware trigger signals can be provided from TRGMUX outputs. This feature enables synchronous conversion of two independent ADC instances in parallel. If ADC is in Idle state (that is, no conversion phase ongoing and the MCR[PWDN] and MCR[ACKO] fields are 0) and the MCR[XSTRTEN] is set, an event on the external start signal causes ADC to start either normal or injected conversion operation. The MCR[NSTART]/MCR[JSTART] field is automatically set respectively. The normal conversion sync pulse is used with normal conversion trigger to synchronize the start timing of normal conversion between multiple ADC instances.

Table 268. Hardware triggers

TRGMUX output number	Hardware trigger functions
0	ADC_0 Normal Conversion
1	ADC_0 Injected Conversion
2	ADC_0 Normal Conversion Sync Pulse

Table continues on the next page...

Table 268. Hardware triggers (continued)

TRGMUX output number	Hardware trigger functions

57.1.6 ADC Self-Test

It is important to check at regular intervals if the ADC is operating correctly. For this purpose a self test feature is provided. When self-test is enabled, the ADC automatically checks its components and flags errors.

57.1.7 ADC mux-mode channels

There are some channels in ADC which are driven by multiple pads. For this, GPR bits from DCM are used to define which pad is connected to a particular ADC channel.

For example as below, where ADC0 S8 is driven by GPIO_PAD0 (default) and GPIO_PAD45 (mux_mode). ADC2 S8 is driven by GPIO_PAD133 (default) and GPIO_PAD45 (mux_mode). ADC1 S8 has a dedicated pad GPIO45, so its TGATE doesn't need GPR bit gating. Similar implementation is for ADC0_S9 and ADC2_S9. Following DCM GPR bits have been used:

Table 269. ADC mux_mode GPR

ADC channel	GPR_bit	Connected pad
ADC0 Standard channel 8 (ADC0 S8)	DCM.DCMRWF4[1]	0: GPIO PAD0 (default) 1: GPIO PAD45
ADC0 Standard channel 9 (ADC0 S9)	DCM.DCMRWF4[2]	0: GPIO PAD1 (default) 1: GPIO PAD46
ADC 1 standard channel 14 (ADC1 S14)	DCM.DCMRWF4[3]	0: GPIO PAD69 (default) 1: GPIO PAD32
ADC 1 standard channel 15 (ADC1 S15)	DCM.DCMRWF4[4]	0: GPIO PAD4 (default) 1: GPIO PAD33
ADC1 Standard channel 22 (ADC1 S22)	DCM.DCMRWF4[5]	0: GPIO PAD124 (default) 1: GPIO PAD145
ADC1 Standard channel 23 (ADC1 S23)	DCM.DCMRWF4[6]	0: GPIO PAD125 (default) 1: GPIO PAD146
ADC2 Standard channel 8 (ADC2 S8)	DCM.DCMRWF4[9]	0: GPIO PAD133 (default) 1: GPIO PAD45
ADC2 Standard channel 9 (ADC2 S9)	DCM.DCMRWF4[10]	0: GPIO PAD132 (default) 1: GPIO PAD46

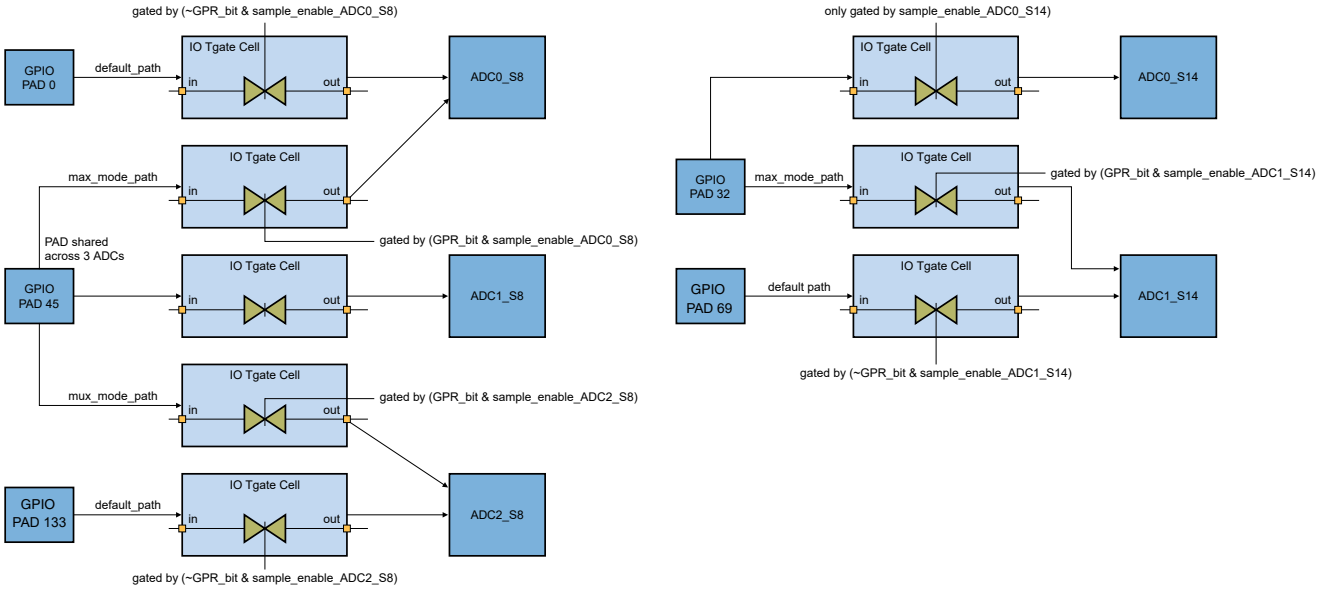

Figure 220. ADC channel interleaving

57.2 Introduction

ADC produces a digital value from an input analog voltage using the SAR algorithm. It features various methods to trigger a conversion and offers flexibility in the selection of input channels. ADC is useful for a wide range of applications.

A configurable self-test capability supports use cases with increased requirements for functional safety.

57.2.1 Features

- Selectable resolution (8-, 10-, 12-, 14-bit). Note that the conversion result is always 15 bits wide, even though the selected resolution is smaller (see CALBISTREG[RESN])
- Conversion data captured in a separate register for each input channel.
- Option to improve accuracy via averaging, which calculates conversion data by averaging the data of up to 32 conversions.
- Conversion triggers:
  - Normal conversion trigger converts a number of input channels, either once per trigger or continuously.
  - Injected conversion trigger interrupts an ongoing normal conversion and converts another set of input channels.
  - BCTU conversion trigger interrupts an ongoing conversion and converts an input channel, in which the input is selected and the conversion is started via the BCTU.
- An analog watchdog optionally monitors conversion data for each input channel and issues an interrupt if the converted data is below or above configurable limits.
- DMA functionality transfers conversion data to other modules.
- Programmable interrupts optionally issue an interrupt when conversion of one or of a set of input channels is finished.
- Self-test functions validate ADC structural integrity during functional operation and generate events with different severities on any finding.
- Conversion clock (AD_clk) control enables the use of ADC in systems with a higher clock frequency by using internal clock dividers.
- Auto turn-off of the conversion clock when ADC is idle.

57.2.2 Block diagram

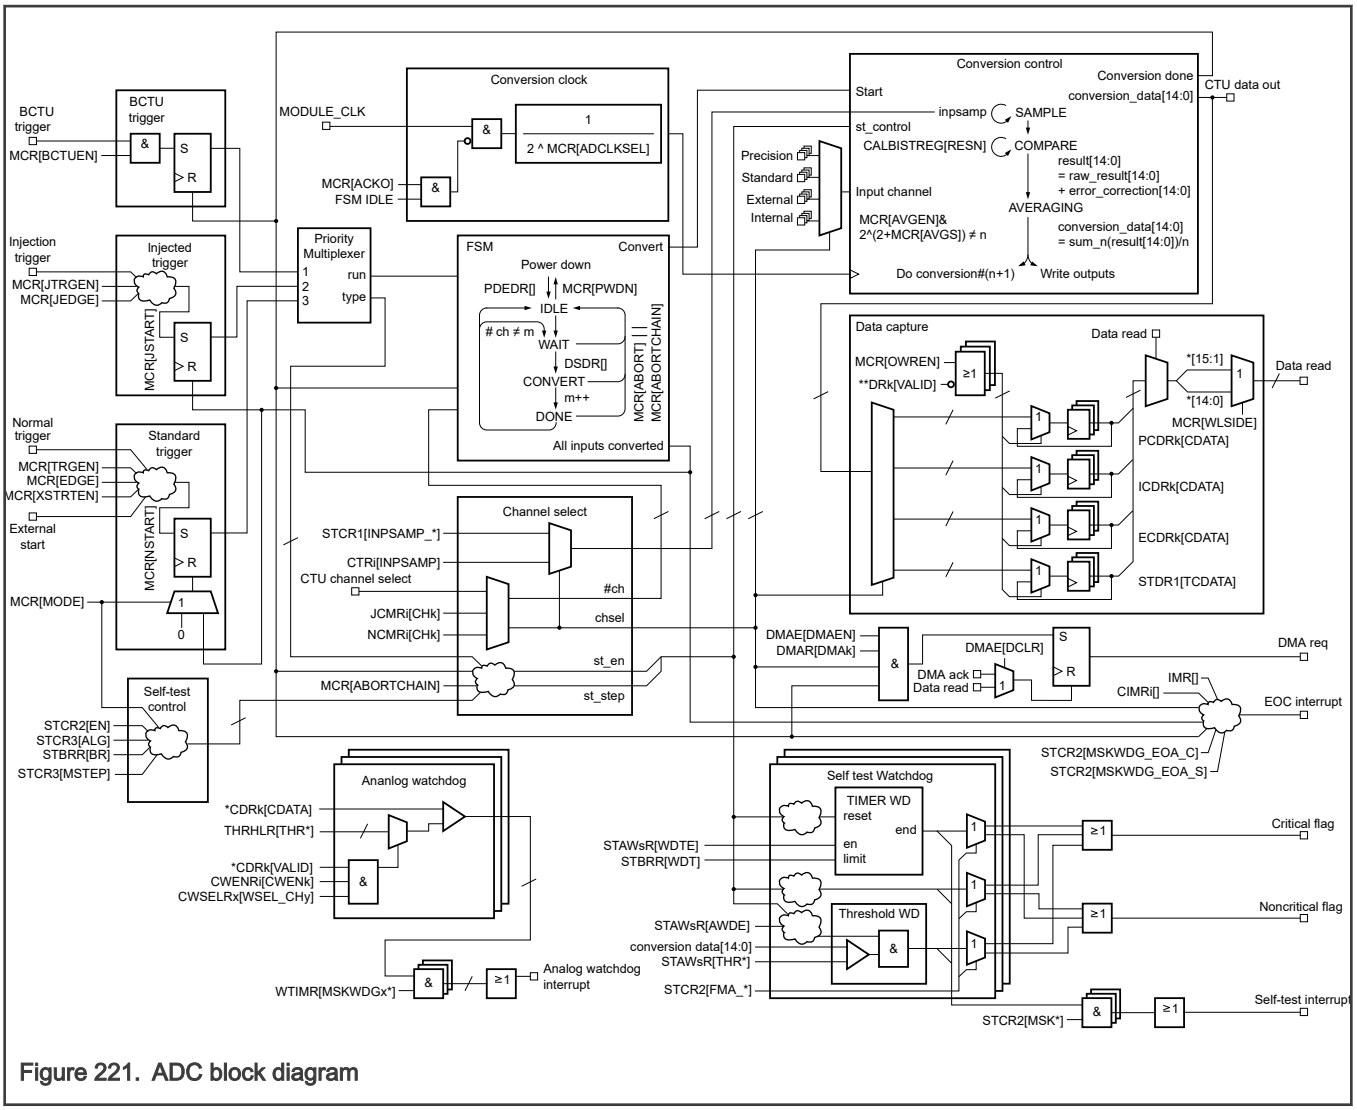

Figure 221. ADC block diagram

Guide to the diagram:

- The signal flow through the diagram is from left to right: inputs to blocks are on the left side, outputs are on the right.
- Block names have the first letters in uppercase and the other letters in lowercase—"Conversion Control," for example).
- Register names are in uppercase followed by a field name in brackets ("MCR[NSTART]," for example). Letters in lowercase are indexes. Asterisks are placeholders for letters (wildcards). Register names in the block diagram map to the names in ADC register descriptions.
- Signal names are in lowercase ("conversion done," for example).
- All digital signals shown are synchronous signals. Asynchronous inputs to the ADC are internally synchronized (synchronizers not shown).

The block diagram shows the signal flow through ADC from the left to the right and from the top to the bottom:

1. When ADC receives one of the three different types of triggers (BCTU, injected, or normal), the priority multiplexer initiates the conversion.
2. The input to be converted is selected in the Channel Select subblock, based on the type of trigger and on the self-test configuration.

3. The state machine (FSM) transitions from Idle state to Convert state. In case the channel to convert changed since the last conversion and this new channel is an external channel, the conversion starts after a delay configured by DSDR[DSD].
4. After a conversion begins, the Conversion Control block holds the internal capacitance network CDAC in the sample phase for a time defined by CTRi[INPSAMP].
5. During the compare phase, CALBISTREG[RESN] defines the number of steps used to execute the successive approximation algorithm. The error_correction values, determined during calibration, are added to the raw result. If averaging is enabled (MCR[AVGEN] = 1), up to 32 (specified via MCR[AVGS]) conversion results are averaged to obtain the result.
6. When the conversion completes and all averaging steps have completed:
    a. The conversion done signal indicates completion.
    b. Conversion_data[14:0] is written to the result registers in the Data Capture subblock.
    c. The FSM transitions into Done state.
7. The next input in the Channel Select block is selected and the next conversion is started by the transition of the FSM to Convert state. This continues until all selected inputs have been converted.
8. If an analog watchdog is enabled, the conversion result is compared to the configured threshold. If the limits are exceeded, an interrupt can be triggered.
9. Self-test can check the integrity of ADC, either interleaved with normal conversions or as a standalone check.
10. If an ongoing conversion is aborted (by writing 1 to MCR[ABORT]) or an ongoing conversion of a set of input channels is aborted (by writing 1 to MCR[ABORTCHAIN]), the FSM transitions into Idle state. The Conversion Control block stops the current conversion if MCR[ABORT] was written with 1, or finishes the current conversion if MCR[ABORTCHAIN] was written with 1. In both cases, the conversion done output signal of the Conversion Control block is set to 1.

Some details are not shown in the block diagram:

- Calibration must be performed to determine the error_correction values (see Calibration) before ADC can do meaningful conversions.
- An input can presample the internal low or high reference voltages to avoid a memory effect that may be present in the comparison due to a previous conversion (see Presampling).
- Monitor ADC status via status flags.
    - See Main Status (MSR) for the FSM state.
    - See Interrupt Status (ISR) to monitor interrupts.
    - See Channel End Of Conversion Flag For Precision Inputs (CEOCFR0) for conversion phase per input.
    - See the following registers to monitor analog watchdogs:
        - Analog Watchdog Out Of Range For Precision Inputs (AWORR0)
        - Analog Watchdog Out Of Range For Standard Inputs (AWORR1)
        - Analog Watchdog Out Of Range For External Inputs (AWORR2)

      See Analog Watchdog Threshold Interrupt Status (WTISR) to monitor analog watchdog interrupts.
    - See Self-Test Status 1 (STSR1) – Self-Test Status 4 (STSR4) to monitor self-test.

57.2.3 Modes of operation

ADC is always in Functional mode. No other mode selection exists.

- Put ADC into Power Down state by writing 1 to MCR[PWDN] to reduce power consumption.
- Gate the clock signal by writing 1 to MCR[ACKO] when ADC is in Idle state.

57.3 Functional description

57.3.1 Clock

ADC is controlled by one clock signal, the module clock. Internally, the conversion circuit is controlled by the conversion clock, which is derived from the module clock.

The frequency of the conversion clock has to be within the limits defined in the data sheet. If the module clock frequency is higher than the maximum frequency of the conversion clock allowed during the functional conversion or during the calibration (see the chip data sheet), then you must configure the ADC conversion clock divider (MCR[ADCLKSEL]) so that the frequency of the conversion clock is within allowed limits. For some conversion clock frequencies, you must write 3d to AMSIO[HSEN]. See Table 270.

Table 270. Clock configuration for highest conversion speeds

Module Clock Frequency f_mc[1]	Configuration during calibration	Configuration during functional conversion
40 MHz < f_mc ≤ 80 MHz	MCR[ADCLKSEL] = 1h AMSIO[HSEN] = 0h	MCR[ADCLKSEL] = 0h AMSIO[HSEN] = 0h
80 MHz < f_mc ≤ 120 MHz	MCR[ADCLKSEL] = 1h AMSIO[HSEN] = 3h	MCR[ADCLKSEL] = 0h AMSIO[HSEN] = 3h
120 MHz < f_mc ≤ 160 MHz	MCR[ADCLKSEL] = 2h AMSIO[HSEN] = 0h	MCR[ADCLKSEL] = 1h AMSIO[HSEN] = 0h
160 MHz < f_mc ≤ 240 MHz	MCR[ADCLKSEL] = 2h AMSIO[HSEN] = 3h	MCR[ADCLKSEL] = 1h AMSIO[HSEN] = 3h
240 MHz < f_mc ≤ 320 MHz	MCR[ADCLKSEL] = 3h AMSIO[HSEN] = 0h	MCR[ADCLKSEL] = 2h AMSIO[17] = 0h
320 MHz < f_mc ≤ 480 MHz	MCR[ADCLKSEL] = 3h AMSIO[HSEN] = 3h	MCR[ADCLKSEL] = 2h AMSIO[HSEN] = 3h

1. Lower resulting frequencies are allowed—see the chip data sheet.

When ADC is not converting (state machine is in Idle state), the conversion clock can be turned off (MCR[ACKO]).

57.3.2 Conversion

ADC measures the voltage of a signal—it converts an analog input value into a digital representation. When you read the conversion result, you must divide this conversion result by the number of codes (defined by selected conversion resolution in CALBISTREG[RESN]), and multiply it with the reference voltage value. This calculation provides the voltage value of the converted signal.

To convert an analog input voltage into its digital representation, ADC:

1. Receives a signal, referred to as a trigger, indicating it is to perform a conversion.
2. Captures the voltage of a signal via internal capacitances in a process referred to as sampling.
3. Compares the voltage to the reference voltage, using the SAR algorithm.

Before a conversion can be performed, you must select:

- The trigger source(s) to use (on the chip level)

- The input channel(s) to convert (NCMR0–2, JCMR0–2)

Additionally, you can tailor the conversion to meet your needs by changing the default configuration. For example, you can:

- Configure ADC to convert the selected input channel(s) only once or continuously in a loop (MCR[MODE]).
- Specify the duration that ADC samples the input signal (CTR0/1/2).
- Specify the resolution of the conversion result by selecting the number of bits (CALBISTREG[RESN]).
- Enable an analog watchdog to generate an interrupt when a conversion result falls outside a specified range (see Analog watchdog functions).
- Enable the DMA interface to send requests and receive acknowledgments (see DMA functionality).
- Check the operational integrity of ADC by running a self-test (see Self-test).

After power-up or a functional reset, ADC remains in Power Down state until enabled by writing 0 to MCR[PWDN]. After the system is powered on, you must run the calibration (see Calibration), before you can do a meaningful conversion with ADC.

Some configuration fields (listed below) are writeable only in Power Down state. If you intend to write to them, you must do so before exiting Power Down state.

- Select the conversion clock frequency to be within the allowed limits for a conversion.

57.3.3 Normal trigger

Select the input channels to convert by configuring the fields in NCMR0, NCMR1, and NCMR2.

These registers must be programmed before the start of conversion. You cannot reconfigure them until the conversion of all selected channels is complete. The sequence is always to convert the selected input channels in this order:

1. Start from the lowest input channel of the precision input channels.
2. Proceed through the standard input channels in ascending order.
3. End with the highest input channel of the external input channels.

57.3.3.1 Starting conversions in normal conversion mode

After programming the required fields of the following registers, you can start a conversion by writing 1 to MCR[NSTART]:

- Normal Conversion Enable For Precision Inputs (NCMR0)
- Normal Conversion Enable For Standard Inputs (NCMR1)
- Normal Conversion Enable For External Inputs (NCMR2)
- Main Configuration (MCR)

A hardware trigger can also start a normal conversion.

- If the external trigger is enabled (MCR[TRGEN] = 1), an external trigger enable is detected to start the conversion. The enable is checked only during start of conversion.
- Detection of an active edge defined by MCR[EDGE] (rising = 1, falling = 0) on an external trigger transitions MCR[NSTART] to 1 and starts the normal conversion.
- When MCR[TRGEN] = 1 (for example, when external trigger is enabled), conversion can be started by software.
- Any external trigger or software initiated conversion in normal conversion mode is ignored during any ongoing conversion chain.

NOTE

To have reliable operation there must be a gap of 3 clock cycles between configuration of NCMRx and the start of a conversion (by writing 1 to MCR[NSTART], or arrival of an external or internal hardware start trigger). ADC calculates the number of channels to be converted during this period.

57.3.3.2 Operation modes in normal conversions

Two operational modes are available during normal conversion:

- One-Shot mode
- Scan mode

For normal conversion, select the mode via MCR[MODE]. The first phase of the conversion process involves sampling the analog channel. The next phase is the conversion phase, curing which the sampled analog value is converted to digital as shown in the following figure.

Figure 222. Normal conversion flow

In One-Shot mode (MCR[MODE] = 0), a sequential conversion specified in the NCMR*n* mask registers is performed only once. At the end of each conversion, the digital result of the conversion is stored in the corresponding data register (CDR*n*).

For example: Channels A→B→C→D→E→F→G→H are present in a device where channels B→D→E are to be converted in One-Shot mode. Conversion begins with channel B, followed by conversion of channels D and E. At the end of conversion of channel E, the scanning of channels stops.

MSR[NSTART] automatically transitions to 1 when a normal conversion starts. At the same time, MCR[NSTART] is reset to zero by hardware, enabling software to program a new start of conversion in advance. In this case, the new requested conversion starts after completion of the running/current conversion. However, for correct functioning of the device, you should program MCR[NSTART] for the new conversion only after completion of the current conversion. The application can wait for an ECH interrupt prior to writing 1 to MCR[NSTART] again.

If an external trigger starts the conversion chain, ADC does not observe the trigger input until the conversion chain is finished. After the chain is finished, the next chain can be triggered by another hardware trigger edge.

In Scan mode operation (MCR[MODE]=1), a sequential conversion of N channels specified in the NCMR*n* registers is continuously performed. At the end of each conversion, the result is stored in the corresponding data register, as in One-Shot mode.

MSR[NSTART] automatically transitions to 1 when a normal conversion starts. Unlike One-Shot mode, MCR[NSTART] is not reset to 0 in Scan mode. It can be reset by software when you must exit Scan mode. In that case, ADC completes the current chain and after the last conversion, it resets MCR[NSTART] to 0.

For example: Channels A→B→C→D→E→F→G→H are present in the device where channels B→D→E are to be converted in Scan mode. MCR[MODE] = 1 selects Scan mode operation. Conversion starts from channel B followed by conversion of channels D→E. After conversion of channel E, the scanning of channel B starts followed by conversion of the channels D→E. This sequence repeats itself until MCR[NSTART] is reset to 0 by software.

If an external trigger starts a conversion, then MCR[NSTART] does not transition to 1. This scan chain can be stopped by writing 0 to MCR[NSTART]. The conversion stops when the ongoing chain is finished. Consequently, after it starts, the only way to stop Scan mode conversion is to write 0 to MCR[MODE].

End of conversion

In both modes, at the end of each conversion, an End of Conversion (EOC) interrupt is issued if enabled by the corresponding mask fields in CIMR*n* and IMR).

After conversion of all selected channels in NCMR*n* is complete, the conversion operation is considered finished. Then ISR[ECH] transitions to 1 and the End of Chain (ECH) interrupt is issued (if enabled in IMR[MSKECH]).

The corresponding channel field in the CEOCFR*n* register(s) is updated to indicate that data is available on data register CDR*n* of the respective channel.

If there is no channel selected in NCMR*n* and there is a start-of-conversion trigger, then ISR[ECH] is set to 1 and the End of Chain (ECH) interrupt is immediately issued (if enabled).

57.3.4 Injected trigger

An injected trigger enables you to convert a set of input channels although the standard trigger has already started conversion of another set of input channels. Each channel can be individually enabled by writing 1 to the corresponding field in JCMR0, JCMR1, or JCMR2.

The set of input channels of the injected trigger is converted only once. A continuous conversion of a set of input channels in a loop is only possible when started by a standard trigger. When an injected trigger is received, an ongoing conversion started by a standard trigger is interrupted. After the set of input channels of the injected trigger is converted once, the interrupted conversion of the set of input channels of the standard trigger resumes from the input channel that was interrupted, as shown in the following figure.

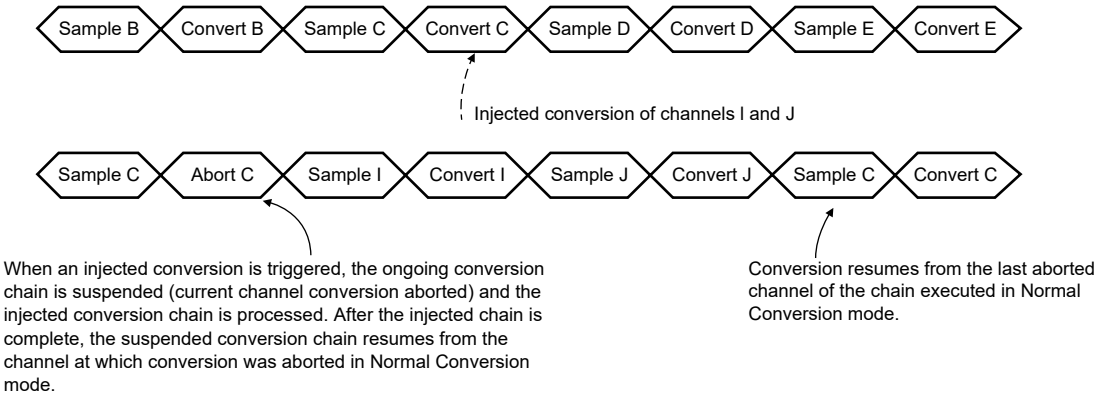

Figure 223. Injected trigger conversion sequence

57.3.4.1 Starting conversions in injected conversion mode

An injected conversion chain can be started:

- By software: When external triggering is disabled (MCR[JTRGEN] = 0), you can write 1 to MCR[JSTART], which causes the current conversion chain processed in Normal Conversion mode to be suspended and the injected chain to be processed.
- By external trigger: When external triggering is enabled (MCR[JTRGEN] = 1), a programmed event (rising/falling edge depending on the value of MCR[JEDGE]) on the injection external input starts the injected conversion.

MCR[JSTART] automatically transitions to 1 when the injected conversion chain starts. At the same time MCR[JSTART] is reset to 0, enabling software to program a new start of conversion in advance. In that case the new requested conversion starts after the running conversion completes.

At the end of each conversion, an End Of Injected Conversion (JEOC) interrupt is issued, if enabled by the corresponding mask field in Interrupt Mask (IMR). At the end of a chain, an End Of Injected Chain (JECH) interrupt is issued, if enabled by the corresponding mask field. Additionally, ADC writes 1 to ISR[JECH].

NOTE

If the content of all the Injected Conversion mask registers (JCMR*n*) is zero, that is, no channel is selected, the JECH interrupt is immediately issued after the start of conversion.

To have reliable ADC operation, there must be a gap of 3 cycles between configuration of JCMRx and starting of conversion (writing 1 to MCR[JSTART] or arrival of either an external or internal hardware start trigger). ADC calculates the total channel numbers to be converted during this period.

The corresponding channel bit in the CEOCFR*n* register is updated to indicate data is available in the channel's conversion data register, CDR*n*.

After starting, an injected chain conversion cannot be interrupted.

57.3.5 BCTU interface

The BCTU interface enhances ADC's injected conversion capability. It contains control inputs to select the channels to be converted from the appropriate event configuration register. Figure 224 shows the interface.

The BCTU generates a trigger (bctu_trigger) and a channel number (bctu_numchannel) to be converted. A single channel is converted for each request. After performing the conversion, ADC returns the result on the bctu_dataout bus together with two output signals named bctu_nextcmd and bctu_push. The assertion of signal bctu_nextcmd means ADC is ready to accept the next trigger from BCTU. The bctu_push signal is asserted at the end of conversion, meaning that conversion is finished and the conversion result available at output bctu_dataout is valid.

The conversion result is also saved in the corresponding channel's data register and is compared with analog watchdog thresholds if requested.

The signals bctu_trigger, bctu_nextcmd and bctu_push are all of type single-cycle active-high-pulse in the ADC clock domain. The channel number provided from BCTU must be valid when bctu trigger is active-high. The result data from ADC is valid with bctu_push high.

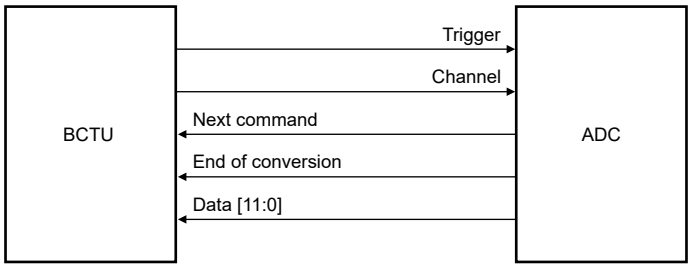

Figure 224. BCTU interface

The BCTU interface has two modes of operation:

- Trigger
- Control

To enable the BCTU interface, write 1 to MCR[BCTUEN]. The operating mode (Trigger or Control) can be fixed or programmable.

57.3.5.1 BCTU Trigger mode

In Trigger mode, normal and injected conversions can also be performed. All types of conversions can be initiated in this mode. The priorities among the three types of conversions are discussed below.

When a trigger is received, the channel number is taken as an injected channel value and the triggered injected conversion starts. MSR[BCTUSTART] transitions to 1 automatically at this point and it is also automatically reset to 0 when the triggered injected conversion is completed.

BCTU conversions must be requested only after successful ADC calibration. The application must prevent any BCTU trigger during calibration.

If a BCTU trigger is received during an ongoing injected conversion, the injected chain is aborted immediately and only the BCTU-triggered injected conversion proceeds. Additionally, MSR[JSTART] is reset to zero. The abort of an injected conversion is indicated by MSR[JABORT].

If a BCTU trigger is received during an ongoing normal conversion, the ongoing normal channel conversion is suspended and the BCTU-triggered injected conversion is processed. Normal conversion resumes from the suspended channel after completion of the BCTU-triggered conversion.

If a normal conversion is requested during BCTU conversion (MSR[BCTUSTART] = 1), the normal conversion starts after the BCTU conversion completes (MSR[BCTUSTART] is reset to zero).

Any injected conversion is discarded if requested during BCTU conversion and MCR[JSTART] is immediately reset to zero.

57.3.5.2 BCTU Control mode

In BCTU control mode (MCR[BCTU_MODE] = 0), only the BCTU can start a conversion. All other trigger sources are ignored.

Along with BCTU trigger, the information provided with signal bctu_numchannel is taken as the channel number for injected channel and BCTU triggered conversion starts. MSR[BCTUSTART] transitions to 1 automatically at the start of the conversion and it remains 1 unless BCTU is disabled by writing 0 to MCR[BCTUEN].

The conversion must be requested (generating bctu_trigger) when calibration has finished successfully. If a BCTU trigger is received during calibration execution, calibration is stopped immediately in order to satisfy the BCTU request. Calibration fails in this case.

57.3.6 Aborting a conversion

Two abort functions are provided:

- Abort of a single channel
- Abort of a chain

To abort an ongoing conversion, write 1 to MCR[ABORT]. The current conversion aborts and conversion of the next channel of the chain begins immediately.

Depending on the current state of a conversion, an Abort action may take 1 to 4 cycles of the bus clock. At the start of any conversion, and at the end of a particular conversion when internal state counters are changing, an abort action is delayed by a maximum of 3 cycles to put all states in a stable condition.

To ensure that the abort action completes, do not change MCR[ABORT] for the next 3 cycles.

Avoid writing 1 to MCR[ABORT] along with, and within 3 cycles of, writing 1 to MCR[NSTART] or MCR[JSTART].

During an abort:

- MCR[NSTART] and MCR[JSTART] remain 1, if not in the last channel of the chain.
- MCR[ABORT] is reset to 0 when the channel is aborted.
- The EOC interrupt corresponding to the aborted channel is not generated. This behavior applies to normal and injected conversions. If the last channel of a chain is aborted, the end of chain is reported by generating an ECH interrupt.

It is possible to abort the current chain of conversions by writing 1 to MCR[ABORTCHAIN]. In this case, the behavior of ADC depends on the value of MCR[MODE] (One-Shot/Scan operation modes). If Scan operation mode is disabled, MCR[NSTART] is automatically reset to 0 along with MCR[ABORTCHAIN]. Otherwise, in Scan Operation mode, a new chain is started. The EOC interrupt of the current aborted conversion is not generated but an ECH interrupt is generated to signal the end of the chain.

NOTE

For a single channel chain, an ECH interrupt is not generated for an abort or abort chain.

When an abort chain is requested while an injected chain is running over a suspended normal chain, both the injected and normal chains are aborted, and both MCR[NSTART] and MCR[JSTART] are reset to 0.

57.3.7 Configuring ADC clock divider and sample time settings

You can scale the AD_clk frequency via MCR[ADCLKSEL]. ADCLKSEL can only be written in Power Down state (MCR[PWDN] = 1). Depending on the frequency of the module clock, there might be different settings necessary for functional conversion and for calibration. See the chip data sheet for ADC electrical characteristics.

Three conversion timing registers are used (CTR*n*) to support different sampling times for the different types of channels. An exception exists for the temperature sensor channel, which always uses the Conversion Timing For Standard Inputs (CTR1) value. See the register description for details.

57.3.8 Presampling

The presampling feature enables precharge or discharge of the ADC internal sample capacitor node to a defined level before sampling of the selected analog input channel starts. This is useful for resetting information (history effect/offset) from the most recent conversion. During presampling, ADC samples the internally generated voltage. During the sampling phase, ADC samples analog input coming from pads.

Enable presampling on a per-channel basis by setting the corresponding fields in the PSR*n* registers to one.

After enabling presampling for a channel, the normal sequence of operation for the channel is:

1. Presampling
2. Sampling
3. Evaluation

You can bypass sampling of all channels by writing 1 to PSCR[PRECONV]. When sampling of a channel is bypassed, the sampled and stored internal voltage applied during the presampling phase is converted (Figure 225). See Conversion time for the timing equation for conversion.

Presampling does not apply for self-test channels.

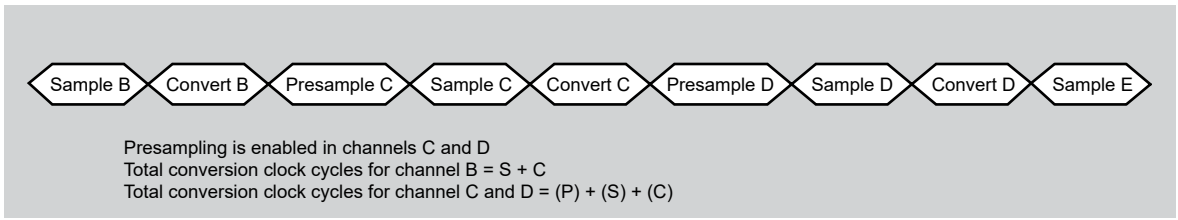

Figure 225. Presampling sequence

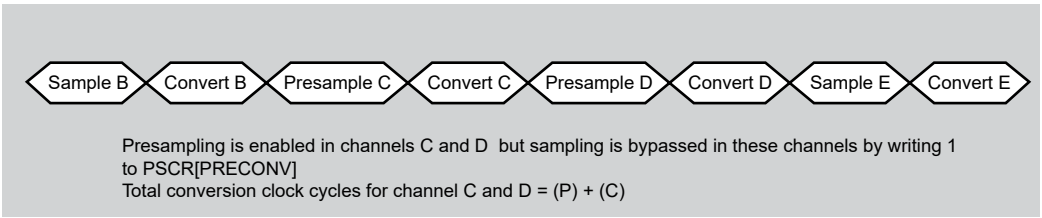

Figure 226. Presampling sequence with PRECONV=1

57.3.8.1 Enabling presampling per channel

Enable presampling for specific channels by programming Presampling Control (PSCR). You can select between two internally generated voltages by configuring the PREVAL*n* fields in Presampling Control (PSCR) to the appropriate values, as given in the following table.

Table 271. Presampling voltage selection via PREVAL*n*

PREVAL*n*	Presampling voltage
0	Presample voltage – 0: VREFL
1	Presample voltage – 1: VREFH

The presampling configuration field(s) (PSCR[PREVAL0], PSCR[PREVAL1], PSCR[PREVAL2]) are located in Presampling Control (PSCR). These fields enable selection of the presampling channel.

The temperature sensor channel has an exception. This channel is mapped with a fixed channel depending on device configuration, but it uses the presampling configuration defined for channel group 2. So, when the temperature sensor channel is selected, the presampling voltage defined by PSCR[PREVAL1] is selected. This voltage might be different from the one selected for channel group 1 via PSCR[PREVAL0].

57.3.9 Analog watchdog functions

When enabled, an analog watchdog monitors conversion results for an associated channel and reports an issue if it determines a result is outside customer-defined limits (as shown in Analog watchdog configuration (up to 16 watchdogs)). These limits are specified by an upper and a lower threshold value named THRH and THRL respectively.

After the conversion of the selected channel a comparison is performed between the converted value and the threshold values. If the converted value is outside that threshold value, then ADC generates a corresponding threshold violation interrupt.

The comparison result is stored as HAWIFx and LAWIFx fields in Analog Watchdog Threshold Interrupt Status (WTISR), as explained in the following table. Depending on the values of WTIMR[LAWIFENx] and WTIMR[HDWIFENx] mask fields, an interrupt is generated on a threshold violation.

Table 272. Values of HAWIFx and LAWIFx

HAWIFx	LAWIFx	Conversion result
1	0	Conversion result > THRH
0	1	Conversion result < THRL
0	0	THRH ≥ conversion result ≥ THRL

Depending on the chip's factory settings, up to 16 analog watchdogs are available. See the chip-specific configuration information for availability.

There are two types of mutually exclusive settings for analog watchdogs. Both types are described in the following sections. The availability depends on device configuration. See the chip-specific configuration information for availability.

Different capabilities are available with the two settings, as described below.

57.3.9.1 Channel analog watchdog select registers

ADC configuration includes selecting the analog watchdog threshold register (THRHLR*n*) that provides limits to monitor inputs of a given type. You select the THRHLR*n* using CWSELR*a*l*n* registers.

Table 273. CWSELR*a*l*n* register naming

Index	Description
a	ADC input type associated with a CWSELR*a*l*n* register. • P = Precision inputs • S = Standard inputs • E = External inputs
n	0-indexed register number.

57.3.9.2 Analog watchdog configuration (up to 16 watchdogs)

ADC can have up to 16 watchdogs in the factory configuration. (See the chip-specific configuration information for availability.) For each watchdog there is one threshold value register, THRHLR*n*, that contains the high and low thresholds.

You can independently enable the analog watchdog for each channel by programming the appropriate CWENR*n* register.

The threshold values for each channel can be selected independently from a maximum of 16 threshold registers (THRHLR*n*) using the corresponding WSEL_CH*n* field in the appropriate CWSELR*a*l*n*, where *a* indicates the input type:

- P = precision
- S = standard
- E = external

Each CWSELR*a*l*n* register is associated with 8 consecutive channels. CWSELR*a*l0 holds 8 WSEL_CH fields for channels 0 to 7. CWSELR*a*l1 is for channels 8 to 15 and so on. The availability of fields and registers depends on device configuration. See the chip-specific configuration information for availability.

If the conversion result of a selected channel is outside the range specified by threshold values, then the corresponding field in the Analog Watchdog Out of Range register (AWORR*n*) transitions to 1. For example, if channel 7 is to be monitored with the threshold values in THRHLR3, then CWSELR*a*l0[WSEL_CH7] must be programmed with 3. Enabling the watchdog is done by writing 1 to the corresponding field for channel 7 in CWENR0.

In this configuration, a set of threshold values (THRHLR*n*) can be linked to several ADC channels. The threshold values to be selected for a channel must be programmed only once in CWSELR*a*l*n*,.

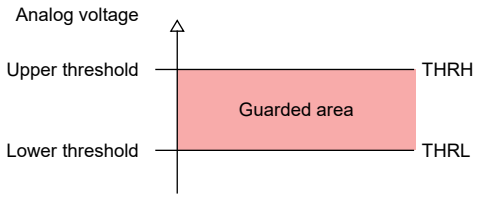

Figure 227. Guarded area

NOTE

If the higher threshold of the analog watchdog is programmed below the lower threshold and the conversion result is below the lower threshold, then the WDG*n*L interrupt for the low threshold violation transitions to 1. If the conversion result is greater than the lower threshold (and therefore also greater than the higher threshold), then the interrupt WDG*n*H for high threshold violation is generated. Thus you should take care to avoid that situation, as it could lead to misinterpretation of the watchdog interrupts.

57.3.10 DMA functionality

Conversion result data from any channel can be transferred from a register to system memory via Direct Memory Access (DMA). DMA transfers are enabled by writing 1 to DMAE[DMAEN]. After being enabled, the on-chip DMA controller can receive a DMA request after the conversion of each channel by writing 1 to the respective masking field in DMA Request Enable For Precision Inputs (DMAR0), DMA Request Enable For Standard Inputs (DMAR1), or DMA Request Enable For External Inputs (DMAR2). DMA masking registers must be programmed before starting any conversion.

A DMA request to the DMA controller can be cleared at different times in two modes:

- Mode-1: Clearing of DMA request on acknowledgment from DMA controller (DMAE[DCLR] = 0)
- Mode-2: Clearing of DMA request on read to data registers (DMAE[DCLR] = 1)

The figures below show the operation of DMA in two modes (cycle counts are typical values).

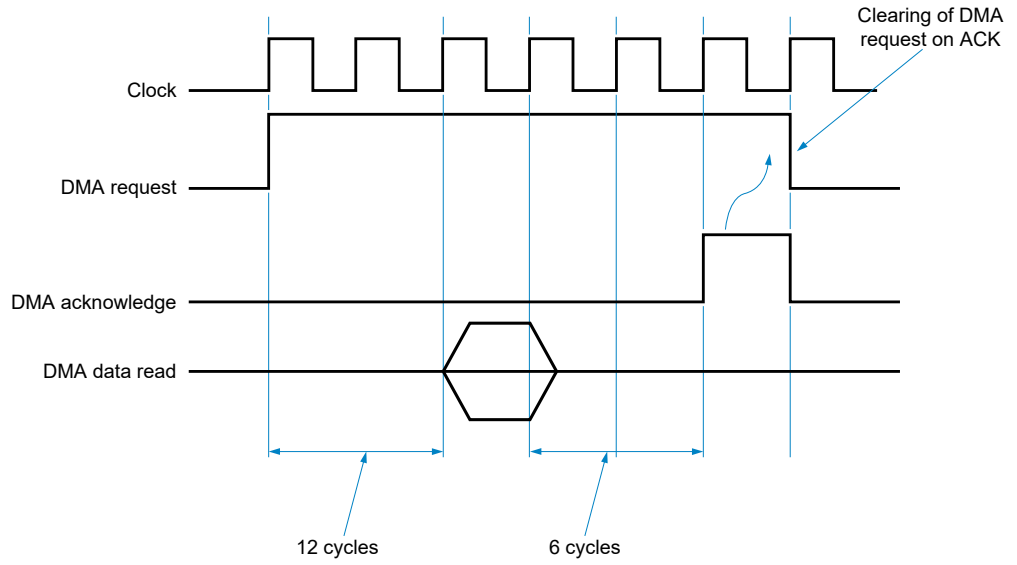

Figure 228. DMA operation Mode-1 (DMAE[DCLR] = 0)

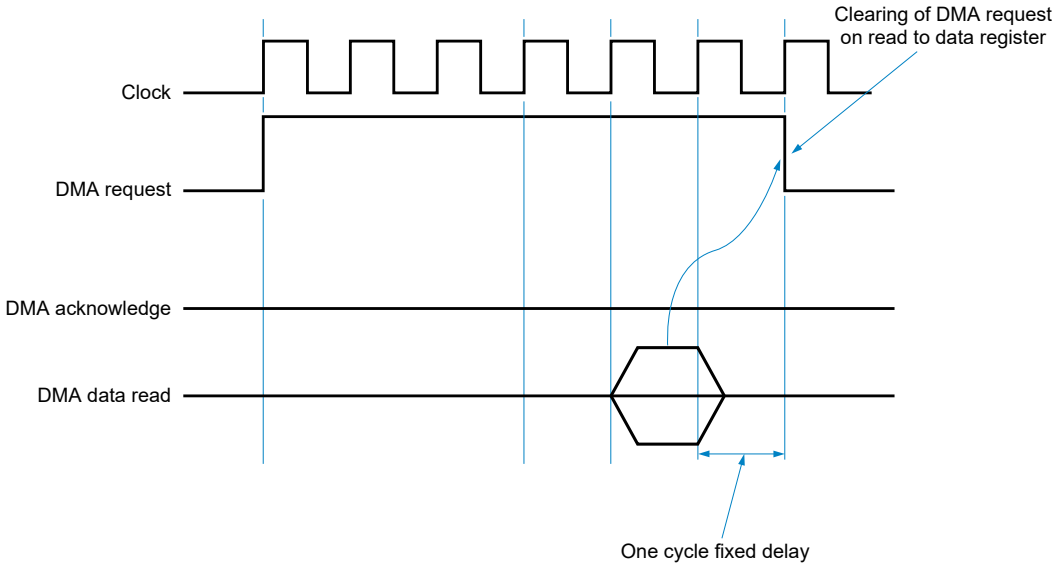

Figure 229. DMA operation Mode-2 (DMAE[DCLR] = 1)

57.3.11 Interrupts

ADC generates the following maskable interrupts:

- EOC (End of Conversion)
- ECH (End of Chain)
- JEOC (End of Injected Conversion)
- JECH (End of Injected Chain)
- EOBCTU (End of BCTU-triggered Conversion)
- LAWIFx and HDWIFx (Watchdog threshold)

- Self-testing interrupts

Interrupts are generated during the conversion process to signal events such as End Of Conversion (EOC), and so on, as described in Interrupt Status (ISR). ISR and another register, Interrupt Mask (IMR), are provided to check and enable the interrupt request to an external interrupt controller.

Interrupts can be individually enabled on a per-channel basis by programming EOC Interrupt Enable For Precision Inputs (CIMR0).

CEOCFR*n* are used for pending End of Conversion interrupts, with one field per channel to indicate completed conversions on a per-channel basis.

Interrupts generated due to the analog watchdogs are managed by two 32-bit registers, Analog Watchdog Threshold Interrupt Status (WTISR) and Analog Watchdog Threshold Interrupt Enable (WTIMR), to check and enable the interrupt request. A watchdog interrupt causes two corresponding fields to transition to 1 for each channel monitored. One field is in WTISR[WDG*n*H] and another in WTISR[WDG*n*L].

Generated events are logged into status registers and used to generate interrupts if enabled in corresponding Mask registers.

There are three different interrupt outputs. The interrupt structure is shown in Figure 230.

Each interrupt is generated by combining a group of events.

The following interrupts are combined (logic OR) into one interrupt output.

- EOC
- ECH
- EOBCTU
- JEOC
- JECH
- End of self-test algorithm (WDG_EOA_S and WDG_EOA_C)

Interrupts of all HDWIFx and LAWIFx are combined on the second interrupt output.

Interrupts of all self-test errors (watchdog threshold, sequence, and timer violations) in Self-Test Status 1 (STSR1) are combined on the third interrupt output. The errors are:

- WDSERR
- WDTERR
- ERR_S0
- ERR_S1
- ERR_S2
- ERR_C

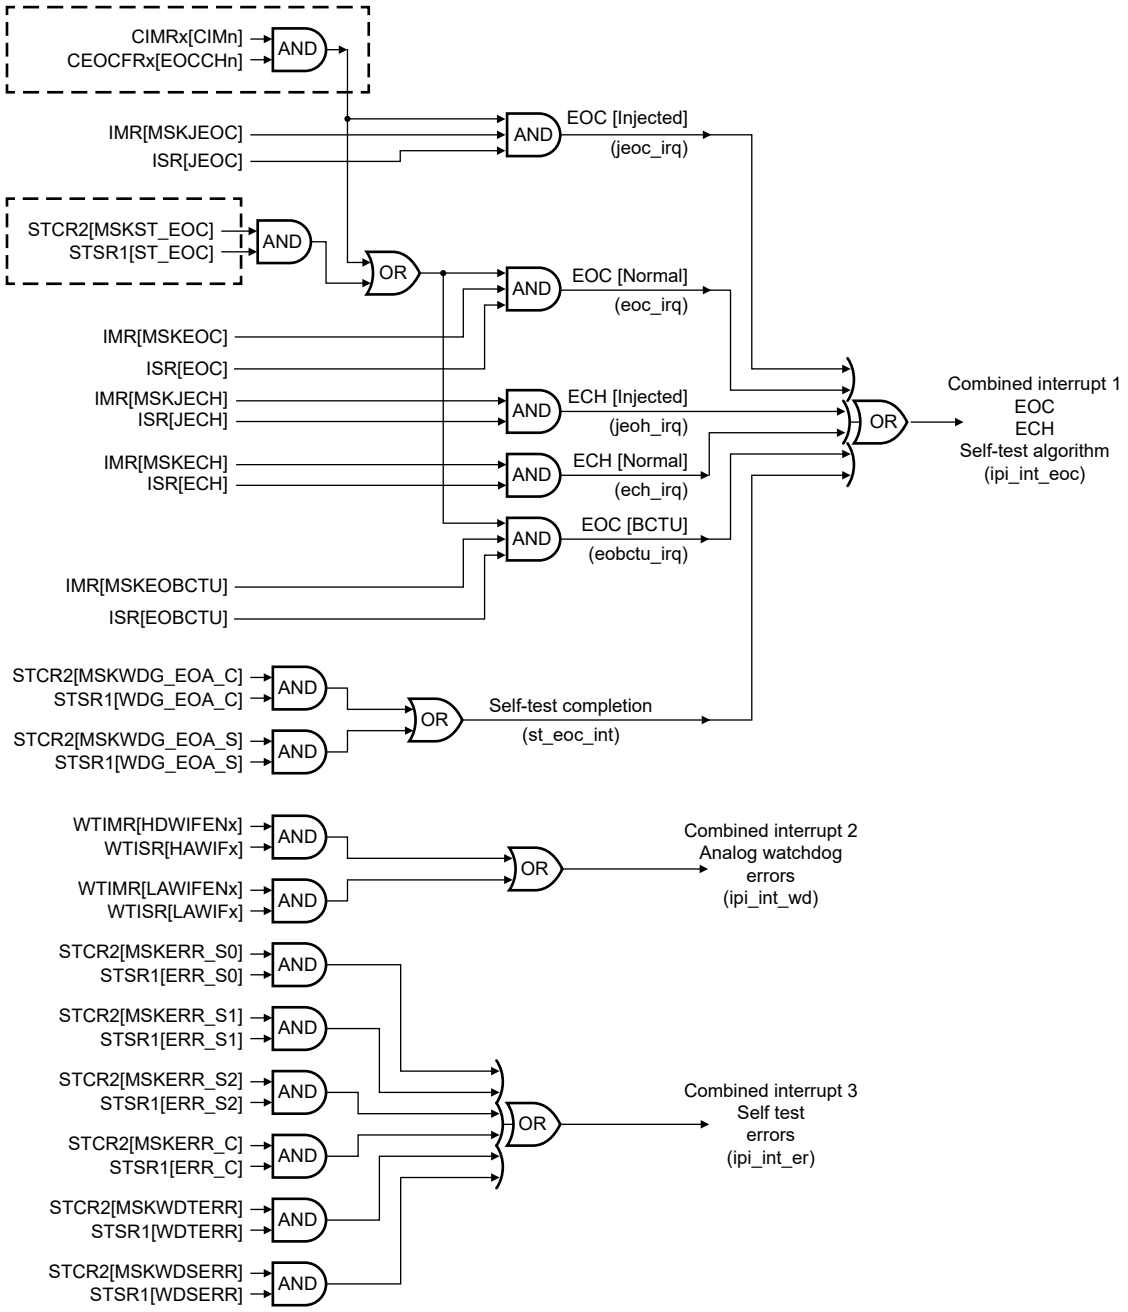

Figure 230. Interrupt structure of ADC

Interrupt Status (ISR) Indicates the interrupt pending request status. Write 1 to the corresponding status field to clear the pending interrupt flag (at this write operation all the other fields in Interrupt Status (ISR) must be maintained at 0).

ISR checks for three types of interrupts.

The first type, Interrupt 1, relates to the following:

- End of normal or injected conversion (EOC or JEOC)
- End of normal or injected conversion chain (ECH or JECH)
- End of algorithm C or algorithm S self-test (WD_EOA_C or WD_EOA_S)

Perform the following actions for this type of interrupt:

1. Read Interrupt Status (ISR) to determine whether the event is an EOC, JEOC, ECH, JECH, or EOBCTU event.
2. Read Self-Test Status 1 (STSR1) to identify the end of self-test algorithm events (WDG_EOA_S or WDG_EOA_C), if present.
3. If the interrupt is an EOC or JEOC event:
   - Clear the respective channel pending field in the appropriate CEOCFR*n* register for an EOC by writing a 1 to it.
   - Clear ISR[EOC] or ISRJEOC] by writing a 1 to it.
4. If the interrupt is an ECH or JECH, clear ISR[ECH] or ISR[JECH] by writing 1 to it.
5. If the interrupt is EOBCTU, clear ISR[EOBCTU] by writing 1 to it.
6. If the interrupt is for self-test end of algorithm, clear STSR1[WDG_EOA_S] or STSR1[WDG_EOA_C] by writing 1 to it.

The second type, Interrupt 2, relates to analog watchdog errors. Perform the following actions for this type of interrupt:

1. Read Analog Watchdog Threshold Interrupt Status (WTISR) to determine which watchdog triggered the interrupt.
2. Read the AWORRx register(s) to determine which channel's data caused the interrupt (if present).
3. Clear the respective field of the WTISR[WDG*n*H/WDG*n*L] register, where *n* = watchdog number, by writing 1 to it.
4. Clear the respective field of the AWORR*n*[AWOR_CH*n*] register, where x = register, n = channel, by writing 1 to it.

The third type, Interrupt 3, relates to self-test errors. Perform the following actions for this type of interrupt:

1. Read Self-Test Status 1 (STSR1) to determine the type of error encountered in self-test (WDSERR, WDTERR, ERR_S0, ERR_S1, ERR_S2, ERR_C, and so on) if present.
2. Clear the respective field in Self-Test Status 1 (STSR1) by writing 1 to it.

The connectivity of interrupt lines at the chip level (external to ADC) determines whether software must read all the registers for all three interrupts or any one or combination of any two.

57.3.12 External decode signals delay

The ADC provides three external decode signals which it uses to select one channel out of eight in the external analog multiplexers. There can be a maximum of four such multiplexers used to connect the 32 external channels. The ADC automatically sets the decode signals to control these external analog multiplexers, based on the current channel selected for conversion. Delay Start Of Data Conversion (DSDR) is provided to take the switching time of the external analog multiplexer into account. It enables you to program the delay between the decoding signal selection and the actual start of conversion.

If presampling is enabled, the DSD delay starts after the presample phase (presampling time is the same duration as sample time).

57.3.13 Power Down state

The analog part, along with the ADC controller, can be put in Power Down state by writing 1 to MCR[PWDN]. This shuts down ADC and stops the clock to the ADC controller. After release of reset, MCR[PWDN] remains 1, so the ADC analog module is kept in Power Down state by default. You must exit this state before starting any operation, by writing 0 to MCR[PWDN]. In Power Down state, no conversion can be started. If a BCTU trigger pulse is received during this state, it is discarded. You must ensure that a BCTU trigger is not initiated to ADC before writing 0 to MCR[PWDN], as it may cause the BCTU module to be stuck in a wait state.

You can set MCR[PWDN] by writing 1 to it at any time. If a conversion is ongoing, ADC does not move into Power Down state immediately. ADC enters Power Down state only after completion of the ongoing conversion. During scan operation, the ongoing operation should be aborted manually by writing 0 to MCR[NSTART] before or after writing 1 to MCR[PWDN].

ADC Power Down state status is indicated by MSR[ADCSTATUS] when ADC enters into Power Down state.

If the BCTU is enabled and MSR[BCTUSTART] = 1, then you cannot write 1 to PWDN. When BCTU Trigger mode is enabled, the application must wait for the end of conversion (MSR[BCTUSTART] is automatically reset to 0). When BCTU Control mode is enabled, before entering Power Down state the application must write 0 to BCTUEN also.

If Power Down state is entered by writing 1 to MCR[PWDN], the process running before entry into Power Down state must be restarted manually (by writing 1 to the appropriate START field in Main Configuration (MCR)) after exiting Power Down state.

NOTE

Writing 0 to MCR[PWDN] and writing 1 to MCR[NSTART] or MCR[JSTART] during the same cycle is not supported.

57.3.14 Low Power mode support

For low-power operation, ADC must be in Idle state and then put into Power Down state to ensure proper signal condition at the analog boundary.

From any of the states listed below, follow the sequence of steps shown to put ADC into Power Down state.

1. Idle condition
    a. Verify that ADC is in Idle state (MSR[ADCSTATUS] = 000b).
    b. Write 1 to MCR[PWDN], to shut off the clock to the hard macro with the proper state of signals required for Low Power mode.
    c. Verify that ADC is in Power Down state (MSR[ADCSTATUS] = 001b).
2. During calibration

    NOTE

    Writing 1 to MCR[PWDN] during calibration is prohibited. After calibration is started it should be allowed to finish normally. Alternatively, it can be terminated by starting a normal conversion before writing 1 to MCR[PWDN].

    a. Check the current ADC state either via MSR[ADCSTATUS] (000b = Idle, 011b = Calibration), or via CALBISTREG[C_T_BUSY] (1 = calibration is in progress).
    b. When ADC is in Idle state, write 1 to MCR[PWDN] to shut off the clock to the hard macro with the proper state of signals required for Low Power mode.
    c. Verify that ADC is in Power Down state (MSR[ADCSTATUS] = 001b).
3. During conversion (normal [one-shot]/Injected/BCTU):
    a. Write 1 to MCR[PWDN].
    b. ADC enters Power Down mode after completing the current conversion chain (for normal and injected conversions) or the conversion for conversion triggered by BCTU.
    c. Check the ADC state via MSR[ADCSTATUS] (000b = Idle state, 001b = Power Down state).
4. During Scan mode operation of normal conversion

    NOTE

    Writing 1 to MCR[PWDN] during scan mode operation has no effect other than to prevent software from starting a new normal or injected conversion. It does not stop a conversion in progress and cannot put ADC into Power Down state.

    a. Software must write 0 to MCR[NSTART] to stop the ongoing scan conversion before (or after) writing 1 to MCR[PWDN]. This stops conversion at the current chain boundary.
    b. ADC enters Power Down mode after coming to an Idle state after MCR[PWDN] is written with 1. This shuts the clock off to the hard macro and puts analog inputs in the proper state required for Low Power mode.
    c. Verify that ADC is in Power Down state (MSR[ADCSTATUS] = 001b).

57.3.15 Auto Clock Off mode

To reduce power consumption during Idle state (without going into Power Down state), an auto-clock-off feature can be enabled by writing 1 to MCR[ACKO]. When enabled, the internal ADC operating clock (AD_Clk) is automatically switched off during an idle period (for example, no conversion is programmed).

57.3.16 Calibration and self-test

57.3.16.1 Calibration

ADC must be calibrated before it can do meaningful conversions. The application must prevent any start of conversion before the ongoing calibration has finished successfully. No conversion trigger may be received during calibration.

During calibration, a known reference voltage is sampled and converted under controlled conditions to determine the correction values (calibration values) for offset, gain, and capacitor mismatch.

These calibration values (except gain calibration) are used in a post-processing step after conversion, reducing or eliminating the various error contribution effects. The gain calibration is used during sample phase to define the additional charge to be loaded to compensate for gain failure.

You must run calibration after every power-up reset (check device-specific reset connectivity for appropriate reset applied). You must also run calibration if it is indicated by the self-test (see Self-test).

Configuration and start of calibration is done by programming the Control And Calibration Status (CALBISTREG). During calibration, internal hardware averaging function should be enabled. Maximum averaging is recommended, and 16 should be the minimum.

Calibration status is captured by a status flag (CALBISTREG[TEST_FAIL]) to indicate any fault detected during calibration execution or if calibration was prematurely aborted. Calibration is aborted if any normal conversion is initiated during the calibration execution, which is called premature termination. (Flag TEST_FAIL = 1 indicates a calibration fail, for example when a calibration value is out of internally defined limits.)

To execute the calibration algorithm, perform the following steps:

1. Select the conversion clock frequency to be within the allowed limits for the calibration.
2. Bring ADC from Power Down state to active conversion (program MCR[PWDN] = 0b).
3. Configure the Control And Calibration Status (CALBISTREG). The default values are set for maximum accuracy (recommended).
4. Disable the error correction for the smaller capacitances in the CDAC of the ADC (write 0h to CAL2[ENX]).
5. Start calibration (program CALBISTREG[TEST_EN] = 1b), and calibration starts immediately.
6. Poll the status of CALBISTREG[C_T_BUSY] for 0 (wait until it transitions to 0).
7. Check CALBISTREG[TEST_FAIL] to determine the final status. If 1, then calibration failed.
8. Check the status of MSR[CALIBRTD]. If calibration was successful this field is 1.

57.3.16.2 Self-test

For safety applications, it is important to verify correct operation at regular intervals. ADC has a self-test feature for this purpose. When self-test is enabled, ADC automatically checks its components and flags errors, if any are found.

Tests can be enabled to check the reference (VrefH) and calibrated values.

The following test algorithms have been implemented:

- Supply self-test (algorithm S): It includes the conversion of the band gap and VREF voltages. It includes a sequence of num_supply_steps test conversions (steps). The supply test conversions must be an atomic operation (that is, all supply algorithm conversions must be performed one after another with no functional conversions in between).

- Capacitive self-test (algorithm C): It includes a sequence of test steps per definition of algorithm C (see Table 274) which executes the capacitive matrix of the CDAC used for sampling and conversion.

Individual steps can take up to 1 µs at 80 MHz ADC clock frequency.

Table 274. Self-test steps

STCR3[ALG]	STCR3 [step](per algorithm definition)	Description	Outcome	Comment
00 (algorithm S)	0	Supply self-test (band gap voltage)	Measures the internal band gap voltage	
	1	Supply self-test (reference voltage high)	Measures ADC high reference voltage	
	2	Supply self-test (reference voltage high)	Measures ADC high reference voltage	
01 (Reserved)	Reserved			
10 (algorithm C)	0 – 11	Capacitive self-test. One of the calibration steps is being run.	The difference/error of the individual offset value from the previously calibrated value is being returned as an ADC result that is compared with the programmed value in the self-test analog watchdog register(s) to detect any fault.	The ideal result value is expected to be 0. If the returned value is higher, it indicates a runtime fault or accuracy shift. The error is indicated in the status register and can be used to generate an interrupt also. It that indicates ADC should be recalibrated to check whether the reported error can be managed by calibration or that permanent damage occurred to ADC.
11 (algorithm S + C)	0 – 2 (S), 0 – 11 (C)	Supply for One-Shot mode and (supply + capacitive) for Scan mode only.	Same as above.	

ADC:

- Schedules self-testing algorithms using configuration registers.
- Monitors the converted data using analog watchdog registers.
- Flags any errors to a fault control unit (FCCU), if one exists.

Self-test steps can be activated from software (CPU) or BCTU.

ADC mode	TEST algorithm (CPU)	TEST algorithm/step (BCTU)
CPU mode (MCR[BCTUEN] = 0)	Yes	No

Table continues on the next page...

Table continued from the previous page...

ADC mode	TEST algorithm (CPU)	TEST algorithm/step (BCTU)
	• One-Shot operation mode • Scan operation mode	
BCTU mode	No	Yes

57.3.16.2.1 CPU mode

In this mode, self-test conversion is similar to normal conversion. You enable self-test by writing 1 to STCR2[EN].

Self-test conversions execute along with the functional conversions. The sequencing of steps of the selected algorithm depends on the operating mode of normal conversions (selected by MCR[MODE]).

In One-Shot operation mode, if self-test is enabled, only one step of the selected self-testing algorithm is executed at the end of the chain. The step number and algorithm to be executed are programmed in Self-Test Status 3 (STSR3). In One-Shot operation mode the sequence is:

1. Program NCMR*n* to select channels to be converted for normal conversion.
2. Write 0 to MCR[MODE] to select one-shot operation.
3. Configure the self-test algorithm threshold values (see Table 275).
4. Program sampling duration values in STCR1[INPSAMP*m*] (*m* = S, C).
5. Select the self-testing algorithm (in STCR3[ALG]), and step (in STCR3[MSTEP]). The default is algorithm S, step 0.
6. Enable self-testing by writing 1 to STCR2[EN].
7. Start the normal conversion by writing 1 to MCR[NSTART].
8. All normal conversions are executed as usual.
9. At the end of all normal conversions in the chain, the step number (programmed in STCR3[MSTEP]) of the self-testing algorithm (selected by STCR3[ALG]), is executed similar to a normal functional channel.
10. At the end of the conversion for the self-test channel:
    - The result is written to STDR1[TCDATA].
    - STDR1[VALID] transitions to 1.
    - ISR[EOC], ISR[ECH], and STSR1[ST_EOC] transition to 1.
11. ADC returns to Idle state.

For example: Channels A→B→C→D→E→F→G→H are present in the device where channels B→D→E are to be converted in One-Shot operation mode. At the end of conversion for channels B→D→E, self-test conversion is performed and ISR[ECH] and ISR[EOC] transition to 1. The sequence is B→D→E→self-test step.

MSR[NSTART] transitions to 1 when the normal conversion starts and transitions to 0 at the end of conversion for the test channel.

In Scan operation mode, consecutive steps of the selected self-test algorithm are converted continuously at the end of each chain of normal conversions. The number of channels converted at the end of each chain is 1 (except for algorithm S, in which all the steps are performed sequentially without any functional conversion interleaved). So, in Scan operation mode the sequence is:

1. Program NCMR*n* to select the channels to be converted for normal conversion.
2. Write 1 to MCR[MODE] to select Scan operation mode.
3. Configure the self-test algorithm threshold values (see Table 275).
4. Program sampling duration values in STCR1[INPSAMP*m*] field (*m* = S, C).

5. Select the self-testing algorithm in STCR3[ALG]. By default, all algorithms (supply and capacitive) are selected, that is, all algorithms are executed step-by-step, one after the other.
6. Enable self-testing by writing 1 to STCR2[EN].
7. Start the normal conversion by writing 1 to MCR[NSTART].
8. All normal conversions are executed as usual.
9. At the end of the chain of normal conversions (assuming the default value of STCR3[ALG]), all steps of algorithm S are performed (as algorithm S is always atomic). MSR[SELF_TEST_S] transitions to 1.
10. At the end of the conversion of the self-test channel for the last step of algorithm S, the result is written to STDR1[TCDATA] and STDR1[VALID] transitions to 1. At the same time, MSR[SELF_TEST_S] transitions to 0. The following registers also transition to 1:
    - ISR[EOC]
    - ISR[ECH]
    - STSR1[ST_EOC]
11. The next chain of normal conversions then starts.
12. At end of the chain of normal conversions, ADC executes step 0 of algorithm C.
13. At the end of the conversion of the test channel for step 0 of algorithm C, the result is stored in STDR1[TCDATA] and STDR1[VALID] transitions to 1 (if STSR1[OVERWR] is 1). Also, ISR[EOC] and ISR[ECH] transition to 1. STSR1[ST_EOC] also transitons to 1.
14. The next chain of normal conversion then starts.
15. At the end of the normal conversion chain, ADC executes step1 of algorithm C.

This process continues for all steps of all three algorithms. The state machine returns to Idle state when MCR[NSTART] transitions to 0.

For example: channels A→B→C→D→E→F→G→H are present in the device where channels B→D→E are to be converted in Scan operation mode. At the end of every conversion chain for channels B→D→E, one step of the self-test conversion is performed and ISR[ECH] and ISR[EOC] transition to 1.

The sequence is:

B→D→E→ST-S0→ST-S1→ST-S2→B→D→E→ST-C0→B→D→E→ST-C1→B→D→E→ST-C2→ . . . B→D→E→ST-C11→B→D→E→ST-S0 . . .

ST-Sx - Self-test supply step x (x = 0, 1, 2)

ST-Cx - Self-test capacitive step x (x = 0 to 11)

MSR[NSTART] transitions to 1 when normal conversion starts.

NOTE

- If instead of starting normal conversion by software (by writing 1 to MCR[NSTART]), it is started by an external trigger, the self-test behavior remains the same.
- Self-test channel conversion is not performed for injected conversions. It is performed only during normal conversions.
- If, during a test channel conversion, an injected conversion arrives, the test conversion is aborted (just as a normal functional channel) and the injected conversion is performed. After the injected conversion is complete, the test conversion resumes from the step at which it was aborted. In this case, MSR[SELF_TEST_S] remains 1 during the injected conversion.
- For self-test, MCR[MODE] should be programmed (at least one cycle) before writing 1 MCR[NSTART] and should not be changed until the conversion is finished or terminated.

Table 275. Recommended self-test threshold values

Register field	Hex value	Decimal value	Comment
STAW0R[THRH]	3669h	13929	The threshold values depend on the stability of the supply and the reference voltage. When you see voltage variations, widen the limits.
STAW0R[THRL]	5 V reference: 1A7Fh 3 V reference: 2B27h	5 V reference: 6784 3 V reference: 11047	
STAW1R[THRL]	3FF9h	16377	
STAW2R[THRL]	3FF9h	16377	
STAW4R[THRH]	20h	32	
STAW4R[THRL]	7FE0h	–32	
STAW5R[THRH]	20h	32	
STAW5R[THRL]	7FE0h	–32	

57.3.16.2.2 BCTU mode

BCTU mode is enabled by writing 1 to MCR[BCTUEN].

Self-test conversion behaves in the same way for all BCTU operating modes (Trigger mode and Control mode). In both cases, if MCR[BCTUEN] = 1, the self-test conversion can be started only by BCTU—software cannot start it. MCR[BCTUEN] must not be changed during normal conversion. The interface between BCTU and ADC (for self-test) is shown in the following figure.

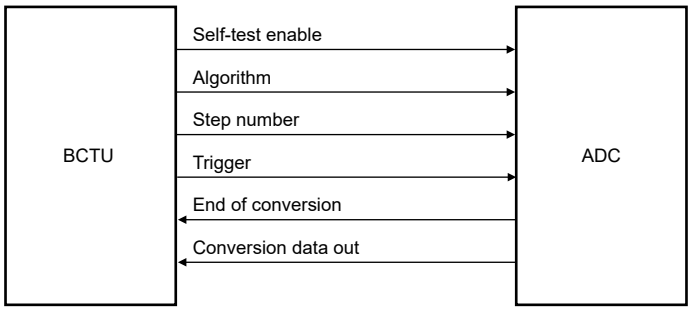

Figure 231. Self-test interface between ADC and BCTU

For self-test conversions in BCTU mode, BCTU asserts self-test enable along with the Trigger command. The algorithm and the step number to be executed is put on algorithm and step number, respectively. The other commands (Trigger, End Of Conversion, and Conversion Data Out) have the same meaning, like normal BCTU functional conversion.

As already mentioned for algorithm S, the three steps must be atomic. In BCTU mode, this is managed by BCTU, that is, BCTU sends three triggers (one for each step) asserting self-test enable and updating test_step for each step.

57.3.16.2.3 Abort and abort chain for self-testing channel

Writing 1 to MCR[ABORT] during self-test channel conversion has no effect.

In One-Shot operation mode, if you write 1 to MCR[ABORTCHAIN] during the self-test channel conversion, the self-test channel is aborted and ISR[ECH] transitions to 1. In this case, ISR[EOC] for the self-test channel is not generated.

In Scan operation mode, if MCR[ABORTCHAIN] = 1 when self-test channel step *n* is ongoing, self-test channel step *n* is aborted and the next chain conversion begins. At the end of the chain, the step *n* conversion is performed again. (For algorithm S, the full algorithm is executed again).

57.3.16.2.4 Self-test analog watchdog

ADC provides monitoring options for conversion data generated by self-test algorithms. Analog watchdogs determine whether the conversion results for self-test algorithms are in the range of a particular guard area. ADC provides separate self-test analog watchdog registers for each algorithm.

After the conversion of each step of a self-test algorithm, ADC compares the converted value and the threshold values if the analog watchdog feature has been enabled by writing 1 to STAW*n*R[AWDE] (for example, STAW0R[AWDE]). If the converted value is not between the upper and lower threshold values specified by the Self-Test Analog Watchdog Register for the particular algorithm, the corresponding error flag, STSR1[ERR_x], transitions to 1 and the step number in which error occurred is captured in STSR1[STEP_x] (for algorithm C). Erroneous data is written to STSR4[DATA*n*]. The STSR1[ERR_x] flags generate an interrupt if enabled by the corresponding mask bit in Self-Test Configuration 2 (STCR2). The fault indication is also forwarded to the fault control unit, if present, so that necessary action can be taken at the chip level. The fault type (critical or noncritical) is specified by the configuration in Self-Test Configuration 2 (STCR2).

The analog watchdog feature works differently for algorithm S. Algorithm S is always an atomic operation. Self-Test Status 1 (STSR1) has a separate error field for each step of algorithm S to avoid overwrite in case an error occurs in more than one step. Therefore, there are separate mask bits for each step in STCR1. For the same reason, the status registers (Self-Test Status 2 (STSR2) and Self-Test Status 3 (STSR3)) have separate fields for each step to store erroneous data.

In step 0 of the supply algorithm, ADC measures the band gap voltage (1.2 V), which is assumed to be stable. The conversion result of step 0 is compared against high (THRH) and low (THRL) thresholds as defined in Self-Test Analog Watchdog S0 (STAW0R), if enabled (STAW0R[AWDE] = 1). The STSR1[ERR_S0] flag transitions to 1 if any of the thresholds are violated. STSR1[ERR_S0] is cleared by writing 1 to it. The conversion result of ADC can be calculated with the following formula:

- ADC data (decimal) = (Vin × 2^{15} ÷ (Vrh - Vrl))

Where:

- Vin: input voltage (band gap voltage in this case)
- Vrh: ADC reference high voltage
- Vrl: ADC reference low voltage

The upper and lower threshold value can be calculated with the above formula using maximum and minimum values of Vin, Vrh, Vrl (Vin is the band gap supply voltage in this case):

- Upper threshold (THRH, decimal) = (Vin[max] × 2^{15}) ÷ (Vrh[min] - Vrl[max])
- Lower threshold (THRL, decimal) = (Vin[min] × 2^{15}) ÷ (Vrh[max] - Vrl[min])

The minimum and maximum voltages can be obtained from the chip data sheet. The band gap voltage tolerance, as well as the actual reference voltage used and its tolerances, must be considered when calculating high and low thresholds.

For algorithm S steps 1 and 2, (VREF/VREF) is measured in order to check the integrity of the sampling signal. For these particular conversions, no higher threshold value is required as the ideal value is FFFh. Only the lower threshold value is programmed in Self-Test Analog Watchdog S1 (STAW1R) and Self-Test Analog Watchdog S2 (STAW2R).

For algorithm C, a separate register is provided for step 0. In step 0 an offset for other steps is measured. The converted data is compared with the threshold values in Self-Test Analog Watchdog C (STAW5R) if STAW4R[AWDE] = 1. For other steps, this offset is subtracted from converted data before performing watchdog checks.

57.3.16.2.5 Watchdog timer

The watchdog timer is an additional check that monitors the sequence of the self-testing algorithm that has been implemented, and also checks whether the algorithm is completed within a safe time period. The watchdog timers are enabled for CPU as well as BCTU conversions. Each algorithm has an independent watchdog timer. The watchdog timer for a particular algorithm is enabled by writing 1 to STAWxR[WDTE]. The safe time value is programmed in STBRR[WDT] (the default value is 10 ms, assuming an 80 MHz clock).

The safe time is measured starting from step 0 of the algorithm (including all normal chain conversions in between) to the point where step 0 of the same algorithm starts again.

The programming sequence is:

1. Program NCMR*n* to select the channels for normal conversion in Scan operation mode (MCR[MODE] = 1).
2. Select the self-test algorithm in STCR3[ALG]. By default, all algorithms (supply and capacitive) are selected (all algorithms are executed step-by-step, one after the other).
3. Enable the self-test channel by writing 1 to STCR2[EN].
4. Program the safe period value in STBRR[WDT].
5. Enable the watchdog timer by writing 1 to STAWxR[WDTE]. Assume writing 1 to STAWxR[WDTE] occurs at time *t*0. It is important to do all configuration programming before writing 1 to STAWxR[WDTE], because the safe time check is also performed between writing 1 to STAWxR[WDTE] and the start of step 0. This is to verify that the algorithm has started within the safe time.
6. Start the normal conversion by writing 1 to MCR[NSTART].
7. At the end of the first conversion chain, three steps (steps 0, 1, and 2) of algorithm S are executed in sequence. Assume the start of Step 0 occurs at time *t*1.
8. After completion of algorithm S, ADC performs conversion of the next chain.
9. At the end of the the conversion chain, the first step (step 0) of algorithm C is performed.
10. In this way, one step of algorithm C is performed after completion of one conversion chain until all steps are finished. Steps are executed in sequence (steps 0–11)
11. After the last step of algorithm C, another chain conversion is executed. At the end of this chain conversion, step 0 of algorithm S is started again, repeating the whole sequence. Assume this time (starting of step 0 of the supply algorithm) to be at time *t*2.
12. For algorithm S, if (*t*1 - *t*0) > safe period or (*t*2 - *t*1) > safe period, the watchdog timer flags an error and STSR1[WDTERR] transitions to 1. ADC asserts a fault signal per the criticality configuration (critical or noncritical) and an interrupt is generated, if enabled (STCR2[MSKWDTERR] = 1). Otherwise, the watchdog timer counter is reset and starts again to monitor the next sequence.
13. A similar sequence is followed for watchdog timers for algorithm C.

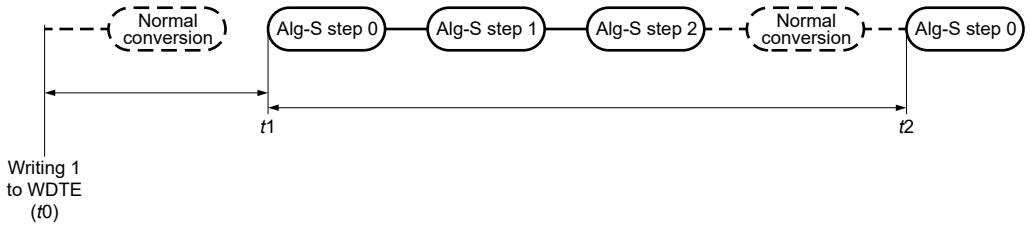

Figure 232. Watchdog timer monitor for algorithm S

NOTE

1. Because BCTU may not incorporate any safe period checking mechanism, the watchdog timers can also be enabled for BCTU conversions.
2. You must disable watchdog timers for self-test algorithms that are not executed.

57.3.16.2.5.1 Watchdog sequence checking

The self-test watchdog timer incorporates sequence checking features to verify that the steps of each algorithm are executed in the correct order. If the steps are not in the correct order, STSR1[WDSERR] transitions to 1 to indicate the error. A fault is indicated by an interrupt flag if STCR2[MSKWDSERR] = 1. A fault is also asserted as per criticality configuration (critical or noncritical) and an interrupt generated if STCR2[MSKWDSERR] = 1.

A watchdog sequence error is flagged in the following cases:

- The steps of any algorithm are not executed in proper order.
- The step numbers provided by BCTU for a BCTU conversion are not in order. Watchdog sequence checking is significant only for BCTU burst mode.
- When an abort chain occurs during a self-test channel conversion, that step must be repeated at the end of the next chain. This generates a sequence error as soon as the self-test channel conversion resumes. There is an exception, however. If an abort chain occurs during the last step of algorithm S, the sequence error is not flagged because the whole algorithm must be repeated.

If an injected conversion occurs during self-test channel conversion, a watchdog sequence error is not flagged, although the ongoing step number is aborted and is repeated.

NOTE

The watchdog timer feature is applicable for Scan operation mode but not for One-Shot operation mode.

57.3.16.2.6 Baud rate control for test channel

The baud rate control feature controls the scheduling of self-test channel conversions between normal conversion chains. The scheduling rate is specified by STBRR[BR].

By default, if the self-test channel is enabled, one step of the selected algorithm is executed after each normal conversion chain. The bandwidth consumed by the self-test channel depends on the number of channels in the normal chain. For example, if you have 50 normal conversions in a chain, then the self-test channel consumes only 2% of the total bandwidth, which is very small. If the number decreases to just 3 channels, the bandwidth consumed by the self-test channel is 25%, which is significant (and may not be desirable because it slows down the normal conversion rate).

STBRR[BR] provides flexibility by scheduling the self-test channel conversion to be performed not at the end of every chain, but at the end of BR + 1 chains. For example, if STBRR[BR] = 5, a single step of the selected algorithm for the test channel is performed after 6 chain conversions. The next step is performed at the end of the next six chain conversions, and so on. By default, STBRR[BR] = 0.

NOTE

This feature is applicable only for Scan operation mode and not for One-Shot operation mode. STBRR[BR] should be written with 0 for One-Shot operation mode.

To use the baud rate control feature in Scan operation mode, NCMR*n* should have a nonzero value.

57.3.16.2.6.1 Abort chain when baud rate is nonzero

As already described, for a nonzero value of STBRR[BR], the self-test channel conversion is performed at the end of BR + 1 chains. If an abort chain occurs during the chain in which a self-test channel conversion is scheduled to be performed, the self-test channel conversion is performed after the next BR + 1 chains.

For example, if STBRR[BR] = 2, the sequence is two normal chains (without any self-test channel conversion), followed by a chain with the self-test channel converted at the end. If an abort chain occurs during the first two chains, it is treated as a normal chain abort and the self-test channel is converted at the end of the third chain only (as in the case without any abort chain). However, if an abort chain occurs during the third chain in which the self-test channel is scheduled to be converted, the self-test channel is converted after the next three chains (for example, at the end of the sixth chain, counting from the beginning).

57.3.17 Conversion time

Total conversion time depends on the conversion clock frequency, which is configured by programming MCR[ADCLKSEL].

The components of conversion time and affecting configurations are:

- PST
- ST
- CT

- DP
- TPT

Presample phase time is equal to the sample time with a one AD_clk cycle delay for phase transition from presample phase to sample phase. CTR*n*[INPSAMP] controls sample time for different types of channels and is specified in terms of AD_clk cycles, so the presampling time is sample time plus one cycle of AD_clk. The minimum value of sample time is 8. If the value programmed is less than 8, it has no effect on sample time and the sample time is 8 AD_clk cycles.

Compare phase time is controlled by:

- The evaluation time of a single bit
- The number of bits converted

For *n*-bit conversions, the value of CT is *n* multiplied by the evaluation time of a single bit in terms of AD_clk cycles.

The evaluation time of a single bit is 4 AD_clk cycles if AMSIO[HS] = 0h, and 5 AD_clk cycles if AMSIO[HS] = 1h.

The data processing time is 2 cycles of AD_clk. During these cycles raw converted data is corrected for offset, gain, capacitor mismatch, and so on.

Trigger processing time consists of:

- One module_clock cycle, which is required to prepare the channel and calculate the initial gain value used by ADC for the first conversion.
- BCTU triggering time:
  - Triggers from the synchronous BCTU interface require 1 cycle of the module clock for processing. One more cycle is required to register the BCTU trigger in synchronous mode.

The total conversion time, in terms of the module clock cycles, is calculated using the following equation for normal and injected conversions:

Total_conversion_time = ([(PST + ST + CT + DP) × chain_length] + TPT) × TAD_clk

Example:

The ADC controller clock is equal to the module clock (80 MHz, clock cyle = 12.5 ns)

- ADC resolution 12 bit + 1 bit for a special capacitor (CS)
- Three channels are programmed in NCMR*n*, so a chain of three is to be converted
- Default sample time (22 cycles) is specified
- No presampling
- Conversion time (4 cycles per bit)

The total time for the three conversions = [(0 + 22 + (4×13) + 2) × 3] + 1 = 229 cycles ~= 2.862 µs

Conversion timing in Calibration for full test:

- Single conversion time = [sample time (CALBISTREG[TSAMP]) + compare time (11 × 4) + data proc(2)]
- Inter-conversion gap = 1 cycle
- Total number of tests = 12
- Averaging = 32

One test duration = (single conversion time + inter-conversion gap) × averaging samples

Total test duration = ((one test duration) × total number of tests).

Example: sample time = 22

Total test time = ((((22 + (11×4) +2)+1) × 32) × 12) = 26496 cycles × 12.5 ns (80 MHz) = 331200 ns

Conversion time in self-test:

Self-test conversion time equals one test period multiplied by the number of consecutive (atomic) steps. For supply self-test, the atomic step is 3 and for other tests it is 1.

One test period for self-test is as below.

- For supply tests: ([sample_time + (13 × 4) + 2])
- For other algorithms: ([sample_time + (11 × 4) + 2])

NOTE

Algorithm S steps (conversions) always run in atomic operation, required for an algorithmic procedure. In Scan operation mode, when all algorithms are selected, three steps of algorithm S run together after the end of the conversion chain. algorithm C steps are not required to be run together, so after each conversion chain one step is executed serially. Conversion time with self-test must also be calculated accordingly.

Example.

- Channels in chain A→B→C.
- Scan operation mode.
- All self-test algorithms are selected.

So, the resulting conversion order is:

[A→B→C→AS_step0→AS_step1→AS_step2→A→B→C→AC_step0→A→B→C→AC_step1→A→B→C→AC_step2→.....→A→B→C→AC_step11]→[same sequence repeats]

NOTE

- AS = Algorithm S (supply self-test)
- AC = Algorithm C (capacitive self-test)

57.3.18 Conversion data processing

Raw converted data contains many types of errors, such as offset, gain, and so on. ADC processes raw conversion data before writing the result to a data register, to reduce or eliminate error contributions. The process of error correction happens in parallel with bit-by-bit evaluation, using the correction values generated during the offset determination and calibration process.

The error correction value is subtracted from the raw conversion result whenever the comparator output for one of the calibrated capacitors evaluates high during the conversion period.

To reduce data processing time, error correction is done in parallel during each bit evaluation of a conversion. Lower-weighted capacitors (smaller than C9) are not calibrated, so no error correction is performed for these capacitors. However, they are self-tested to guarantee that the error contribution is below specified accuracy limits.

The final result is checked for any overflow or underflow. When the processed data is above the maximum value that can be represented by ADC resolution, the output data is forced to all 1s (FFFh for 12-bit resolution). Similarly, if the processed data is negative then output data is forced to all 0s (000h for 12-bit resolution).

57.3.19 User-defined offset and gain values

In addition to the ADC-calculated offset value and gain value, ADC enables you to specify another set of offset and gain values in Offset And Gain User (OFSGNUSR). These values must be stored in two's complement format, where the leftmost bit (the most significant bit) is the sign bit.

ADC subtracts these values from the final processed conversion result. The values are used to removed fixed DC bias or any other known errors—for instance those caused by board design, sensors, and so on.

57.4 Clock frequency

ADC's internal blocks are designed for an input clock frequency up to the Fin (Input Signal Bandwidth) maximum (see the ADC electrical specification section in the chip data sheet). The specified speed can be achieved with this clock frequency. If the

input clock frequency exceeds the specified maximum frequency, ADC accuracy degrades and, in the worst case scenario, ADC malfunctions. ADC accuracy also degrades if the input clock frequency is below the specified minimum frequency. Sampling time has an absolute maximum value to guarantee the specified parameters and accuracy. For slower clocks, the sampling clock count must be programmed accordingly.

57.5 Memory map and register definition

ADC has a wide range of configurations to tailor its operation to application requirements. This comes with the drawback of possible corner cases. To avoid unintended behavior, configure ADC before starting a conversion and change any configuration only when ADC is idle, in other words when MSR[ADCSTATUS] = 0.

57.5.1 Transfer error description

The following register accesses cause a transfer error and do not change register content:

- Any access to an unused address.
- Any write access to a read-only register.

Fields

Field	Function
31 OWREN	Overwrite Enable Specifies whether a conversion data register accepts new data before the current conversion data has been read. When enabled, the new conversion result overwrites the older data, regardless of the validity of the older conversion data. When PCDR*n*[VALID] = 1, the conversion data has not been read. 0b - Disable 1b - Enable
30 WLSIDE	Write Left-Aligned Specifies whether conversion data is right-aligned or left-aligned when written to one of the conversion data registers: • PCDR*n* • ICDR0*n* • ECDR*n* Right-aligned data occupies *CDR[14:0]. Left-aligned data occupies *CDR[15:1], 0b - Right aligned

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Left-aligned
29 MODE	Normal Conversion Mode Specifies whether the set of input channels selected for a normal conversion are converted only once per start event or continuously after a start event. If a conversion is done only once, ADC enters an idle state after conversion is complete. For continuous conversion, all input channels selected for the normal conversion are converted continuously in a loop. Stop the loop by writing 0 to NSTART. 0b - Single conversion 1b - Continuous conversion
28 —	Reserved
27 TRGEN	External Trigger Enable Specifies whether the normal trigger input starts a conversion. 0b - Normal trigger input does not start a conversion 1b - Normal trigger input starts a conversion
26 EDGE	External Trigger Edge Selection Selects which edge of the normal trigger input starts a conversion. 0b - Falling edge 1b - Rising edge
25 XSTRTEN	Auxiliary External Start Enable Enables the auxiliary normal trigger source to start a conversion. You can use this field to synchronize the start of a conversion of two ADC instances. 0b - Disable 1b - Enable
24 NSTART	Start Normal Conversion Starts a normal conversion. If the continuous mode is selected (MODE = 1), the value of this field remains 1. Write 0 to this field to stop the in-progress conversion loop after conversion of the last input channel of the selected set of input channels is complete. If continuous mode is not selected (MODE = 0), this field automatically resets to 0 after writing 1. 0b - No effect 1b - Starts conversion
23 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
22 JTRGEN	Injection Trigger Enable Enables the injected trigger input as a source to start a conversion. 0b - Disable 1b - Enable
21 JEDGE	Injected Trigger Edge Selection Selects which edge of the injected trigger input starts an injected conversion. 0b - Falling edge 1b - Rising edge
20 JSTART	Injected Start Interrupts any ongoing normal conversion and starts an injected conversion. This field automatically resets to 0. If an injected conversion is already ongoing, the field value remains 1 until the next injected conversion starts. This field can only be written with 1. 0b - Injected conversion can be started 1b - Starts an injected conversion
19-18 —	Reserved
17 BCTUEN	Body Cross Trigger Unit Enable Enables BCTU as a trigger source. 0b - Disable 1b - Enable
16 BCTU_MODE	Body Cross Trigger Unit Mode Select Specifies whether sources other than BCTU can start a conversion when the BCTU is enabled as a trigger source (BCTUEN = 1). This field is writeable only when ADC is in Power Down state (PWDN = 1). 0b - Only BCTU can trigger conversion 1b - All trigger sources can trigger conversion
15 STCL	Self-Test Configuration Lock Protects the following registers from writing: • STCR1 • STCR2 • STCR3 • STBRR • STAW0R

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• STAW1R • STAW2R • STAW4R • STAW5R 0b - Registers are writeable 1b - Registers are read-only
14-12 —	Reserved
11 AVGEN	Averaging Enable Enables conversion averaging. 0b - Disable 1b - Enable
10-9 AVGS	Averaging Select Specifies the number of conversions ADC uses to calculate the conversion result. 00b - 4 conversions 01b - 8 conversions 10b - 16 conversions 11b - 32 conversions
8 —	Reserved
7 ABORTCHAIN	Abort Chain Aborts the conversion of the selected set of input channels (chain of input channels). The currently ongoing conversion completes. This field always reads 0. This field cannot be programmed during BCTU conversion. **NOTE** This field behaves differently for read and write operations. When reading 0b - Undefined When writing 0b - Conversion continues 1b - Conversion aborted

Table continues on the next page...

Table continued from the previous page...

Field	Function
6 ABORT	Abort Conversion Aborts an ongoing conversion. This field always reads 0 and cannot be written during BCTU conversion. **NOTE** This field behaves differently for read and write operations. When reading 0b - Undefined When writing 0b - Conversion continues 1b - Conversion aborted
5 ACKO	Auto Clock Off Reduces power consumption by turning off the clock of the analog part of ADC when it is in Idle state. 0b - Clock always active 1b - Clock gated
4-3 —	Reserved
2-1 ADCLKSEL	Conversion Clock (AD_clk) Frequency Selection Selects the frequency for the clock signal of the conversion circuit (AD_clk = module clock ÷ ($2^{ADCLKSEL}$)). This field can be written only when ADC is in Power Down state (PWDN = 1). 00b - Module clock frequency 01b - Module clock frequency ÷ 2 10b - Module clock frequency ÷ 4 11b - Module clock frequency ÷ 8
0 PWDN	Power Down Reduces power consumption by turning off power to the analog portion of ADC. 0b - ADC enters a functional state 1b - ADC enters Power Down state

57.5.2.3 Main Status (MSR)

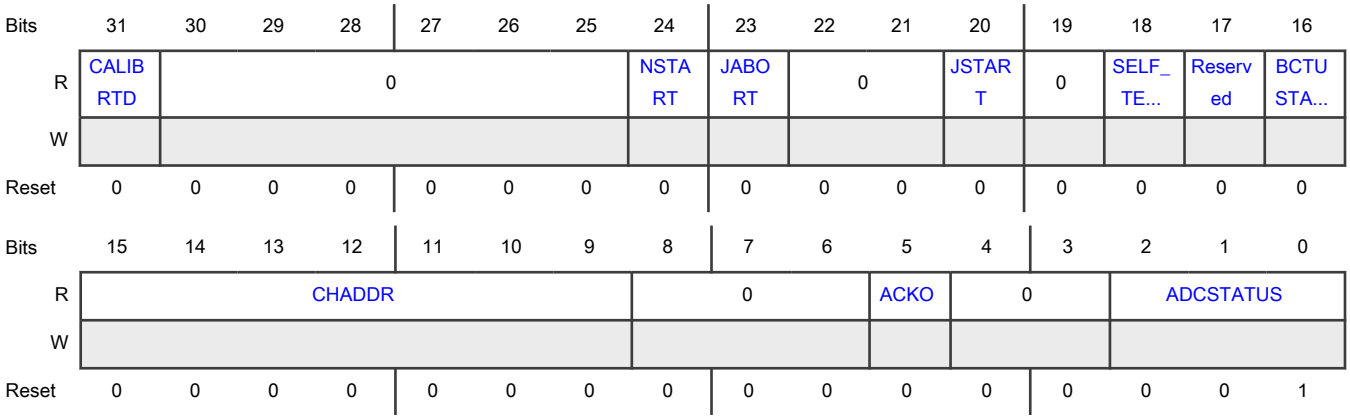
Offset

Register	Offset
MSR	4h

Function

Contains flags that indicate the current ADC state.

Diagram



Fields

Field	Function
31 CALIBRTD	Calibration Status Indicates ADC calibration status. 0b - Uncalibrated or calibration unsuccessful 1b - Calibrated
30-25 —	Reserved
24 NSTART	Normal Conversion Started Shows whether a normal conversion is in progress. 0b - Not in progress 1b - In progress
23 JABORT	Injected Conversion Aborted Indicates whether the conversion of a set of inputs selected for injected conversion has been aborted. This field resets to 0 when a new injected conversion is started. 0b - Not aborted 1b - Aborted
22-21 —	Reserved
20 JSTART	Injected Conversion Started Indicates whether an ongoing conversion was started by the injection trigger.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Not an injected conversion 1b - Injected conversion
19 —	Reserved
18 SELF_TEST_S	Indicates whether an ongoing conversion is for self-test. 0b - Not self-test 1b - Self-test
17 —	Reserved
16 BCTUSTART	BCTU Conversion Started Indicates whether a BCTU conversion is ongoing. This field is 1 when a BCTU trigger event is received and the BCTU conversion starts. When the BCTU trigger mode is selected, this field is automatically reset to 0 when conversion is completed. Otherwise, if BCTU control mode is selected, this field resets to 0 when the BCTU is disabled (BCTUEN = 0). 0b - Conversion was not triggered by BCTU 1b - Ongoing conversion was triggered by BCTU
15-9 CHADDR	Input Under Measure Contains the number of the input that is currently converted. 000_0000b-011_1111b - Input number
8-6 —	Reserved
5 ACKO	Auto Clock-Off On Indicates whether the auto clock-off feature is active, and the conversion circuit is not receiving a clock signal. When auto clock-off is inactive, the conversion circuit is clocked. 0b - Inactive 1b - Active
4-3 —	Reserved
2-0 ADCSTATUS	ADC State Indicates the current state of the ADC Finite State Machine (FSM).

Fields

Field	Function
31-5 —	Reserved
4 EOBCTU	End Of BCTU Conversion

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Indicates the status of the End of BCTU Conversion (EOBCTU) interrupt, which is generated after a BCTU conversion completes. **NOTE** This field behaves differently for read and write operations. When reading 0b - No EOBCTU interrupt generated 1b - EOBCTU interrupt generated When writing 0b - No effect 1b - Clears flag
3 JEOC	End Of Injected Conversion Indicates the status of the End of Injected Conversion (JEOC) interrupt, which is generated after an injected conversion completes. **NOTE** This field behaves differently for read and write operations. When reading 0b - No JEOC interrupt generated 1b - JEOC interrupt generated When writing 0b - No effect 1b - Clears flag
2 JECH	End Of Injected Chain Conversion Indicates the status of the End of Injected Chain (JECH) interrupt, which is generated after injected conversion of a set of inputs completes. **NOTE** This field behaves differently for read and write operations. When reading 0b - No JECH interrupt generated 1b - JECH interrupt generated When writing 0b - No effect 1b - Clears flag
1	End Of Conversion

Table continues on the next page...

Table continued from the previous page...

Field	Function
EOC	Indicates the status of the End of Conversion (EOC) interrupt, which is generated after a normal conversion completes. **NOTE** This field behaves differently for read and write operations. When reading 0b - No EOC interrupt generated 1b - Interrupt generated When writing 0b - No effect 1b - Clears flag
0 ECH	End Of Chain Conversion Indicates the status of the End of Chain (ECH) conversion interrupt, which is generated after a set of inputs has been converted normally. **NOTE** This field behaves differently for read and write operations. When reading 0b - Indicates no ECH interrupt generated 1b - Indicates an ECH interrupt has been generated When writing 0b - No effect 1b - Clears flag

57.5.2.5 Channel End Of Conversion Flag For Precision Inputs (CEOCFR0)

Offset

Register	Offset
CEOCFR0	14h

Function

Contains flags that indicate whether conversion is complete for a precision input.

Offset

Register	Offset
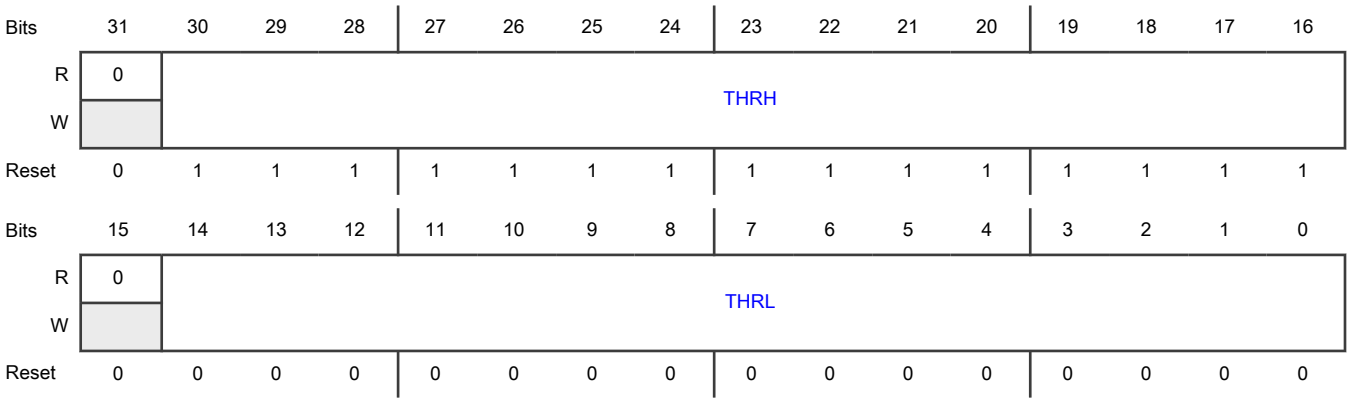
THRHLR0	60h
THRHLR1	64h
THRHLR2	68h
THRHLR3	6Ch

Function
Specifies limits for the valid operating range of a monitored input.

Diagram



Fields

Field	Function
31 —	Reserved
30-16 THRH	High Threshold Value If enabled, flags an interrupt when the converted data of the input is higher than this value.
15	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
14-0 THRL	Low Threshold Value If enabled, flags an interrupt when the converted data of the input is lower than this value.

57.5.2.19 Presampling Control (PSCR)

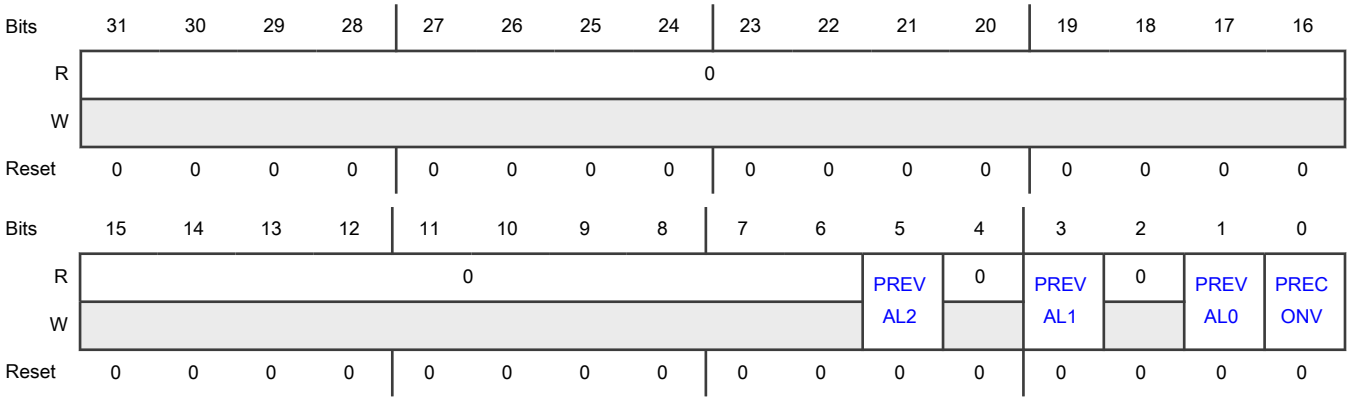
Offset

Register	Offset
PSCR	80h

Function

Configures ADC to presample an internal voltage before the actual input is converted.

Diagram



Fields

Field	Function
31-6 —	Reserved
5 PREVAL2	Presampling Voltage Select For External Inputs Selects the internal voltage that is presampled for external inputs. **NOTE** This field is not supported in every instance. The following table includes only supported registers.

57.5.2.31 Injected Conversion Enable For External Inputs (JCMR2)

Offset

Register	Offset
JCMR2	BCh

Function

Selects the external inputs to be converted during an injected conversion.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
ADC_0	JCMR2	—
ADC_1	JCMR2	—
ADC_2	—	JCMR2

57.5.2.32 Delay Start Of Data Conversion (DSDR)

Offset

Register	Offset
DSDR	C4h

Function

Delays the start of the conversion when another input channel is selected. The necessary delay depends on the device characteristics of, for example, the input channel multiplexer.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
ADC_0	DSDR	—
ADC_1	DSDR	—
ADC_2	—	DSDR

15-0 DSD	Delay Specifies the delay in terms of the number of module clock cycles.

57.5.2.33 Power Down Exit Delay (PDEDR)

Offset

Register	Offset
PDEDR	C8h

Function

Delays the transition out of Power Down into Idle state to wait for necessary settling times. See the device data sheet for the minimal time between the power-down exit request and when ADC can start a conversion.

Fields

Field	Function
31-20 —	Reserved
19 VALID	Conversion Data Available Indicates whether new conversion data is available. This field is automatically reset to 0 when the data is read.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No unread conversion data 1b - Unread conversion data is available
18 OVERW	Overwrite Status Flag Indicates whether the previous conversion data was overwritten without having been read, in which case the overwritten data is lost. The ability to overwrite conversion data is controlled by MCR[OWREN]. 0b - No unread data is overwritten 1b - Unread data is overwritten
17-16 RESULT	Conversion Data Type Indicates the type of trigger that started the conversion for this conversion data. 00b - Normal trigger 01b - Injected trigger 10b - BCTU trigger
15-0 CDATA	Conversion Data Contains conversion data from precision input *n*, determined by the successive approximation algorithm. The conversion data is always 15 bits wide, regardless of the conversion resolution selected (CALBISTREG[RESN]). Depending on the value of MCR[WLSIDE], the conversion data can be in bits [14:0] (MCR[WLSIDE] = 0), or in bits [15:1] (MCR[WLSIDE] = 1).

57.5.2.35 Standard Input n Conversion Data (ICDR0 - ICDR23)

Offset

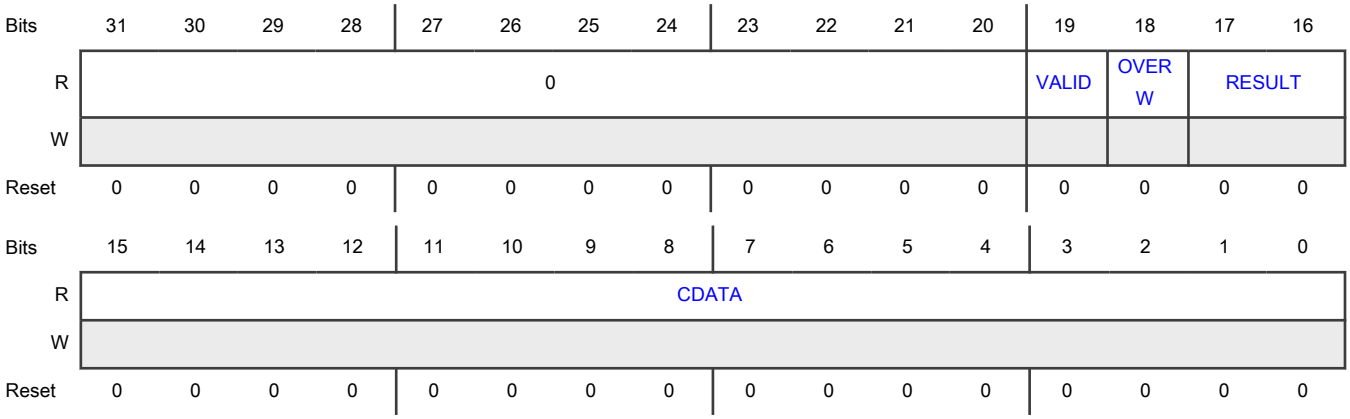
For a = 0 to 23:

Register	Offset
ICDRa	180h + (a × 4h)

Function

Contains conversion data from standard input *n*.

Diagram



Fields

Field	Function

Fields

Field	Function
31-0 AWOR_CHn	Analog Watchdog Out Of Range For External Inputs Indicates whether a data conversion on external input *n* is out of the limits defined by the selected analog watchdog threshold value. **NOTE** This field behaves differently for read and write operations. When reading

Table continues on the next page...

Field	Function
	0b - Conversion is within limits 1b - Conversion is not within limits When writing 0b - No effect 1b - Clears flag

57.5.2.52 Self-Test Configuration 1 (STCR1)

Offset

Register	Offset
STCR1	340h

Function

Specifies the input sampling duration in terms of conversion clock cycles.

Conversion clock frequency depends on the configuration of MCR[ADCLKSEL].

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-24 INPSAMP_C	Input Sampling Time Algorithm C Specifies the sample duration for test conversions related to algorithm C. The minimum acceptable value is 8. Specifying a lower value automatically forces a value of 8.
23-16 —	Reserved
15-8	Input Sampling Time Algorithm S

Table continues on the next page...

Table continued from the previous page...

Field	Function
INPSAMP_S	Specifies sample duration for test conversions related to algorithm S. The minimum value is 8. Specifying a lower value automatically forces a value of 8.
7-0 —	Reserved

57.5.2.53 Self-Test Configuration 2 (STCR2)

Offset

Register	Offset
STCR2	344h

Function

Configures ADC self-test functions.

Diagram

Fields

Field	Function
31-28 —	Reserved
27 MSKWDSERR	Mask Interrupt Self-Test Watchdog Sequence Error Generates an interrupt when the WDSERR flag transitions to 1. 0b - No interrupt is generated 1b - Interrupt is generated

Table continues on the next page...

Table continued from the previous page...

Field	Function
26 SERR	Self-Test Error Injection Writes 1 to the STSR1[ERR_C], STSR1[ERR_S0], STSR1[ERR_S1], and STSR1[ERR_S2] status fields, causing an error. This field is reset to 0 immediately after writing. **NOTE** This field behaves differently for read and write operations. When reading 0b - Error can be injected 1b - Error is being injected When writing 0b - No effect 1b - Injects a self-test error
25 MSKWDTERR	Mask Interrupt Self-Test Watchdog Timer Error Generates an interrupt when the WDTERR flag is set. 0b - No interrupt is generated 1b - Interrupt is generated
24 —	Reserved
23 MSKST_EOC	Mask Interrupt Self-Test End Of Conversion Generates an interrupt when the ST_EOC flag is set. 0b - No interrupt is generated 1b - Interrupt is generated
22-19 —	Reserved
18 MSKWDG_EOA_C	Mask Error Interrupt End Of Algorithm C Generates an interrupt when the WDG_EOA_C flag is set. 0b - No interrupt is generated 1b - Interrupt is generated
17 —	Reserved
16 MSKWDG_EOA_S	Mask Error Interrupt End Of Algorithm S Generates an interrupt when the WDG_EOA_S flag is set.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No interrupt is generated 1b - Interrupt is generated
15 MSKERR_C	Mask Error Interrupt Algorithm C Generates an interrupt when the ERR_C flag is set. 0b - No interrupt is generated 1b - Interrupt is generated
14 —	Reserved
13 MSKERR_S2	Mask Error Interrupt Algorithm S2 Generates an interrupt when the ERR_S2 flag is set. 0b - No interrupt is generated 1b - Interrupt is generated
12 MSKERR_S1	Mask Error Interrupt Algorithm S1 Generates an interrupt when the ERR_S1 flag is set. 0b - No interrupt is generated 1b - Interrupt is generated
11 MSKERR_S0	Mask Error Interrupt Algorithm S0 Generates an interrupt when the ERR_S0 flag is set. 0b - No interrupt is generated 1b - Interrupt is generated
10-8 —	Reserved
7 EN	Self-Test Enable Enables ADC structural self-test. When BCTU is enabled, this field has no effect. This field must be 1 before starting normal conversion and must not be changed during conversion. This field must be reset to 0 only after end of conversion for the last self-test channel has been received. 0b - Disable 1b - Enable
6-5 —	Reserved
4	Fault Mapping Self-Test Watchdog Sequence Error

Table continues on the next page...

Table continued from the previous page...

Field	Function
FMA_WDSERR	Specifies whether a self-test watchdog sequence error sets the flag on the critical or noncritical fault line. 0b - Noncritical fault line 1b - Critical fault line
3 FMA_WDTERR	Fault Mapping Self-Test Watchdog Timer Error Specifies whether a self-test watchdog timer error sets the flag on the critical or noncritical fault line. 0b - Noncritical fault line 1b - Critical fault line
2 FMA_C	Fault Mapping Algorithm C Specifies whether a fault in algorithm C sets the flag on the critical or noncritical fault line. 0b - Noncritical fault line 1b - Critical fault line
1 —	Reserved
0 FMA_S	Fault Mapping Algorithm S Specifies whether a fault in algorithm S sets the flag on the critical or noncritical fault line. 0b - Noncritical fault line 1b - Critical fault line

57.5.2.54 Self-Test Configuration 3 (STCR3)

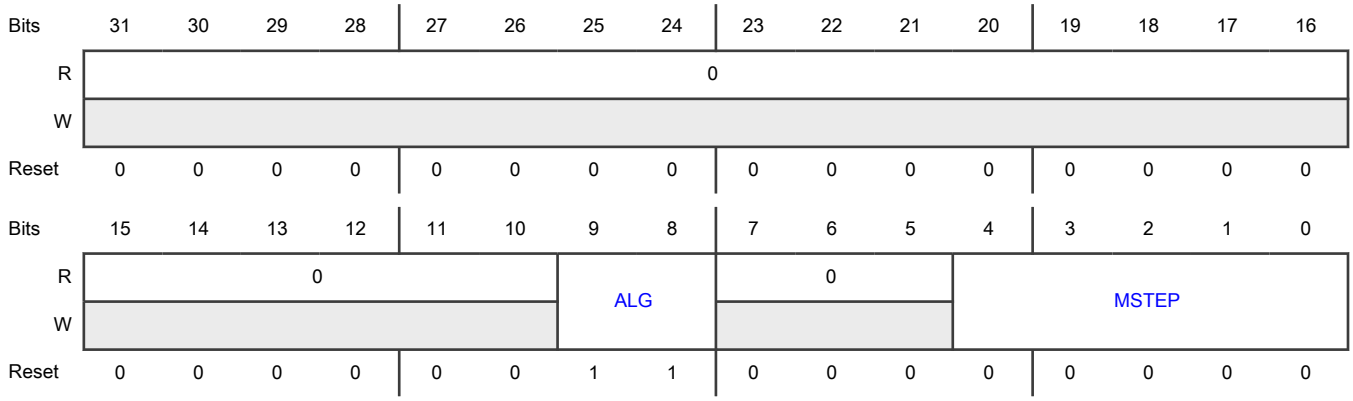
Offset

Register	Offset
STCR3	348h

Function

Configures ADC self-test functions. When BCTU is enabled, writes to the fields registers have no effect. This register must be programmed before starting a conversion and must not be changed when conversion is ongoing.

Diagram



Fields

Field	Function
31-10 —	Reserved
9-8 ALG	Algorithm Selection One-Shot operation mode: • 00 Algorithm S (single step = MSTEP) • 01 Reserved • 10 Algorithm C (single step = MSTEP) • 11 Algorithm S (default) (use for test/debug purposes) Continuous conversion mode: • 00 Algorithm S • 01 Reserved • 10 Algorithm C • 11 Algorithm S + algorithm C (default)
7-5 —	Reserved
4-0 MSTEP	Algorithm Step For One-Shot operation mode: • MSTEP = 0 to 2 for algorithm S • MSTEP = 0 to 11 for algorithm C Unused codes are reserved and must not be used. For Scan operation mode:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field is not used in Scan operation mode because single-step execution (interleaved mode) is always performed. This field must be programmed to zero in Scan operation mode.

57.5.2.55 Self-Test Baud Rate (STBRR)

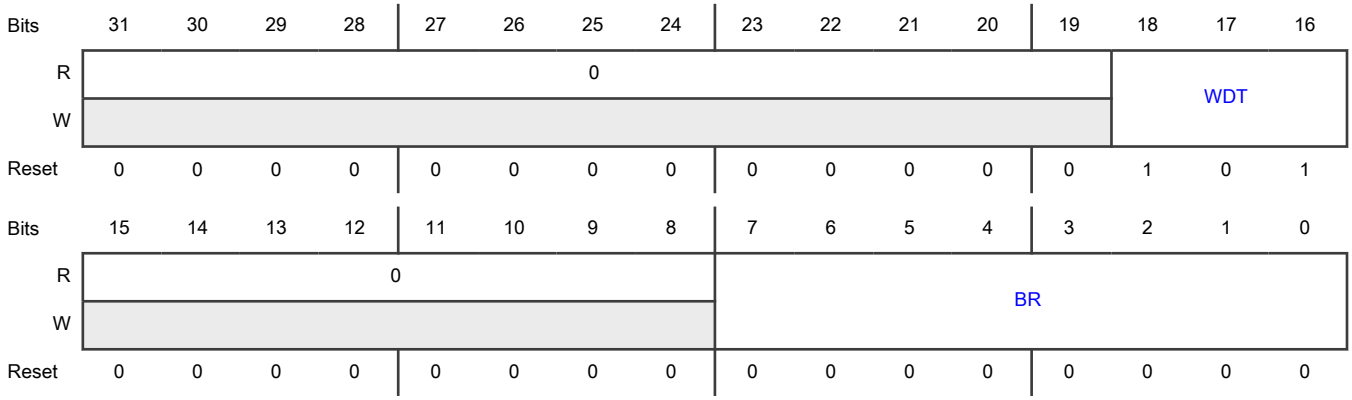
Offset

Register	Offset
STBRR	34Ch

Function

Specifies when the self-test algorithm steps are executed and the maximum time allowed for self-test to finish.

Diagram



Fields

Field	Function
31-19 —	Reserved
18-16 WDT	Self-Test Watchdog Timer Specifies the safe time period in terms of conversion clock cycles. The safe time period is the maximum duration until the running self-test is expected to finish. 000b - 8192 conversion clock cycles (~0.1 ms at 80 MHz) 001b - 39,936 conversion clock cycles (~0.5 ms at 80 MHz) 010b - 79,872 conversion clock cycles (~1 ms at 80 MHz)

Table continues on the next page...

Table continued from the previous page...

Field	Function
	011b - 159,744 conversion clock cycles (~2 ms at 80 MHz) 100b - 400,384 conversion clock cycles (~5 ms at 80 MHz) 101b - 799,744 conversion clock cycles (~10 ms at 80 MHz) 110b - 1,599,488 conversion clock cycles (~20 ms at 80 MHz) 111b - 3,999,744 conversion clock cycles (~50 ms at 80 MHz)
15-8 —	Reserved
7-0 BR	Baud Rate Selects the number of conversions of the selected inputs, after which the next self-test algorithm step executes. This field must be programmed when STCR2[EN] is zero, that is, before enabling self-test. 0000_0000b - A step of the selected self-test algorithm is executed every time after the set of selected inputs has been converted. 1111_1111b - A step of the selected self-test algorithm is executed after the set of selected inputs has been converted 256 times.

57.5.2.56 Self-Test Status 1 (STSR1)

Offset

Register	Offset
STSR1	350h

Function
Indicates self-test status.

Diagram

Fields

Field	Function
31-28 —	Reserved
27 WDSERR	Self-Test Watchdog Sequence Error Indicates whether the selected self-test algorithm has executed in the correct sequence. **NOTE** This field behaves differently for read and write operations. When reading 0b - Algorithm executed in correct sequence 1b - Algorithm did not execute in correct sequence When writing 0b - No effect 1b - Clears flag
26 —	Reserved
25 WDTERR	Self-Test Watchdog Timer Error Indicates whether the self-test algorithm has finished within the defined safe time period. **NOTE** This field behaves differently for read and write operations. When reading 0b - Algorithm finished within the safe time period (or safe time period not yet elapsed). 1b - Algorithm did not finish within safe time period. When writing 0b - No effect 1b - Clears flag
24 OVERWR	Self-Test Error Status Overwrite Indicates whether an error occurred when the respective error status flag (ERR_S0, ERR_S1, ERR_S2, or ERR_C) was set. **NOTE** This field behaves differently for read and write operations. When reading 0b - No self-test error status flag overwritten

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Self-test error status flag overwritten When writing 0b - No effect 1b - Clears flag
23 ST_EOC	Self-Test End Of Conversion Indicates whether a self-test conversion has completed. **NOTE** This field behaves differently for read and write operations. When reading 0b - Not complete 1b - Complete When writing 0b - No effect 1b - Clears flag
22-19 —	Reserved
18 WDG_EOA_C	Self-Test Watchdog End Of Algorithm C Indicates whether self-test algorithm C has completed. **NOTE** This field behaves differently for read and write operations. When reading 0b - Not complete 1b - Complete When writing 0b - No effect 1b - Clears flag
17 —	Reserved
16 WDG_EOA_S	Self-Test Watchdog End Of Algorithm S Indicates whether self-test algorithm S has completed.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for read and write operations. When reading 0b - Not complete 1b - Complete When writing 0b - No effect 1b - Clears flag
15 ERR_C	Error Algorithm C Indicates whether an error occurred during execution of algorithm C. **NOTE** This field behaves differently for read and write operations. When reading 0b - No error 1b - Error When writing 0b - No effect 1b - Clears flag
14 —	Reserved
13 ERR_S2	Error Algorithm S Step 2 Indicates whether an error occurred during execution of step 2 of algorithm S. **NOTE** This field behaves differently for read and write operations. When reading 0b - No error 1b - Error When writing 0b - No effect 1b - Clears flag
12 ERR_S1	Error Algorithm S Step 1 Indicates whether an error occurred during execution of step 1 of algorithm S.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for read and write operations. When reading 0b - No error 1b - Error When writing 0b - No effect 1b - Clears flag
11 ERR_S0	Error Algorithm S Step 0 Indicates whether an error occurred during execution of step 0 of algorithm S. **NOTE** This field behaves differently for read and write operations. When reading 0b - No error 1b - Error When writing 0b - No effect 1b - Clears flag
10 —	Reserved
9-5 STEP_C	Step Of Algorithm C Indicates the step of self-test algorithm C in which an error occurred. Although this register field is read-only, no transfer error is generated when writing to it.
4-0 —	Reserved

57.5.2.57 Self-Test Status 2 (STSR2)

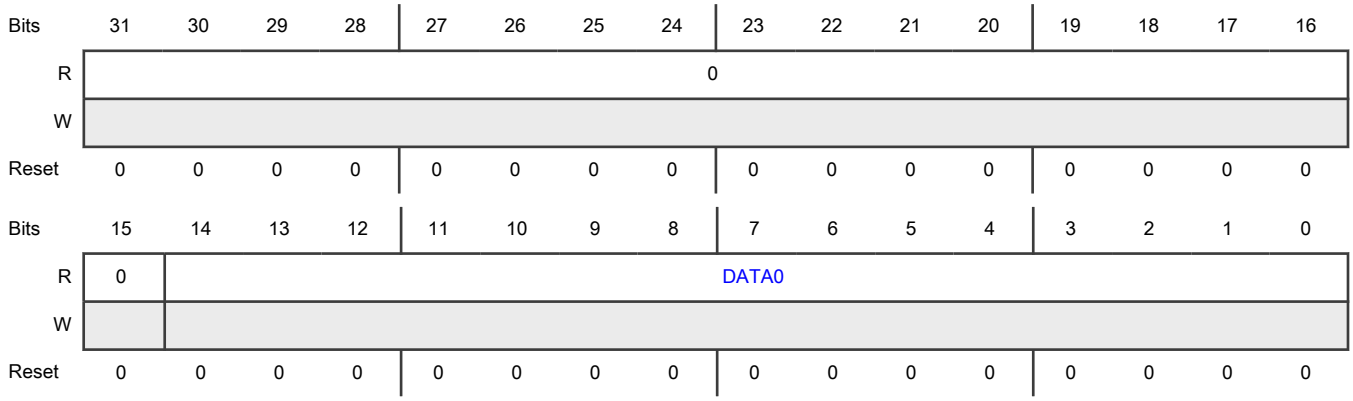
Offset

Register	Offset
STSR2	354h

Function

Contains the conversion result when an error in step 1 of algorithm S has occurred.

Diagram



Fields

Field	Function
31-16 —	Reserved
15 —	Reserved
14-0 DATA0	Conversion Data ERR_S1 Contains conversion data from the moment when the error in step 1 of algorithm S has occurred.

57.5.2.58 Self-Test Status 3 (STSR3)

Offset

Register	Offset
STSR3	358h

Function

Contains the conversion result when an error has occurred in step 2 or step 0 of algorithm S.

Diagram

30-16 DATA1	Conversion Data ERR_C Conversion data from the moment when the error in algorithm C has occurred.
15-0 —	Reserved

57.5.2.60 Self-Test Conversion Data 1 (STDR1)

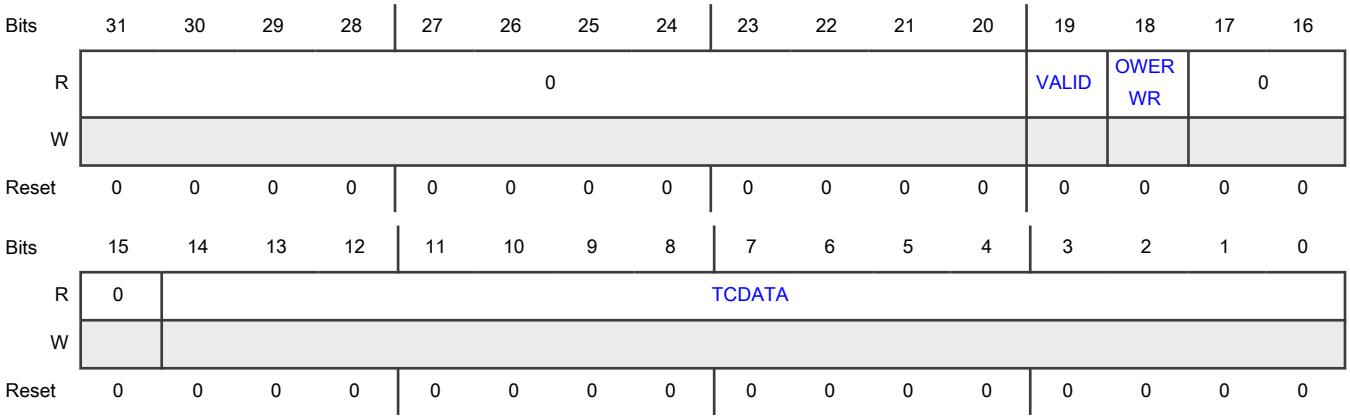
Offset

Register	Offset
STDR1	370h

Function

Contains the result of the self-test conversion.

Diagram



Fields

Field	Function
31-20 —	Reserved
19 VALID	Valid Conversion Data Indicates that conversion data is available in TCDATA. This field is automatically reset to 0 when the conversion data is read. 0b - No unread conversion data 1b - Unread conversion data is available
18 OWERWR	Conversion Data Overwrite Status Indicates whether the conversion data in TCDATA has been overwritten over previous data that had not been read. 0b - Current conversion data not overwritten 1b - Current conversion data was overwritten
17-16 —	Reserved
15 —	Reserved
14-0 TCDATA	Test Channel Conversion Data Contains the conversion data from self-test. If overwrite is enabled (MCR[OWREN]=1), the conversion data is from the last-executed self-test conversion. When overwrite is not enabled, conversion data is available (not overwritten) until it is read by software. The conversion data in this register is in two's complement format.

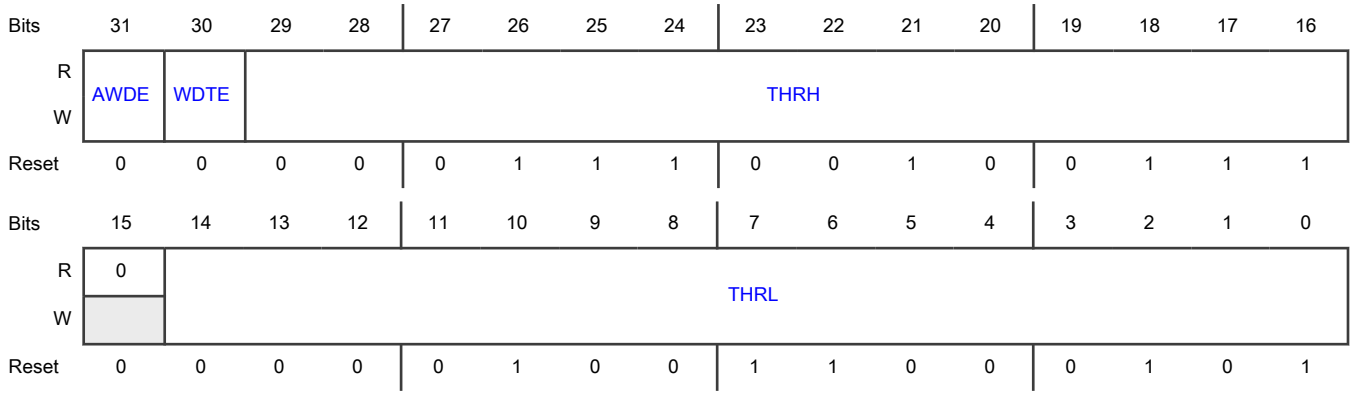
57.5.2.61 Self-Test Analog Watchdog S0 (STAW0R)

Offset

Register	Offset
STAW0R	380h

Function
Configures self-test for step 0 of algorithm S.

Diagram



Fields

Field	Function
31 AWDE	Self-Test Watchdog Enable Enables the self-test watchdog for step 0 of algorithm S. 0b - Disable 1b - Enable
30 WDTE	Self-Test Watchdog Timer Enable Enables the self-test watchdog timer for algorithm S. The self-test watchdog timer verifies: • Correct sequence of execution of the steps of the algorithm • Execution of the algorithm within the safe time period as defined by STBRR[WDT] This field must be 1 only in continuous conversion mode (MCR[MODE]=1). The safe time period starts when this field is written with 1. If the safe time period has elapsed before algorithm S starts, the WDTERR flag is set. The safe time period is restarted each time algorithm S starts. 0b - Disable 1b - Enable
29-16	Higher Threshold Value

Table continues on the next page...

Table continued from the previous page...

Field	Function
THRH	Sets the ERR_S0 flag when a self-test conversion value is greater than this value.
15 —	Reserved
14-0 THRL	Lower Threshold Value Sets the ERR_S0 flag when a self-test conversion value is less than this value.

57.5.2.62 Self-Test Analog Watchdog S1 (STAW1R)

Offset

Register	Offset
STAW1R	388h

Function

Configures self-test for step 1 of algorithm S.

Fields

Field	Function
31 AWDE	Self-Test Watchdog Enable Enables the self-test watchdog for algorithm C. 0b - Disable 1b - Enable
30	Self-Test Watchdog Timer Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
WDTE	Enables the self-test watchdog timer for algorithm C. The self-test watchdog timer verifies: • Correct sequence of execution of algorithm steps • Execution of the algorithm within the safe time period as defined by STBRR[WDT] This field must be 1 only in continuous conversion mode (MODE 1). The safe time period starts when this field is written with 1. If the safe time period elapses before algorithm C starts, the WDTERR flag is set. The safe time period is restarted each time algorithm C starts. 0b - Disable 1b - Enable
29-16 THRH	Higher Threshold Value Sets the ERR_C flag when a self-test conversion value is greater than this value. This value must be in two's complement format and must be positive. This value is valid only for step 0 of algorithm C (see STAW5R for the values used for the other steps of algorithm C).
15 —	Reserved
14-0 THRL	Lower Threshold Value Sets the ERR_C flag when a self-test conversion value is less than this value. This value must be in two's complement format and must be negative. (With the reset value of this bit field, the test always fails. You must set at least STAW4R[14]=1, in order to have a negative value in this bit field.) This value is used only for step 0 of algorithm C (see STAW5R for the values used for the other steps of algorithm C).

57.5.2.65 Self-Test Analog Watchdog C (STAW5R)

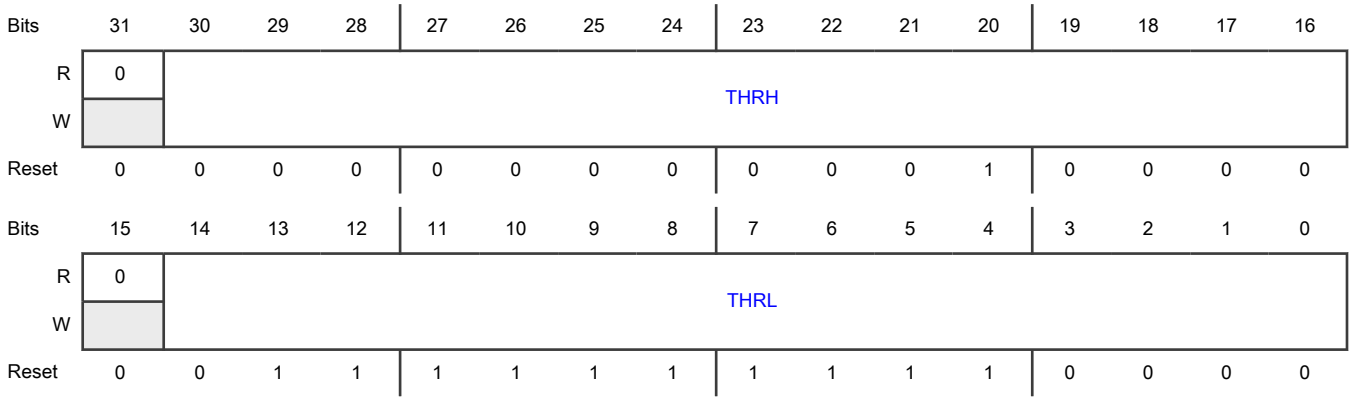
Offset

Register	Offset
STAW5R	398h

Function

Configures self-test for steps 1–11 of algorithm C.

Diagram



Fields

Field	Function
31 —	Reserved
30-16 THRH	Higher Threshold Value Sets the ERR_C flag when a self-test conversion value is greater than this value. This value must be entered in two's complement format and must be positive. This value is valid only for steps 1–11 of algorithm C (see STAW4R for the value used for step 0 of algorithm C).
15 —	Reserved
14-0 THRL	Lower Threshold Value Sets the ERR_C flag when a self-test conversion value is less than this value. This value must be in two's complement format and must be negative. This value is used only for steps 1–11 of algorithm C (see STAW4R for the value used for step 0 of algorithm C).

57.5.2.66 Analog Miscellaneous In/Out register (AMSIO)

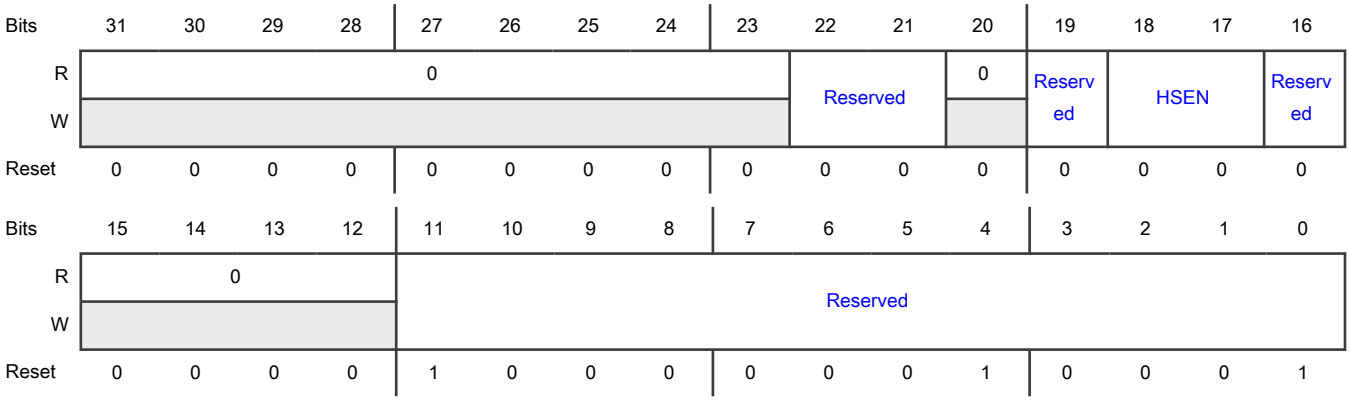
Offset

Register	Offset
AMSIO	39Ch

Function

Configures the SAR algorithm compare step. In case you want to do a high-speed calibration or a high-speed conversion (see Table 270), you must write 3d to HSEN. All other values in this register must stay at their reset value and may not be written.

Diagram



Fields

Field	Function
31-23 —	Reserved
22-21 —	Reserved
20 —	Reserved
19 —	Reserved
18-17 HSEN	High-Speed Enable Enables high-speed conversion or calibration when set. All other bits must always keep their reset value. 00b - Normal conversion speed 11b - High-speed conversion All other values - reserved
16 —	Reserved
15-12 —	Reserved
11-0 —	Reserved

57.5.2.67 Control And Calibration Status (CALBISTREG)

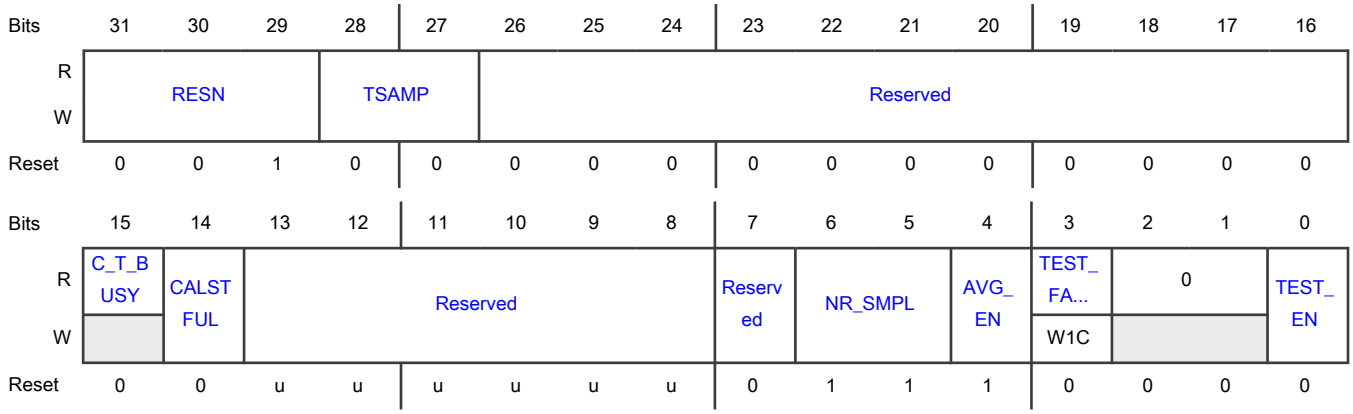
Offset

Register	Offset
CALBISTREG	3A0h

Function

Controls several ADC functions for data conversion, calibration, and calibration status.

Diagram



Fields

Field	Function
31-29 RESN	Conversion Resolution Specifies the number of significant bits per conversion data (functional conversion only, not for calibration or self-test). Reducing this number speeds up the conversion because the SAR algorithm executes fewer steps. This field must be modified only when ADC is idle. 000b - 14-bit resolution 001b - 12-bit resolution 010b - 10-bit resolution 011b - 8-bit resolution
28-27 TSAMP	Sample Period In Calibration Specifies the number of conversion clock cycles during which the reference voltage is sampled. 00b - 22 conversion clock cycles 01b - 8 conversion clock cycles 10b - 16 conversion clock cycles 11b - 32 conversion clock cycles

Table continues on the next page...

Table continued from the previous page...

Field	Function
26-16 —	Reserved The value of this field must not be modified.
15 C_T_BUSY	Calibration Busy Indicates whether calibration is running. 0b - Calibration can be started 1b - Calibration is in progress
14 CALSTFUL	Calibration And Self-Test Full Range Comparison Specifies the range of conversion data bits compared when ADC is calibrated or running self-test. Because the results from calibration and self-test are so low that the significant bits are in the lower 11 bits only, the comparison cycles for the upper 4 bits can be skipped to reduce the execution duration of the calibration and of the self-test. 0b - Lowest 11 bits are compared. 1b - All 15 bits are compared.
13-8 —	Reserved **CAUTION** This field contains a value that ADC uses internally. Writing to this field can cause ADC to operate unreliably.
7 —	Reserved This field is reserved and always has the value 0. Only the reset value can be written to this field.
6-5 NR_SMPL	Calibration Averaging Number Specifies the number of data conversions per result (averaging) during calibration. 00b - 4 samples 01b - 8 samples 10b - 16 samples 11b - 32 samples
4 AVG_EN	Calibration Averaging Enable Enables averaging of the calibration results over several conversion iterations to improve accuracy. This field only affects the calibration process. 0b - Disable 1b - Enable
3 TEST_FAIL	Calibration Status Indicates calibration status. This field reads 0 when calibration is in progress. This field is reset to 0 when calibration starts.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for read and write operations. When reading 0b - Calibration finished successfully or has not been run since the last reset 1b - Calibration did not finish successfully When writing 0b - No effect 1b - Clears flag
2-1 —	Reserved
0 TEST_EN	Calibration Enable Calibrates ADC. This field automatically resets to 0 after the calibration is complete or is interrupted. 0b - Wait to start a calibration 1b - Start calibration

57.5.2.68 Offset And Gain User (OFSGNUSR)

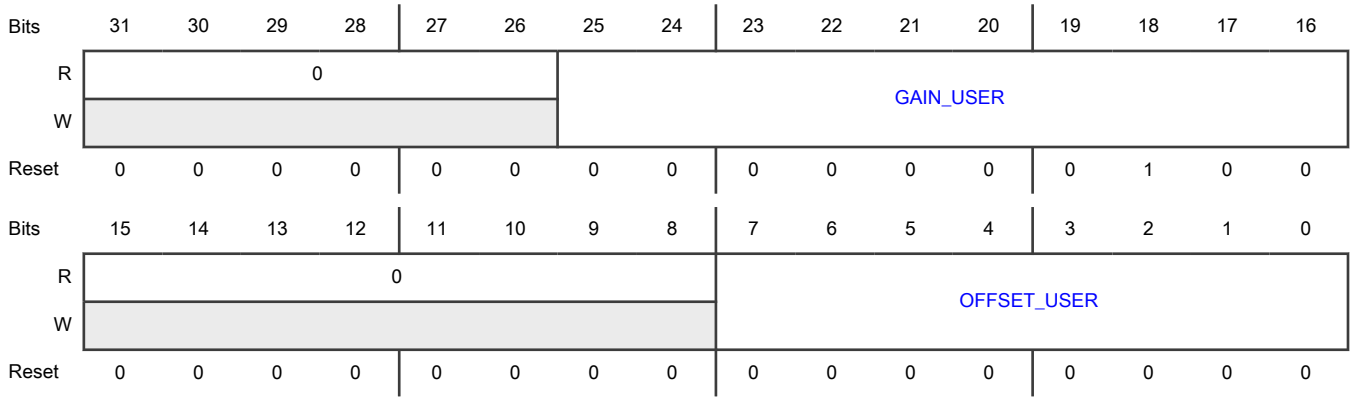
Offset

Register	Offset
OFSGNUSR	3A8h

Function

Specifies the user-configured offset and gain values used by the SAR algorithm. The values must be written in two's complement format and can be either positive or negative.

Diagram



Fields

Field	Function
31-26 —	Reserved
25-16 GAIN_USER	Gain User Adds extra gain to the gain calculated during calibration. The value must be in two's complement format.
15-8 —	Reserved
7-0 OFFSET_USER	Offset User Adds extra offset to the offset calculated by calibration. The value is must be in two's complement format.

57.6 Glossary

CDAC	Capacitive digital to analog converter
CT	Compare phase time
DMA	Direct memory access
DP	Data processing time
PST	Presample phase time
ST	Sample phase time
SAR	Successive approximation
TPT	Trigger processing time
VrefH	Reference voltage high
VrefL	Reference voltage low

Chapter 58
Low Power Comparator (LPCMP)

58.1 Chip-specific LPCMP information

58.1.1 Instantiation information

Table 276. LPCMP instances

Chip	Instance	No. of external inputs
MWCT2D17S	LPCMP_0	8
	LPCMP_1	4
	LPCMP_2	4
MWCT2016S, MWCT2D16S	LPCMP_0	8
	LPCMP_1	4
MWCT2015S	LPCMP_0	8

58.1.2 LPCMP input output connections

See the IOMUX file attached to this document for pin/pad assignments corresponding to CMP pins.

The LPCMP channels can be used as a wakeup source in trigger mode to wakeup the device from standby mode.

58.1.3 LPCMP-DAC "vrefh0" and "vrefh1" references

The 8-bit DAC sub-block supports selection of "vrefh0" and "vrefh1" by CMPx_DCR[VRSEL]. For this device, the references are connected as follows:

- vrefh0 (External Reference): VDD_HV_A
- vrefh1 (Internal Reference): 1.2 V PMC bandgap reference

NOTE

1.2 V internal reference voltage is not available in Standby mode.

58.1.4 LPCMP window control

The window mode operation of all the comparator instances in the chip can be enabled/disabled by the TRGMUX. See the TRGMUX connectivity file attached to this document for details.

NOTE

Window signal must be of minimum 4 cycle pulse for window mode to function.

58.1.5 Comparator Trigger Mode

The comparator modules in the device support trigger mode operation as described in 'Trigger Mode' section. Device can operate in trigger mode in both standby and run mode to continuously scan the input channels. The main features of the device trigger mode operation are:

- Round robin clock: RTC_CLK
- Round robin trigger source: RTC_API

NOTE

It must be ensured that the RTC_CLK period is greater than the comparison time corresponding to the value of C0[PMODE]. It is also required to **not** select the internal reserved channels, if available on the package, for trigger mode operation by INPSEL and INNSEL. See the IOMUX file attached to this document for the pins available in various packages supported for the device.

NOTE

Only SIRC and SXOSC are supported as RTC_CLK for trigger mode operation. The LPCMP initialization delay is not supported by RRCR0[RR_INITMOD] with FXOSC or FIRC as RTC_CLK.

NOTE

In run mode, the generated trigger is delayed by 3 RTC_CLK cycles before being given to comparator trigger input.

58.1.6 Interaction with RTC API to cause wakeup

LPCMP can be used for waking up the chip from standby. For this, RTC-API and LPCMP must be configured before entering into standby mode as per below shown figure.

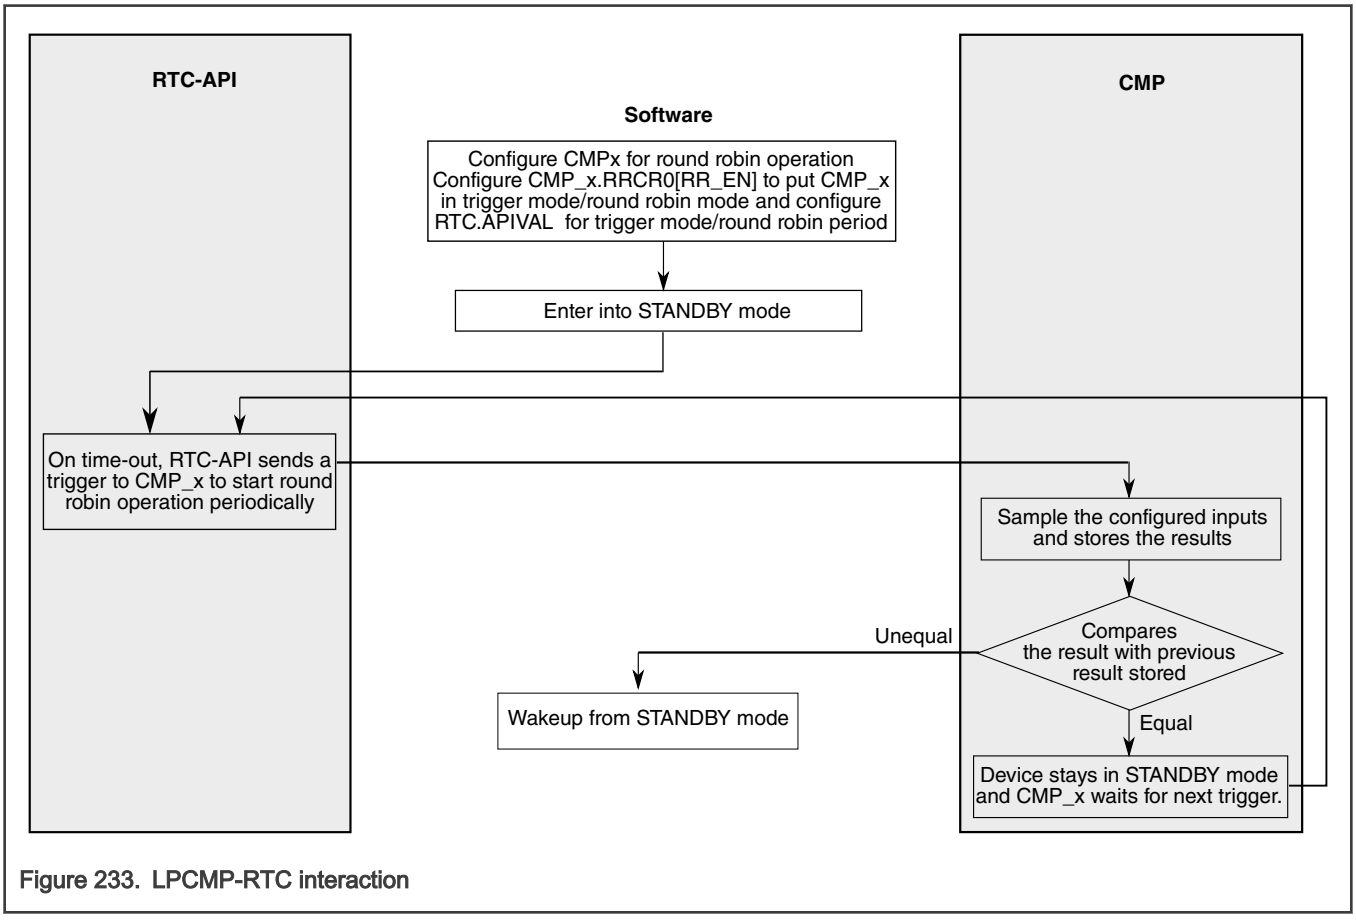

Figure 233. LPCMP-RTC interaction

In the trigger mode operation, only the continuous mode is supported. None of the window/filter/sample functions should be used. Refer to the "Functional Modes" section for details on comparator modes of operation.

Register configurations before entering Standby mode for LPCMP trigger mode operation:

1. Configure RTC.APIVAL to set the period of the round robin operation.
2. Execute standby mode entry.

58.2 Overview

The Low Power Comparator (LPCMP) module provides a circuit for comparing two analog input voltages. It comprises a comparator (CMP), a DAC and an analog mux (ANMUX). See Block diagram for details.

CMP can operate across the full range of the supply voltage, known as rail-to-rail operation.

DAC is a 256-tap resistor ladder network that provides a selectable voltage reference for applications requiring a voltage reference. The 256-tap resistor ladder network divides the supply reference V_{in} into 256 voltage levels. A 8-bit digital signal input selects the output voltage level, which varies from V_{in} to $V_{in}/256$. V_{in} can be selected from two voltage sources, vrefh0 and vrefh1. See the chip-specific LPCMP information for the source of vrefh0 and vrefh1.

NOTE

The LPCMP's internal DAC output is available as an on-chip internal signal only and is not available for an external device pin.

ANMUX allows software to select an analog input signal from among eight channel options. One channel option is the DAC output. Other device resources are connected to the other channels; see the chip-specific LPCMP information section for details. ANMUX can operate across the full range of the supply voltage.

58.2.1 Block diagram

The following figure shows the LPCMP block diagram includes the CMP, DAC, and ANMUX modules.

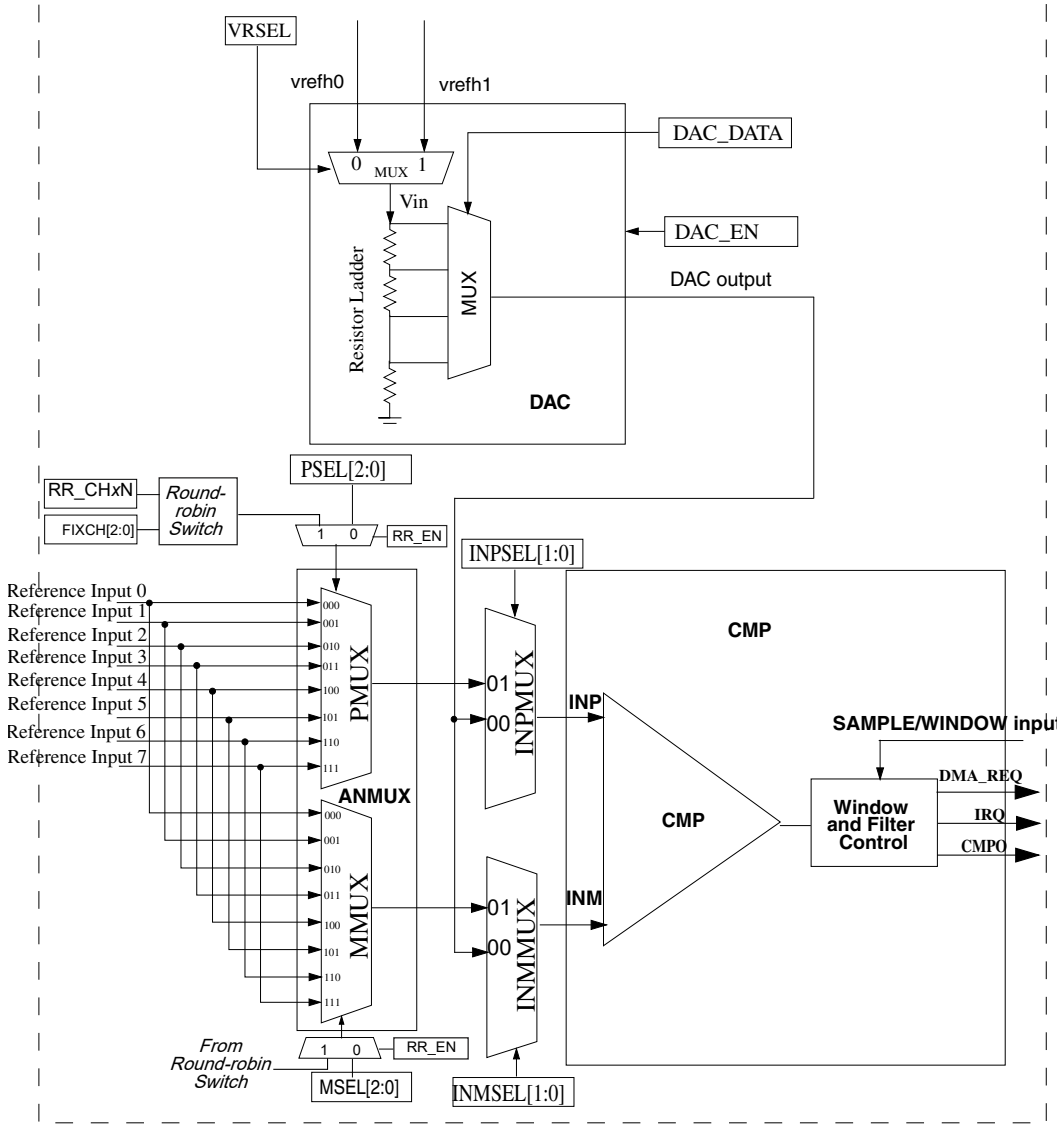

Figure 234. Block Diagram

58.2.2 Features

The features of the LPCMP module include:

- Two 8-to-1 channel MUXes to select input signal from eight channels
- Multiple operation modes to produce a wide range of outputs such as:
  - Sampled
  - Windowed, which is ideal for certain PWM zero-crossing-detection applications
  - Digitally Filtered
- Advanced feature for window and sample
  - WINDOW/SAMPLE signal can be inverted
  - Window can be closed by CMPO rising, falling or both edges

— User can define CMPO level, when window is closed

- Selectable performance levels: low power(speed) mode, high power(speed) mode
- Programmable hysteresis control
- Selectable inversion on comparator output
- External hysteresis can be used at the same time that the output filter is used for internal functions
- Interrupt and DMA support
- Trigger mode
- Includes a 8-bit resolution DAC
- Selectable supply reference source for DAC

58.3 Functional Description

58.3.1 Functional Block Diagram

The following figure shows the functional block diagram.

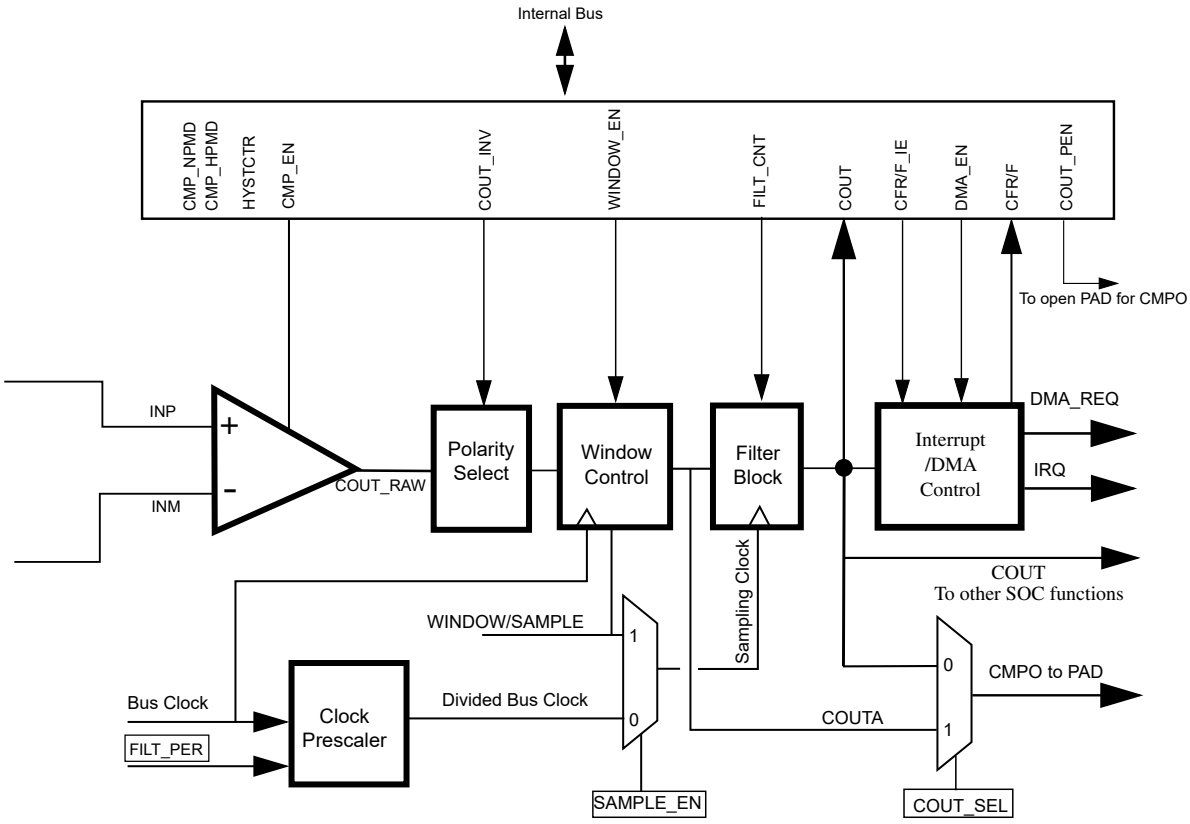

Figure 235. Functional Block Diagram

In the block diagram:

- Two analog input voltages applied to INP and INM are compared. COUT_RAW is high when the INP input voltage is greater than the INM input, and is low when the INP input voltage is less than the INM input.
- This COUT_RAW signal can be inverted if CCR1[COUT_INV] is enabled.

- If CCR1[WINDOW_EN] is enabled, the optionally inverted comparator output COUT_RAW is sampled on every bus clock when window is enabled to generate COUTA. Sampling does NOT occur when window is disabled. This feature can be used to ignore the comparator output during time periods in which the input voltages are not valid. This is especially useful when implementing zero-crossing-detection for certain PWM applications.
- The window control block can be bypassed if CCR1[WINDOW_EN] is disabled.
- The filter block acts as a simple sampler if CCR1[FILT_CNT] is set to 0x01.
- The filter block acts as a filter based on multiple samples when CCR1[FILT_CNT] is set greater than 0x01.
  - If CCR1[SAMPLE_EN] = 1, the external SAMPLE input is used as the sampling clock.
  - If CCR1[SAMPLE_EN] = 0, the divided bus clock is used as the sampling clock.
- The filter block can be bypassed when not in use.

```
Bypass_Filter_Block = (FILT_CNT == 0x00) |  (~SAMPLE_EN & (FILT_PER == 0x00))
```

- Both COUTA and COUT can be configured as module output CMPO by configuring the CCR1[COUT_SEL] bit and are used for different purposes within the system.
- The optionally filtered COUT can be read directly through register bit CSR[COUT].
- The SAMPLE/WINDOW signal can be inverted by setting CCR1[WINDOW_INV].
- The SAMPLE/WINDOW signal can be closed by CMPO's falling edge or rising edge or both edge by setting CCR1[WINDOW_CLS] in window mode.
- In the window mode, when window is closed, COUTA value can be defined as CCR1[COUTA_OW] by setting CCR1[COUTA_OWEN]. If CCR1[COUTA_OWEN] is not set, COUTA holds the last sampled value when window is closed

NOTE

See the chip configuration section for the source of SAMPLE/WINDOW input.

58.3.2 Functional Modes

The comparator window and filter features can be combined as shown in the following table. Individual modes are discussed below the table.

Table 277. Functional modes

Mode #	CMP_EN	WINDOW_EN	SAMPLE_EN	FILT_CNT	FILT_PER	Operation	Maximum latency[1]
1	0	X	X	X	X	See the Disabled Mode (#1).	N/A
2A	1	0	X	0x00	X	See the Continuous Mode (#2A & 2B).	T_{PD}
2B	1	0	0	X	0x00		
3A	1	0	1	0x01	X	See the Sampled, Non-Filtered Mode (#3A & 3B).	$T_{PD} + T_{SAMPLE} + 3T_{per}$
3B	1	0	0	0x01	> 0x00		$T_{PD} + (FILT\_PER * T_{per}) + 3T_{per}$
4A	1	0	1	> 0x01	X	See the Sampled, Filtered Mode (#4A & 4B).	$T_{PD} + (FILT\_CNT * T_{SAMPLE}) + 3T_{per}$

Table continues on the next page...

Table 277. Functional modes (continued)

Mode #	CMP_EN	WINDOW_EN	SAMPLE_EN	FILT_CNT	FILT_PER	Operation	Maximum latency[1]
4B	1	0	0	> 0x01	> 0x00		T_{PD} + (FILT_CNT * FILT_PER x T_{per}) + 3T_{per}
5A	1	1	0	0x00	X	See the Windowed Mode (#5A & 5B).	T_{PD} + 2T_{per}
5B	1	1	0	X	0x00		
6	1	1	0	0x01	> 0x00	See the Windowed/ Resampled Mode (#6).	T_{PD} + (FILT_PER * T_{per}) + 3T_{per}
7	1	1	0	> 0x01	> 0x00	See the Windowed/Filtered Mode (#7).	T_{PD} + (FILT_CNT * FILT_PER x T_{per}) + 3T_{per}
All other combinations of CMP_EN, WINDOW_EN, SAMPLE_EN, FILT_CNT, FILT_PER are illegal.							

1. T_{PD} represents the intrinsic delay of the analog component plus the polarity select logic. T_{SAMPLE} is the clock period of the external sample clock. T_{per} is the period of the bus clock.

58.3.2.1 Disabled Mode (#1)

In disabled mode, the analog comparator is non-functional and consumes no power. CSR[COUT] and CMPO is same as CCR1[COUT_INV] in this mode.

58.3.2.2 Continuous Mode (#2A & 2B)

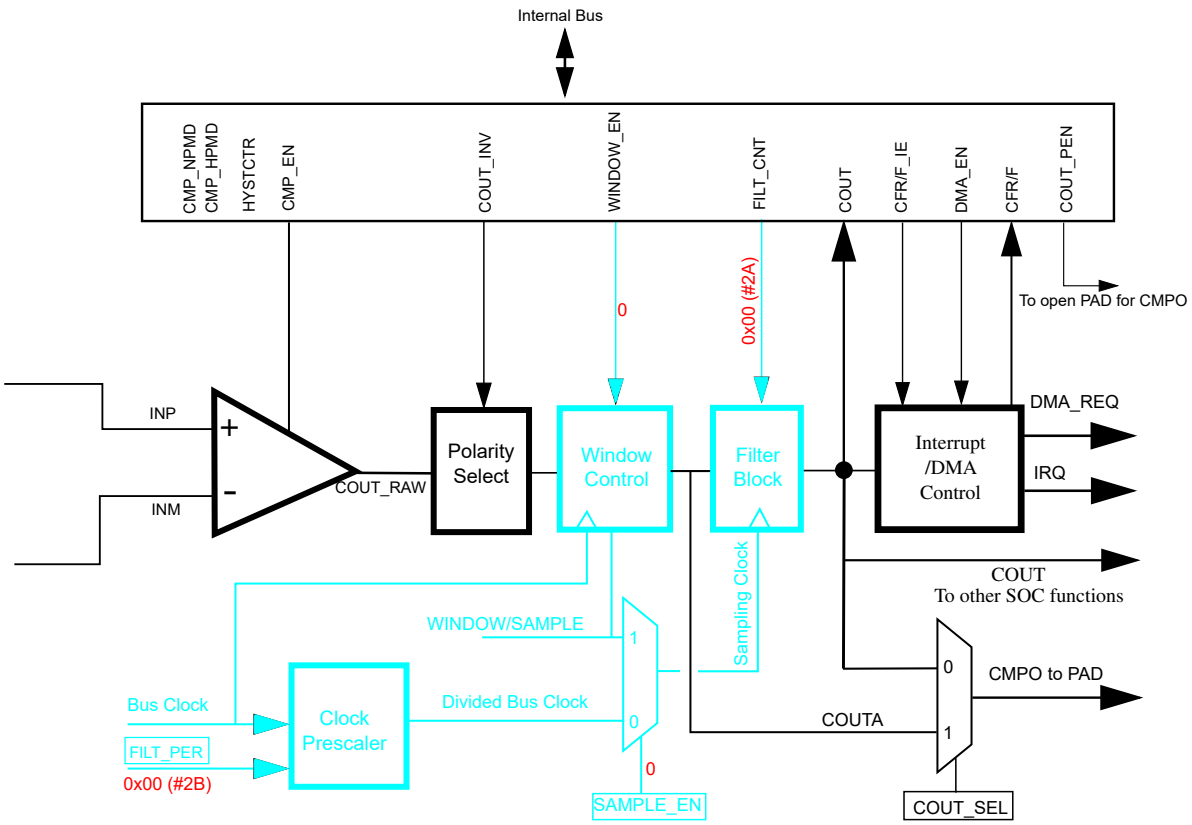

Figure 236. Comparator Operation in Continuous Mode

In this mode, COUT_RAW may be optionally inverted, but is not subject to external sampling or filtering. Both window control and filter blocks are completely bypassed. CSR[COUT] is updated continuously. The path from comparator input pins to output pin is operating in combinational(unclocked) mode. COUT and COUTA are identical.

For cases where a comparator is used to drive a fault input, for example, for a motor-control module such as FTM, it should generally be configured to operate in continuous mode so that an external fault can immediately pass through the comparator to the target fault circuitry.

58.3.2.3 Sampled, Non-Filtered Mode (#3A & 3B)

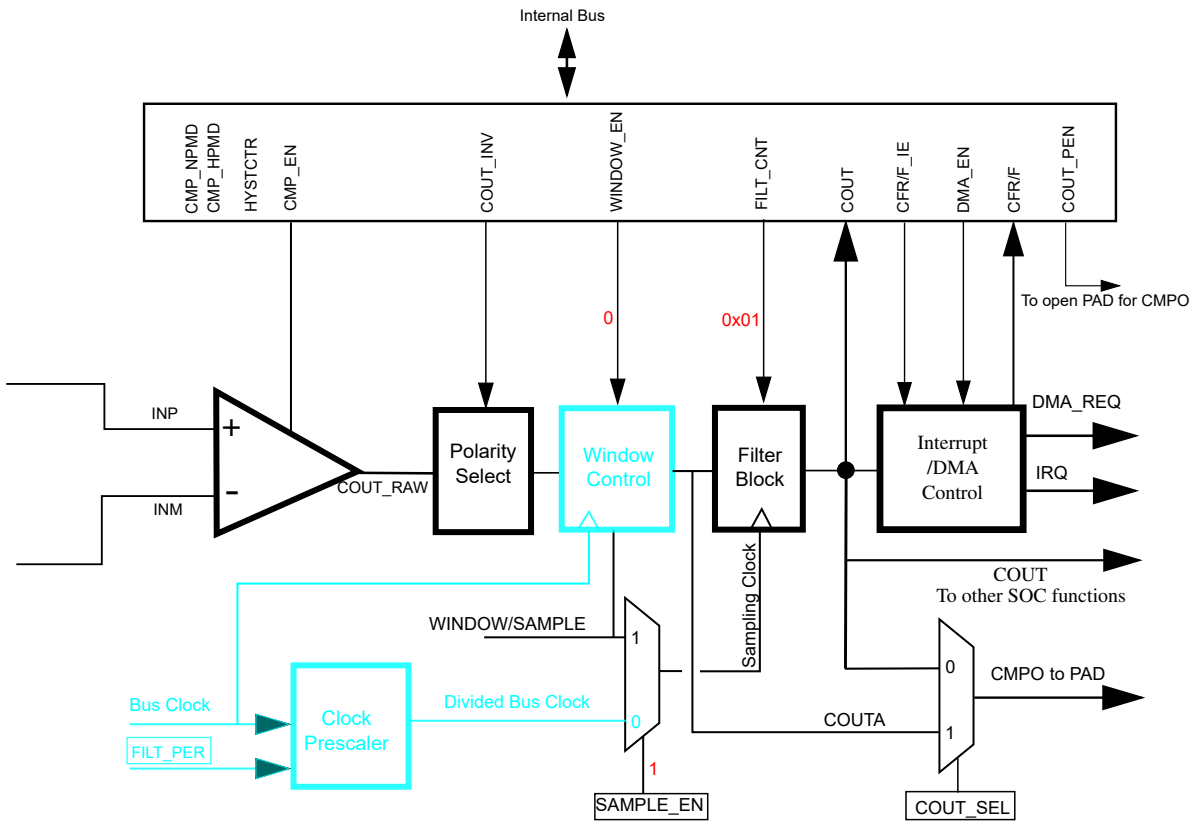

Figure 237. Sampled, Non-Filtered (#3A): Sampling Point Externally Driven

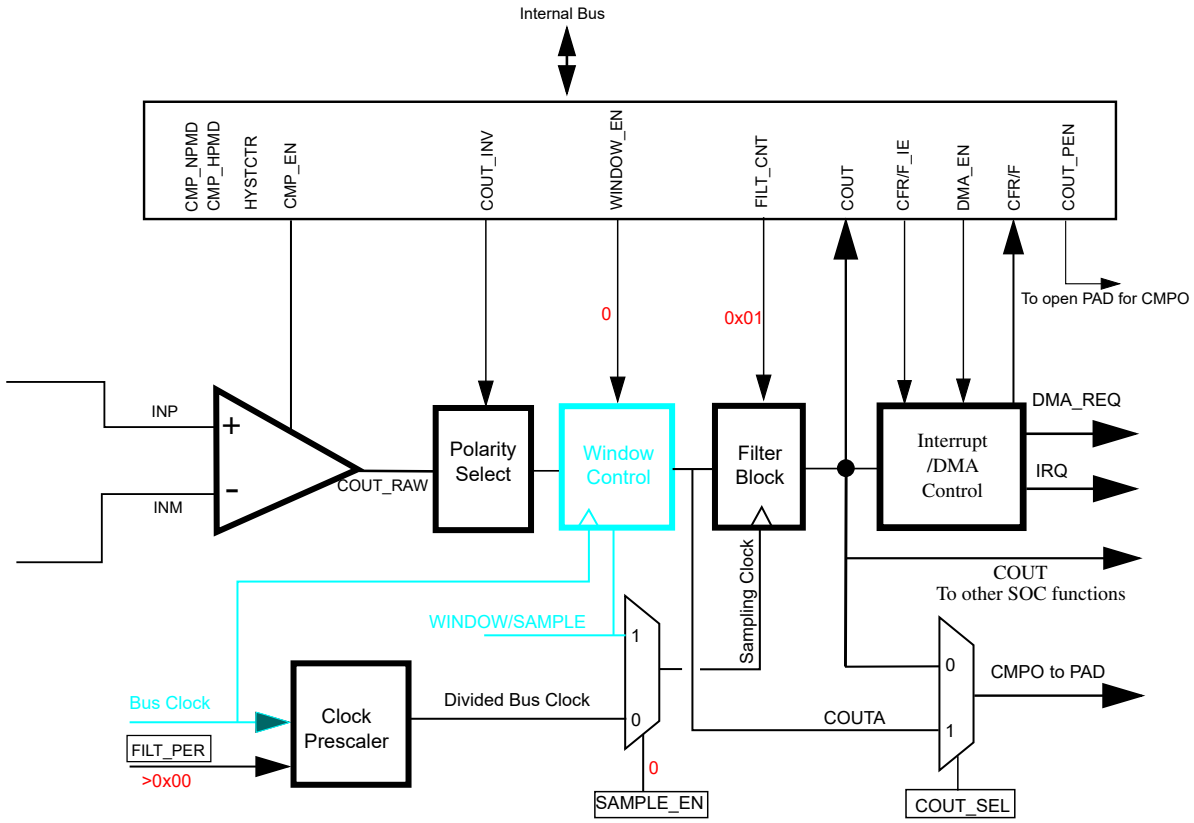

Figure 238. Sampled, Non-Filtered (#3B): Sampling Interval Internally Derived

In this mode, the path from analog inputs to COUTA is combinational(unclocked). Windowing control is completely bypassed. COUTA is sampled whenever a rising edge is detected on the sampling clock.

The only difference in operation between sampled, non-filtered (#3A) and sampled, non-filtered (#3B) is in how the clock to the filter block is derived. In #3A, the clock to filter block is externally derived while in #3B, the clock to filter block is internally derived.

The filter block has no other function than sample/hold of the comparator output in this mode.

The following figure illustrates comparator operation in this mode, assuming that the polarity select is set to non-inverting state.

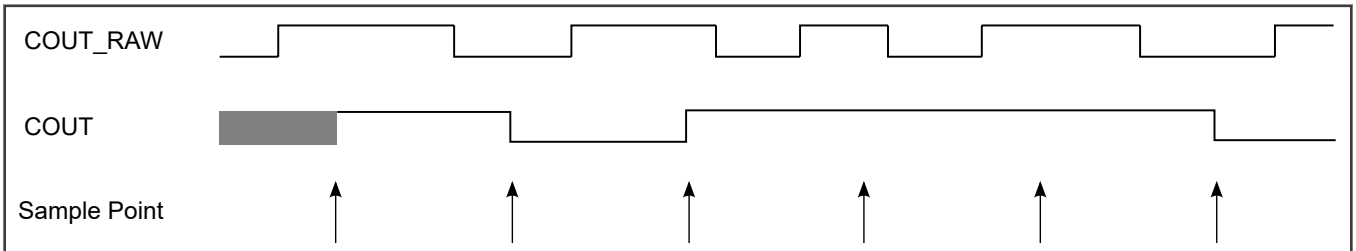

Figure 239. Sampled, Non-Filtered Mode Timing Diagram

58.3.2.4 Sampled, Filtered Mode (#4A & 4B)

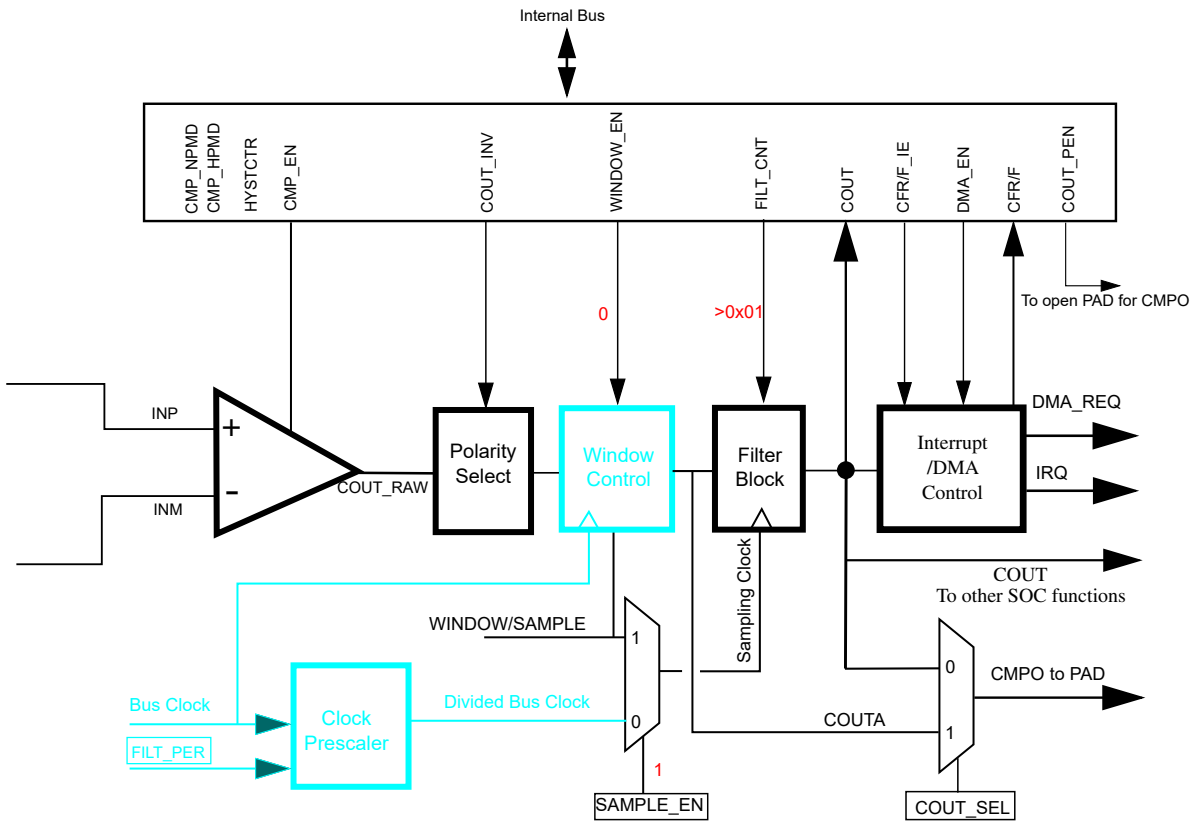

Figure 240. Sampled, Filtered (#4A): Sampling Point Externally Driven

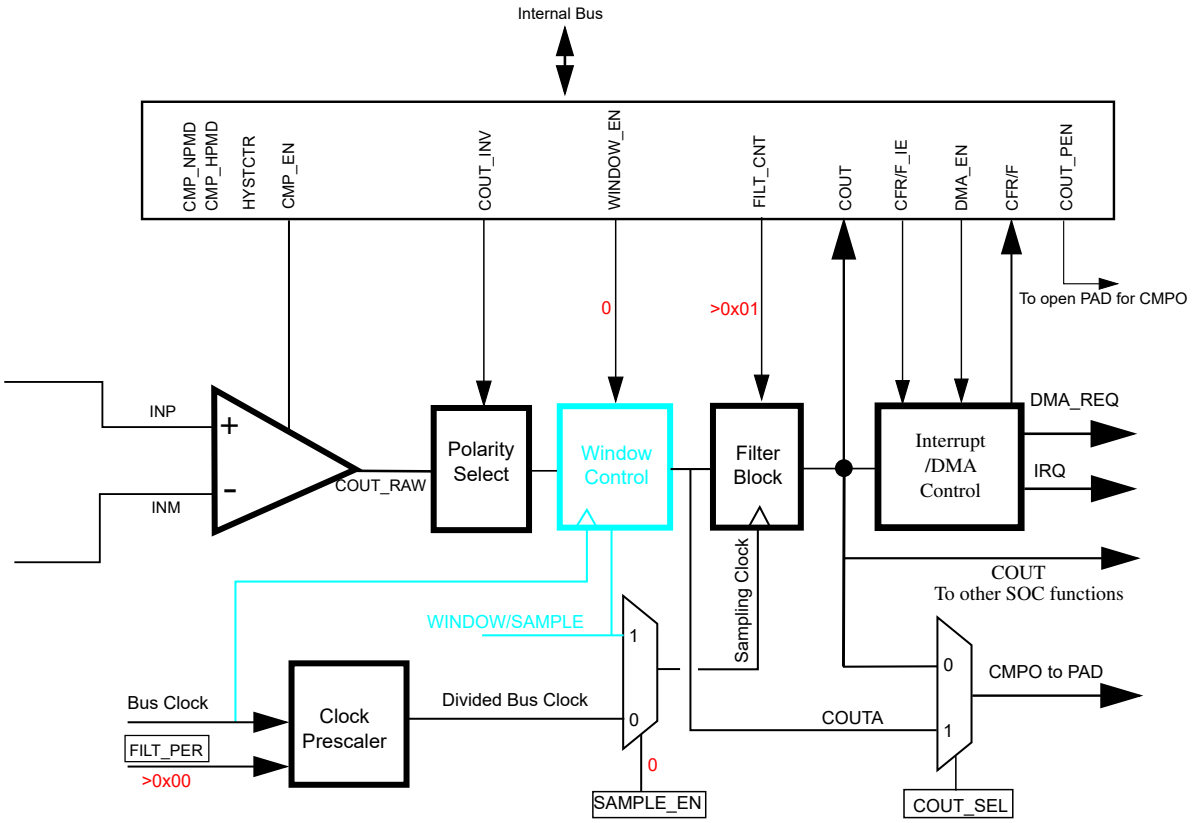

Figure 241. Sampled, Filtered (#4B): Sampling Point Internally Derived

In this mode, the path from analog inputs to COUTA is combinational(unclocked). Windowing control is completely bypassed. COUTA is sampled whenever a rising edge is detected on the sampling clock.

The only difference in operation between sampled, non-filtered (#3A) and sampled, filtered (#4A) is that, now, CCR1[FILT_CNT]>1, which activates filter operation.

The only difference in operation between sampled, non-filtered (#3B) and sampled, filtered (#4B) is that now, CCR1[FILT_CNT]>1, which activates filter operation.

58.3.2.5 Windowed Mode (#5A & 5B)

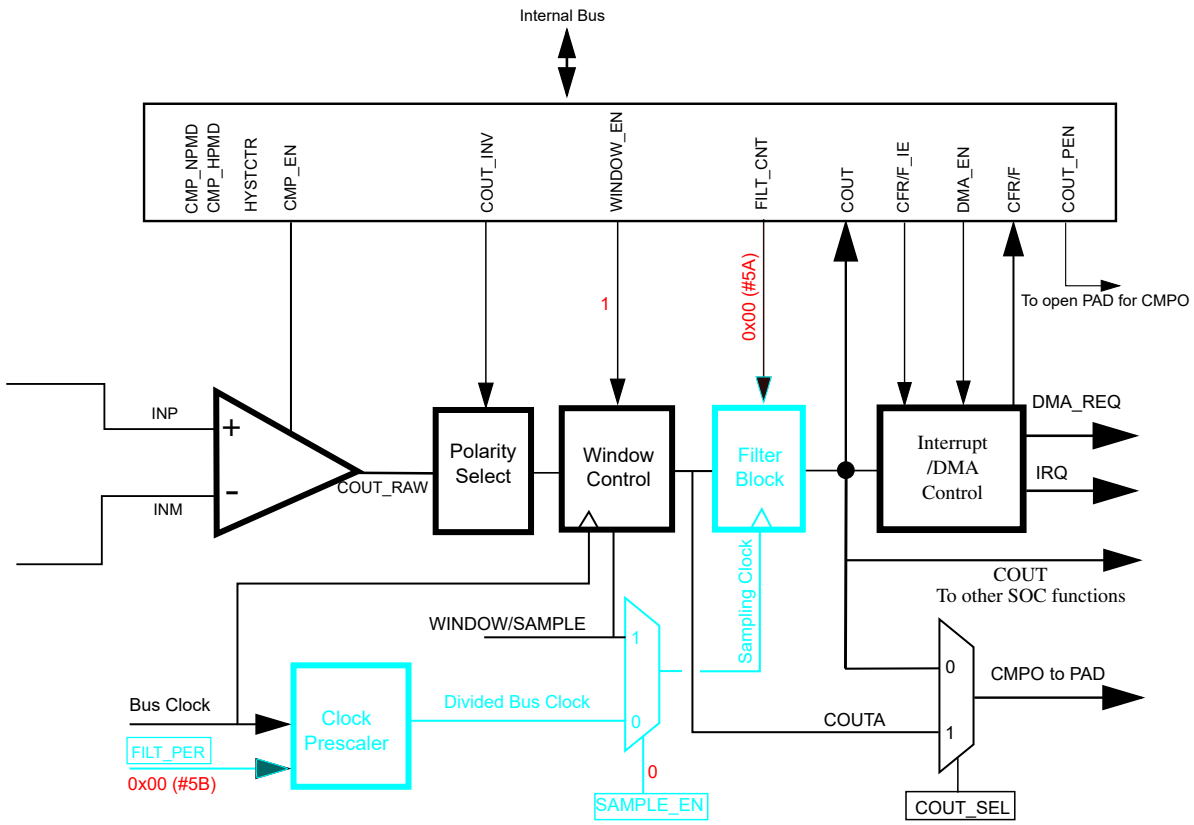

Figure 242. Windowed Mode

In this mode, COUTA is clocked by the bus clock whenever window is enabled. The last latched value is held when window is disabled. The filter block is bypassed.

The following figure illustrates comparator operation in this mode, ignoring latency of the analog comparator, polarity select, and window control block. It also assumes that the polarity select is set to non-inverting state.

In actual operation, COUTA may lag the analog inputs by up to two bus clock cycles plus the combinational path delay through the comparator and polarity select logic.

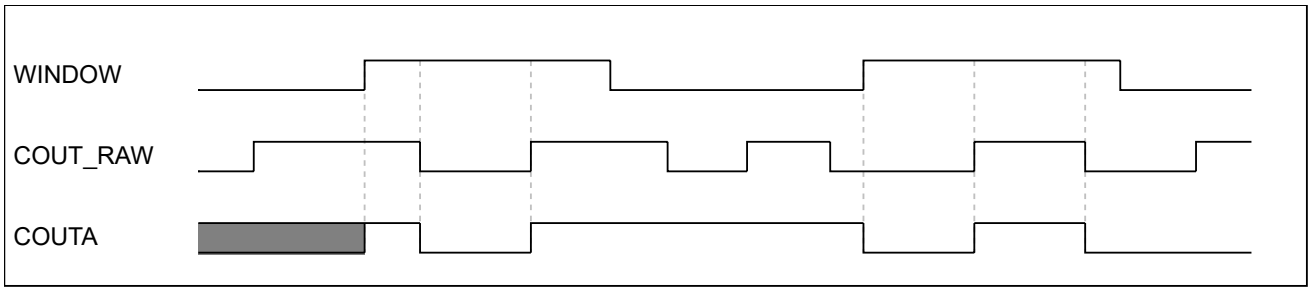

Figure 243. Windowed Mode Timing Diagram

If CCR1[COUTA_OWEN] is set, user can define COUTA level as CCR1[COUTA_OW], when window is closed. Following figures show this case.

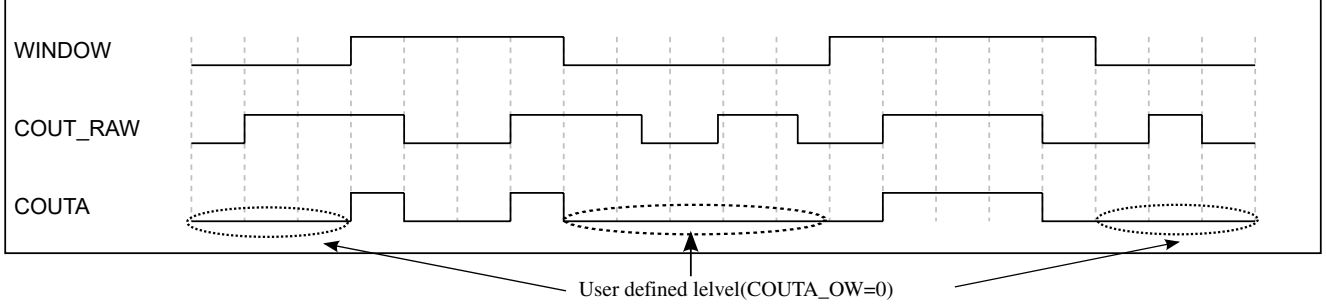

Figure 244. Windowed Mode Timing Diagram With User Defined Value 0 outside WINDOW

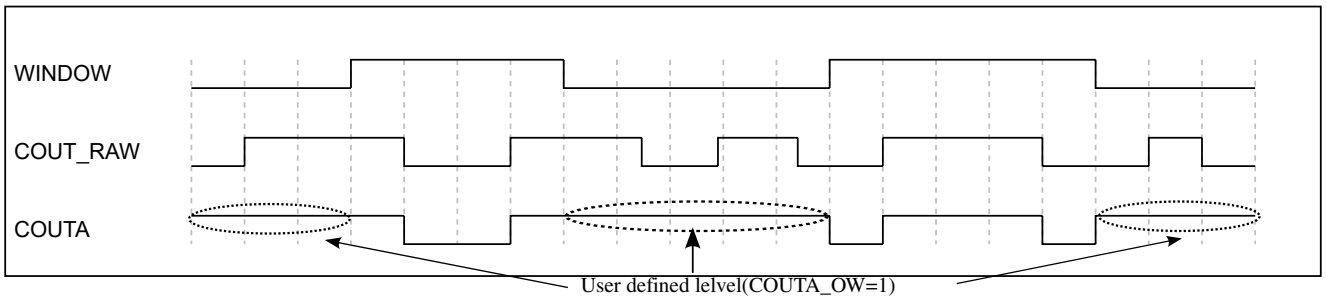

Figure 245. Windowed Mode Timing Diagram With User Defined Value 1 outside WINDOW

NOTE

Obviously, when the window is open, COUT_A will switch from COUTA_OW to COUT_RAW. When the window is closed, COUT_A will switch from COUT_RAW to COUTA_OW. This may generate unnecessary transition flags, CFR or CFF. User needs to choose COUTA_OW carefully according to the actual application, and select the appropriate flag CFR or CFF to generate interrupt.

If CCR1[WINDOW_CLS] is set, user can define the CMPO event (rising, falling or both edges, selected by CCR1[EVT_SEL]) to close the window. The external WINDOW signal has to go to zero and back to one to enable the internal window again. Following figure shows an example that CMPO rising edge close the internal window.

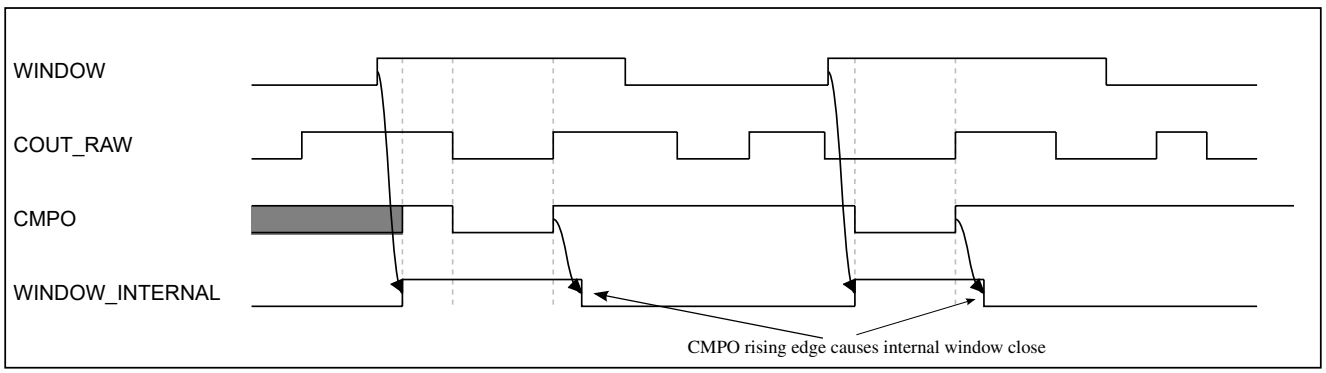

Figure 246. Windowed Mode Timing Diagram With CMPO Rising Edge Close Window

If CCR1[WINDOW_INV] is set, user can invert the window signal before it is used. The following figure shows this case.

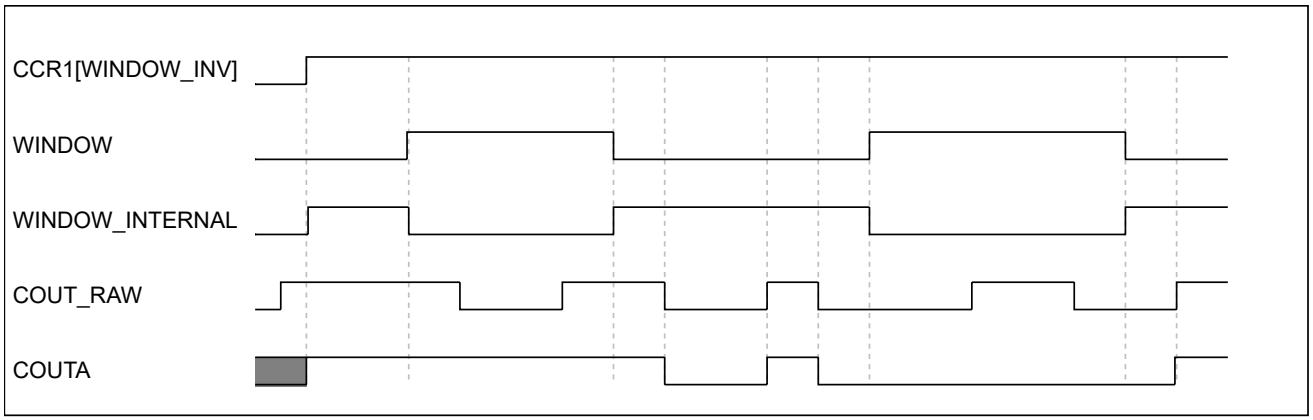

Figure 247. Windowed Mode Timing Diagram With WINDOW Signal Inverted.

58.3.2.6 Windowed/Resampled Mode (#6)

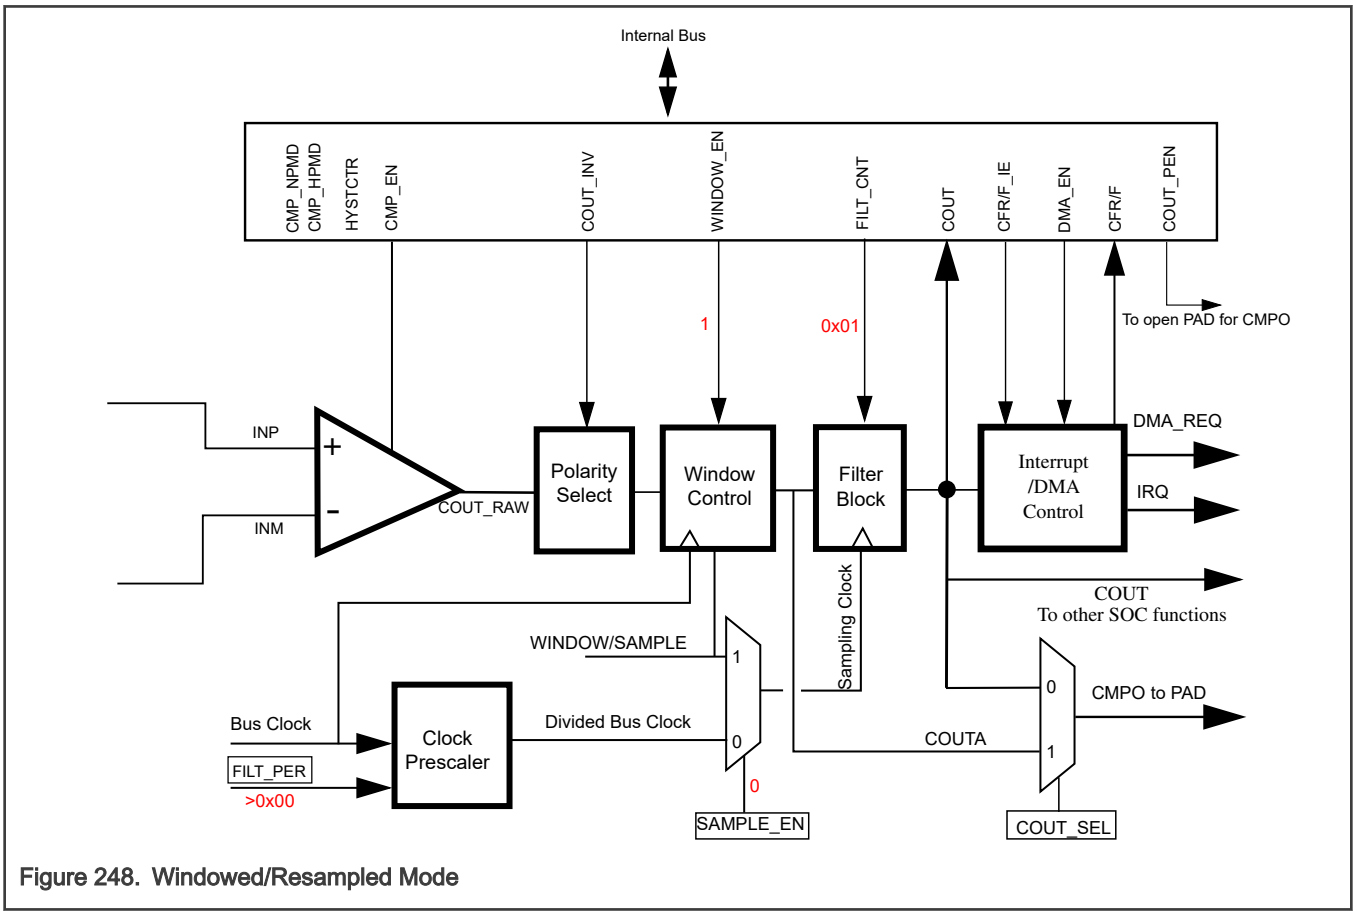

Figure 248. Windowed/Resampled Mode

This mode of operation results in an unfiltered string of comparator samples where the interval between the samples is determined by CCR1[FILT_PER] and the bus clock rate. Configuration for this mode is virtually identical to that for the windowed/filtered mode shown in the next section. The only difference is that the value of CCR1[FILT_CNT] in this mode must be 1.

The following figure uses the same input stimulus shown in Figure 243, and adds resampling of COUTA to generate COUT. Samples are taken at the time points indicated by the arrows in the figure. Again, prop delays and latency are ignored for the sake of clarity.

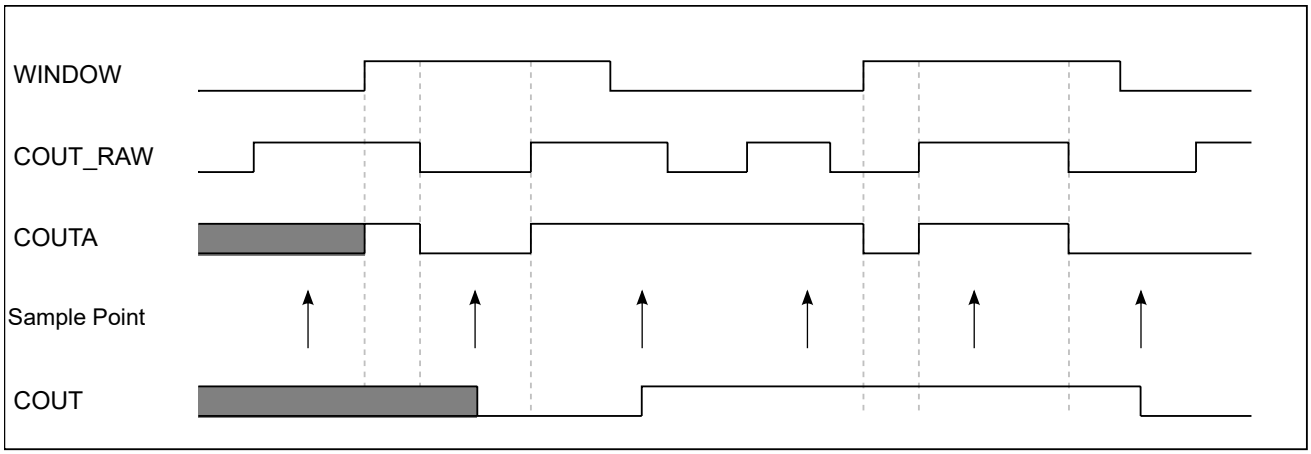

Figure 249. Windowed/Resampled Mode Operation

This example was generated solely to demonstrate operation of the comparator in windowed/resampled mode, and does not reflect any specific application. Depending upon the sampling rate and window placement, COUT may not see zero-crossing events detected by the analog comparator. Sampling period and/or window placement must be carefully considered for a given application.

58.3.2.7 Windowed/Filtered Mode (#7)

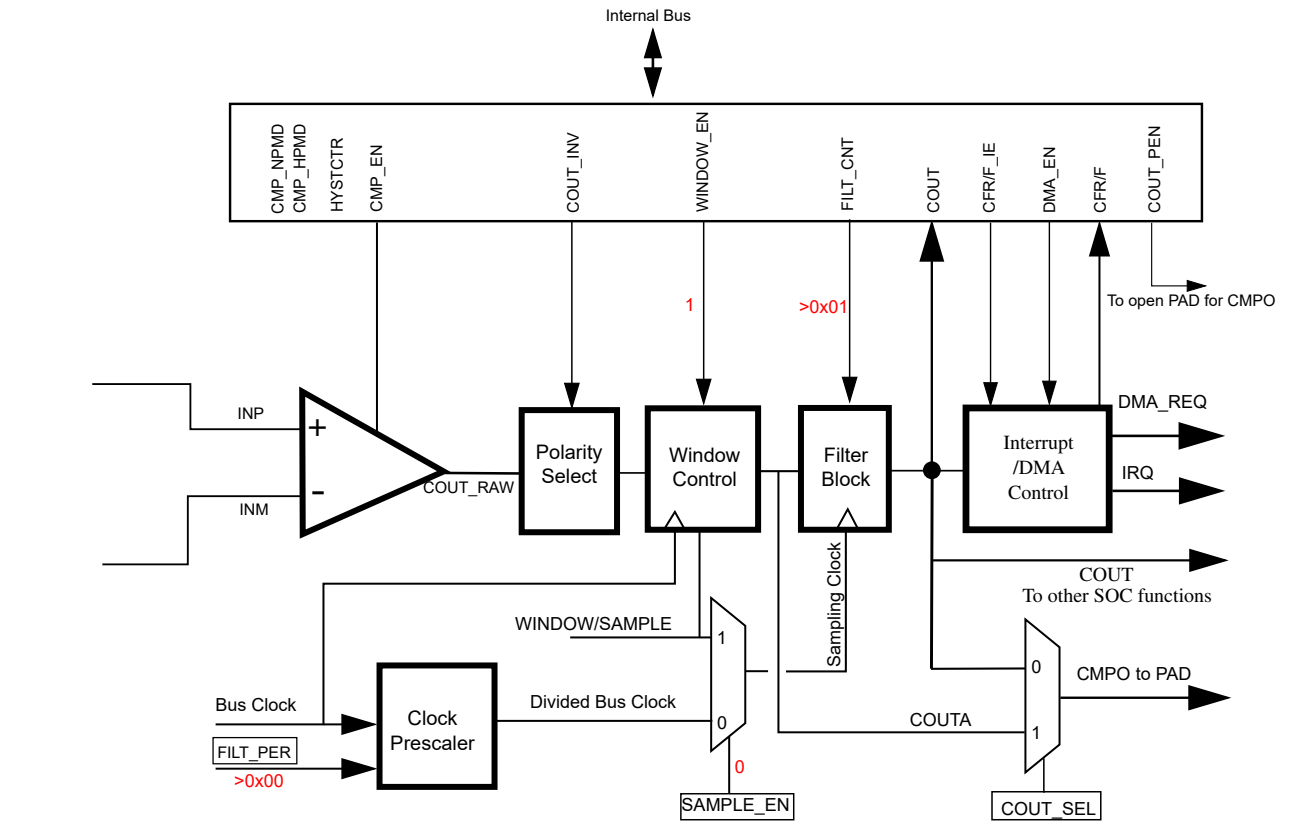

Figure 250. Windowed/Filtered Mode

The only difference in operation between Windowed/Resampled Mode (#6) and Windowed/Filtered Mode (#7) is that, now, CCR1[FILT_CNT]>1, which activates filter operation.

This is the most complex mode of operation for the comparator block, as it utilizes both windowing and filtering features. It also has the highest latency of any of the modes. This can be approximated: up to 2 peripheral clock synchronization in the window function + ((CCR1[FILT_CNT] X CCR1[FILT_PER]) + 1) X peripheral clock for the filter function.

58.3.3 Trigger Mode

The trigger mode is enabled with RRCR0[RR_EN] and CCR0[CMP_EN]. A trigger event will initiate a comparison sequence. The next trigger event should not come before the current sequence completes.

The reference channel for either the plus side MUX or the minus side MUX is selected by RRCR1[RR_FIXP] and RRCR1[FIXCH]. The active channels are selected by RRCR1[RR_CH*n*EN].

When a trigger comes, the analog comparator is enabled. After the comparison sequence completes, the analog comparator is disabled again. The analog stabilization time is controlled by RRCR0[RR_INITMOD]. Make sure that the (RR_INITMOD*round robin clock period) should be longer than the initialization delay in the chip data sheet.

When the stabilization process completes, the round robin manner comparison sequence begins. After the configurable number of operation clocks defined by RRCR0[RR_NSAM], the comparison result is sampled for the selected active channel.

After all the active channels are sampled/compared, if the comparison result changes from its pre-programmed state, the corresponding flag in RRSR[RR_CH*n*F] is set. The pre-programmed state for each channel is configured by writing to RRCSR[RR_CH*n*OUT] field. RRCSR[RR_CH*n*OUT] is updated to store the last comparison result for each channel. If any flag in RRSR[RR_CH*n*F] is set, flag CSR[RRF] will be set. If IER[RRF_IE] is set, an asynchronous interrupt is asserted. Note that these flags do not support generating a DMA transfer event.

The following diagram shows the basic flow of this mode. In the diagram, RRCR1[RR_CH1EN], RRCR1[RR_CH3EN], and RRCR1[RR_CH4EN] are set, so channels #1, #3, and #4 are selected for round robin depended on their priority setting. RRCR0[RR_NSAM] is set to 2'b01, so one clock later the comparison result of the selected channel is sampled. When channel #4 is compared, the result is sampled, and round robin ends. If any of the comparison results from channel #1, #3, or #4 changed from their programmed value (written to RRCSR[RR_CH1OUT], RRCSR[RR_CH3OUT], and RRCSR[RR_CH4OUT]), an interrupt is generated. Software can then poll the RRSR[RR_CH*n*F] to see which channel input(s) changed value.

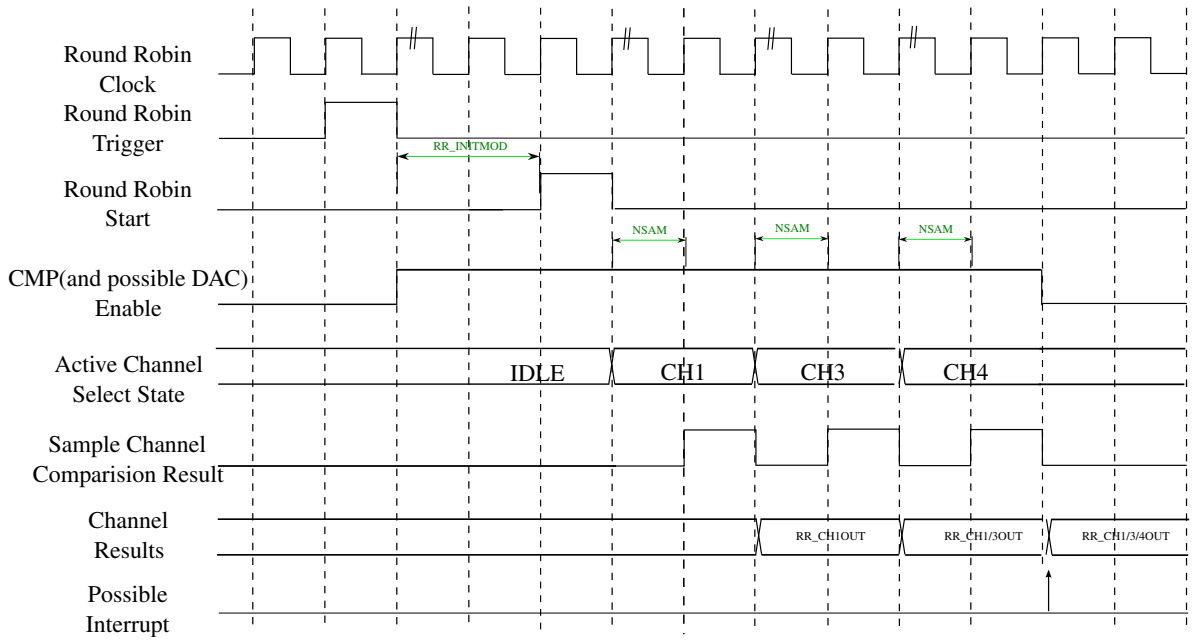

Figure 251. Trigger Mode

Below table shows the channel decode in both functional mode and trigger mode. Other cases not in the table are illegal.

Table 278. CMP Channel Decode in Functional Mode and Trigger mode

Mode	RR_EN	PSEL[2:0]	MSEL[2:0]	INPSEL[1:0]	INMSEL[1:0]	FIXP	FIXCH[2:0]	RR_CHxN	INP	INM	CMP Behavior
Functional Mode	0	x[1]	0~7	0	1	x	x	x	DAC	Channel decoded from MSEL[2:0]	Channel 0~7 can be compared with DAC
		0~7	x	1	0	x	x	x	Channel decoded from PSEL[2:0]	DAC	Channel 0~7 can be compared with DAC
		0~7	0~7	1	1	x	x	x	Channel decoded from PSEL[2:0]	Channel decoded from MSEL[2:0]	Channel 0~7 can be compared with channel 0~7[2]
Trigger Mode	1	x	x	0	1	0	x	0~7	DAC	Channel sweep (RR_CHxN)	Channel 0~7 can be swept with DAC
		x	x	1	0	1	x	0~7	Channel sweep (RR_CHxN)	DAC	Channel 0~7 can be swept with DAC
		x	x	1	1	0	0~7	0~7	Channel fixed by FIXCH[2:0]	Channel sweep (RR_CHxN)	Channel 0~7 can be swept with a fixed channel(0~7)[3]
		x	x	1	1	1	0~7	0~7	Channel sweep (RR_CHxN)	Channel fixed by FIXCH[2:0]	Channel 0~7 can be swept with a fixed channel(0~7)[3]

1. "x" means "do not care"
2. PSEL should not be same as MSEL.
3. Channel in the sweep side should not be same as the fixed side.

Trigger Mode Programming Recommendation

It is recommended to configure the Trigger Mode as following steps. Register fields in same register can be configured at one time.

1. Configure the comparison cycles by RRCR0[RR_NSAM]. Note: It is a mandatory request that the round robin cycling period must be set longer than the time that all the active channels complete the specified comparison cycles set by RRCR0[RR_NSAM].
2. Configure CMP initialization delay by RRCR0[RR_INITMOD] Note: In programming the RRCR0[RR_INITMOD] registers, the RR_INITMOD x round robin clock period must be longer than the initialization delay, which can be referred from the chip data sheet.
3. Configure the RRCR1[FIXP] to select the fixed port of CMP and
    a. If using one input channel to compare with other channels, configure the RRCR1[FIXCH] to select the fixed channel
    b. If using DAC output to compare with input channels, configure the CCR2[INPSEL] or CCR2[INMSEL](according to RRCR1[FIXP])to select the DAC output
4. Configure channels for comparison by RRCR1[RR_CHnEN]
5. Write RRCSR[RR_CHnOUT] to define the pre-set state of channel n.
6. Clear channel flags RRSR[RR_CHnF]
7. Enable round robin interrupt by IER[RRF_IE] (disable IER[CFR_IE] and IER[CFF_IE])
8. Enable round robin mode by RRCR0[RR_EN]
9. Enable comparator by CCR0[CMP_EN]

58.3.4 Low-Pass Filter

The low-pass filter operates on the unfiltered, optionally inverted comparator output COUTA and generates the filtered and synchronized output COUT. Both COUTA and COUT can be configured as module outputs and are used for different purposes within the system.

Synchronization and edge detection are always used to determine status register bit values. They also apply to COUT for all sampling and windowed modes. Filtering can be performed using an internal timebase defined by CCR1[FILT_PER], or using an external SAMPLE input to determine sample time.

The need for digital filtering and the amount of filtering is dependent on user requirements. Filtering can become more useful in the absence of an external hysteresis circuit. Without external hysteresis, high-frequency oscillations can be generated at COUTA when the selected INM and INP input voltages differ by less than the offset voltage of the differential comparator.

58.3.4.1 Enabling Filter Modes

Filter modes can be enabled by:

- Setting CCR1[FILT_CNT] > 0x01 and
- Setting CCR1[FILT_PER] to a nonzero value or setting CCR1[SAMPLE_EN]=1

If using the divided bus clock to drive the filter, it samples COUTA every CCR1[FILT_PER] bus clock cycles.

If CCR1[SAMPLE_EN]=1, the filter samples COUTA on each positive transition of the SAMPLE input. The output state of the filter changes when all the consecutive CCR1[FILT_CNT] samples agree that the output value has changed.

58.3.4.2 Latency Issues

The value of CCR1[FILT_PER] or SAMPLE period must be set such that the sampling period is just longer than the period of the expected noise. This way a noise spike will corrupt only one sample. The value of CCR1[FILT_CNT] must be chosen to reduce the probability of noisy samples causing an incorrect transition to be recognized. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the power of CCR1[FILT_CNT].

The values of CCR1[FILT_PER] or SAMPLE period and CCR1[FILT_CNT] must also be traded off against the desire for minimal latency in recognizing actual comparator output transitions. The probability of detecting an actual output change within the nominal latency is the probability of a correct sample raised to the power of CCR1[FILT_CNT].

Table 277 summarizes maximum latency values for the various modes of operation in the absence of noise. Filtering latency is restarted each time an actual output transition is masked by noise.

58.3.5 Low Power Mode Operation

The following table shows the STANDBY mode operation of the LPCMP module.

Table 279. Low Power Mode Operation

Mode of Operation	Description
STANDBY	LPCMP can operate only in continuous mode or trigger mode.

58.3.6 DMA

When DMA support is enabled by setting CCR1[DMA_EN] and the interrupt is enabled by setting IER[CFR_IE], IER[CFF_IE], or both, the corresponding change on COUT forces a DMA transfer request rather than a CPU interrupt instead. When the DMA has completed the transfer, it sends a transfer completing indicator signal that de-asserts the DMA transfer request and clears the flags (both CSR[CFR] and CSR[CFF]) to allow a subsequent change on comparator output to occur and force another DMA request.

58.3.7 Clocks

LPCMP requires the following clocks to operate:

- Bus clock is used for register access and window/filter function.
- Round robin clock for trigger mode.

58.3.8 Resets

The global chip reset signal resets LPCMP.

58.3.9 Interrupts

When corresponding interrupt enable register bit is set, flags CSR[CFR], CSR[CFF], CSR[RRF] can generate interrupt, assuming the DMA enable bit is not set. The interrupt is de-asserted by clearing either the flag or the interrupt enable register bit.

58.4 External Signals

Table 280. External Signal Descriptions

Signal	Description	I/O
CMPO	Filtered or unfiltered comparator output	O
Input_Analog_Channels	Analog input channels(Refer to the chip-specific information for the connections)	I
VREFH_EXT	External reference voltage for the CMP-DAC(Refer to the chip-specific information for the connections)	I

58.5 Initialization

To enable LPCMP, configure the control registers(CCR1, CCR2, DCR, etc) before setting the CCR0[CMP_EN] bit. To disable the module, clear the CCR0[CMP_EN] bit. Switching operation modes or changing control register bits on the fly (when

CCR0[CMP_EN] is 1) may cause noise on the COUT or COUTA signals. To avoid unwanted signal noise, be sure to disable the module before switching modes or changing control bits.

The time required to stabilize COUT is the power-on delay of the comparators plus the largest propagation delay from a selected analog source through the analog comparator, windowing function, and filter. See the data sheet for power-on delays of the comparators. The delay caused by windowing and filter function is specified in the Table 277.

During operation, the propagation delay of the selected data paths must always be considered. It can take many bus clock cycles for COUT and CSR[CFR]/CSR[CFF] to reflect an input change or a configuration change to one of the components involved in the data path.

58.6 Application Information

58.6.1 Round-robin clock(RCLK) frequency requirement

(1) RCLK High Frequency Limit

RCLK high frequency limit depends on two facts:

1. The analog CMP and DAC initialization time(See the chip data sheet for the initialization time.)
   - Register field RR_INITMOD provides a maximum 63 RCLK cycles for the analog CMP and DAC initialization.
   - Rclk must be slow enough to satisfy: 63 * (1/f_{RCLK}) > $T_{inialization}$, where f_{RCLK} is in MHz, and $T_{inialization}$is in microsecond.
   - so f_{RCLK} < 63 / $T_{inialization}$
   - Example: $T_{inialization}$ = 40 microsecond, then f_{RCLK} should be smaller than 1.575MHz.
2. The analog CMP propagation delay(See the chip datasheet for the CMP propagation delay.)
   - Register field NSAM field provides a maximum 4 RCLK cycles for the analog CMP propagation delay.
   - Rclk must be slow enough to satisfy: 4 * (1/f_{RCLK}) > $T_{propagation}$, where f_{RCLK} is in MHz, and $T_{propagation}$ is in microsecond.
   - so f_{RCLK} < 4 / $T_{propagation}$
   - Example: $T_{propagation}$ = 0.1 microsecond, then f_{RCLK} should be smaller than 40 MHz.

(2) RCLK Low Frequency Limit

In theory, RCLK frequency has no low limit. But the lower the RCLK frequency, the longer the scan time. Therefore, the lower limit of the RCLK frequency depends on the system application.

58.7 LPCMP register descriptions

The memory map comprises of 32-bit aligned registers which can be accessed via 8-, 16- or 32-bit reads and 32-bit write. Attempted accesses using unsupported write data sizes, writes to read-only resources, or to reserved spaces are terminated with an error. Read access to reserved address will also generate a transfer error and the read data bus will show all 0s.

58.7.1 LPCMP memory map

LPCMP_0 base address: 4037_0000h

LPCMP_1 base address: 4037_4000h

LPCMP_2 base address: 404E_8000h

Offset	Register	Width (In bits)	Access	Reset value

Table continues on the next page...

Table continued from the previous page...

Field	Function
2 LINKEN	CMP-to-DAC Link Enable Controls the link from the CMP enable to the DAC enable. 0b - Disable the CMP-to-DAC link: enabling or disabling the DAC is independent from enabling or disabling the CMP. 1b - Enable the CMP-to-DAC link: the DAC enable/disable is controlled by the CMP_EN bit instead of DCR[DAC_EN]. Also, when the CMP is auto-disabled because software selects the same signal for both the plus and minus comparator inputs, the DAC is disabled too.
1 CMP_STOP_EN	Comparator STANDBY Mode Enable Allows software to enable the analog comparator or the DAC when the device is in STANDBY mode. **NOTE** CMP_STOP_EN has no effect in trigger mode. 0b - Disable the analog comparator regardless of CMP_EN. 1b - Allow the analog comparator to be enabled by CMP_EN.
0 CMP_EN	Comparator Enable Enables the analog comparator. **NOTE** When CCR0[LINKEN]=1, CMP_EN also controls the enabling/disabling of the DAC instead of DCR[DAC_EN]. 0b - Disable (The analog logic remains off and consumes no power.) 1b - Enable

58.7.5 Comparator Control Register 1 (CCR1)

Offset

Register	Offset
CCR1	Ch

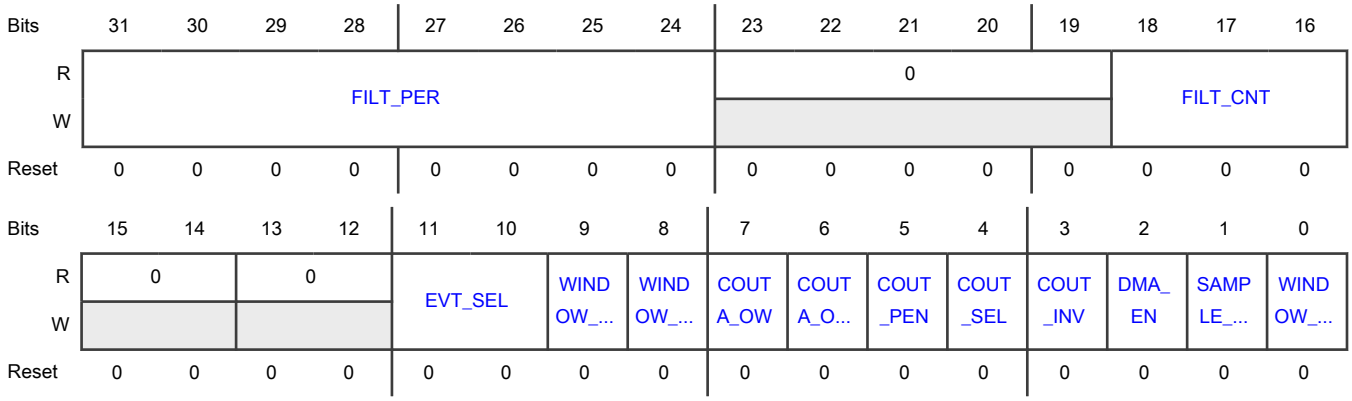
Function

Contains configuration options for comparator operation, such as enabling Sampling or Windowing mode.

NOTE

Sampling and Windowing modes cannot both be enabled at the same time. Sampling mode takes precedence over Windowing mode. If software attempts to set both SAMPLE_EN and WINDOW_EN, only SAMPLE_EN is set.

Diagram



Fields

Field	Function
31-24 FILT_PER	Filter Sample Period Specifies the sampling period (in bus clock cycles) of the comparator output filter. Programming FILT_PER to 0x00 bypasses the filter. Filter programming and latency details are provided in the functional description section. **NOTE** FILT_PER has no effect in Sampling mode (CCR1[SAMPLE_EN]=1).
23-19 —	Reserved
18-16 FILT_CNT	Filter Sample Count Specifies the number of consecutive samples that must agree before the comparator ouput filter accepts the sample as a new valid output state. For information regarding filter programming and latency, see the functional description section. 000b - Filter is bypassed: COUT = COUTA 001b - 1 consecutive sample (Comparator output is simply sampled.) 010b - 2 consecutive samples 011b - 3 consecutive samples 100b - 4 consecutive samples 101b - 5 consecutive samples 110b - 6 consecutive samples 111b - 7 consecutive samples
15-14 —	Reserved
13-12	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
11-10 EVT_SEL	CMPO Event Select Selects which CMPO signal edge (rising, falling, or both) defines a CMPO event. **NOTE** Valid only in Windowing mode. 00b - Rising edge 01b - Falling edge 1xb - Both edges
9 WINDOW_CLS	CMPO Event Window Close Enables a CMPO event (defined as a CMPO rising edge, falling edge, or both) to close an active window. See the EVT_SEL field to configure the CMPO event. **NOTE** The WINDOW signal has to go to zero and back to one again to re-activate the window. Valid only in Windowing mode. 0b - CMPO event cannot close the window 1b - CMPO event can close the window
8 WINDOW_INV	WINDOW/SAMPLE Signal Invert Inverts the WINDOW/SAMPLE signal. 0b - Do not invert 1b - Invert
7 COUTA_OW	COUTA Output Level for Closed Window Defines the COUTA signal value when the window is closed. **NOTE** Valid only in Windowing mode and when COUTA_OWEN=1. 0b - COUTA is 0 1b - COUTA is 1
6 COUTA_OWEN	COUTA_OW Enable Enables the COUTA signal value to be defined by the COUTA_OW bit when the window is closed. **NOTE** Valid only in Windowing mode. 0b - COUTA holds the last sampled value 1b - COUTA is defined by the COUTA_OW bit

Table continues on the next page...

Table continued from the previous page...

Field	Function
5 COUT_PEN	Comparator Output Pin Enable Enables the comparator output to become an available signal option for a selected package pin. 0b - Not available 1b - Available
4 COUT_SEL	Comparator Output Select Selects which comparator output option, COUT or COUTA, to use for CMPO. 0b - Use COUT (filtered) 1b - Use COUTA (unfiltered)
3 COUT_INV	Comparator Invert Selects the polarity of the analog comparator function, affecting the value driven to the COUT output (on both the device pin and as CSR[COUT]) when CCR0[CMP_EN] is 0. **NOTE** COUT_INV has no effect in trigger mode. 0b - Do not invert 1b - Invert
2 DMA_EN	DMA Enable Enables DMA transfers triggered from the LPCMP module. When DMA_EN and the corresponding interrupt enable bit are set, a DMA request is asserted when CFR or CFF is set. 0b - Disable 1b - Enable
1 SAMPLE_EN	Sampling Enable Enables Sampling mode. 0b - Disable 1b - Enable
0 WINDOW_EN	Windowing Enable Enables Windowing mode. **NOTE** Valid only when SAMPLE_EN=0. 0b - Disable 1b - Enable

58.7.6 Comparator Control Register 2 (CCR2)

Offset

Register	Offset
CCR2	10h

Function

Contains configuration options for comparator operation, such as selecting the plus and minus comparator inputs and the hysteresis levels.

NOTE

When an inappropriate operation selects the same signal for both the plus and minus comparator inputs, the analog comparator automatically shuts down (regardless of CMP_EN) to prevent itself from becoming a noise generator.

58.7.8 Interrupt Enable Register (IER)

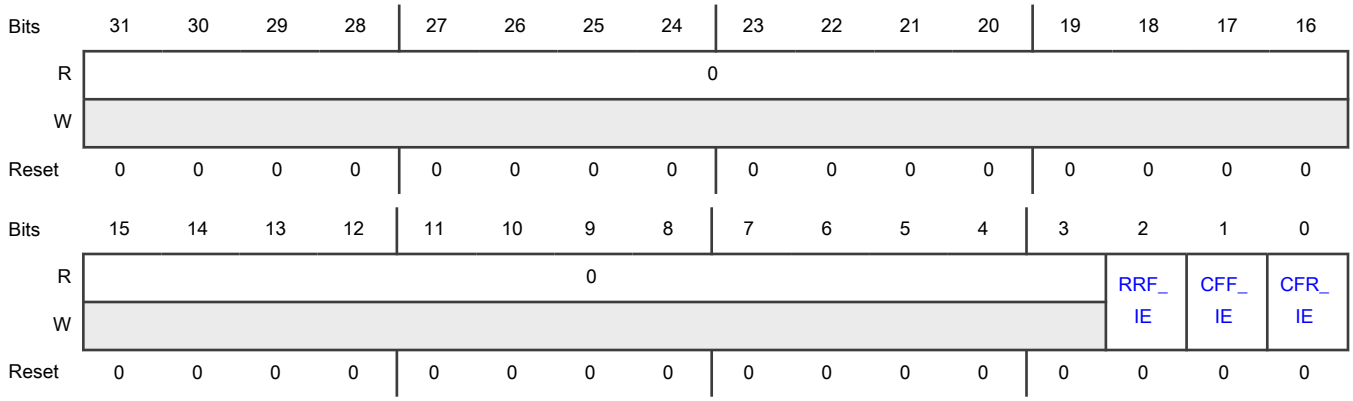
Offset

Register	Offset
IER	1Ch

Function

Provides enable bits for the comparator and round-robin flag interrupts.

Diagram



Fields

Field	Function
31-3 —	Reserved
2 RRF_IE	Round-Robin Flag Interrupt Enable Enables the Round-Robin Flag interrupt. 0b - Disable 1b - Enable: Assert an interrupt when the comparison result changes for a given channel.
1 CFF_IE	Comparator Flag Falling Interrupt Enable Enables the Comparator Flag Falling interrupt. 0b - Disable 1b - Enable: Assert an interrupt when CFF is set.
0 CFR_IE	Comparator Flag Rising Interrupt Enable Enables the Comparator Flag Rising interrupt. 0b - Disable 1b - Enable: Assert an interrupt when CFR is set.

58.7.9 Comparator Status Register (CSR)

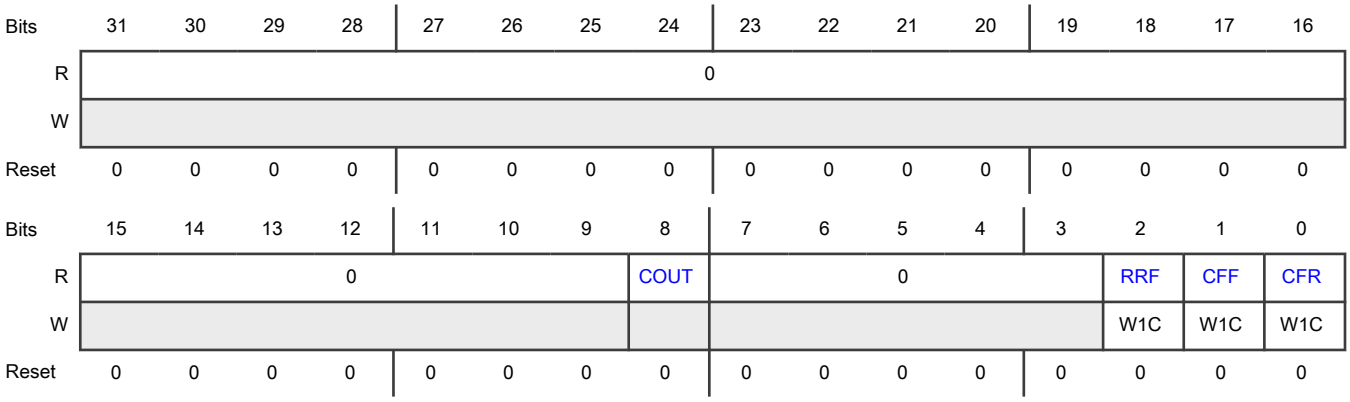
Offset

Register	Offset
CSR	20h

Function

Provides the COUT, and CFF, CFR, RRF flags.

Diagram



Fields

Field	Function
31-9 —	Reserved
8 COUT	Analog Comparator Output Returns the current value of the analog comparator output, when read. The field is reset to 0 and reads as CCR1[COUT_INV] when the analog comparator module is disabled, that is, when CCR0[CMP_EN] = 0. Writing to this field is ignored.
7-3 —	Reserved
2 RRF	Round-Robin Flag Detects when any channel's last comparison result is different from the pre-set value in trigger mode. To clear RRF, write 1 to it. RRF is cleared when CCR0[CMP_EN] or RRCR0[RR_EN] is not set. 0b - Not detected 1b - Detected
1 CFF	Analog Comparator Flag Falling Detects when a falling edge on COUT occurs. CFF is cleared by writing 1 to it when CCR1[DMA_EN] is disabled. If CCR1[DMA_EN] is enabled, the flag is automatically cleared when DMA is done. CFF is cleared when CCR0[CMP_EN] is not set. 0b - Not detected 1b - Detected
0 CFR	Analog Comparator Flag Rising Detects when a rising edge on COUT occurs. CFR is cleared by writing 1 to it when CCR1[DMA_EN] is disabled. If CCR1[DMA_EN] is enabled, the flag is automatically cleared when DMA is done. CFR is cleared when CCR0[CMP_EN] is not set. 0b - Not detected 1b - Detected

58.7.10 Round Robin Control Register 0 (RRCR0)

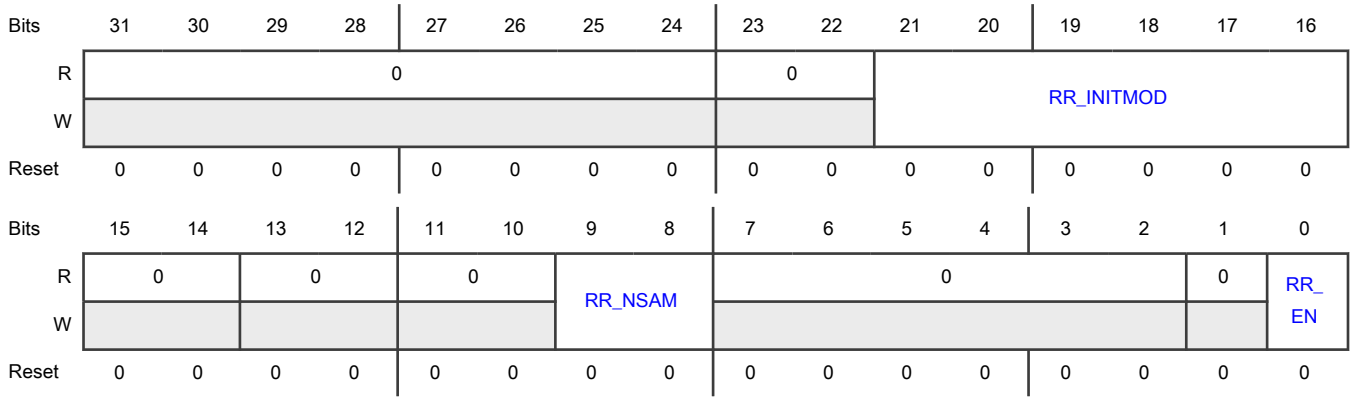
Offset

Register	Offset
RRCR0	24h

Function

Contains configuration options for round robin operation, such as enabling it and specifying the initialization delay.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-22 —	Reserved
21-16 RR_INITMOD	Initialization Delay Modulus Specifies the number of round-robin clock cycles used to determine the comparator and DAC initialization delay as specified in the chip datasheet. The initiallization delay is calculated as: RR_INITMOD * (round-robin clock period). For example, if the initialization delay is 80us and the round-robin clock is 100kHz, program RR_INITMOD to be 80us/10us = 8. 00_0000b - 63 cycles (same as 111111b) 00_0001b-11_1111b - 1 to 63 cycles
15-14 —	Reserved
13-12 —	Reserved
11-10 —	Reserved
9-8 RR_NSAM	Number of Sample Clocks Specifies how many round-robin clock cycles to wait after the active channel is scanned before sampling the channel's comparison result. After the next cycle of the round-robin clock, the sampling takes place RR_NSAM clocks later.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	00b - 0 clocks 01b - 1 clocks 10b - 2 clocks 11b - 3 clocks
7-2 —	Reserved
1 —	Reserved
0 RR_EN	Round-Robin Enable Enables round-robin operation. 0b - Disable 1b - Enable

58.7.11 Round Robin Control Register 1 (RRCR1)

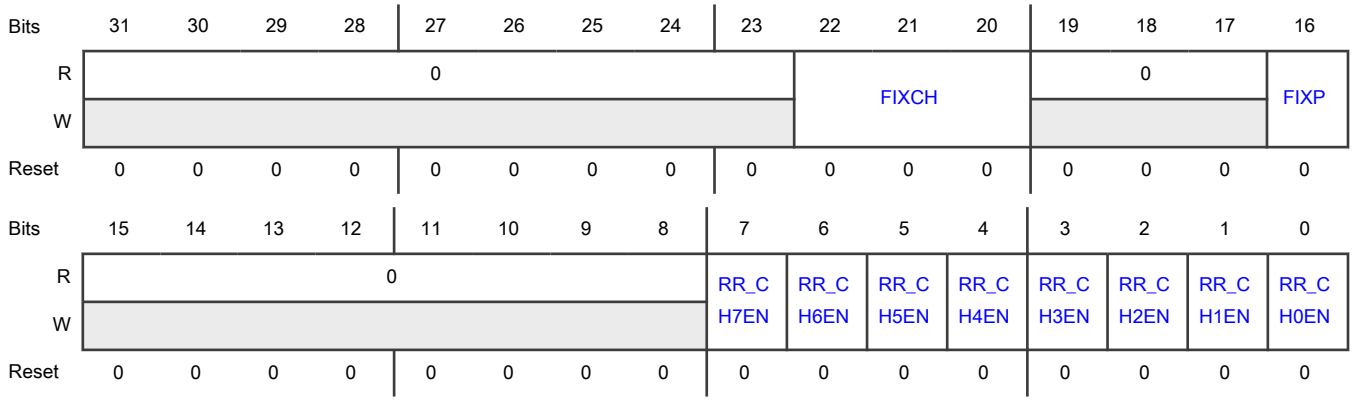
Offset

Register	Offset
RRCR1	28h

Function

Contains configuration options for round robin operation, such as enabling individual channels to participate.

Diagram



Fields

Field	Function
31-23 —	Reserved
22-20 FIXCH	Fixed Channel Select Selects which channel in the mux port to fix for a given trigger mode application. 000b - Channel 0 001b - Channel 1 010b - Channel 2 011b - Channel 3 100b - Channel 4 101b - Channel 5 110b - Channel 6 111b - Channel 7
19-17 —	Reserved
16 FIXP	Fixed Port Fixes (locks) an analog mux port (Plus or Minus) for trigger mode. The inputs to the non-fixed port are swept during each round. 0b - Fix the Plus port. Sweep only the inputs to the Minus port. 1b - Fix the Minus port. Sweep only the inputs to the Plus port.
15-8 —	Reserved
7-0 RR_CHnEN	Channel n Input Enable in Trigger Mode Enables channel n of the non-fixed mux port to have its voltage value checked when in trigger mode. **NOTE** RR_CHnEN has no effect when the same channel is selected as the reference voltage. 0b - Disable 1b - Enable

58.7.12 Round Robin Control and Status Register (RRCSR)

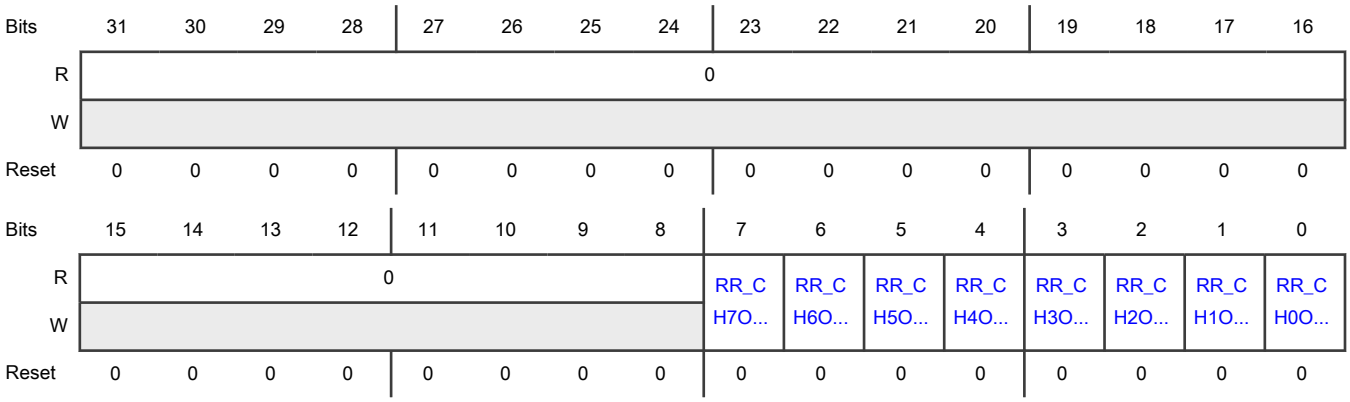
Offset

Register	Offset
RRCSR	2Ch

Function

Contains the latest comparison results of the individual channels with the fixed mux port. It also allows software to define the pre-set state for each channel.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 RR_CHnOUT	Comparison Result for Channel n Reading RR_CHnOUT returns the latest comparison result for channel n. Writing RR_CHnOUT defines the pre-set state for channel n.

58.7.13 Round Robin Status Register (RRSR)

Offset

Register	Offset
RRSR	30h

Function

Contains individual channel flags indicating when a channel's last comparison result is different from its pre-set value.

ANMUX	Analog multiplexer

Chapter 59
Logic Control Unit (LCU)

59.1 Chip-specific LCU information

59.1.1 LCU instances

This chip has two identical LCU instances, LCU_0 and LCU_1.

59.2 Introduction

LCU selects multiple inputs from timers, pulse width modulation (PWM) signals, and input/output (I/O) pads, and combines them using a programmable logic function to create output waveforms for use by other IPs.

It consists of 3 LCs, each of which takes four inputs and creates four outputs using user-defined logic mapping. LCU also has 3 force inputs that can override the output logic and force a user-defined value directly on the output signals. Additionally, LCU has 2 sync inputs that can control when the inputs are updated to produce new output signals.

LCU generates the interrupts and DMA requests based on output signals and force input signals.

59.3 Feature list

- 3 LCs with programmable logic function for generating output results
- 12 inputs to and 12 outputs from each LC
- Muxing to map any input to any LC
- Independent filters for the rising and falling output states of each LC
- Software override logic for inputs using multiple modes
- 3 force inputs with programmable edge filtering to force output states using multiple modes
- 2 sync inputs to control transition timing
- Lock bit to block writes to configuration registers
- Interrupt request generation based on output change or force event
- DMA transfer request generation based on output change or force event

59.4 Block diagram

This figure illustrates an example implementation of LCU with:

- Three LCs
- Four force inputs
- Four sync inputs

For the number of each resource in this chip, see Feature list.

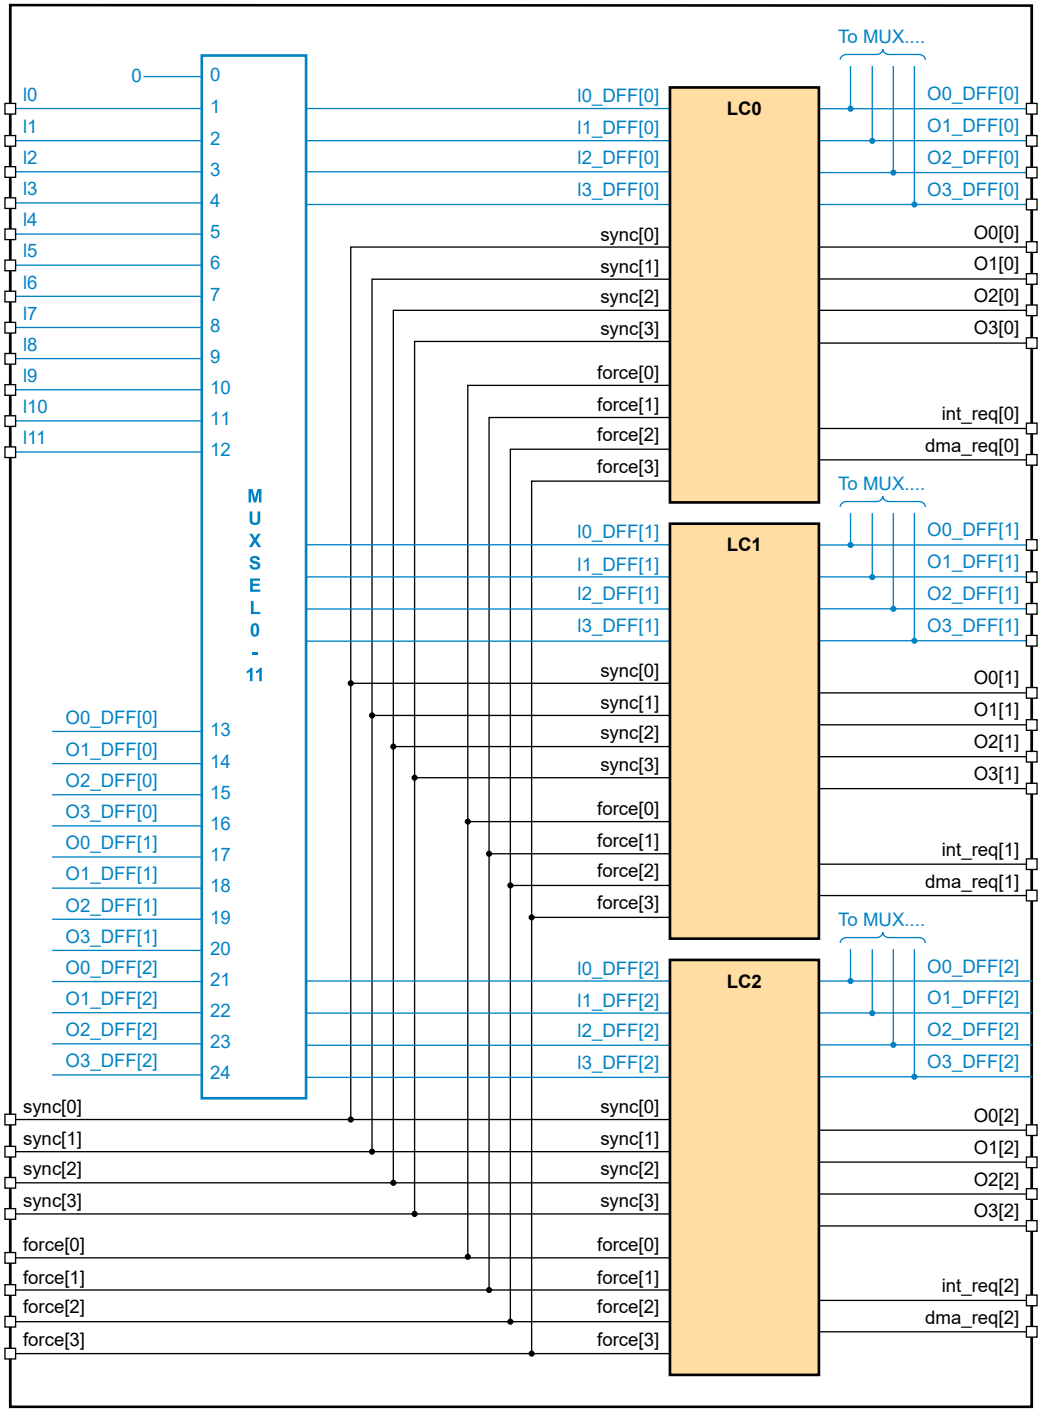

Figure 252. Block diagram

59.5 LC operation

59.5.1 Overview

An LC performs logic operations based on the LUT principle, as described in Logic operations.

Each LC supports the following features:

- Independent filter thresholds for the rising and falling output states support different transition delays.
- Bypass of the output state filter by setting the filter threshold to zero. Bypassing the filter causes the aynchronous signal to propagate to the output of the LC.
- Force logic that instantly switches an LC output to the inactive state upon external fault signal assertion. The return from the inactive state to the output state is either:
  - Instantaneous: when LCU deasserts the force signal.
  - Instantaneous synchronized: when LCU deasserts the force signal and then the sync input asserts.
  - Manual: when you write 1 to the force status bit and then the LCU deasserts the force input.
  - Manual synchronized: when you write 1 to the force status bit and LCU deasserts the force input, and then the sync input asserts.
- Input software override logic to override external inputs by writing to the following registers:
  - LC*n* Sync Control (LC*n*_SCTRL[SW_MODE])
  - Software Override Value (SWVALUE[SWVALUE])
  - Software Override Enable (SWEN[SWEN])
- Generation of interrupt requests or DMA transfer requests.

59.5.2 LC diagram

This figure illustrates an example LC implementation with:

- One LC
- Four force inputs
- Four sync inputs

For the number of each resource in this chip, see Feature list.

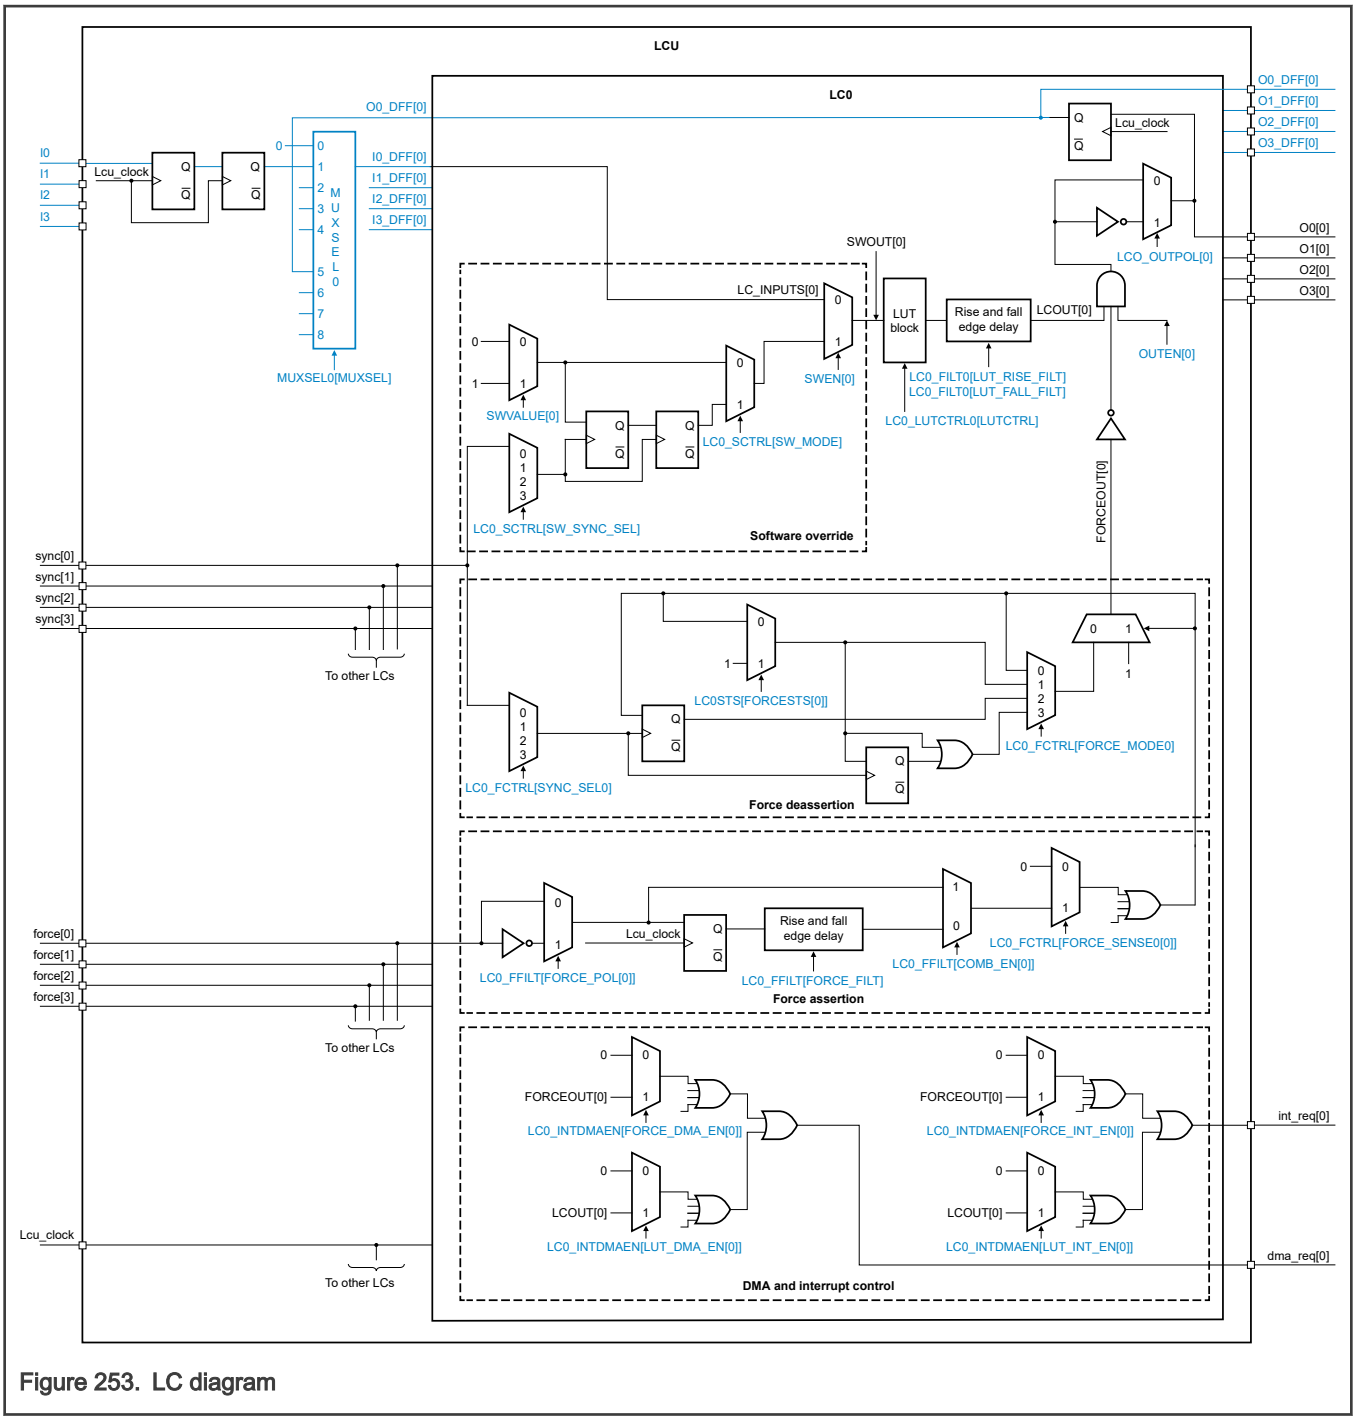

Figure 253. LC diagram

59.5.3 Logic operations

An LC reads its set of inputs (inputs 3, 2, 1, and 0) as a four-bit binary value, with Input 3 as the most-significant bit and Input 0 as the least-significant bit. For example, if:

Input 0 = 0

Input 1 = 1

Input 2 = 0

Input 3 = 1

then the combined input value is 1010b (10 decimal).

Each possible four-bit input value corresponds to a bit position in the LUT Control (LCn_LUTCTRLm[LUTCTRL]), as illustrated in LC LUT. For a given LC output, if the combined LC input value corresponds to a bit position in that output's LUTCTRL value that equals 1, then the LC asserts that output.

For example, if you write 35h to LUTCTRL (shown in the Example column of the LC LUT), then the combined input values 0 (0000b), 2 (0010b), 4 (0100b), and 5 (0101b) cause assertion of the output. All other input values cause deassertion of the output.

LCU processes each look-up table asynchronously.

59.5.4 LC LUT

The LUT maps the combined LC input value to a bit position in LC*n*_LUTCTRL*m*.

Table 281. LC LUT

Input 3	Input 2	Input 1	Input 0	LUTCTRL bit position	Example LUTCTRL value: 35h
0	0	0	0	0	1
0	0	0	1	1	0
0	0	1	0	2	1
0	0	1	1	3	0
0	1	0	0	4	1
0	1	0	1	5	1
0	1	1	0	6	0
0	1	1	1	7	0
1	0	0	0	8	0
1	0	0	1	9	0
1	0	1	0	10	0
1	0	1	1	11	0
1	1	0	0	12	0
1	1	0	1	13	0
1	1	1	0	14	0
1	1	1	1	15	0

59.5.5 LC output filters

Each LC supports two optional digital filters, a Rise Filter (LC*n*_FLIT*m*[LUT_RISE_FILT]) and a Fall Filter (LC*n*_FLIT*m*[LUT_FALL_FILT]), to post-process the LUT output and delay the output signal change.

Each filter starts accumulating clock cycles on the occurrence of the associated LUT event. The Rise Filter counts from an output assertion, and the Fall Filter counts from an output deassertion. When the number of clock cycles reaches the filter threshold (matches the specified filter value), the output flips to the new state. For example, if you specify a Rise Filter value of 100h, and the LUT event triggers an output assertion, the output signal does not assert until the 256th clock cycle after the event.

A filter value of 0 bypasses the filter.

59.6 Behavior in different chip modes of operation

Operation mode	Status of outputs
Normal	• Controlled by LC*n*_LUTCTRL*m* and MUXSEL*n* • Toggled based on the states of the selected inputs
Debug	Inactive or normal operation controlled by Debug Mode Enable (DBGEN)

59.7 Use-case examples

59.7.1 Two-channel multiplexer

59.7.1.1 Overview

A multiplexer (or mux) takes multiple inputs and, based on some control mechanism, passes only one of those inputs to the output. You can implement a two-channel multiplexer controlled by an external signal or a software override using three inputs and one output of a single LC, as illustrated in Logic diagram and Implementation.

This example implementation controls the multiplexer with the SEL input signal and a software override. The software override controls the multiplexer output regardless of the SEL signal state. To use software override, you must enable it for the corresponding output (SWEN[SWEN]). You assert software override by writing 1 to the corresponding bit of the Software Override Value (SWVALUE[SWVALUE]).

59.7.2 Binary to Gray code converter

59.7.2.1 Overview

Gray code, also known as reflected binary code (RBC), is a non-weighted, minimum change code. In this code, any two adjacent code numbers differ by only one bit. This code solves the problem of physical switch transitions by changing only one switch at a time, so there is never any ambiguity of position.

You can implement binary to Gray code conversion using a single LC, as illustrated in Logic diagram and Implementation.

In this example, the LC also generates a DMA request on each rising edge of output 3, which is bit 0 of the Gray code (G0).

59.7.3 Manchester encoder and decoder

59.7.3.1 Overview

Manchester encoding (also known as phase encoding) is a data-modulation technique for binary data transfer based one of these signals:

- Analog
- RF
- Optical
- High-speed-digital
- Long-distance-digital

The fundamental idea behind Manchester encoding is to use voltage transitions, instead of voltage levels, to represent 1s and 0s. It performs an exclusive OR of data and clock signals to encode and decode data. A high-to-low transition on the falling clock edge indicates 0. A low-to-high transition on the rising clock edge indicates 1.

59.7.3.8 Waveforms for encoder

This figure includes the Manchester-encoded waveform (labeled PE) of the input waveform (labeled "Data in"). The PE waveform is delayed by two clock cycles because of two-stage input synchronization.

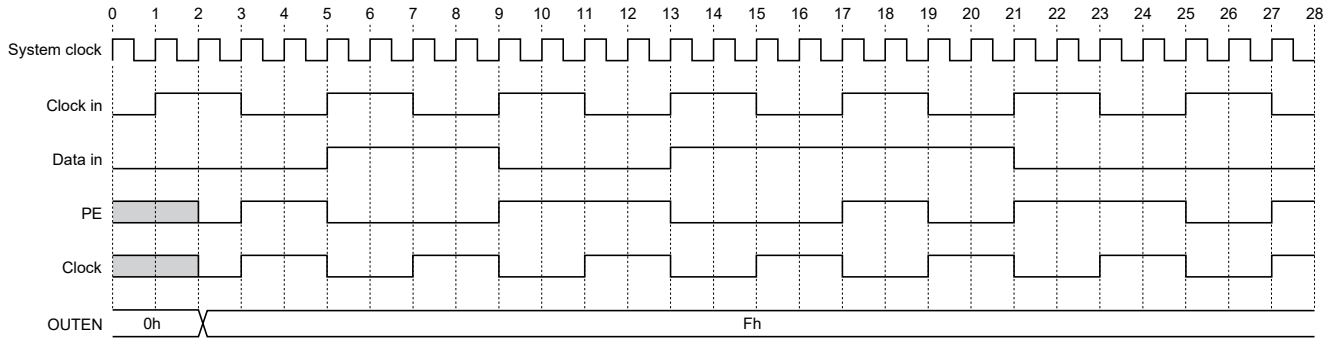

Figure 262. Waveforms for encoder

59.7.3.9 Waveforms for decoder

The output waveform (labeled "Data out") is delayed by four clock cycles from the input waveform (labeled "Data in") because of two-stage input synchronization. In this example, the Manchester encoder also propagates the Clock waveform that the decoder uses to reconstruct the "Data in" waveform from the Manchester-decoded waveform (labeled PE).

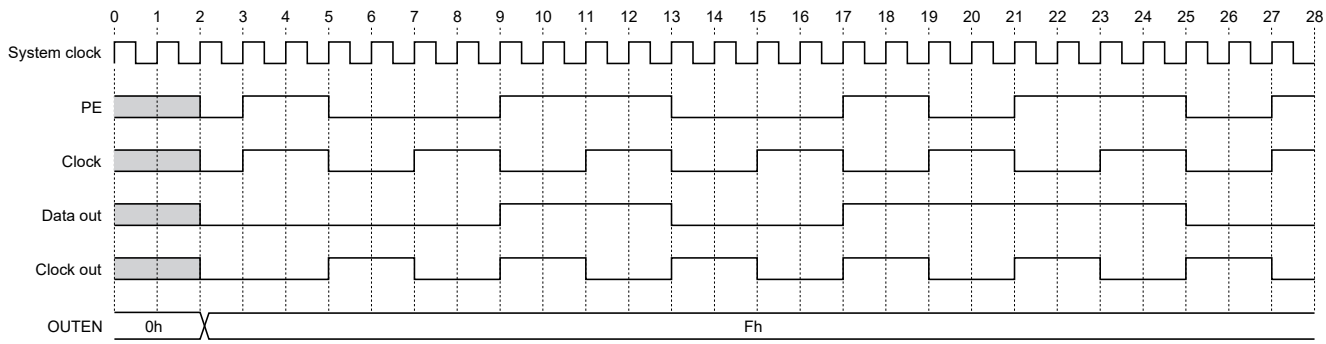

Figure 263. Waveforms for decoder

59.7.4 Adjustable PWM/FM generator

59.7.4.1 Overview

In many cases, it is useful to route an LC output back to one of its inputs, as illustrated in Implementation. In addition, you can delay outputs with a digital filter with different time constants for delaying rising and falling edges. Combining these capabilities, you can use an LC to generate output waveforms with adjustable pulse width and frequency.

In addition to waveform generation, the software-override feature forces the generator output low or high by software. You control the override via Software Override Enable (SWEN) and Software Override Value (SWVALUE).

59.7.4.2 Implementation

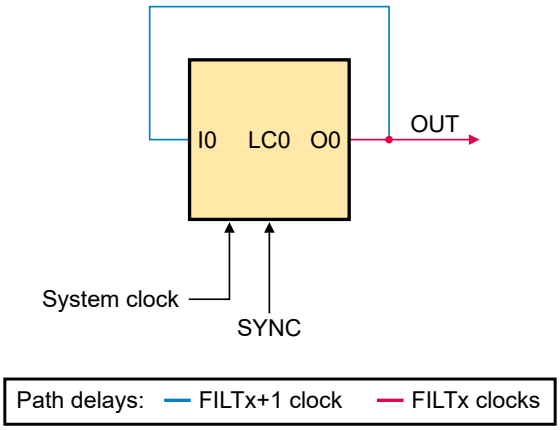

Figure 264. Implementation

59.7.4.3 Connections and controls

Table 293. Connections and controls

Name	Description
I0	Delayed output routed back to LC input
O0 and OUT	Delayed output
System clock	Clock frequency supplied to LC
SYNC	Software override synchronization signal

59.7.4.4 Truth table

This example generates an adjustable PWM/FM waveform according to the following table. In the table:

- OUT is the LC output signal that is also routed to the LC input using an internal multiplexer.
- TdH is the digital filter value to delay the rising edge of the output signal.
- TdL is the digital filter value to delay the falling edge of the output signal.

Table 294. Truth table

I0	OUT
0	1 delayed by TdH (see Output edge delays)
1	0 delayed by TdL (see Output edge delays)

In this example, software override control is synced with the rising edges of the SYNC waveform.

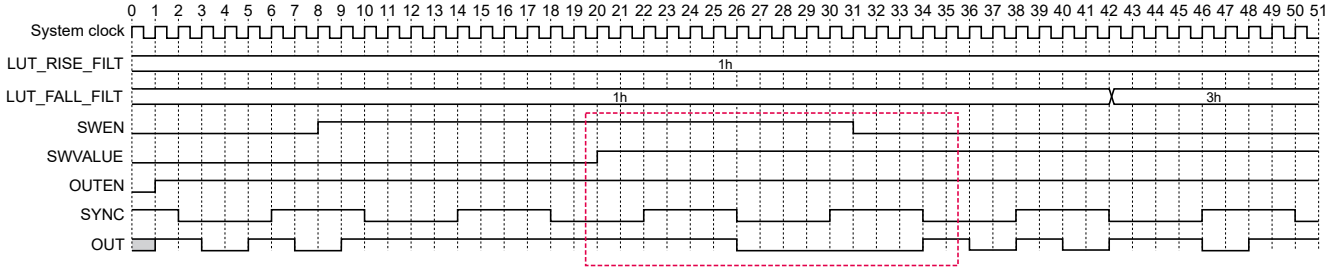

Figure 267. Waveforms for synced software override

59.7.5 SR latch

59.7.5.1 Overview

An SR latch is the simplest bistable device and a fundamental component of data storage.

This example implementation uses one LC that includes an internal feedback path configured by the internal multiplexer, as illustrated in Implementation. Output Q responds to inputs S (set) and R (reset). It changes with a delay of two clock cycles—the time required for the S and R signal inputs to pass through the internal two-stage synchronizers. This example implementation bypasses the Q digital filter; therefore, the loop of Q back to the input experiences a delay of one clock cycle." See Waveforms.

59.7.6 D flip-flop

59.7.6.1 Overview

A D flip-flop stores and outputs whatever logic level is applied to its data terminal at the time its clock input goes high.

You can implement a D flip-flop element using an LC as illustrated in Implementation. On a clock rising edge, the LC either asserts or deasserts the Q output based on the D input.

The Q output and CLKO digital filters are bypassed. Therefore, the states of these variables are fed to inputs with a delay of one clock cycle. See Waveforms.

59.7.7 JK flip-flop

59.7.7.1 Overview

A JK flip-flop is a gated SR latch (see SR latch) with an added clock input circuit that prevents the illegal or invalid output condition that can occur when both SR-latch inputs (S and R) are asserted.

Truth table for JK flip-flop presents the four possible input combinations for a JK flip-flop. All output changes occur at the clock rising edge.

You can create a JK flip-flop using two LCs, as illustrated in Implementation. The first LC detects rising edges of the CLK clock input (see Truth table for LC0). The second LC processes J and K inputs at every rising clock edge (see Truth table for LC1).

Output Q and CLKO digital filters are bypassed. Therefore, the states of these variables are fed to inputs with a delay of one clock cycle (see Waveforms).

59.7.7.8 Waveforms

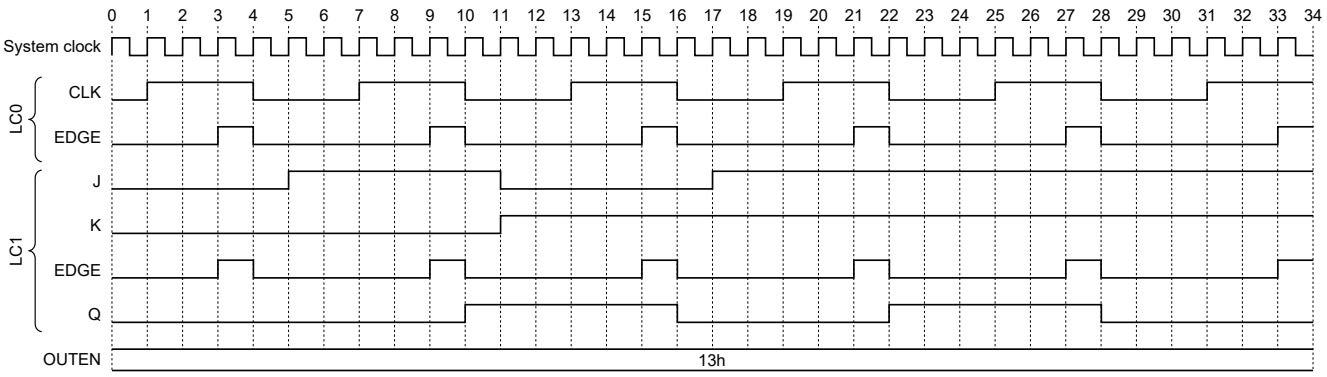

Figure 273. Waveforms

59.7.8 Incremental encoder

59.7.8.1 Overview

An incremental encoder provides A and B pulse outputs in the form of 90-degree shifted waveforms (see Outputs). The decoding circuit processes these waveforms to detect the rotor position and the direction of rotation.

This example implementation requires two LCs (see Implementation):

- LC0 provides pulse streams on CW or CCW output at every A and B signal edge. If the encoder rotation is CW (A signal leading), then pulses appear at the CW output. If the encoder rotation is CCW (B signal leading), then pulses appear at the CCW output. Two pulse counters accumulate these pulse streams to provide the actual absolute encoder position in the respective direction of rotation.
- LC1 then uses the LC0 outputs to detect the direction of the rotation.

59.7.8.2 Outputs

59.7.8.8 Waveforms

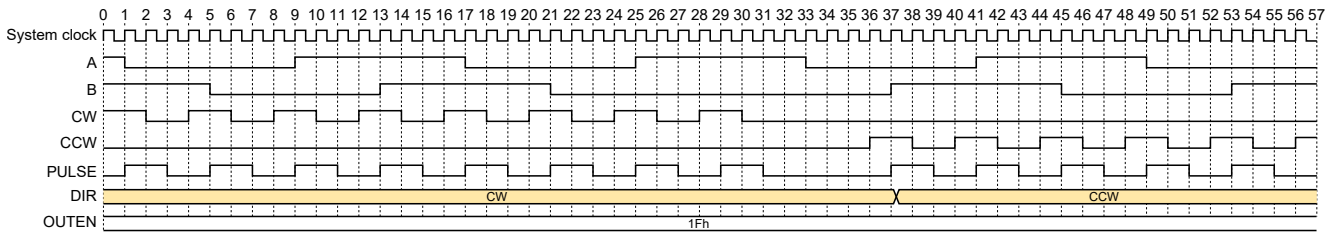

Figure 276. Waveforms

59.7.9 AC motor PWM controller

59.7.9.1 Overview

Driving a three-phase AC motor requires dedicated PWMs to perform:

- Complementary signal generation
- Dead time insertion
- Fault-state assertion
- Manual or automatic fault recovery

LCU enhances basic timer functionality with the necessary complementary features available only on dedicated motor control PWMs.

Implementation for AC motor controller shows all input and output signals of LCU in a typical three-phase motor control application.

TdH is the time delay preceding each rising edge of the complementary PWM output signals. See Truth table for details.

Fault signals are routed from analog comparators or external protection circuits to protect power switches against damage caused by overcurrent. Any active fault must immediately change all PWM outputs to the inactive state. Force logic causes PWM outputs to transition to the inactive state upon an external fault event. See Truth table for details.

The dead time is one clock cycle. On a fault event, both PWM outputs transition to the inactive state (logic 0). When the fault event deasserts, both PWM signals start operating according to FORCE_MODE = 00 (cleared on force deassertion). See Waveforms for force cleared on force deassertion for details.

59.7.9.7 Waveforms for force cleared on force deassertion

This example shows two behaviors, depending on the Force Clearing mode (LC0_FCTRL[FORCE_MODE0]).

00b - Both PWM signals start normal operation when the fault event deasserts. See Waveforms for force cleared on force deassertion for details.

01b - Both PWM signals start normal operation on rising sync after the fault event deasserts. See Waveforms for force cleared on rising sync after force deassertion for details.

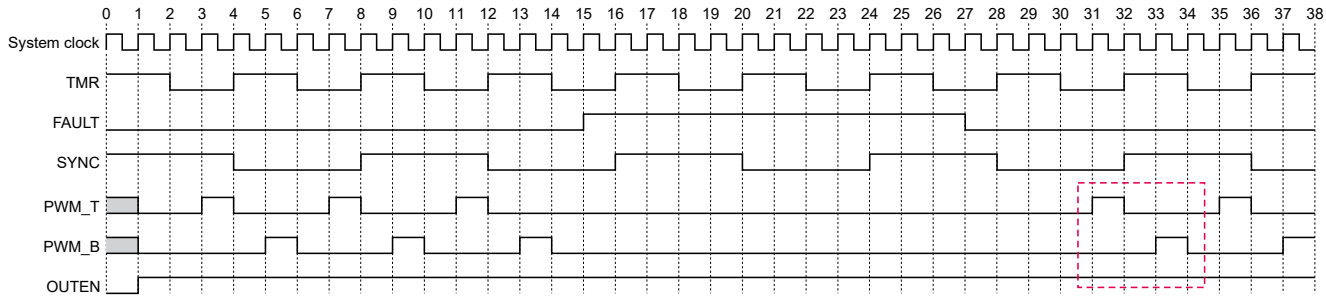

Figure 279. Waveforms for force cleared on force deassertion

59.7.9.8 Waveforms for force cleared on rising sync after force deassertion

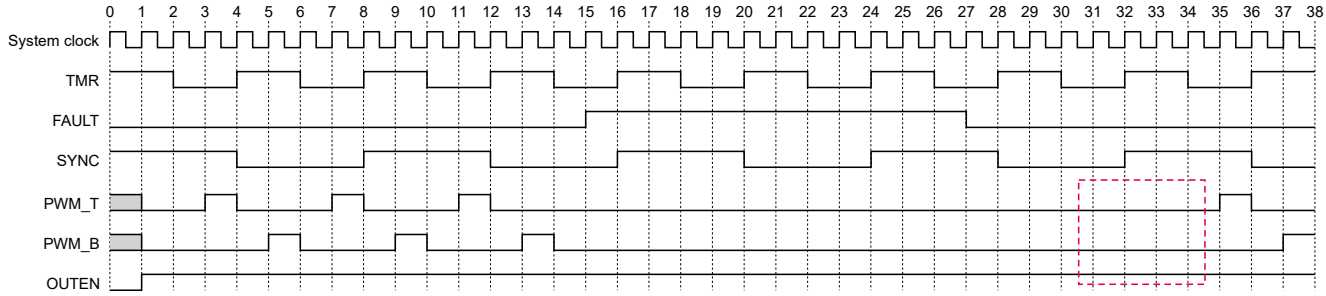

Figure 280. Waveforms for force cleared on rising sync after force deassertion

59.7.10 AC motor double-switching controller

59.7.10.1 Overview

The simplest method of obtaining motor winding currents is to measure the current in each phase by placing a shunt resistor in two or three inverter legs (phases).

This example implementation of an AC motor drive for low-cost and high-volume applications uses a single shunt on the DC bus return path, as illustrated in AC motor power stage schematic. LCU supports double-switching by XORing two timer channel outputs. The implementation uses two LCs arranged to perform double switching, dead time generation, and the processing of three external fault signals.

59.7.10.2 Double-switching

The double-switching technique requires:

- Six synchronized timer pulses
- Three fault signals
- Six PWM outputs for controlling top and bottom power switches
- A sync signal for automatic fault recovery

Waveforms for double-switching technique example applies the PWM switching cycle to an AC motor to reconstruct currents in three phases using a single DC bus shunt resistor (RSH). It applies the non-zero switching vectors 100, 110, and 101 to the power switches, which sample currents IA[0], -IC[0], -IC[1], and IA[1]. Because the durations (T1) of active vectors 110 and 101 are the same, it also applies the zero switching vector (000) with durations T2 and T3 in the middle of the switching cycle to

allow phase current reconstruction. This technique can only be used by PWM modules targeted at motor control and power conversion applications.

59.7.10.3 Fault inputs and deadtime insertion

Fault signals are routed from analog comparators or external protection circuits to protect power switches against damage caused by overcurrent. You must program the Combinational Force Path (LCn_FFILT[COMB_EN]) to enable an active fault input to immediately force all PWM outputs to the inactive state.

59.7.10.4 Deadtime insertion

In Waveforms for generation of PWM complementary signals using an LC, the PWMA_T output is generated by XORing timer outputs TMR0 and TMR1. The PWMA_B output is complementary to PWMA_T. Digital filters insert a dead time of one system clock cycle to delay the rising edges of both PWM signals.

59.7.10.5 Fault events

Waveforms for force cleared on force deassertion shows the reaction to the fault event. On a fault event, both the PWM outputs transition to the inactive state (logic 0). When fault event deasserts, both the PWM signals start operating according to FORCE_MODE = 00 (cleared on force deassertion).

Alternatively, after the fault event deasserts, fault clearing can be performed according to FORCE_MODE = 01 (cleared on rising sync force deassertion). See Waveforms for force cleared on rising sync after force deassertion for details.

59.7.11 Brushless DC (BLDC) motor PWM controller

59.7.11.1 Overview

You can use LCU to replace the mechanical commutator in the BLDC motor control application with Hall-sensor position measurement.

In this example implementation, LC0 receives the direction (DIR) and Hall A, Hall B, and Hall C sensor output states, and from those inputs generates the switching states S1, S2, and S3. LC1 and LC2 convert the switching states to PWM or on-off signals for controlling power switches, as illustrated in Waveforms for BLDC motor control technique.

BLDC motor power stage schematic and BLDC motor electrical arrangement illustrate a three-phase BLDC motor power stage with switching pulses and phase currents controlling motor rotation in the CCW direction. The state of the Hall sensors is 010. As the rotor shaft rotates, Hall sensors track the motor position. You accelerate or decelerate the motor by controlling the width of the PWM signal. You can include one or more faults (force inputs) to force power switches instantaneously into the inactive state if there is an overcurrent.

59.7.11.13 Waveforms for reversing BLDC motor

This figure illustrates the waveforms for controlling a reversing BLDC motor. The DIR input indicates the direction of rotation:

- Logic 0 for CW rotation
- Logic 1 for CCW rotation

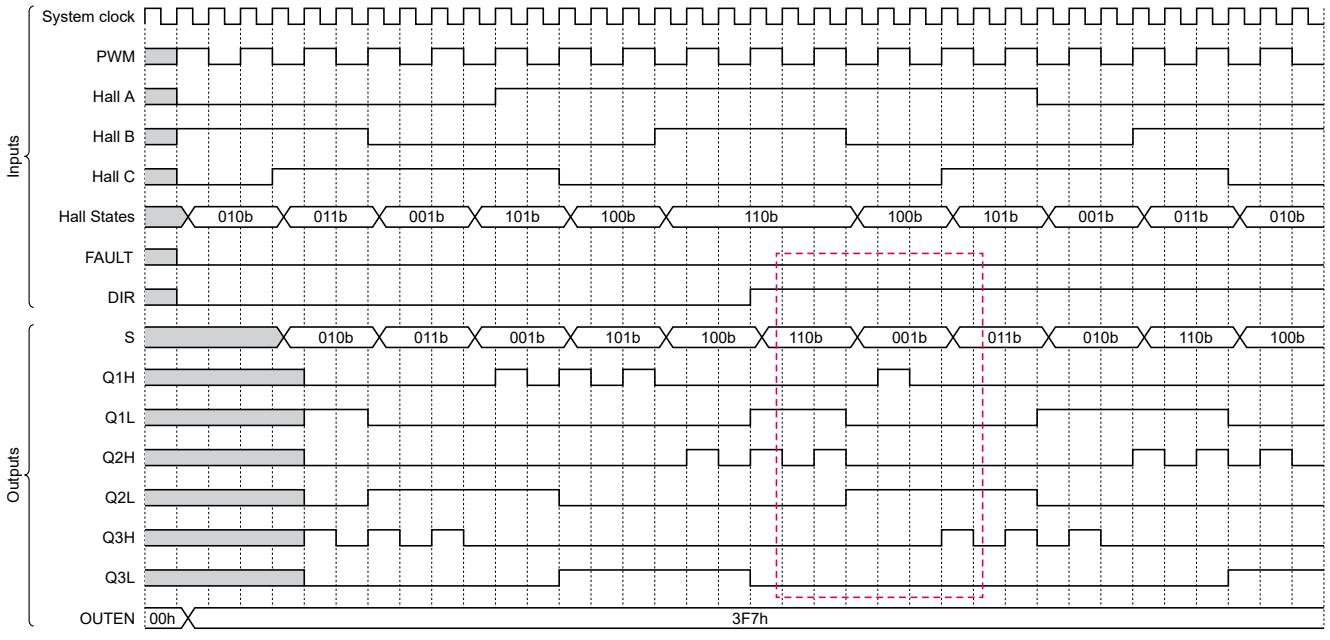

Figure 292. Waveforms for reversing BLDC motor

59.7.11.14 Waveforms for reversing BLDC motor with fault assertion

This figure illustrates the waveforms for the reaction to an external fault in addition to reversing the BLDC motor. On the occurrence of an external fault event, the power switches transition to the inactive state (logic 0). Two clock cycles after external fault deassertion, the power switches start operating normally.

Switching state outputs S1, S2, and S3, generated by LC0, receive an additional delay of one clock cycle on their way to the inputs of other LCs (digital filters bypassed).

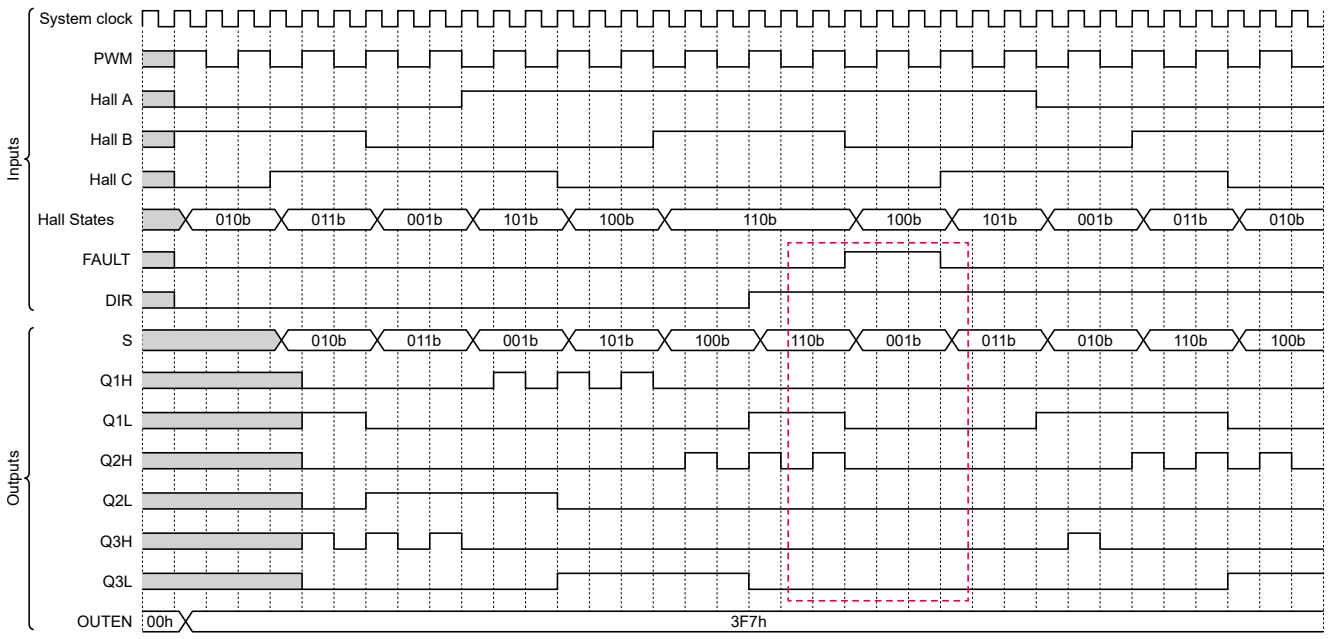

Figure 293. Waveforms for reversing BLDC motor with fault assertion

59.8 Registers

59.8.1 Mapping of 16-bit input, output, and state fields

This table maps inputs, outputs, or states to the bit positions in the following 16-bit fields:

- SWEN[SWEN]
- SWVALUE[SWVALUE]
- OUTEN[OUTEN]
- LCIN[LC_INPUTS]
- SWOUT[SWOUT]
- LCOUT[LCOUT]
- FORCEOUT[FORCEOUT]
- FORCESTS[FORCESTS]
- DBGEN[DBGEN]

LC	Input, output, or state	Bit
0	0	0
	1	1
	2	2
	3	3
1	0	4
	1	5
	2	6
	3	7

Fields

Field	Function
31-16 —	Reserved
15-0 LUTCTRL	LUT Control Specifies the LUT positions, based on the combined LC input value, that result in assertion of this output. For more information, see Logic operations.

59.9.3 LC n Output m Filter (LC0_FILT0 - LC2_FILT3)

Offset

For n = 0 to 2; m = 0 to 3:

Register	Offset
LCn_FILTm	10h + (n × 40h) + (m × 4h)

Function

Specifies the rising- and falling-edge thresholds for the LC output filters.

Diagram

Output	Bit
0	28
1	29
2	30
3	31

27 —	Reserved

Table continues on the next page...

Table continued from the previous page...

<table>
<tr><th>Field</th><th>Function</th></tr>
<tr><td>26-24
COMB_EN</td><td>Combinational Force Path (CFP) Enable
Enables an active force input to combinationally affect the LC outputs. When CFP is not enabled, force inputs must be synchronized and then optionally filtered. When you enable CFP (write 1 to one of these bits), the corresponding force input bypasses synchronization and filtering and immediately affects the LC output.
The Force Filter (FORCE_FILT) is still in effect. Force inputs that do not meet the pulse width requirements for synchronization and filtering are not registered in Force Status (FORCESTS) and you do not need to write 1 to change the bit to 0.
CFP provides a safety factor when the LC outputs drive a motor and immediate response is required. In some topologies, an oscillation can result if the assertion of the force input causes the LC output to turn off. This situation in turn leads to deassertion of the force input and the output turning back on. In general, you must disable CFP unless the LCU outputs drive a motor or similar safety-critical application, which requires an immediate response without synchronization delays.</td></tr>
<tr><td>23-19
—</td><td>Reserved</td></tr>
<tr><td>18-16
FORCE_POL</td><td>Force Input Polarity
Specifies the polarity of the force inputs to this LC.

Chapter 60
Enhanced Modular IO Subsystem (eMIOS)

60.1 Chip-specific eMIOS information

60.1.1 eMIOS configuration

This chip has up to three instances of eMIOS that are each configured as shown in the following tables.

Table 324. eMIOS instances

Instance	MWCT2D17S	MWCT2015S/ MWCT2016S/MWCT2D16S
eMIOS_0	Yes	Yes
eMIOS_1	Yes	Yes
eMIOS_2	Yes	No

Table 325. eMIOS configuration

Parameter	eMIOS_0	eMIOS_1	eMIOS_2
Timer width	16 bits	16 bits	16 bits
Number of channels	24	24	24
Channels configuration	See EMIOS channel configuration figure below		
Local Channel prescaler width	4	4	4
Number of global counter buses	2	2	2
Number of global prescaler	1	1	1
Global channel prescaler width	8	8	8

NOTE

eMIOS is clocked by CORE_CLK.

60.1.2 Channel types

The eMIOS contain 4 different types of channel, which are listed below.

Table 326. eMIOS channel types

Mode Description	Name	Ch TypeX	Ch TypeY	Ch TypeG	Ch TypeH
General Purpose Input / Output	GPIO	X	X	X	X
Single Action Input Capture	SAIC	X	X	X	X

60.1.3 Channel configuration

The eMIOS channel configuration with respect to Type and Counter_bus is shown below.

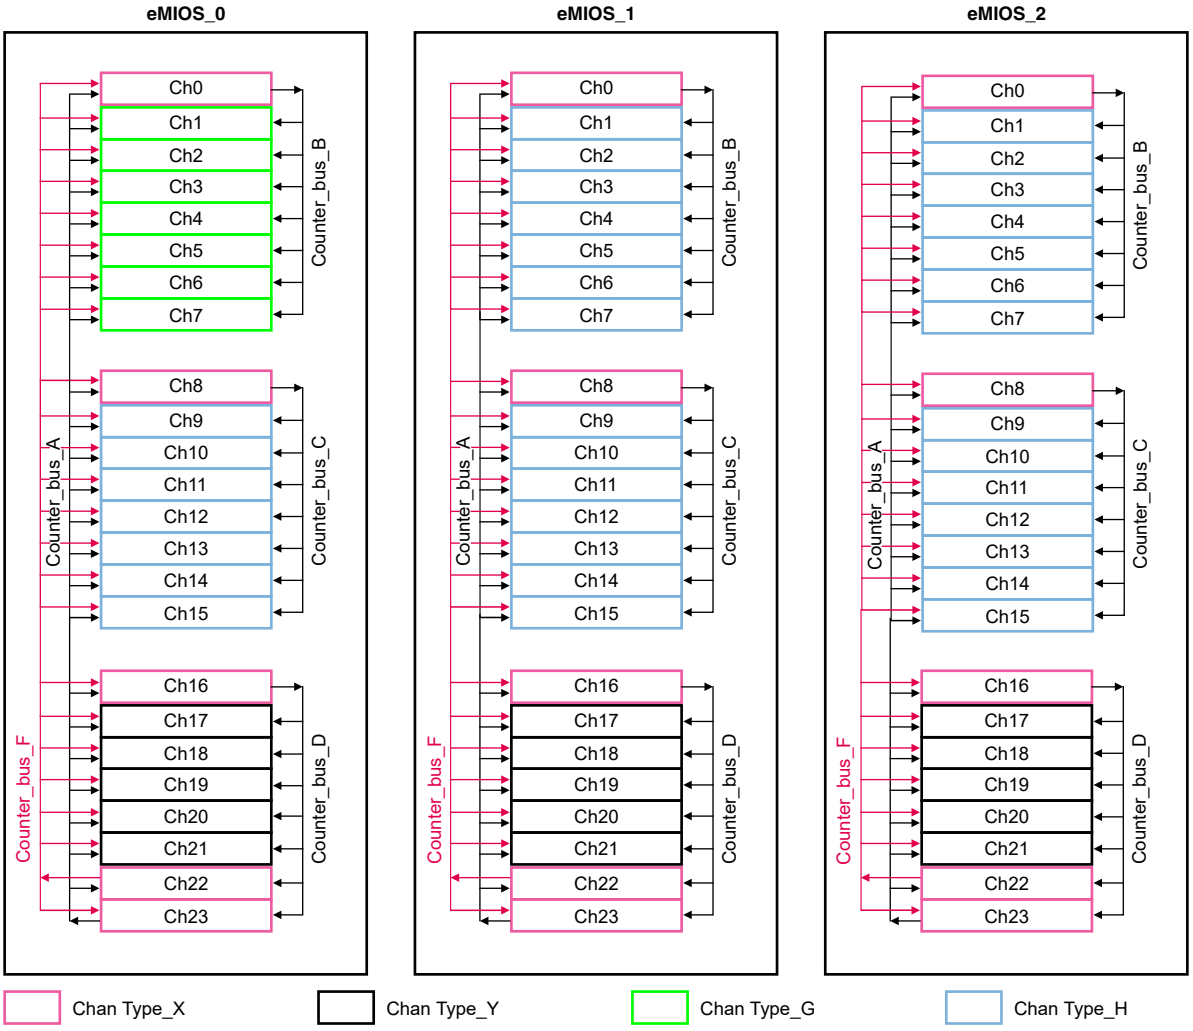

Figure 294. EMIOS channel types

60.1.4 eMIOS disabling

eMIOS can disable it's output using it's disable inputs. Disable inputs[3:0] are driven from the flag out bits[11:8].

Disable inputs	
eMIOS0 Output disable input[3:0]	trgmux_output[31:28]
eMIOS1 Output disable input[3:0]	trgmux_output[31:28]
eMIOS2 Output disable input[3:0]	trgmux_output[31:28]

For details, see the TRGMUX connectivity file attached to this document.

60.1.5 BCTU Interface

Each eMIOS channel, with the exception of the main counterbus channel (ch[23]) is capable of triggering the BCTU. See BCTU chapter for mapping. BCTU allows triggering from as many eMIOS modes as possible.

60.3 Introduction

eMIOS provides independent channels, UCs, that you configure to generate or measure time events for different functions in different chip applications.

eMIOS distributes these channels across a number of global and local counter buses. Each local bus is dedicated to a group of eight contiguous channels. Each channel can generate its own timebase, and each counter bus has its timebase provided by a dedicated channel. For a list of counter buses with their assigned channels and timebase sources, see Counter buses, channels, and timebase sources.

60.4 Block diagram

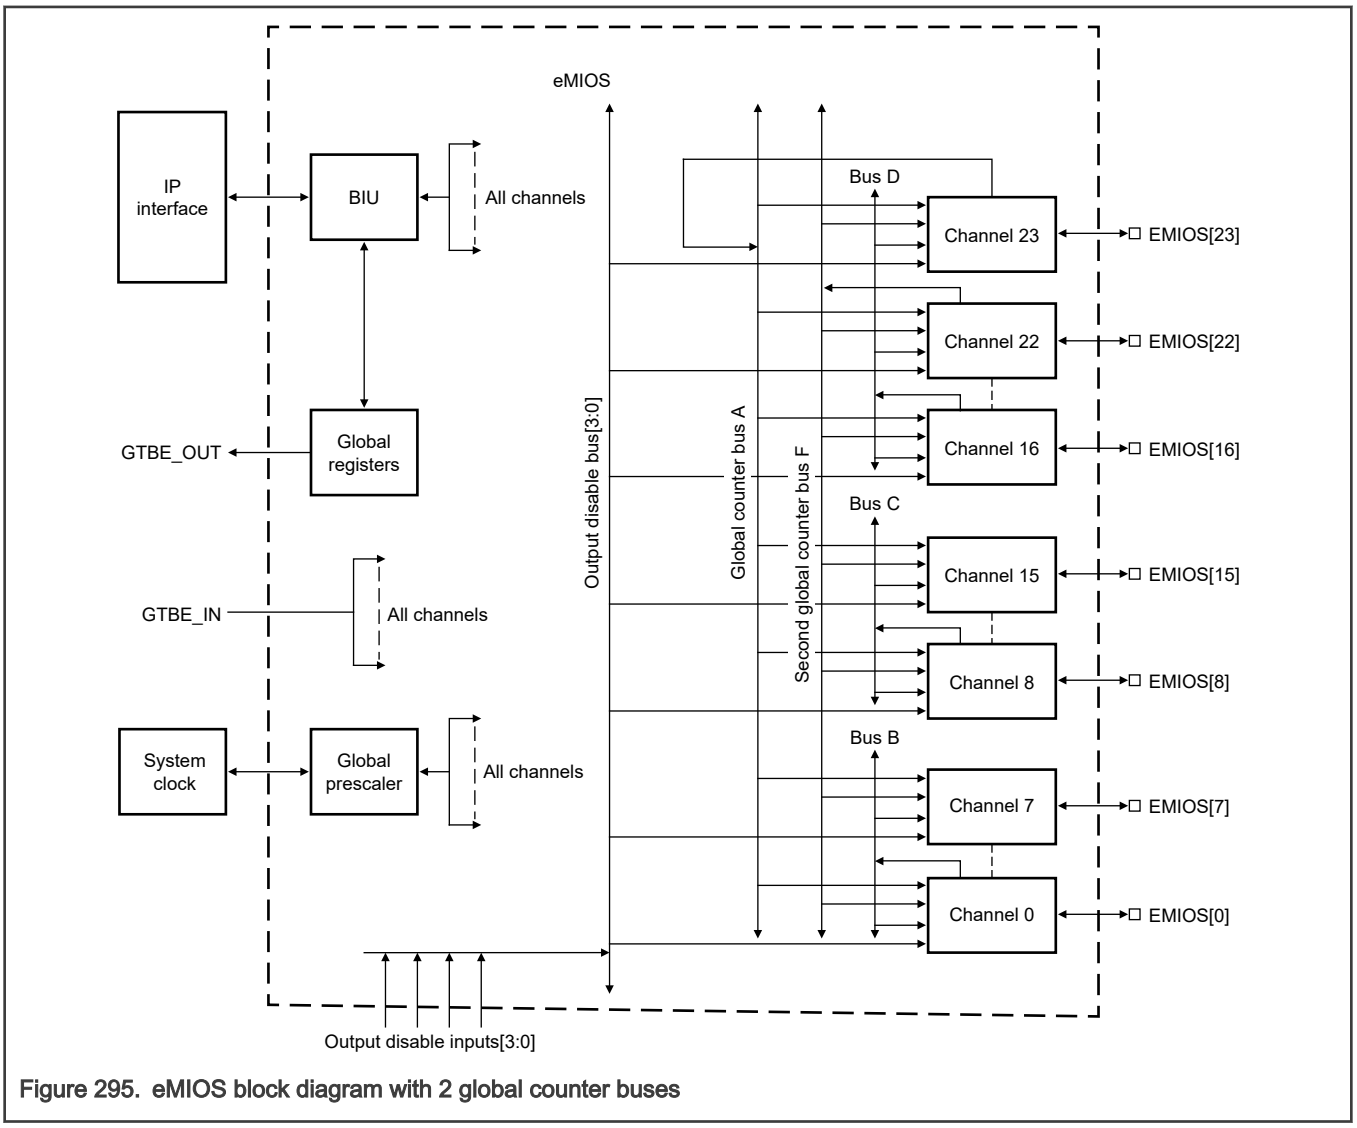

Figure 295. eMIOS block diagram with 2 global counter buses

60.5 Features

- 24 UCs distributed across local counter buses as shown in Counter buses, channels, and timebase sources
- Global counter bus A driven by UC23
- Global counter bus F driven by UC22
- Synchronized timebases shared through the counter buses

- Dedicated timebase for each channel, distinct from the counter buses
- Global clock prescaler (GCP)
- One CP per channel
- Dedicated set of control and status registers for each UC
- 16-bit–wide data registers
- Shadow flag register (GFLAG) to access all channel flags with one read access
- Ability to freeze the UC state for debug purposes
- Motor control capability

60.6 Functional description

60.6.1 Reset

eMIOS resets asynchronously. Reset affects all registers.

On reset, UCs enter GPIO input mode.

60.6.2 Counter buses, channels, and timebase sources

Table 328. Counter buses, channels, and timebase sources

Counter bus	Channels	Timebase channel
Global bus A	All UCs	23
Local bus B	• UC0 • UC1 • UC2 • UC3 • UC4 • UC5 • UC6 • UC7	0
Local bus C	• UC8 • UC9 • UC10 • UC11 • UC12 • UC13 • UC14 • UC15	8
Local bus D	• UC16	16

Table continues on the next page...

	• UC17 • UC18 • UC19 • UC10 • UC21 • UC22 • UC23	
Global bus F	All UCs	22

60.6.3 Unified channels (UC)

60.6.3.1 Overview

Each UC contains the following:

- Two double-buffered data registers, A*n* and B*n*, that allow up to two events—input capture, output compare, or both—to occur before software intervention is needed
- Two comparators, A and B, that indicate when the selected counter bus is equal to the value in A*n* and B*n*
- An internal counter (CNT*n*[C]) that runs in all modes except GPIO.

  You can use this counter as a local timebase or to count input events. You can use it as a timebase if CNT*n*[C] is not used in the current mode.
- An output flip-flop that holds the logic level to be applied to the output pin
- A status register, UC Status n (S0 - S23), that flags input capture and match events, indicates flag overruns and overflows, and shows the input and output pin states
- A control register, UC Control n (C0 - C23), that controls UC operation

You control the following operational characteristics for each UC:

- The logic (C*n*[MODE]) that specifies the behavior of the UC (see UC modes)
- The counter bus (C*n*[BSL]) that provides the timebase for all timing functions
- The CP (C*n*[UCPRE] and C2_*n*[UCEXTPRE])
- The minimum input pulse width (C*n*[IF]) for the input filter that determines valid pin transitions
- Which input edges to detect (C*n*[EDSEL])
- Which of four output disable input signals (C*n*[ODISSL]) to use for disabling outputs
- For all output modes except GPIO, whether to disable the output flip-flop (C*n*[ODIS])

UC block diagram illustrates the basic UC architecture.

For a list of counter buses and their assigned channels and timebase sources, see Counter buses, channels, and timebase sources.

60.6.3.2 UC block diagram

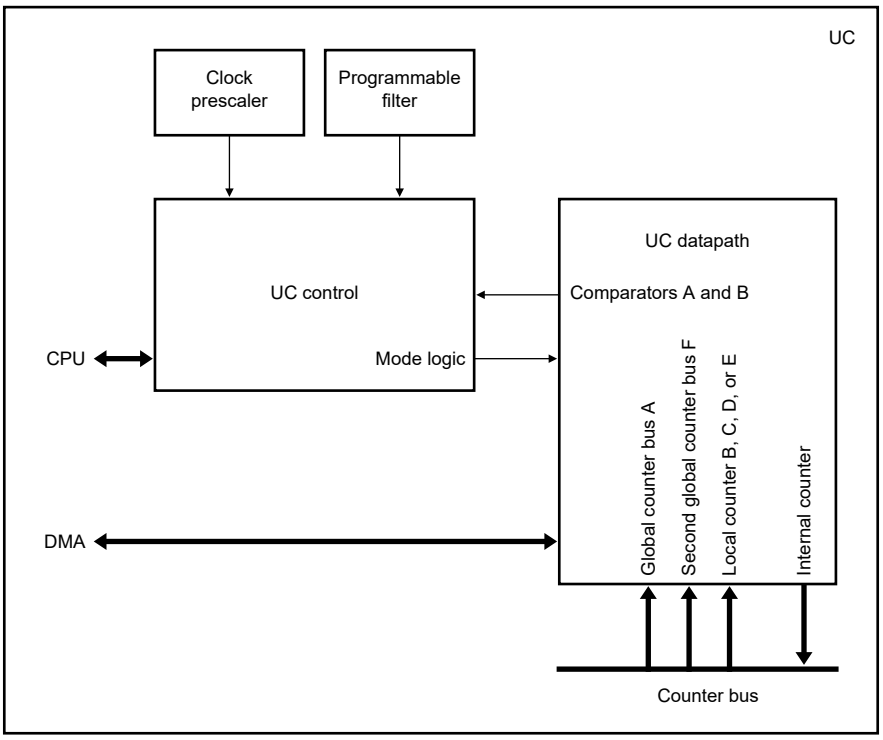

Figure 296. UC block diagram

60.6.3.3 Buffered modes

To provide smooth waveform generation even when A*n*[A] and B*n*[B] are changing, the following modes double buffer the A*n* and B*n* registers:

- Modulus Counter Buffered (MCB) mode
- Output Pulse Width and Frequency Modulation Buffered (OPWFMB) mode
- Output PWM Buffered (OPWMB) mode

These modes appear in separate sections because there are several basic differences in UC operation between them and their corresponding nonbuffered modes.

60.6.3.4 UC control and datapath

As illustrated in UC control and datapath diagram, the UC contains control and datapath subblocks.

The control subblock generates signals to control the multiplexers in the datapath subblock. eMIOS implements each UC mode in dedicated logic independent from the other modes. The UC modes share a set of registers allowing the storing of sequential events.

The datapath block contains the channel A and B registers, the internal timebase, and the comparators. Multiplexers receive inputs from the control subblock to configure the datapath for the specific channel modes. This configuration consists of selecting the input of comparators and data for the register inputs. The outputs of the A and B comparators connect to the control block.

60.6.3.5 UC control and datapath diagram

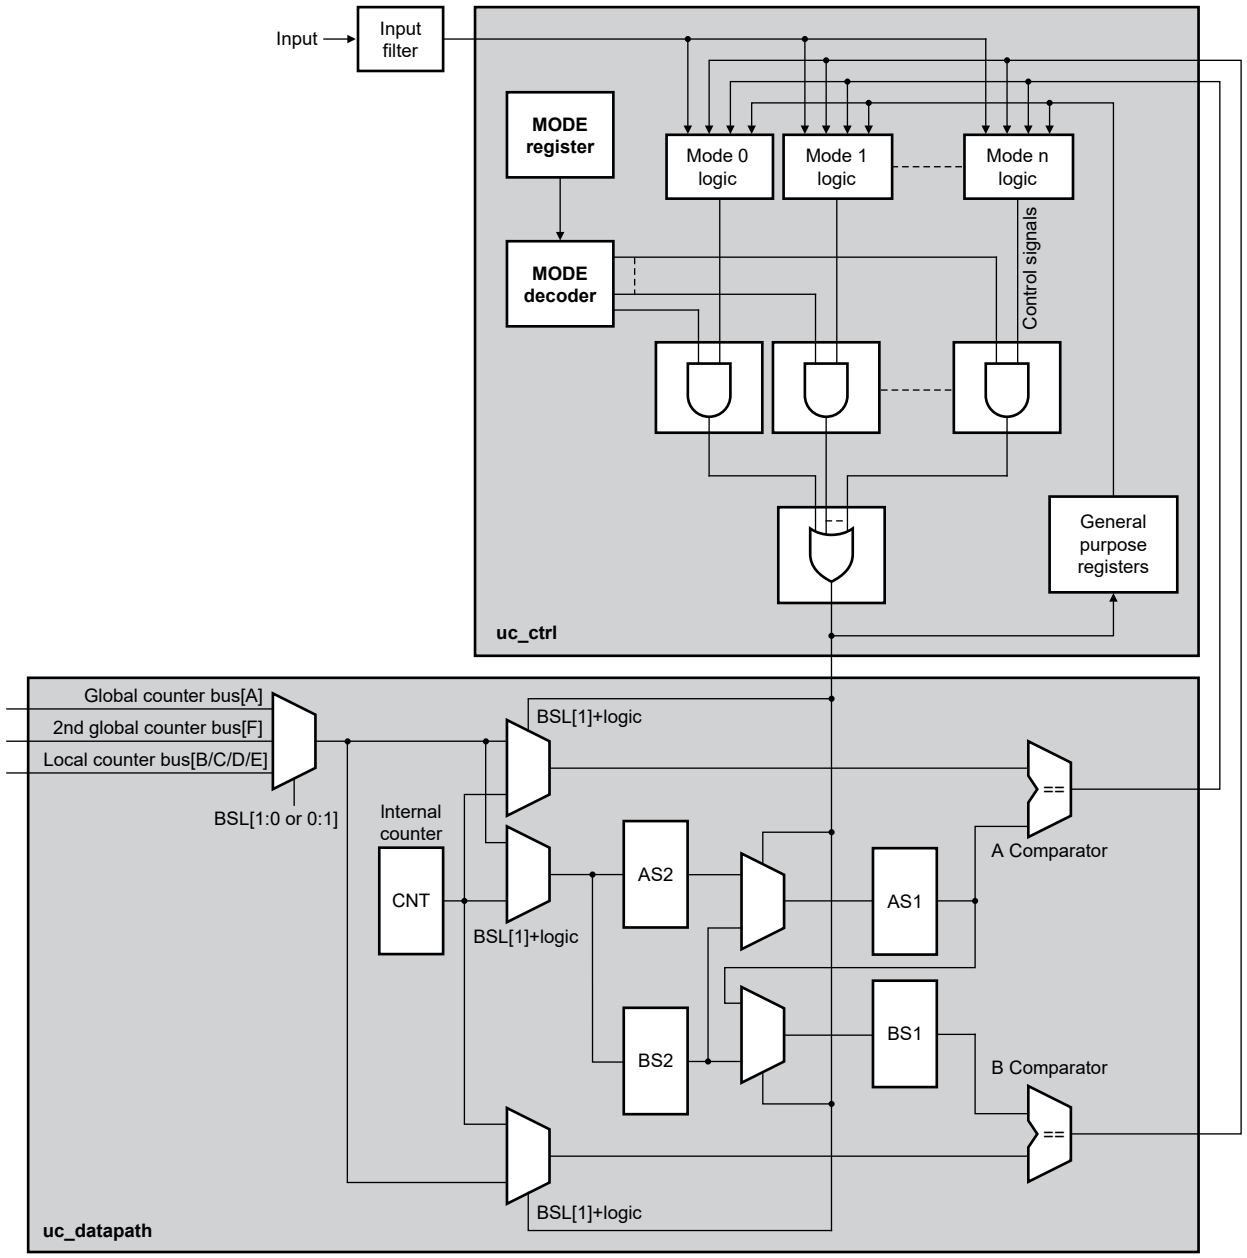

Figure 297. UC control and datapath diagram

60.6.3.6 UC modes

You can configure UCs to operate in the following modes:

- General-Purpose Input and Output (GPIO) mode
- Single Action Input Capture (SAIC) mode
- Single Action Output Capture (SAOC) mode
- Input Pulse Width Measurement (IPWM) mode
- Input Period Measurement (IPM) Mode

- Double Action Output Compare (DAOC) mode
- Pulse Edge Counting (PEC) mode
- Modulus Counter (MC) mode
- Modulus Counter Buffered (MCB) mode
- Output Pulse Width and Frequency Modulation Buffered (OPWFMB) mode
- Center Aligned Output PWM with Dead Time Insertion Buffered (OPWMCB) mode
- Output PWM Buffered (OPWMB) mode
- Output PWM with Trigger (OPWMT) mode

Each channel supports a specific subset of these modes. See the chip-configuration information to see which modes each channel supports.

60.6.3.7 General-Purpose Input and Output (GPIO) mode

60.6.3.7.1 Overview

This mode disables all UC input-capture and output-compare functions, and resets and disables the internal counter (C*n*[C]). All control fields remain accessible.

To change the UC from one operation mode to another, you must first change to GPIO mode and then change to the desired final mode. To prepare the UC for a new operation mode, you must configure AS1, BS1, AS2, and BS2 before exiting GPIO mode and entering the desired final mode (see AS1, AS2, BS1, and BS2 shadow registers). Specifically:

- Writing to A*n*[A] stores the same value in AS1 and AS2.
- Writing to B*n*[B] stores the same value in BS1 and BS2.
- Writing to ALTA*n*[ALTA] stores a value only in AS2.

As its name implies, GPIO mode supports both input and output submodes. See Differences for input and output submodes.

60.6.3.7.2 Differences for input and output submodes

Table 329. Differences for input and output submodes

Submode	To enter submode, write this value to C*n*[MODE]	Characteristics
Input	0	• You control the generation of input-capture flags with C*n*[EDPOL] and C*n*[EDSEL]. • You can determine the input pin status by reading S*n*[UCIN].
Output	1	• The UC performs as a single output port pin. • The value of C*n*[EDPOL] permanently drives the output flip-flop.

60.6.3.8 Single Action Input Capture (SAIC) mode

60.6.3.8.1 Overview

In this mode, when a triggering event occurs on the input pin, eMIOS:

- Captures the selected timebase into AS2
- Changes S*n*[FLAG] to 1 to indicate that an input capture has occurred

A*n*[A] returns the value of AS2. As soon as the UC enters SAIC mode after exiting GPIO mode, the channel is ready to capture events.

eMIOS captures the events as soon as they occur. Therefore, reading A*n*[A] always returns the value of the latest captured event. Subsequent capture events occur regardless of whether you read the previous event from A*n*[A]. Each new capture event sets the input capture flag (writes 1 to S*n*[FLAG]).

The input capture is triggered by an edge transition on the input pin as configured by C*n*[EDPOL] and C*n*[EDSEL].

SAIC with rising edge triggering and SAIC with both edges triggering show how to use the UC for input capture.

60.6.3.8.2 SAIC submodes and MODE field values

Table 330. SAIC submodes and MODE field values

Capture behavior	C*n*[MODE] (binary)
The UC only captures the timestamp.	000_0010
• The UC captures a timestamp. • AS2 bit 0 indicates the input signal level.	100_0010

60.6.3.8.3 Effect of C*n*[EDPOL] on edge capturing

Table 331. Effect of C*n*[EDPOL] on edge capturing

C*n*[EDPOL]	Input signal transition	Resulting value of AS2 bit 0
0	0→1	0
	1→0	1
1	0→1	1
	1→0	0

60.6.3.8.4 SAIC with rising edge triggering

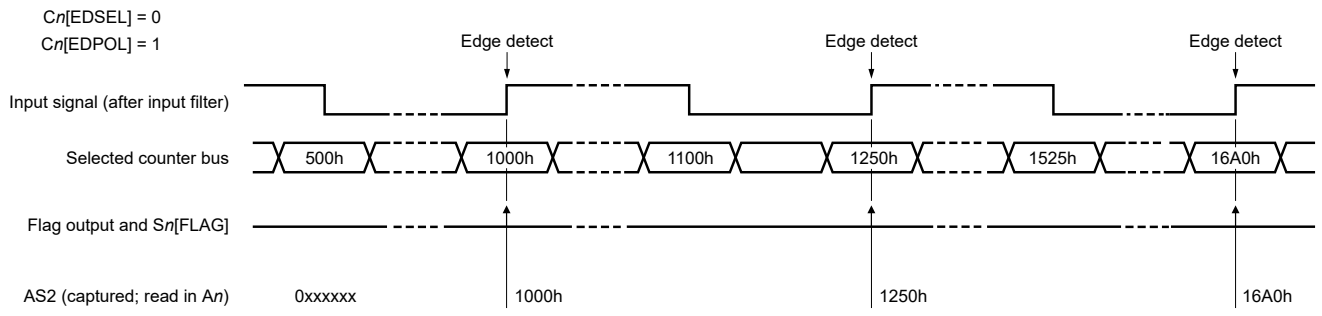

Figure 298. SAIC with rising edge triggering

60.6.3.8.5 SAIC with both edges triggering

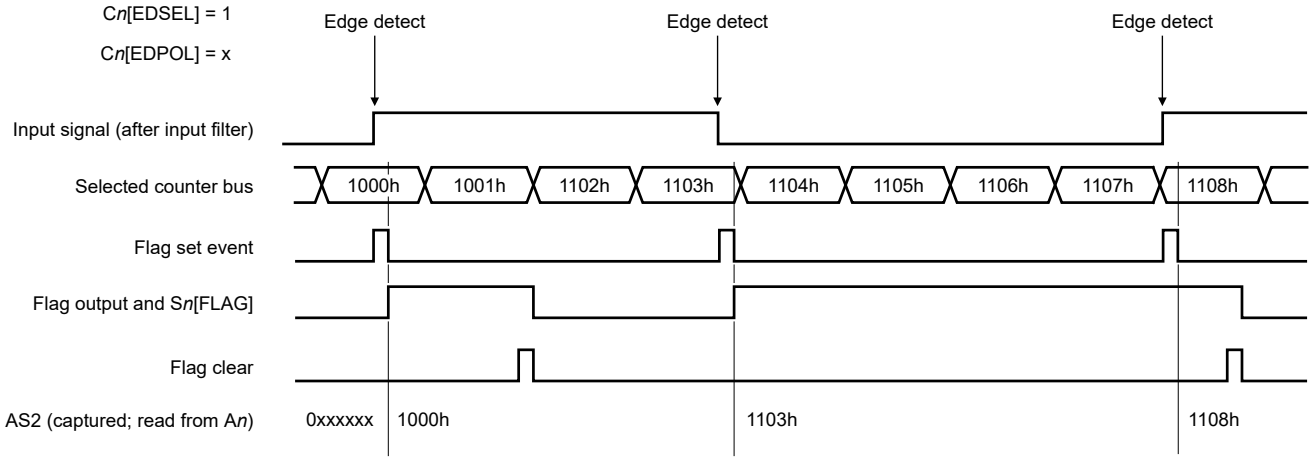

Figure 299. SAIC with both edges triggering

60.6.3.9 Single Action Output Capture (SAOC) mode

60.6.3.9.1 Overview

In this mode, eMIOS loads a match value into AS2 and then immediately transfers it to AS1 for comparison with the selected timebase. When an output-compare match occurs, eMIOS:

- Either toggles the output flip-flop or transfers C*n*[EDPOL] to the output flip-flop, as determined by C*n*[EDSEL].
- Sets the input capture flag (changes S*n*[FLAG] to 1).

Along with the match, S*n*[FLAG] becomes 1 to indicate that the output-compare match has occurred. Writing to A*n*[A] stores the value in AS2, and reading A*n*[A] returns the AS1 value.

The channel internal counter in SAOC mode is free-running. It starts counting as soon as the UC enters SAOC mode.

You can force an output-compare match by writing 1 to C*n*[FORCMA]. A forced output-compare match does not set the input capture flag (S*n*[FLAG]).

When the UC enters SAOC mode after exiting GPIO mode, the output flip-flop value becomes the complement of C*n*[EDPOL].

You select the internal or external counter bus with C*n*[BSL].

SAOC with C*n*[EDPOL] transferred to the output flip-flop shows how to perform a single output compare and transfer C*n*[EDPOL] to the output flip-flop.

SAOC toggling the output flip-flop shows how to perform a single output compare and toggle the output flip-flop at each match.

60.6.3.9.2 Preload the desired match value

eMIOS enables matches immediately after the UC enters SAOC mode. Therefore, you must write the desired match value to AS1 before the UC enters SAOC mode. You can update AS1 at any time. This modifies the match value reflected in the channel-generated output signal. Subsequent capture events occur regardless of whether you write to A*n*[A] again. Each new capture event sets the input capture flag (S*n*[FLAG]). See SAOC with flag behavior.

60.6.3.9.3 SAOC with C*n*[EDPOL] transferred to the output flip-flop

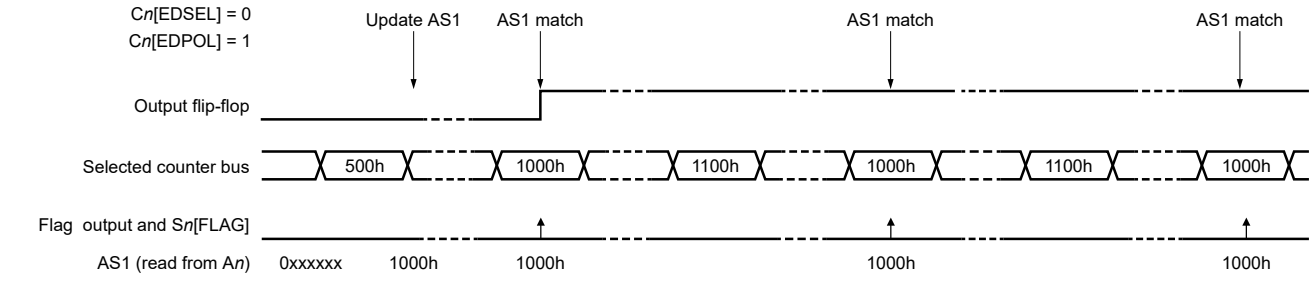

Figure 300. SAOC with C*n*[EDPOL] transferred to the output flip-flop

60.6.3.9.4 SAOC toggling the output flip-flop

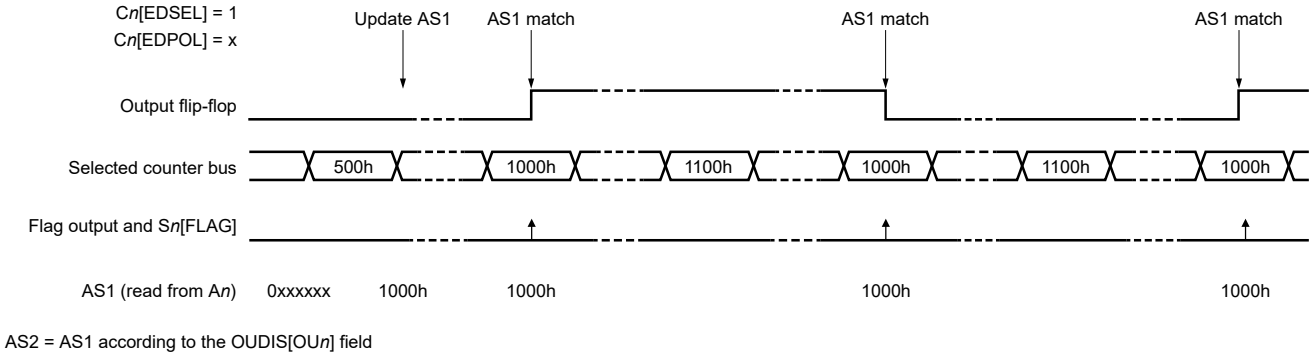

Figure 301. SAOC toggling the output flip-flop

60.6.3.9.5 SAOC with flag behavior

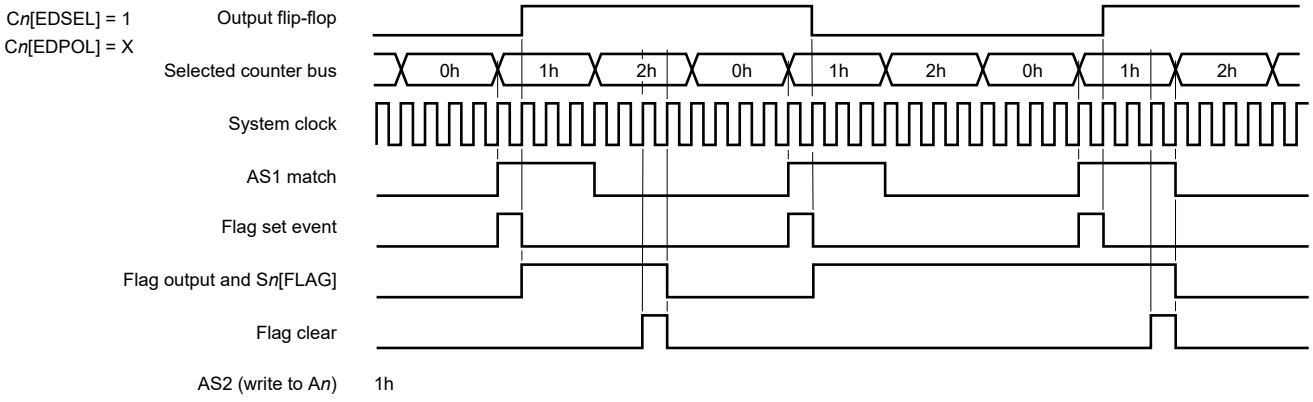

Figure 302. SAOC with flag behavior

60.6.3.10 Input Pulse Width Measurement (IPWM) mode

60.6.3.10.1 Overview

This mode allows you to measure the width of a positive or negative pulse. Select whether to measure from the rising or falling edge with Edge Polarity (Cn[EDPOL]).

The first leading edge:

- Triggers the first input capture, which latches the count value of the selected timebase into BS2 (see AS1, AS2, BS1, and BS2 shadow registers)
- Does not set the input-capture flag (Sn[FLAG])
- Enables AS2 capture

The next trailing edge:

- Latches the selected timebase into AS2
- Sets the input-capture flag (Sn[FLAG])
- Transfers BS2 to BS1 and AS1

eMIOS captures successive values on consecutive edges of opposite polarity. If you initiate subsequent input capture events while the input-capture flag (Sn[FLAG]) is set, eMIOS updates AS2, BS1, and AS1 with the latest captured values and keeps the flag set.

60.6.3.10.2 Coherency

Reading A*n*[A] updates BS1 with AS1. It also disables transfers from BS2 and BS1 until the next read of B*n*[B].

Reading Bn updates BS1 with AS1. It also re-enables transfers from BS2 to BS1, which takes effect at the next trailing edge capture.

Because transfers from BS2 to AS1 are never blocked, to guarantee data coherency you must read An, then read Bn.

If you do not require coherent data, you should read Bn before you read An, although doing so requires a second read of Bn to unblock BS1 updates.

60.6.3.10.3 Timing example: measure pulse width

This figure shows how to measure the input pulse width by subtracting BS1 from AS2.

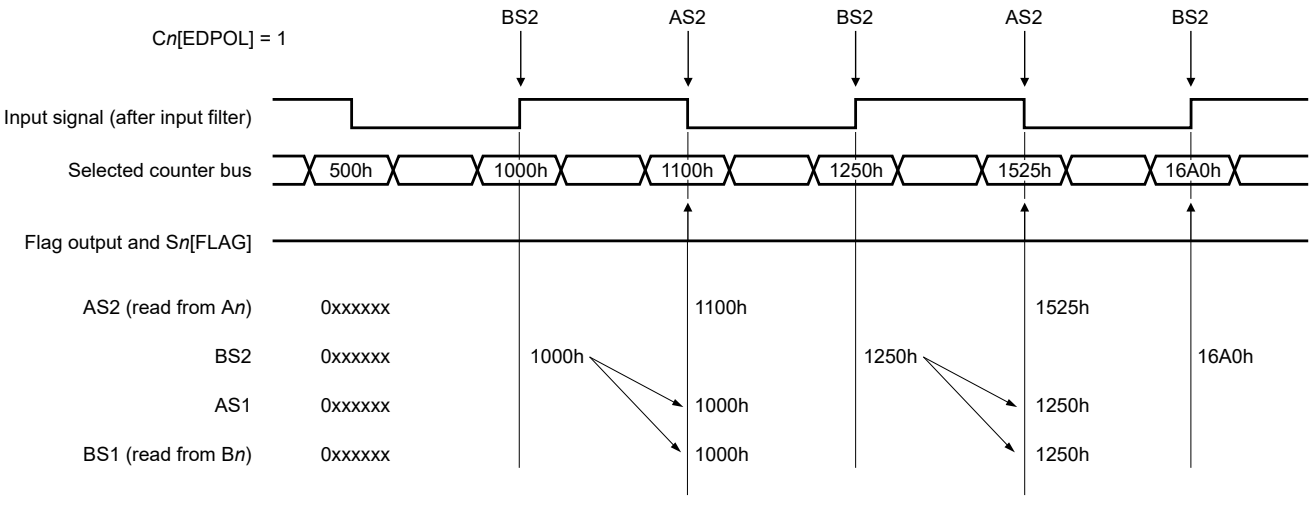

Figure 303. Timing example: measure pulse width

60.6.3.10.4 Timing example: AS1 and BS1 updates on channel reads

This example illustrates AS1 and BS1 updates when you read A*n*[A] and B*n*[B]. AS1 always has coherent data related to AS2 (see Coherency).

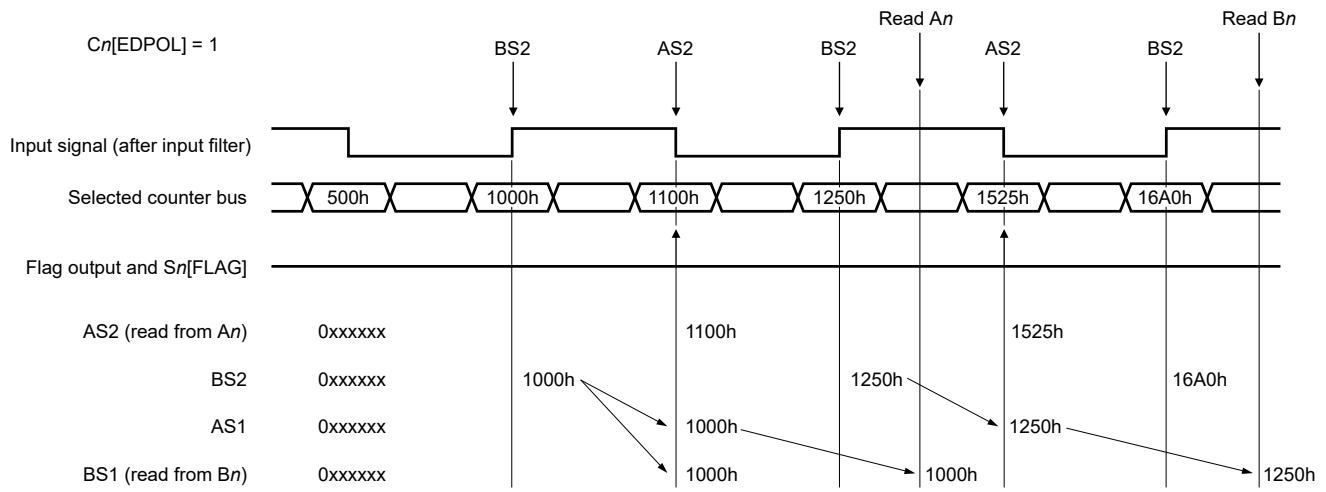

Figure 304. Timing example: BS1 and AS1 updates on channel reads

60.6.3.11 Input Period Measurement (IPM) Mode

60.6.3.11.1 Overview

This mode allows you to measure the period of an input signal. Select whether to measure from the rising or falling edges with Edge Polarity (C*n*[EDPOL]).

The first edge of selected polarity:

- Latches the selected timebase into AS2 and BS2 (see AS1, AS2, BS1, and BS2 shadow registers)
- Transfers BS2 to BS1
- Does not set the input-capture flag (S*n*[FLAG])

The second edge of the same polarity:

- Latches the counter bus value into AS2 and BS2
- Transfers BS2 to BS1 and AS1
- Sets the input-capture flag (S*n*[FLAG])

eMIOS repeats this process for each subsequent capture.

eMIOS captures successive values on two consecutive edges of the same polarity. The measured input signal must have a period of at least four system clock cycles to be properly captured by the synchronization logic at the channel input, even if the input filter is in bypass mode.

60.6.3.11.2 Coherency

Reading A*n*[A] updates BS1 with AS1, which provides coherent data in AS2 and BS1 (see Timing example: AS1 and BS1 updates on channel reads). It also disables transfers from BS2 and BS1 until the next read of B*n*[B].

Reading B*n*[B] updates BS1 with AS1. It also re-enables transfers from BS2 to BS1, which takes effect at the next edge capture.

60.6.3.11.3 Timing example: measure input period

This example illustrates how to measure the input period by subtracting BS1 from AS2.

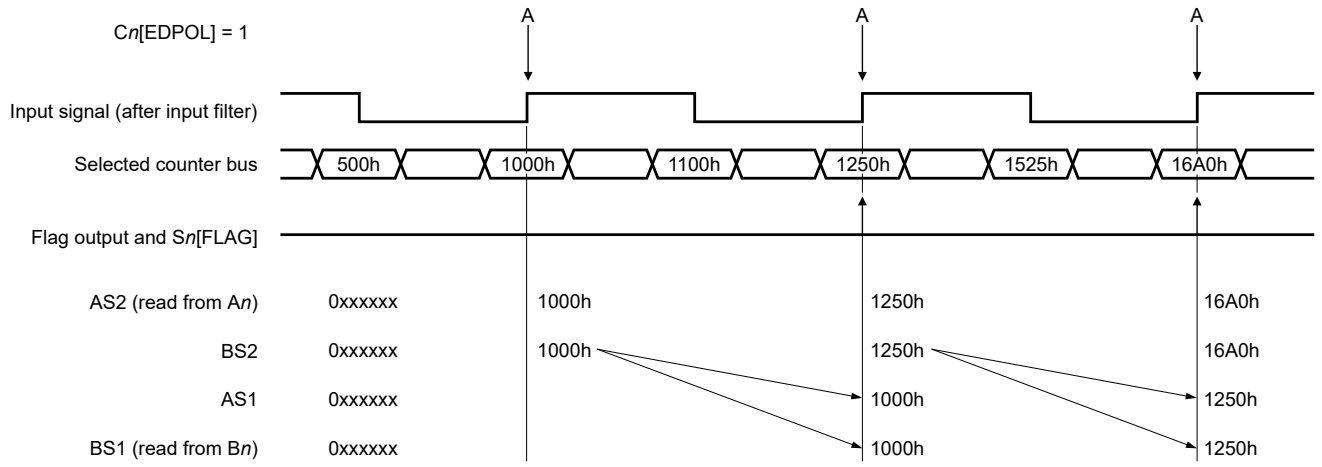

Figure 305. Timing example: measure input period

60.6.3.11.4 Timing example: AS1 and BS1 updates on channel reads

This diagram illustrates AS1 and BS1 updates when you read A*n*[A] and B*n*[B].

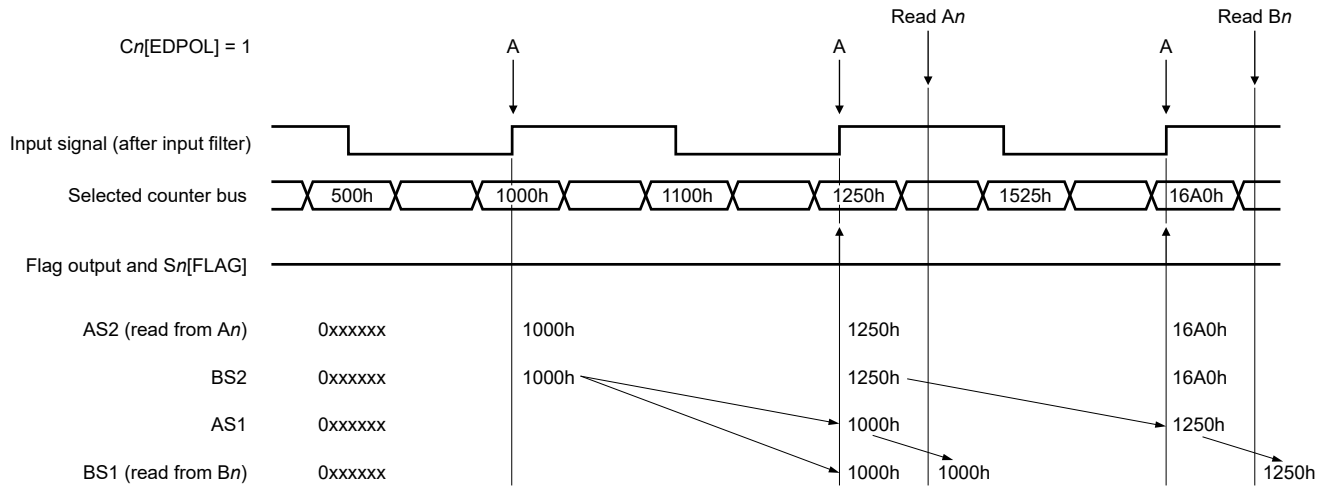

Figure 306. Timing example: AS1 and BS1 updates on channel reads

60.6.3.12 Double Action Output Compare (DAOC) mode

60.6.3.12.1 Overview

In this mode, matches on comparators A and B cause the UC to generate the leading and trailing edges of the variable pulse width output. See DAOC submodes and MODE field values. There is no restriction on the order in which A and B matches occur.

When the UC enters DAOC mode from GPIO mode, eMIOS disables both comparators and drives the complement of Edge Polarity (C*n*[EDPOL]) onto the output flip-flop.

60.6.3.12.2 DAOC submodes and MODE field values

Table 332. DAOC submodes and MODE field values

When set flag event occurs	C*n*[MODE] (binary)
Only on B matches	000_0110
On A or B matches	000_0111

60.6.3.12.3 Data transfer and compare

If you enable output (write 0 to OUDIS[OU*n*]), on the next clock cycle the UC transfers AS2 and BS2 to AS1 and BS1 respectively (see Timing example: leading dead time insertion). If you disable output (write 1 to OUDIS[OU*n*]), no transfer occurs.

eMIOS enables and disables the A and B comparators independently. It enables comparator A only after the transfer to AS1 completes, and disables comparator A on the next A match. Similarly, eMIOS enables comparator B only after the transfer to BS1 completes, and disables comparator B on the next B match.

When a match occurs on comparator A, the output flip-flop acquires the value of Edge Polarity (C*n*[EDPOL]). When a match occurs on comparator B, the output flip-flop acquires the complement of Edge Polarity (C*n*[EDPOL]).

60.6.3.12.4 Differences between flag on A match and flag on A and B matches

In the flag on B match submode (see DAOC submodes and MODE field values), the UC sets the input-capture flag (S*n*[FLAG]) only for matches on the B comparator. In the flag on both A and B matches submode, it sets the flag for matches on either comparator.

If subsequent enabled output compares occur on AS1 or BS1, the UC continues generating pulses regardless of the flag state.

If you load both AS1 and BS1 with the same value, the B match takes precedence and the UC drives the complement of Edge Polarity (C*n*[EDPOL]) onto the output flip-flop.

60.6.3.12.5 Forced operation by Cn[FORCMA] and Cn[FORCMB]

Force Match A (C*n*[FORCMA]) and Force Match B (C*n*[FORCMB]) allow you to force the output flip-flop to the level corresponding to the comparator, Edge Polarity (C*n*[EDPOL]) for an A match, or the complement of Edge Polarity for a B match. The force-match operations do not set the input-capture flag (S*n*[FLAG]).

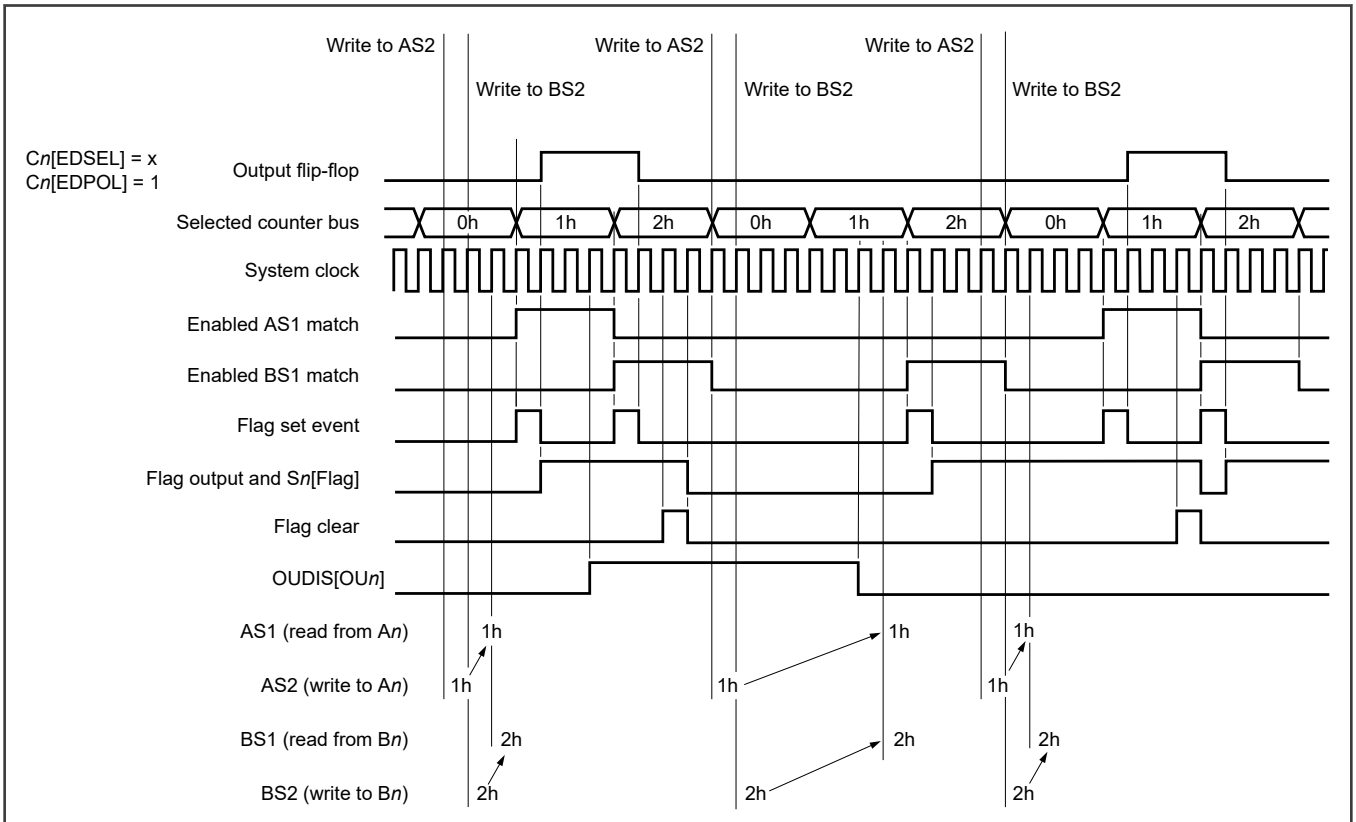

Figure 309. Timing example: transfer disabling

60.6.3.13 Pulse Edge Counting (PEC) mode

60.6.3.13.1 Overview

This mode counts the number of pulses or edges detected on the input for a desired time window. C*n*[EDSEL] and C*n*[EDPOL] determine which edges the UC counts.

Specify the window start time in AS1 and the end time in BS1. After you write to AS1, when the selected timebase matches comparator A, eMIOS resets the internal counter and starts counting input events. When the timebase matches comparator B, eMIOS:

- Disables the internal counter.
- Transfers the counter's content to AS2.
- Sets the input-capture flag (changes S*n*[FLAG] to 1).

You obtain the number of detected pulses by reading C*n*[C] or AS2.

Timing example continuous and Timing example single-shot show how to use the UC in continuous or single-shot operation.

60.6.3.13.2 PEC submodes and MODE field values

Table 333. PEC submodes and MODE field values

Operation	C*n*[MODE] (binary)
Continuous; the next match between comparator A and the selected timebase resets the internal counter and enables counting again. To guarantee coherent measurements when you read C*n*[C] after S*n*[FLAG] becomes 1, you must check if the timebase value is out of the time interval defined by AS1 and BS1. Alternately, AS2 (available in ALTA*n*[ALTA]) always holds the latest available measurement, providing coherent data at any time after the first set-flag event.	000_1010
Single-shot; The next match between comparator A and the selected timebase has no effect until you write to A*n*[A]. eMIOS also transfers the C*n*[C] value to AS2 when a match in the B comparator occurs.	000_1011

60.6.3.14 Modulus Counter (MC) mode

60.6.3.14.1 Overview

In this mode, the UC produces a timebase for a counter bus or as a general purpose timer. The internal counter (C*n*[C]) counts up from the current value until it matches AS1.

Selecting external clock source (see MC submodes and MODE field values) causes the UC to uses the input signal pin as the source. You select the triggering polarity edge using Edge Polarity (C*n*[EDPOL]) and Edge Select (C*n*[EDSEL]).

You must write only non-zero values to A*n*[A]. Writing to A*n*[A] or the internal counter may cause a match to be missed and the counter to roll over and resume operation in the next cycle. The channel writes 0 to BS1, which is not accessible by the MCU. You can read and write BS2, but it is not used in this mode.

60.6.3.14.2 MC submodes and MODE field values

Table 334. MC submodes and MODE field values

Submode or function	C*n*[MODE] (binary)
Internal clock source	001_0pp0[1]
External clock source	001_0pp1[1]
Internal counter reset on match start	001_0p0p[1]
Internal counter reset on match end	001_0p1p[1]
Up Count	001_00pp[1]
Up Count-Down Count	001_01pp[1]

1. *p* = Adjust parameters for submodes and options. See Unified channels (UC).

60.6.3.14.3 Up Count submode

Table 335. Up Count submode operation

Counter reset timing[1]	C*n*[MODE]		
	Bit 1	External clock (Bit 0 = 1)	Internal clock (Bit 0 = 0)
Reset on match start	0	When the AS1 match occurs, the UC: • Writes 0 to the internal counter. • Sets the input-capture flag (S*n*[FLAG]). • Increments the internal counter at the next input event, resulting in a short zero count.	When the AS1 match occurs, the UC: • Writes 0 to the internal counter. • Sets the input-capture flag (S*n*[FLAG]). • Maintains the internal counter at 0 on the next prescaler tick after the match. • Resumes counting on the next prescaler tick.
		See Timebase with the fastest prescaler ratio and Timebase generation with clear on match start and internal clock.	
Clear on match end	1	When the next input event after the AS1 match occurs, the UC: • Writes 0 to the internal counter. • Sets the input-capture flag (S*n*[FLAG]).	When the next internal counter tick after the AS1 match occurs, the UC: • Writes 0 to the internal counter. • Sets the input-capture flag (S*n*[FLAG]).
		See Timebase with the fastest prescaler ratio and Timebase generation with clear on match end.	

1. If you select internal clock source and a prescaler value of 1 for the internal counter, the behavior is the same for both submodes.

See Timing example: Up Count submode.

60.6.3.14.4 Timing example: Up Count submode

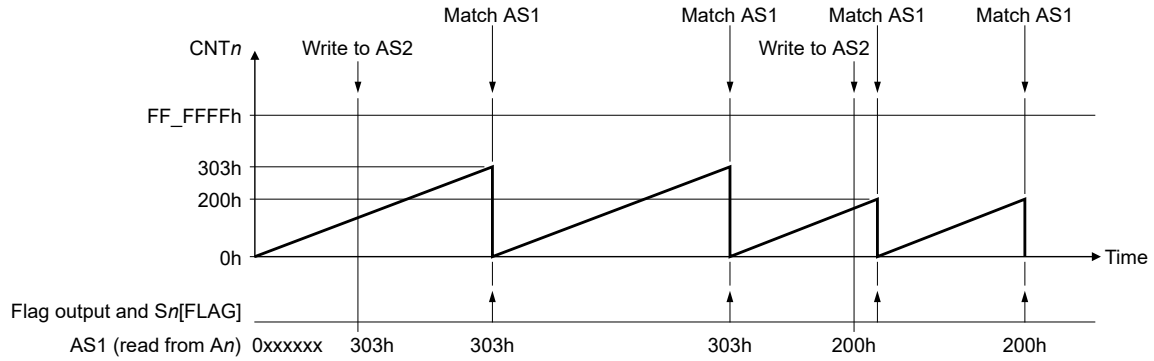

Figure 312. Timing example: Up Count submode

60.6.3.14.5 Up Count-Down Count submode operation

In Up Count-Down Count submode:

- When the internal counter matches AS1, the counter begins decrementing and the UC sets the input-capture flag (S*n*[FLAG]).
- When the internal counter matches BS1, the counter begins incrementing and, if in clear on match end operation (C*n*[1] = 1), the UC sets the input-capture flag (S*n*[FLAG]).

See Timing example: Up Count-Down Count submode.

60.6.3.14.6 Timing example: Up Count-Down Count submode

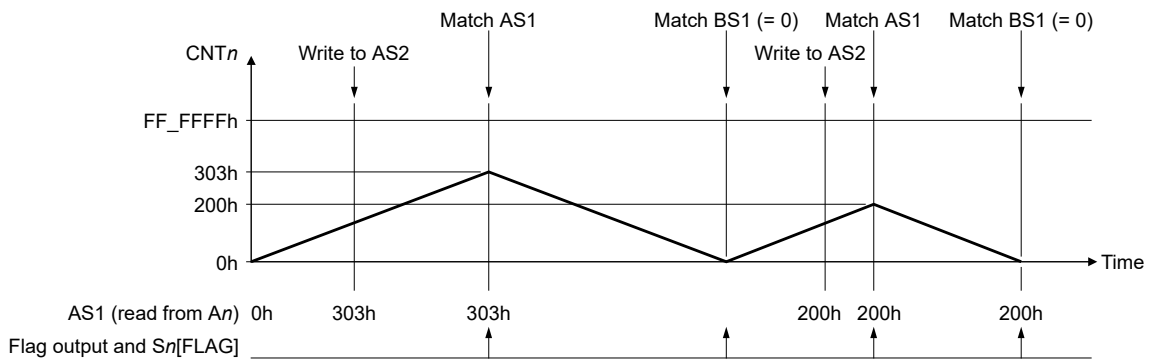

Figure 313. Timing example: Up Count-Down Count submode

60.6.3.14.7 Up Count with delayed reload operation

When the internal counter matches AS1 in the Up Count submode or BS1 in the Up Count-Down Count submode, the UC asserts the counter bus reload signal. You can read the counter bus reload signal in the following modes:

- Output PWM Buffered (OPWMB) mode
- Output Pulse Width and Frequency Modulation Buffered (OPWFMB) mode
- Center Aligned Output PWM with Dead Time Insertion Buffered (OPWMCB) mode

You can use the Reload Signal Output Delay Interval (C2*n*[UCRELDEL_INT]) to cause the UC to assert the reload signal only after a specified number of match events (from 2 to 32).

See Timing example: Up Count mode with delayed reload.

60.6.3.14.8 Timing example: Up Count mode with delayed reload

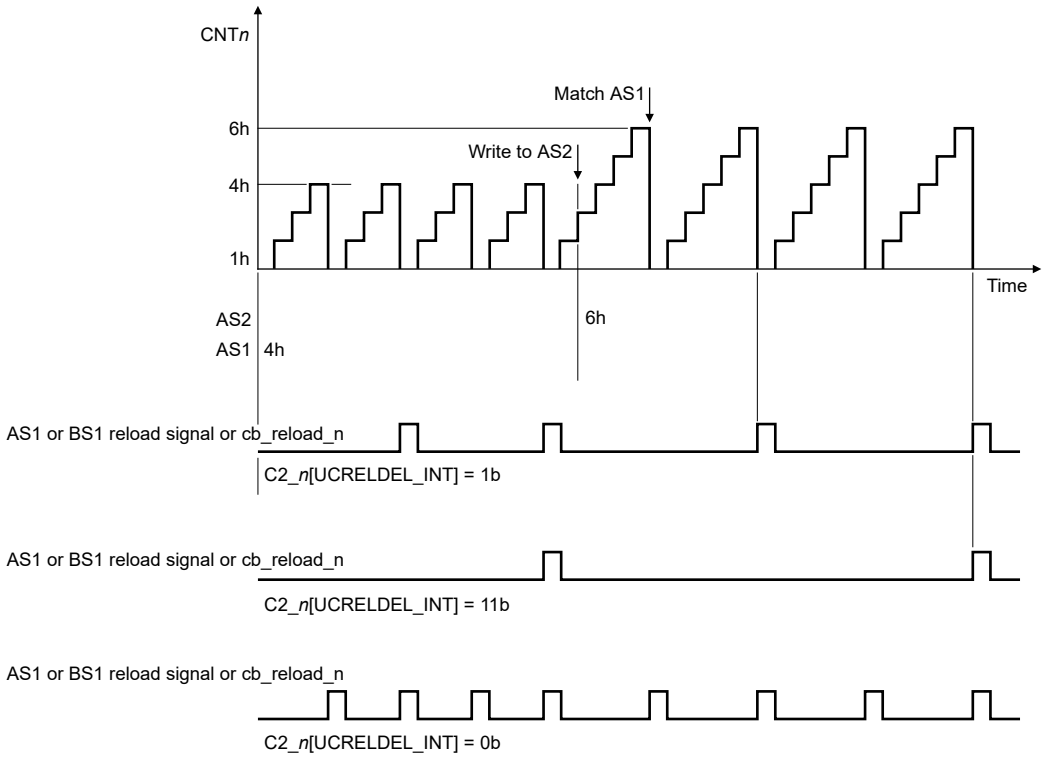

Figure 314. Timing example: Up Count mode with delayed reload

60.6.3.15 Modulus Counter Buffered (MCB) mode

60.6.3.15.1 Overview

In this mode, the UC generates a timebase that can be shared with other channels through the internal counter buses. AS1 is double-buffered, so you can change AS2 at any time with smooth transitions. The UC updates AS1 at the counter period boundary, which is when the internal counter (CNT*n*[C]) transitions to 1h.

Selecting external clock (see MCB submodes and MODE field values) causes the UC to use the input signal as the source. You select the triggering edge with Edge Polarity (C*n*[EDPOL]) and Edge Select (C*n*[EDSEL]).

You must ensure the internal counter is in the range from 1h to the AS1 value; otherwise, the A*n*[A] match does not occur and this causes the internal counter to wrap at the maximum counter value (FFFFh for a 16-bit counter). After a counter wrap occurs, the UC resets the counter to 1h and resumes normal operation.

NOTE

Do not write 1h to the internal counter when the UC is in Freeze state. Doing so can cause the match to be missed and the counter to overflow.

60.6.3.15.2 Changing to MCB mode

To avoid causing an unexpected interrupt or DMA request, you must use the following procedure to change to MCB mode:

1. Put the UC in GPIO mode (write 0b or 1b to C*n*[MODE]).
2. Disable the UC input capture flag (write 0 to C*n*[FEN]).
3. Write the correct values for MCB mode to A*n* and B*n*.

4. Put the UC in MCB mode (write the appropriate value to C*n*[MODE], as described in MCB submodes and MODE field values).
5. Clear the UC input capture flag (write 1 to S*n*[FLAG]).
6. Enable the UC input capture flag (write 1 to C*n*[FEN]).

60.6.3.15.3 MCB submodes and MODE field values

Table 336. MCB submodes and MODE field values

Submode or function	C*n*[MODE] (binary)
Internal clock source	101_0pp0b[1]
External clock source	101_0pp1b[1]
Up Count	101_000p[1]
Reserved	101_001p[1]
Up Count-Down Count	101_01pp[1]
Flag set only on match start	101_010p[1]
Flags also set at counter period boundary	101_011p[1]

1. *p* = Adjust parameters for submodes and options. See Unified channels (UC).

60.6.3.15.4 Up Count submode

In the Up Count submode:

- The internal counter (CNT*n*[C]) starts counting up (incrementing) from its current value.
- When the internal counter matches AS1 and a clock tick occurs (either prescaled clock or input pin event), the UC resets the internal counter to 1h.
- The UC sets the input-capture flag (S*n*[FLAG]) one system clock cycle after the match occurs.

You must write only values greater than 1h to AS1.

The boundary between counter period *n* and period *n*+1 occurs when the UC changes the internal counter from the AS1 value in period *n* to 1h in period *n*+1. AS1 defines the counter period.

The UC asserts the AS1 load signal (which has a duration of one system clock cycle) at the last system clock cycle of a counter period. This causes the UC to update AS1 with AS2 at the period boundary, at the same time that it resets the counter to 1h. Therefore, any value you write to AS2 during period *n* updates AS1 at the next period boundary and the UC uses it in period *n*+1. See Timing example: Up Count submode.

You can use Output Update Disable (OUDIS) to delay the update of AS1 for synchronization.

The UC sets the input-capture flag (S*n*[FLAG]) at the period boundary. See Timing example: Up Count submode flag assertion.

60.6.3.15.5 Timing example: Up Count submode

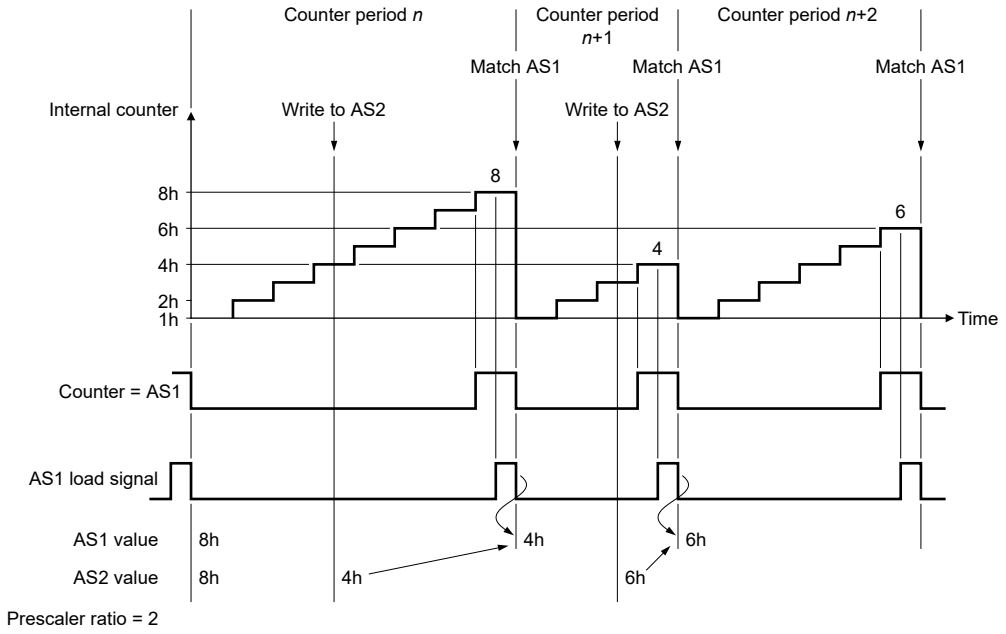

Figure 315. Timing example: Up Count submode

60.6.3.15.6 Timing example: Up Count submode flag assertion

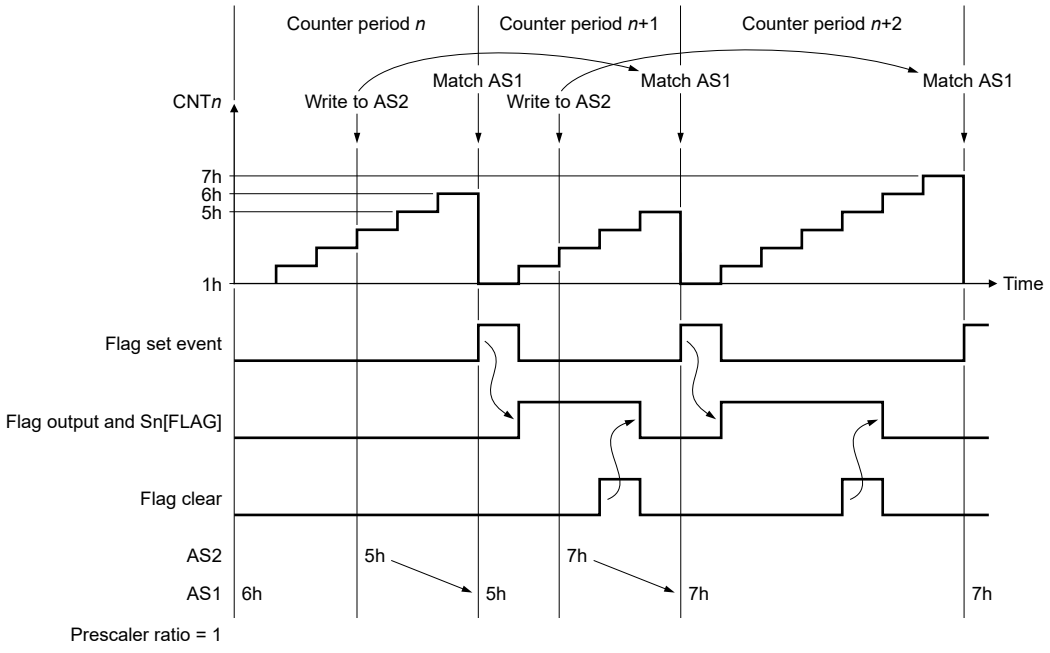

Figure 316. Timing example: Up Count submode flag assertion

60.6.3.15.7 Up Count-Down Count submode

In Up Count-Down Count submode:

- The counter period is: (2 x AS1) – 2. The counter changes direction at AS1 match and counts down (decrements) until it reaches 1h, then counts up (increments) again.
- BS1 generates a match to start the internal counter incrementing, and BS1 cannot be changed in this submode.

The UC updates AS1 at the counter period boundary. If you write AS2 (write A*n*[A]) during period *n*, the UC uses this new value in period *n*+1 for AS1 match. You can disable updates of AS1 (OUDIS[OU*n*]). See Timing example: Up Count-Down Count submode.

The UC sets the input-capture flag (S*n*[FLAG]) at AS1 match start, and may also do so at the period boundary. See Overview and Timing example: Up Count-Down Count submode flag assertion.

60.6.3.15.8 Timing example: Up Count-Down Count submode

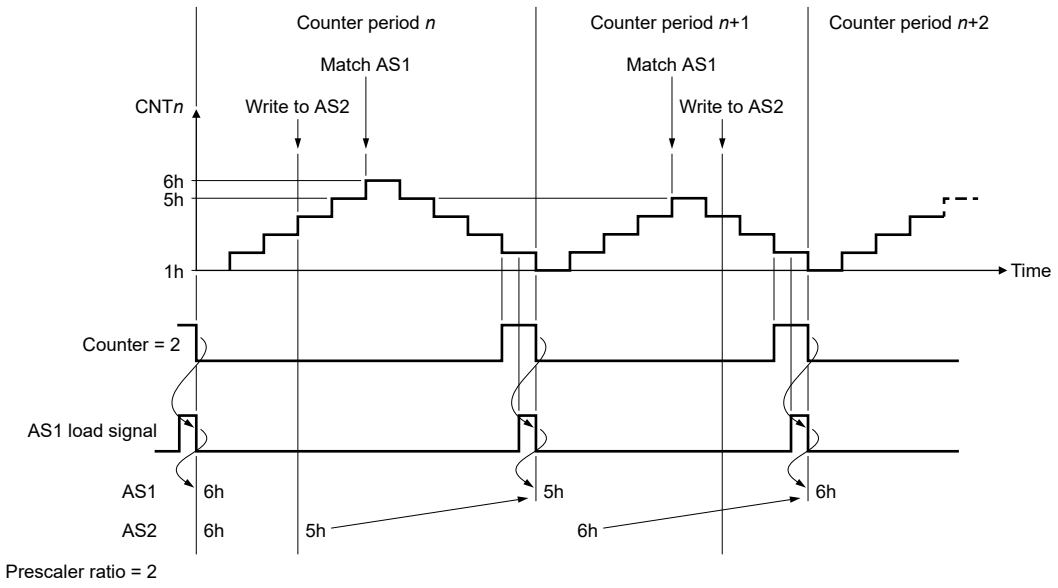

Figure 317. Timing example: Up Count-Down Count submode

60.6.3.15.9 Timing example: Up Count-Down Count submode flag assertion

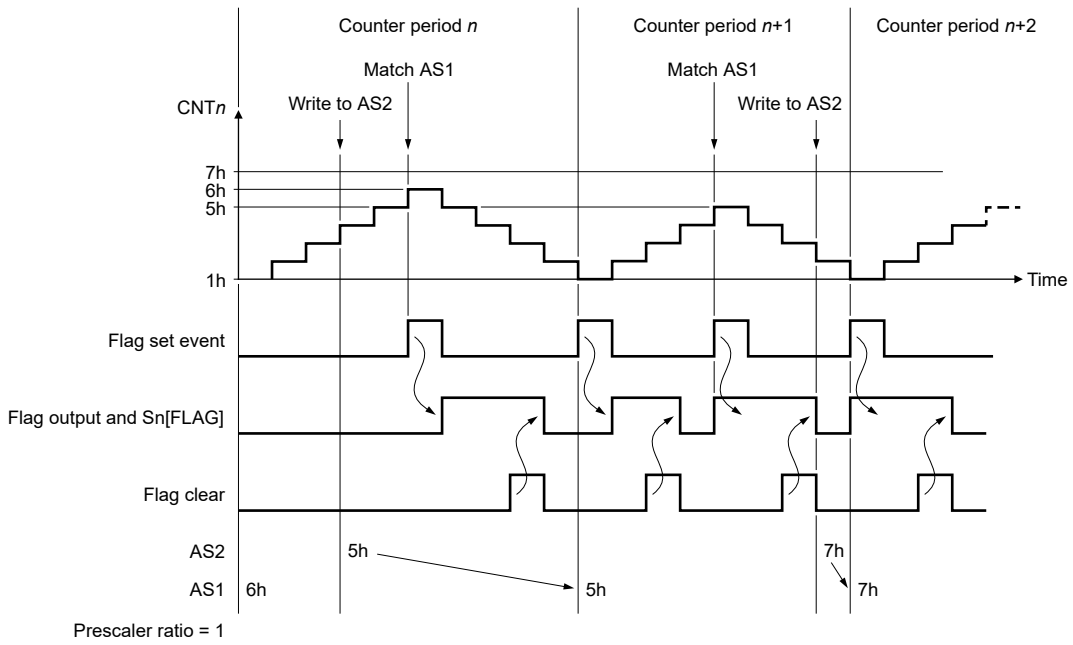

Figure 318. Timing example: Up Count-Down Count submode flag assertion

60.6.3.15.10 Up Count mode with delayed reload operation

When the internal counter matches AS1 in the Up Count submode or 1h in the Up Count-Down Count submode (see MCB submodes and MODE field values), the UC asserts the counter bus reload signal. You can read the counter bus reload signal in the following modes:

- Output PWM Buffered (OPWMB) mode
- Output Pulse Width and Frequency Modulation Buffered (OPWFMB) mode
- Center Aligned Output PWM with Dead Time Insertion Buffered (OPWMCB) mode

You can use the Reload Signal Output Delay Interval (C2[UCRELDEL_INT]) to cause the UC to assert the reload signal only after a specified number of match events (from 2 to 32).

See Timing example: Up Count mode with delayed reload.

60.6.3.15.11 Timing example: Up Count mode with delayed reload

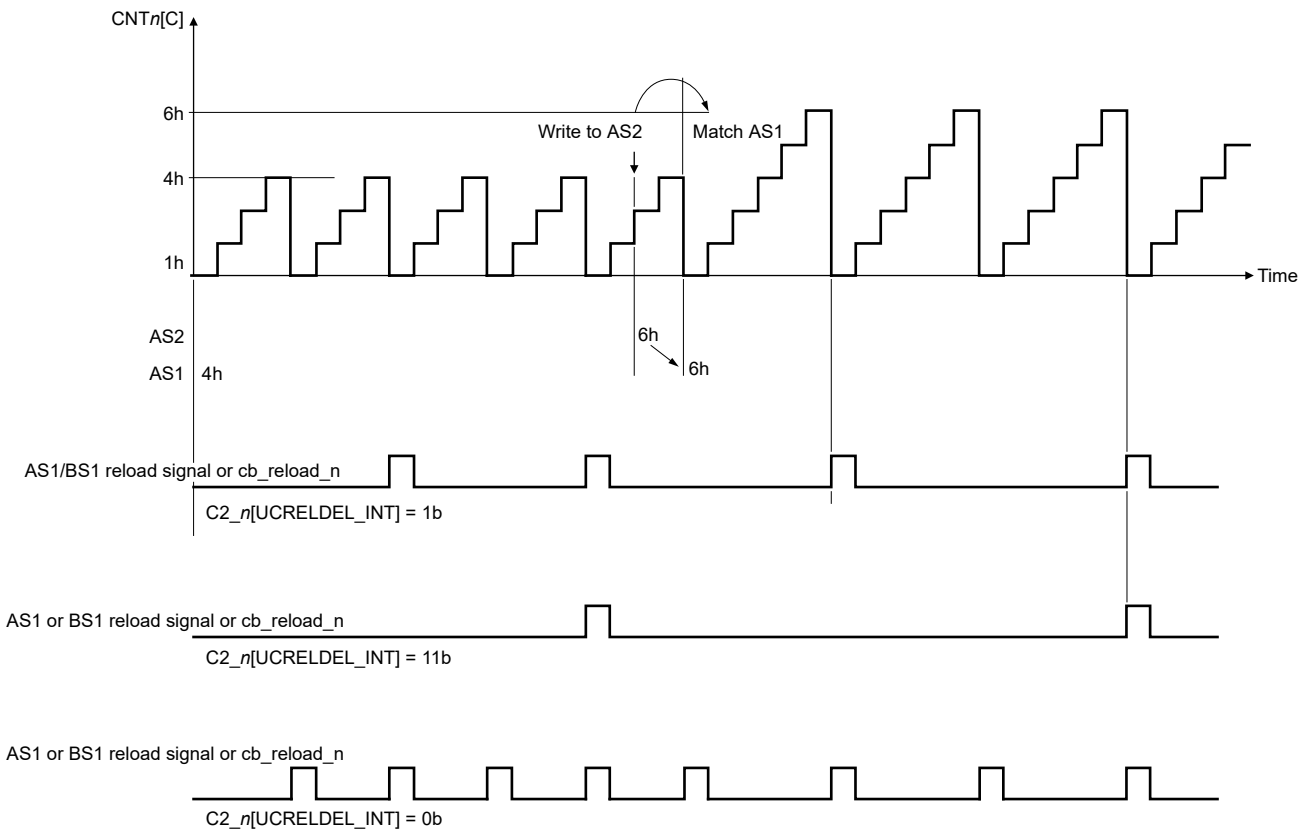

Figure 319. Timing example: Up Count mode with delayed reload

60.6.3.16 Output Pulse Width and Frequency Modulation Buffered (OPWFMB) mode

60.6.3.16.1 Overview

In this mode, the UC produces an output signal that has:

- A duty cycle determined by AS1.
- A period of BS1.

The double-buffered AS1 and BS1 registers produce smooth duty-cycle and period transitions when you change AS1 and BS1 during runtime.

See Table 343 for the values that you must write to C*n*[MODE] to enter this mode.

To provide smooth and consistent channel operation:

- AS1 and BS1 are both double-buffered to allow smooth signal generation when changing the register values.
- There is a delay from the AS1 match to the output pin transition (see AS1 and BS1 match timing).
- The internal counter ranges from 1h to BS1. When you write to BS1, you must write only values greater than 1h. Writing 0h or 1h leads to unpredictable results.

When a match on comparator A occurs, the UC drives C*n*[EDPOL] onto the output flip-flop. When a match on comparator B occurs, the UC drives the complement of C*n*[EDPOL] onto the output flip-flop. A BS1 match also causes the internal counter to transition to 1h, thus restarting the counter cycle.

The UC automatically selects the internal channel counter as the timebase when you select this mode. The mode supports duty cycles ranging from 0% to 100%.

60.6.3.16.2 OPWFMB submodes and MODE field values

Table 337. OPWFMB submodes and MODE field values

Match behavior	C*n*[MODE] (binary)
When BS1 matches the selected counter	101_1000
When AS1 or BS1 match the selected counter	101_1010

60.6.3.16.3 Avoid counter wrapping

When the UC enters OPWFMB mode, the output flip-flop acquires the value of C*n*[EDPOL]. If the UC transitions from GPIO to OPWFMB mode when the internal counter value is not within the range 1h–BS1, then the B match never occurs. Because the match never occurs, the internal counter wraps at the maximum counter value—FFFFh for a 16-bit counter. When the counter wrap occurs, the counter returns to 1h and normal OPWFMB operation resumes. Therefore, to avoid this counter wrapping, ensure that the counter value is within the range 1h–BS1 before the UC enters OPWFMB mode.

60.6.3.16.4 AS1 and BS1 match timing

As illustrated in Timing example: AS1 and BS1 match, the output pin transition occurs when the AS1 or BS1 match signal deasserts, as indicated by the AS1 match negative-edge detection signal. If you write 4h to AS1, the output pin transitions 4 counter increments plus one system clock cycle after the counter period starts.

60.6.3.16.5 Timing example: AS1 and BS1 match

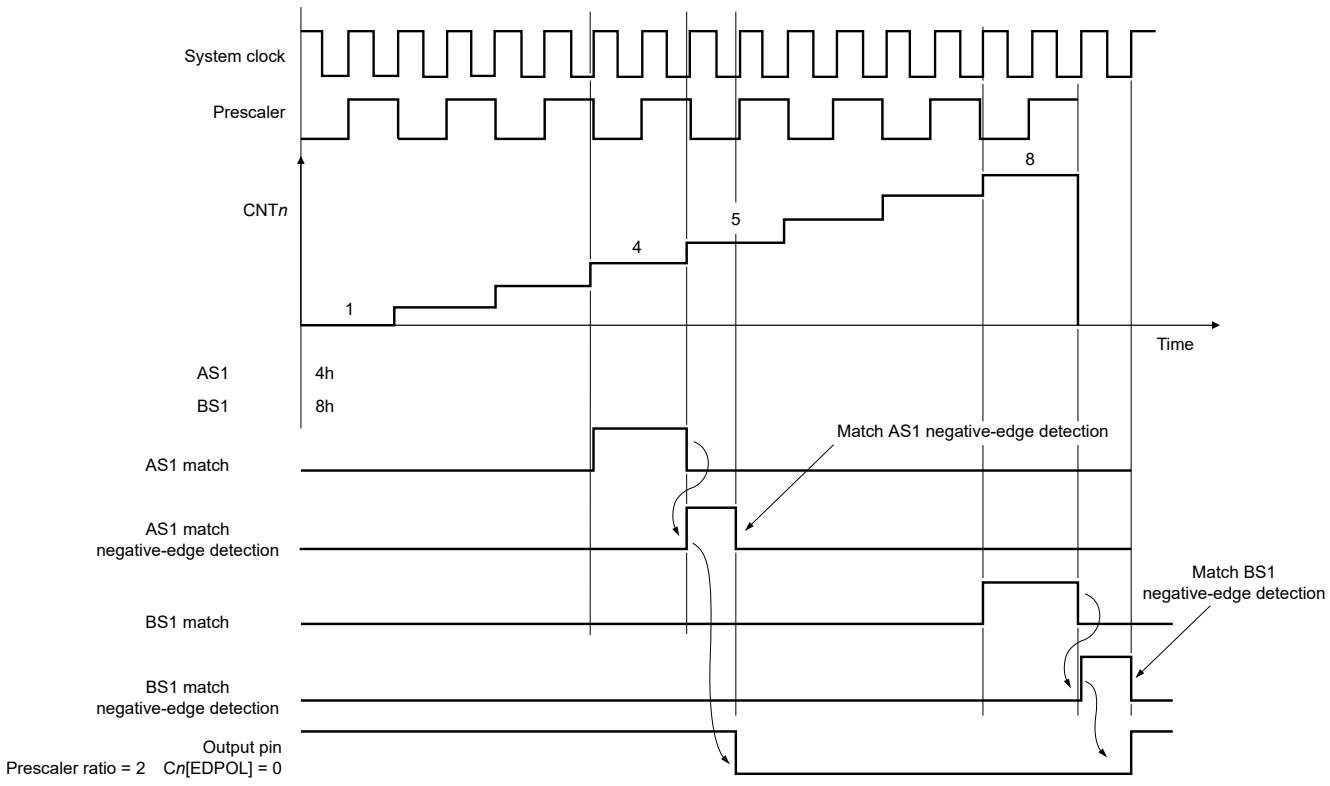

Figure 320. Timing example: AS1 and BS1 match

60.6.3.16.6 0% duty cycle

Timing example: AS1 = 0 illustrates the generated output signal when AS1 = 0, which results in a 0% duty cycle.

Because the internal counter never reaches zero in this situation, the UC infers a match as if AS1 = 1h. However, it is the positive edge of the match signal that triggers the output pin transition instead of the negative edge, which is what happens when AS1 = 1h. The AS1 positive-edge match signal from period *n*+1 occurs at the same time as the BS1 negative-edge match signal from period *n*. This timing allows the AS1 positive-edge match to mask the BS1 negative-edge match when they occur at the same time. As a result, no transition occurs on the output flip-flop and the UC generates a 0% duty cycle.

60.6.3.16.7 Timing example: AS1 = 0

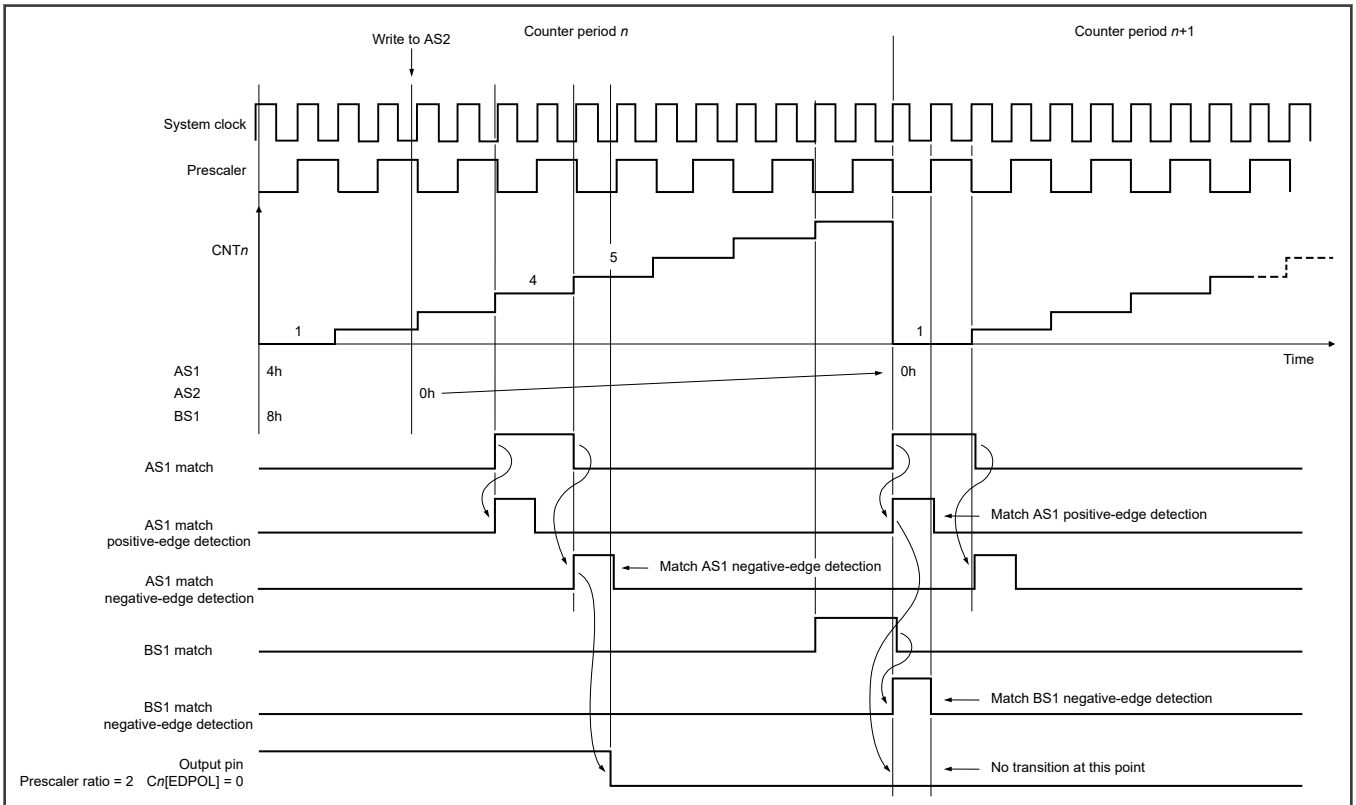

Figure 321. Timing example: AS1 = 0

60.6.3.16.8 Loading AS1 and BS1

As illustrated in Timing example: AS1 and BS1 update and FLAGs, AS1 and BS1 both use the same signal, generated at the last system clock cycle of a counter period. Therefore, eMIOS updates AS1 and BS1 with AS2 and BS2 values, respectively, at the same time that it changes the internal counter (CNT*n*[C]) to 1h. This event is the counter period boundary. The load signal pulse lasts for one system clock cycle. If you write AS2 and BS2 within counter period *n*, their values are available in AS1 and BS1, respectively, at the first clock cycle of counter period *n*+1. The UC then uses these new values for matches at counter period *n*+1. You can use Output Update Disable (OUDIS) to delay updating AS1 and BS1 for synchronization purposes.

60.6.3.16.9 Timing example: AS1 and BS1 update and FLAGs

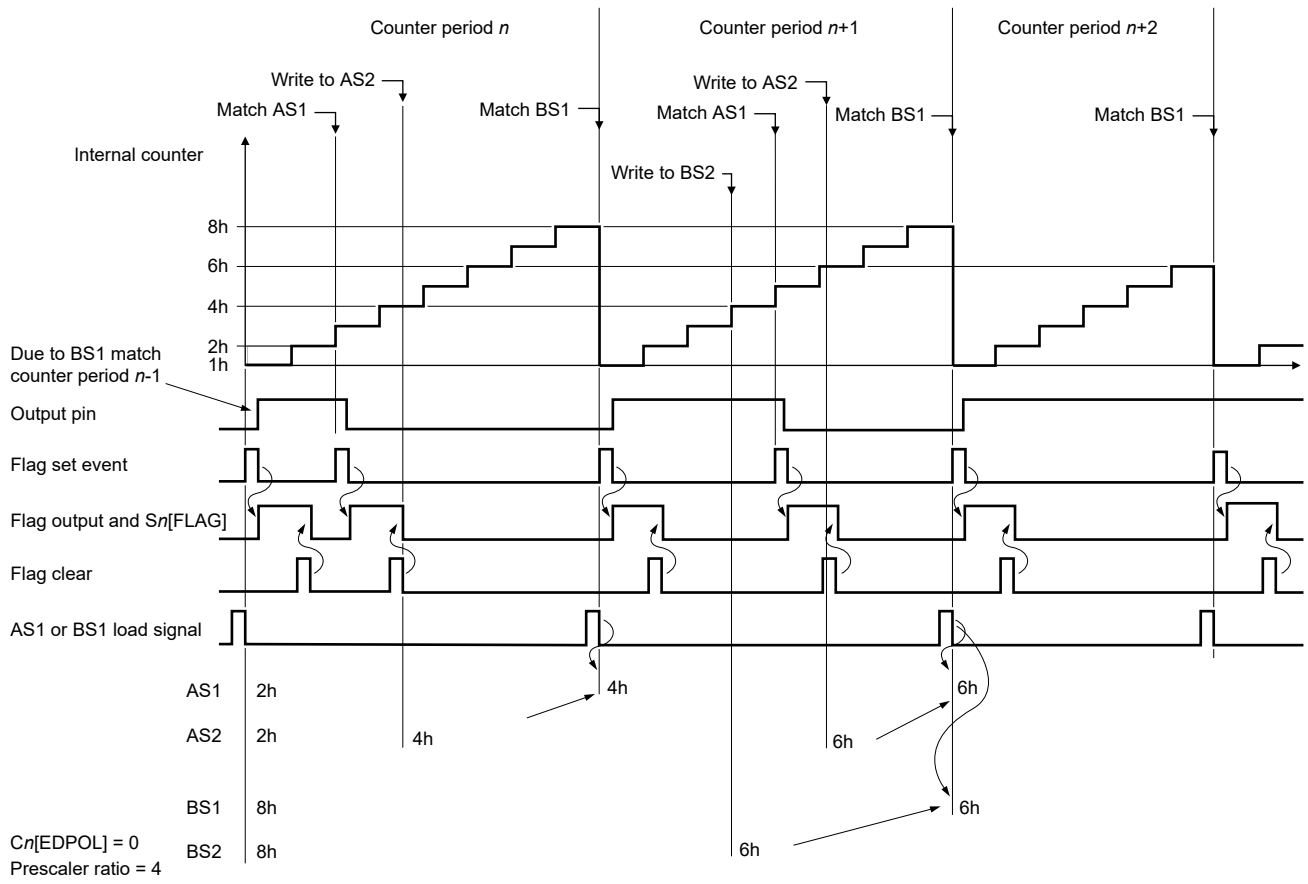

Figure 322. Timing example: AS1 and BS1 update and FLAGs

60.6.3.16.10 Flag generation

Timing example: AS1 and BS1 update and FLAGs assumes that both the channel and global prescalers are 1h (divide ratio of 2), causing the internal counter to transition every four system clock cycles. You can configure flags to be generated only on BS1 matches when bit 1 of C*n*[MODE] is 0, or on both AS1 and BS1 matches when that bit is 1. Because the BS1 flag occurs at the period boundary, you can use this flag to indicate that the AS2 or BS2 data written in period *n* has been loaded to AS1 or BS1, respectively, thereby generating matches in period *n*+1. Flag operation is synchronous, which means the flag sets one system clock cycle after the set-flag event.

60.6.3.16.11 Output disable

As illustrated in Timing example: active output disabled, the output-disable feature in OPWFMB mode forces the channel output flip-flop to the value of C*n*[EDPOL]. This functionality supports applications that use active-high signals and a high-to-low transition at an AS1 match. In this case, you must write 0 to C*n*[EDPOL]. You also must configure the internal counter to transition on every system clock cycle (write 0 to both GCP and CP).

The output-disable feature operates synchronously, meaning that the assertion of the Output Disable input signal causes the channel output flip-flop to transition to C*n*[EDPOL] at the next system clock cycle. If the Output Disable input pin deasserts, the output-signal transition occurs at the next AS1 or BS1 match.

Timing example: active output disabled assumes that the Output Disable input is enabled (using C*n*[ODIS]) and selected (using C*n*[ODISSL]). See UC Control n (C0 - C23) for a detailed description of the ODIS and ODISSL fields that enable and select the Output Disable inputs, respectively.

60.6.3.16.12 Timing example: active output disabled

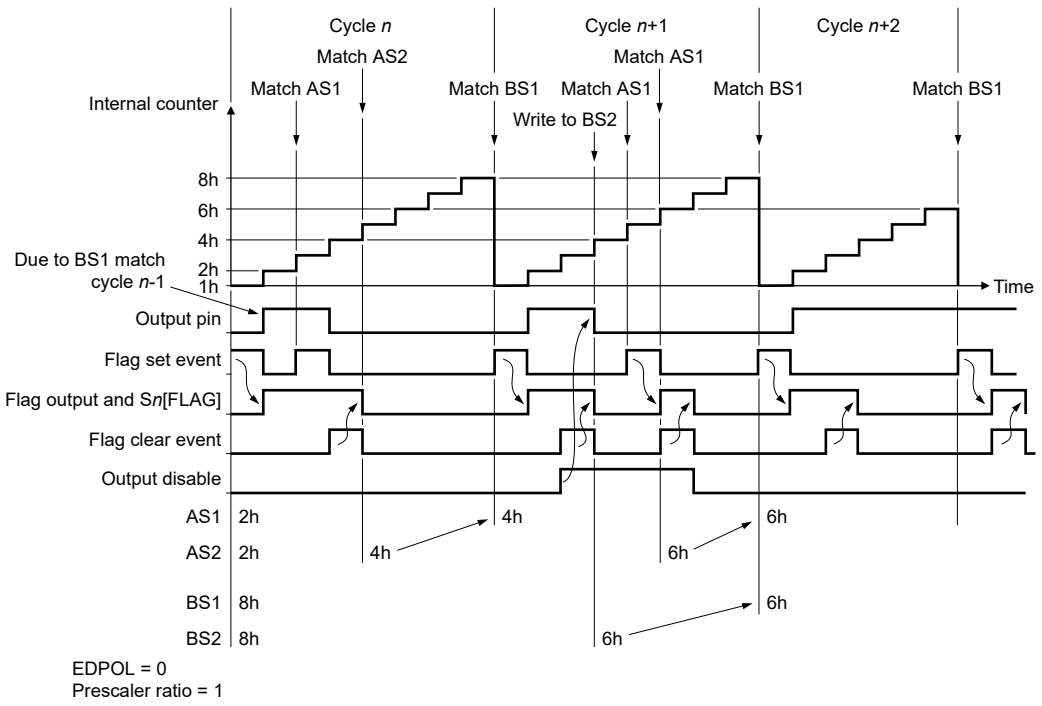

Figure 323. Timing example: active output disabled

60.6.3.16.13 Force match

Force Match A (C*n*[FORCMA]) and Force Match B (C*n*[FORCMB]) allow you to force the output flip-flop to the level corresponding to a match on comparators A or B, respectively. Similarly to a BS1 match, Force Match B changes the internal counter to 1h. The force-match operations do not set the input-capture flag (S*n*[FLAG]).

60.6.3.16.14 100% and 0% duty cycles

Timing example: from 100% to 0% duty cycle illustrates the generation of 100% and 0% duty-cycle signals. Initially, AS1 = 8h and BS1 = 8h. In this case, a BS1 match has precedence over an AS1 match—therefore, the output flip-flop acquires the complement of C*n*[EDPOL]. This configuration corresponds to a 100% duty-cycle signal. The same output signal can be generated for any AS1 value greater than or equal to BS1.

If AS1 is 0, the UC generates a 0% duty-cycle signal. In this case, the BS1 = 8h match from period 8 occurs at the same time as the AS1 = 0h match from period 9. See Timing example: AS1 = 0 for AS1 and BS1 match generation. In this case, an AS1 match has precedence over a BS1 match, and the output signal transitions to C*n*[EDPOL].

60.6.3.16.15 Timing example: from 100% to 0% duty cycle

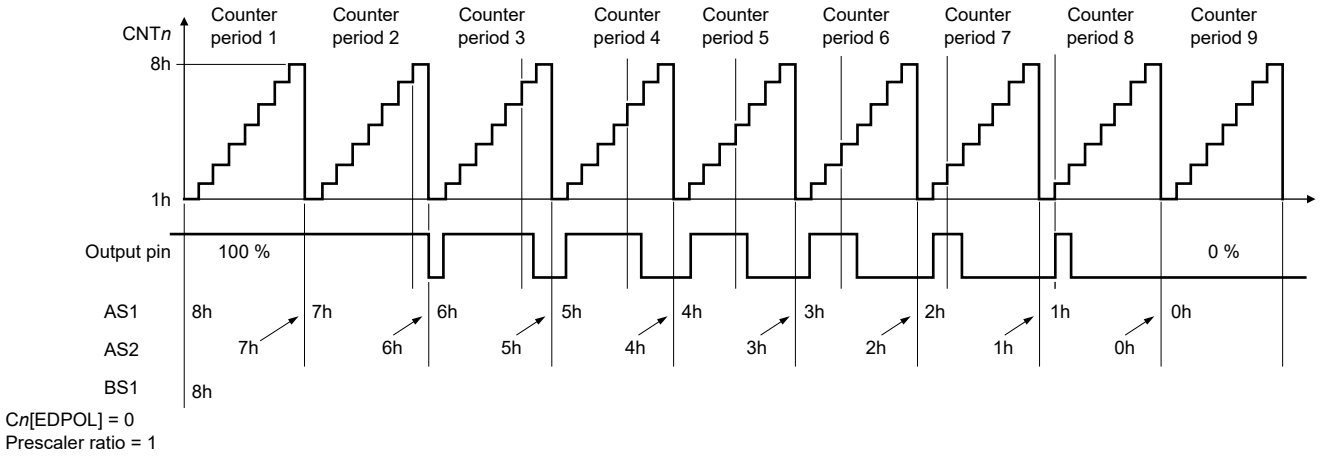

Figure 324. Timing example: from 100% to 0% duty cycle

60.6.3.17 Center Aligned Output PWM with Dead Time Insertion Buffered (OPWMCB) mode

60.6.3.17.1 Overview

In this mode, the UC generates a center-aligned PWM pulse with dead time insertion in the leading or trailing edge. See OPWMCB functions and MODE field values. AS1 and BS1 are double-buffered to allow smooth output signal generation when you change the AS2 or BS2 values.

When the UC enters OPWMCB mode from GPIO mode:

- The UC drives the complement of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.
- Select the timebase using Bus Select (C*n*[BSL]). The timebase you select must be running in Up Count-Down Count mode. See Timing example: Up Count submode flag assertion. You must start the MCB timebase after the UC enters OPWMCB mode to avoid missing a match on the first duty cycle.
- Store the ideal duty cycle for the PWM signal in AS1 (write to A*n*[A]), which the UC compares with the selected timebase.
- Store the dead time value in BS1 (write to B*n*[B]), which the UC compares with the internal counter (CNT*n*[C]).

The internal counter may use the internal prescaler ratio, while the selected timebase may use a different prescaler ratio. The UC always resets the internal counter to 1h when an AS1 match occurs.

As in OPWMB and OPWFMB modes, the UC generates the match signal which compares the selected timebase with AS1 or BS1. When the UC deasserts the channel's combinational comparator output signal, it uses the match signal to assert or negate the channel's output flip-flop. See Timing example: AS1 and BS1 match for an illustration of the delay from match to output flip-flop transition in OPWFMB mode. The operation of OPWMCB mode is similar to OPWFMB mode with respect to match behavior and output pin transition.

See Entering OPWMCB mode.

60.6.3.17.2 OPWMCB functions and MODE field values

Table 338. OPWMCB functions and mode field values

Function	C*n*[MODE] (binary)
Insert trailing edge dead time with duty cycle determined by BS1 + AS1	101_11p0[1]

Table continues on the next page...

Table 338. OPWMCB functions and mode field values (continued)

Function	C*n*[MODE] (binary)
Insert leading edge dead time with duty cycle determined by BS1 – AS1	101_11p1[1]
Assert the input capture flag (Sn[FLAG]) on the trailing edge of the output PWM signal	101_110p[1]
Assert the input capture flag (Sn[FLAG]) on both edges of the output PWM signal	101_111p[1]

1. *p* = Adjust parameters for submodes and options. See Unified channels (UC).

60.6.3.17.3 Entering OPWMCB mode

To enter OPWMCB mode (this procedure assumes the channel is initially in GPIO mode):

1. Disable the GCP (write 0 to MCR[GPREN]).
2. For the timebase (MCB) channel:
   a. Disable the CP (write 0 to C*n*[UCPREN]).
   b. Initialize the internal counter (write 1h to CNT*n*[C]).
   c. Initialize the A data (write appropriate value to A*n*[A]).
   d. Configure the UC for MCB Up Count-Down Count mode (write 101_01*xy*b to C*n*[MODE], where *x* = 0 for flag set on match start or *x* = 1 for flag set at period boundary, and *y* = 0 for internal clock source or *y* = 1 for external clock source).
   e. Select the CP ratio (C*n*[UCPRE]).
   f. Enable the CP (write 1 to C*n*[UCPREN]).
3. For the OPWMCB channel:
   a. Disable the CP (write 0 to C*n*[UCPREN]).
   b. Initialize the A data (write appropriate value to A*n*[A]).
   c. Initialize the B data (write appropriate value to B*n*[B]).
   d. Select the timebase input (C*n*[BSL]).
   e. Configure the UC for MCB Up Count-Down Count mode (write 101_01*xy*b to C*n*[MODE], where *x* = 0 for flag set on match start or *x* = 1 for flag set at period boundary, and *y* = 0 for internal clock source or *y* = 1 for external clock source).
   f. Select the CP ratio (C*n*[UCPRE]).
   g. Enable the CP (write 1 to C*n*[UCPREN]).
4. Enable the GPC (write 1 to MCR[GPREN]).

60.6.3.17.4 Timing example: AS1 and BS1 load

When the selected counter bus transitions from 2h to 1h:

- The UC loads AS1 and BS1 as shown in the following figure.
- This event defines the counter period boundary.

The UC loads the values you write to AS2 or BS2 within period *n* into AS1 or BS1, respectively, and uses them to generate matches in period *n*+1.

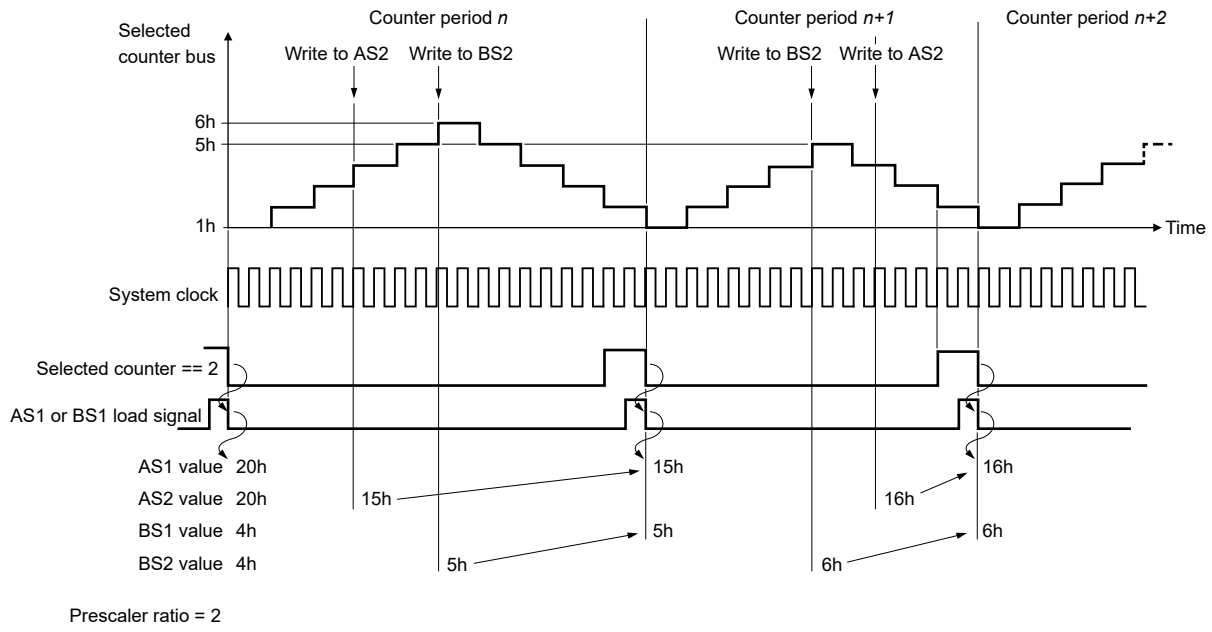

Figure 325. Timing example: AS1 and BS1 load

60.6.3.17.5 Operation sequence with leading edge dead time insertion

When operating with leading edge dead time insertion:

1. When the first AS1 match occurs, the UC writes 1h to the internal counter.
2. When a match between BS1 and the internal timebase occurs, the UC drives the value of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.
3. When the next match between AS1 and the selected timebase occurs, the UC drives the complement of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.

The UC repeats the above sequence continuously.

You must not allow the internal counter to reach 0h as the result of a rollover. To avoid this, you must not write a value greater than

2 x ((external Count Up limit) – A*n*[A])

into B*n*[B].

See Timing example: leading dead time insertion.

60.6.3.17.6 Timing example: leading dead time insertion

This example illustrates two cycles of a center-aligned PWM signal. AS1 and BS1 values change within the same period, which allows you to change the duty cycle and dead time values at the same time.

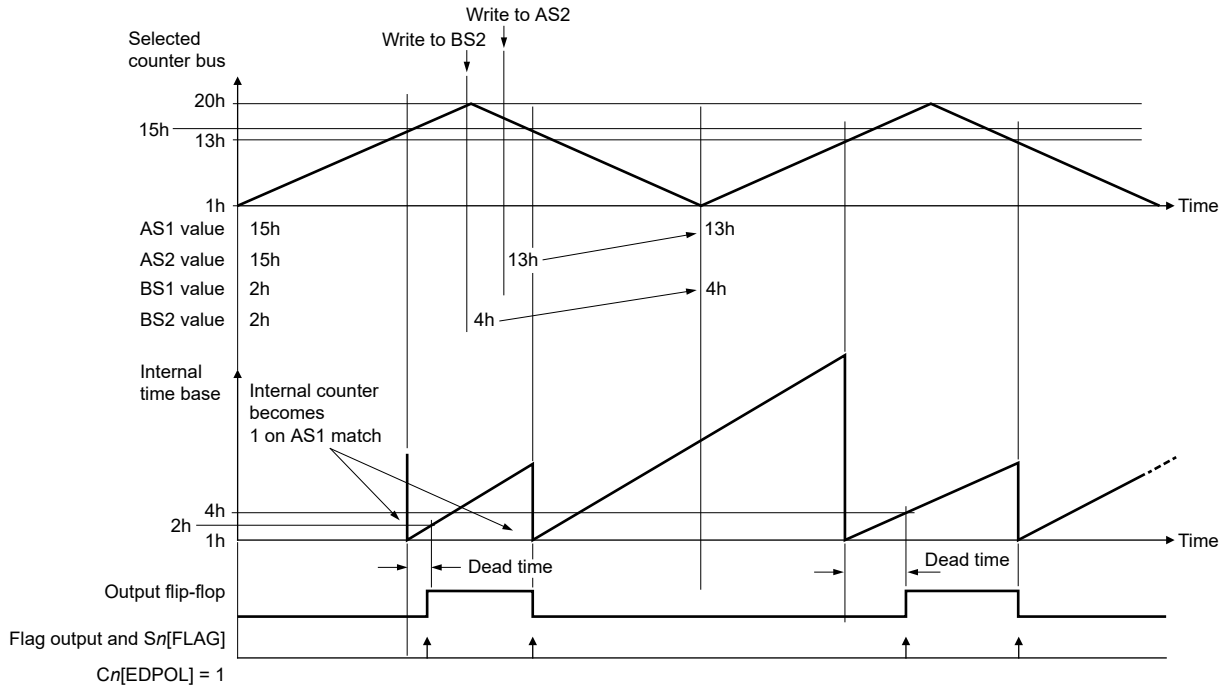

Figure 326. Timing example: leading dead time insertion

60.6.3.17.7 Operation sequence with trailing edge dead time insertion

When operating with trailing edge dead time insertion:

1. When the first match between AS1 and the selected timebase occurs, the UC:
   a. Drives the value of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.
   b. Writes the internal counter (CNT*n*[C]) to 1h.
2. When the second match between AS1 and the selected timebase occurs, the UC:
   a. Writes the internal counter to 1h.
   b. Enables BS1 matches.
3. When a match between BS1 and the selected timebase occurs, the UC drives the the complement of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.

The UC repeats this sequence continuously.

60.6.3.17.8 Timing example: trailing dead time insertion

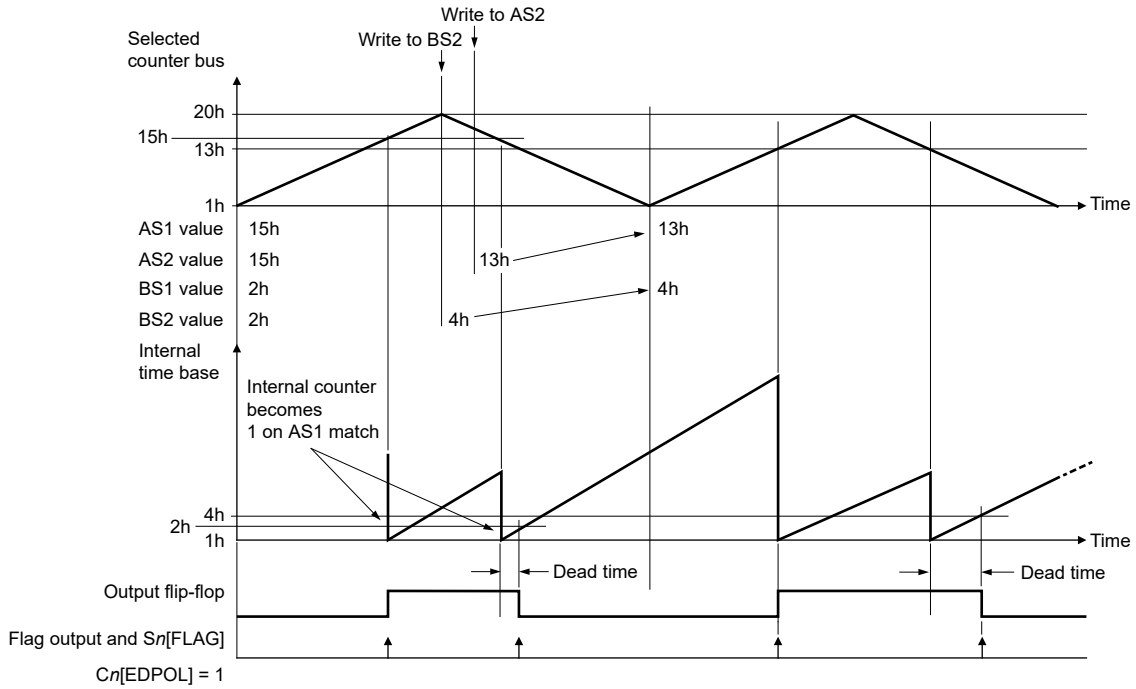

Figure 327. Timing example: trailing dead time insertion

60.6.3.17.9 Force match

Force Match A (C*n*[FORCMA]) and Force Match B (C*n*[FORCMB]) allow you to force the output flip-flop to the level corresponding to a match on comparators A or B, respectively. If subsequent matches occur on comparators A and B, the UC continues to generate PWM pulses regardless of the input capture flag (S*n*[FLAG]). The force-match operations do not set the input-capture flag (S*n*[FLAG]).

When you select leading edge dead time insertion:

- Force Match A drives the complement of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.
- Force Match B drives the value of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.

When you select trailing edge dead time insertion:

- Force Match A drives the value of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.
- Force Match B drives the complement of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.

Force Match operation does not write 1h to the internal timebase.

Force Match operation does not set the input-capture flag.

When you assert Force Match A and Force Match B at the same time, the UC drives the complement of Edge Polarity (C*n*[EDPOL]) on the output flip-flop. This is the equivalent of saying that Force Match A has precedence over Force Match B when you select leading edge dead time insertion, and Force Match B has precedence over Force Match A when you select trailing edge dead time insertion.

Force Match A and Force Match B have the same output transition behavior in both Freeze state and unfrozen state.

60.6.3.17.10 Duty cycle

You generate a duty cycle from 0% to 100% by writing appropriate values to AS1 and BS1 relative to the period of the external timebase.

To generate a 100% duty cycle waveform:

- Select trailing edge dead time insertion (see OPWMCB functions and MODE field values).
- Write 1h to Edge Polarity (C*n*[EDPOL]).
- The BS1 match must occur on or after the counter period boundary (external counter = 1).

You can also generate a 100% duty cycle waveform by writing 1h to AS1. However, if you do this before the UC enters OPWMCB mode, a 100% duty cycle may not occur in the first PWM period depending upon the pin state at mode entry.

To generate a 0% duty cycle waveform:

- AS1 must be greater than the maximum value of the selected counter period.
- The pin must start the current period with the complement value of Edge Polarity (C*n*[EDPOL]). If starting at 100% duty cycle, you can change Edge Polarity (C*n*[EDPOL]) to its complement by forcing the pin (see Force match).

You must write only non-zero values to AS1. If you write the maximum value of the external counter given by

(external counter period)/2

to AS1, the UC constantly drives the value of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.

UC logic prevents matches from one period propagating to the next period. In trailing edge dead time insertion, the UC masks out BS1 matches that occur late in period *n*, so matches in period *n*+1 are unaffected and the output flip-flop does not transition.

60.6.3.17.11 Timing example: duty cycle

To generate a 100% duty cycle output waveform, write 4h to AS1 and 3h to BS1, as illustrated in this diagram. In this case, the trailing edge is at the boundary of counter period *n*+1, which actually belongs to period *n*+2 and therefore does not cause the output flip-flip to transition.

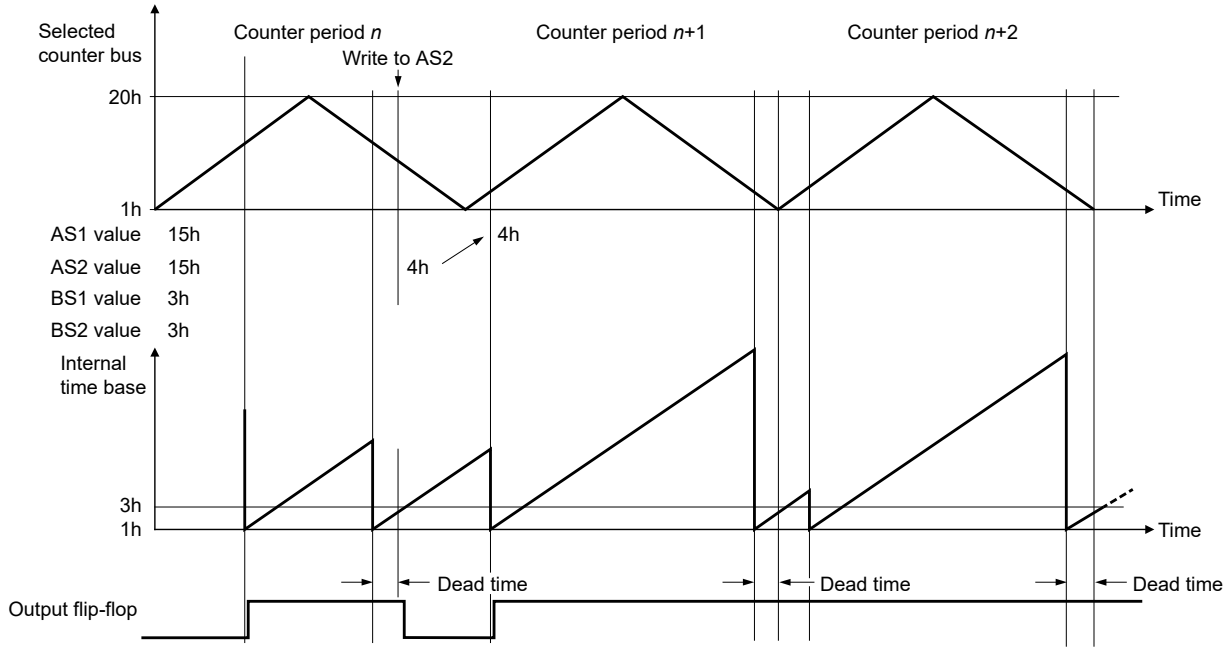

Figure 328. Timing example: duty cycle

60.6.3.17.12 Output disable

You can use Output Update Disable (write 0 to OUDIS[OU*n*]) to disable AS1 and BS1 updates. This allows you to update AS1 and BS1 in the same counter period and synchronize the loading of these registers with the loading of AS1 or BS1 in other channels.

Asserting Output Update Disable drives the complement of Edge Polarity (C*n*[EDPOL]) on output flip-flop. The internal channel matches continue to occur, and therefore the UC continues to set flags.

When you deassert Output Update Disable, the output flip-flop is again controlled by AS1 and BS1 matches. The UC transitions the output flip-flop only on system clock edges.

60.6.3.18 Output PWM Buffered (OPWMB) mode

60.6.3.18.1 Overview

In this mode, the UC produces PWM pulses with programmable leading and trailing edge placement. You must select an external counter driven in MCB Up mode from one of the counter buses. AS1 and BS1 define the first and second edges, respectively. C*n*[EDPOL] defines the output signal polarity. If C*n*[EDPOL] = 0, a negative edge occurs when AS1 matches the selected counter bus and a positive edge occurs when BS1 matches the selected counter bus.

See OPWMB submodes and MODE field values for the values that you must write to C*n*[MODE] to enter this mode.

AS1 and BS1 are double-buffered and updated from AS2 and BS2, respectively, at the cycle boundary. The load operation is similar to the one that occurs in OPWFMB mode. See Timing example: AS1 and BS1 update and FLAGs for more information about AS1 and BS1 updates.

When the UC enters OPWMB mode, the UC drives C*n*[EDPOL] on the output flip-flop.

These rules apply to OPWMB mode:

- If the AS1 and BS1 matches occur at the same time within the same counter period, the BS1 match has precedence over the AS1 match.
- An AS1 = 0 match in period *n* has precedence over a BS1 match in period *n*-1.
- The UC masks out AS1 matches if they occur after a BS1 match within the same period.
- The UC loads any value that you write to AS2 or BS2 in period *n* into AS1 and BS1 at the following period boundary (assuming that the corresponding OU*n* field of Output Update Disable (OUDIS) is 0). Therefore, the UC uses the new values for AS1 and BS1 matches in period *n*+1.

Timing example: 100% to 0% duty cycle illustrates a waveform changing from 100% to 0% duty cycle. In this example, BS1 is programmed to the same value as the period of the external selected timebase. If you write a value smaller than 8h to BS1, you cannot achieve a 0% duty cycle by only changing AS1. Because BS1 matches have precedence over AS1 matches, the flag output transitions to the complement of C*n*[EDPOL] at a BS1 match. For another example, if you write 9h to BS1, a BS1 match does not occur, and the UC generates a 0% duty-cycle signal.

60.6.3.18.2 OPWMB submodes and MODE field values

Table 339. OPWMB submodes and MODE field values

When FLAG generation occurs	C*n*[MODE] (binary)
At a BS1 match	110_0000
At an AS1 or BS1 match	110_0010

60.6.3.18.3 Force match

Force Match A (C*n*[FORCMA]) and Force Match B (C*n*[FORCMB]) allow you to force the output flip-flop to the level corresponding to a match on comparators A or B, respectively. If subsequent matches occur on comparators A and B, the UC continues to generate PWM pulses regardless of the input capture flag (S*n*[FLAG]). The force-match operations do not set the input-capture flag (S*n*[FLAG]).

60.6.3.18.4 Matches and flag operation

Timing example: matches and flags illustrates the operation of OPWMB mode with an emphasis on AS1 and BS1 matches and the transition of the channel output pin. The output pin transitions are based on the negative edges of the AS1 and BS1 match signals. AS1 becomes zero in period *n*+1. In this case, the UC uses the match positive edge instead of the negative edge to transition the output flip-flop.

60.6.3.18.5 Timing example: matches and flags

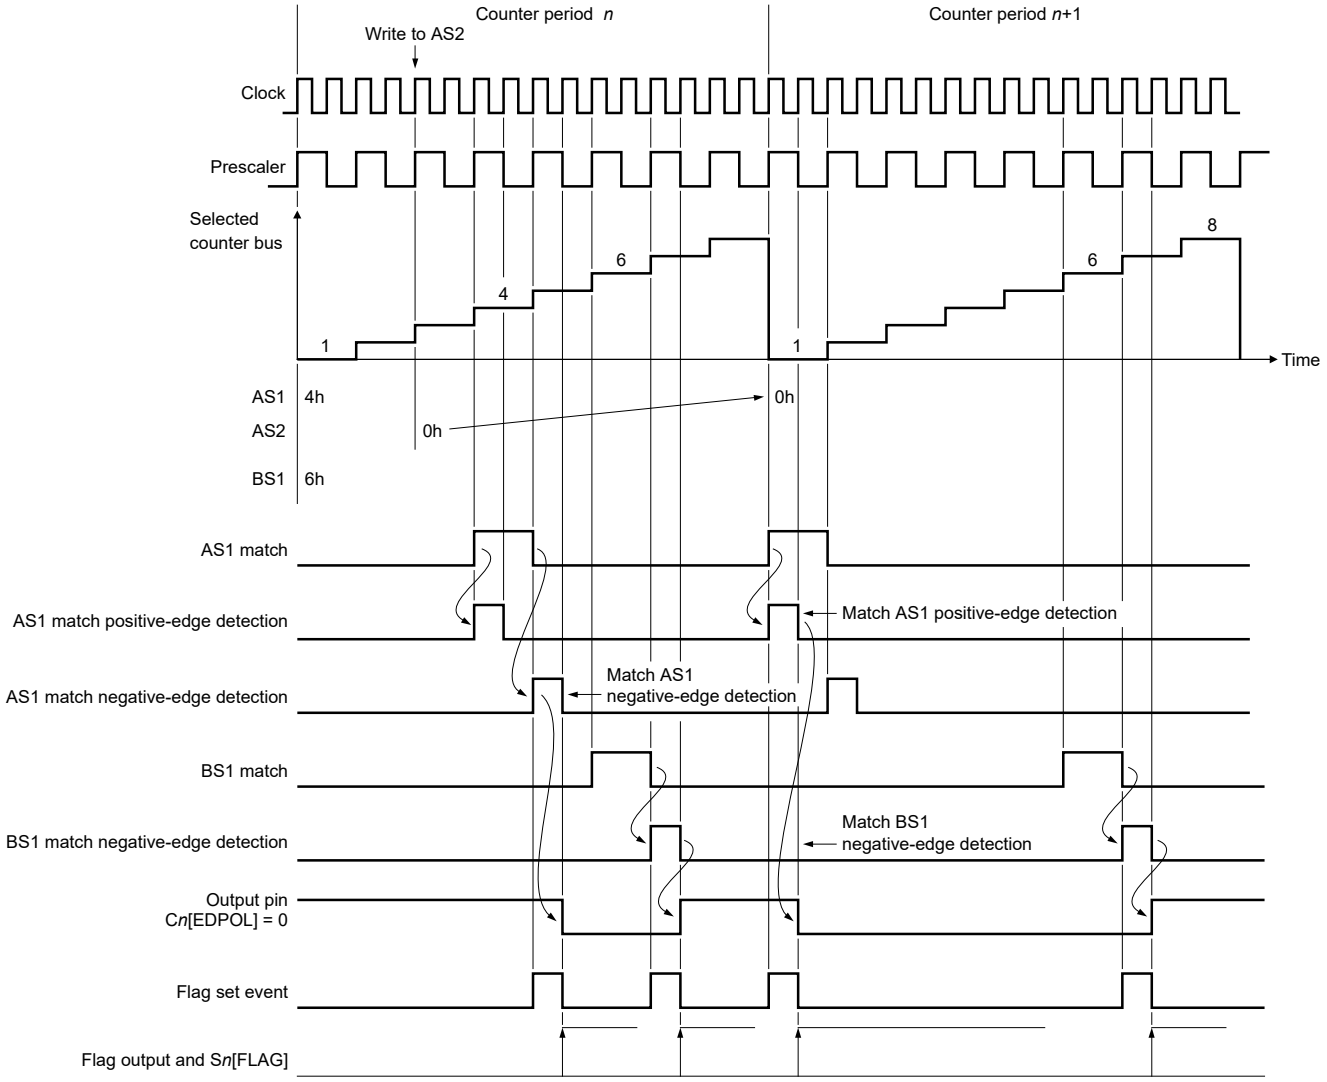

Figure 329. Timing example: matches and flags

60.6.3.18.6 0% duty cycle

Timing example: 0% duty cycle illustrates the channel operation for a 0% duty cycle. The AS1 match positive-edge signal occurs at the same time as the BS1 = 8h negative-edge signal. In this case, the AS1 match has precedence over the BS1 match, causing the output pin to remain at the value of C*n*[EDPOL] and generating a 0% duty-cycle signal.

60.6.3.18.7 Timing example: 0% duty cycle

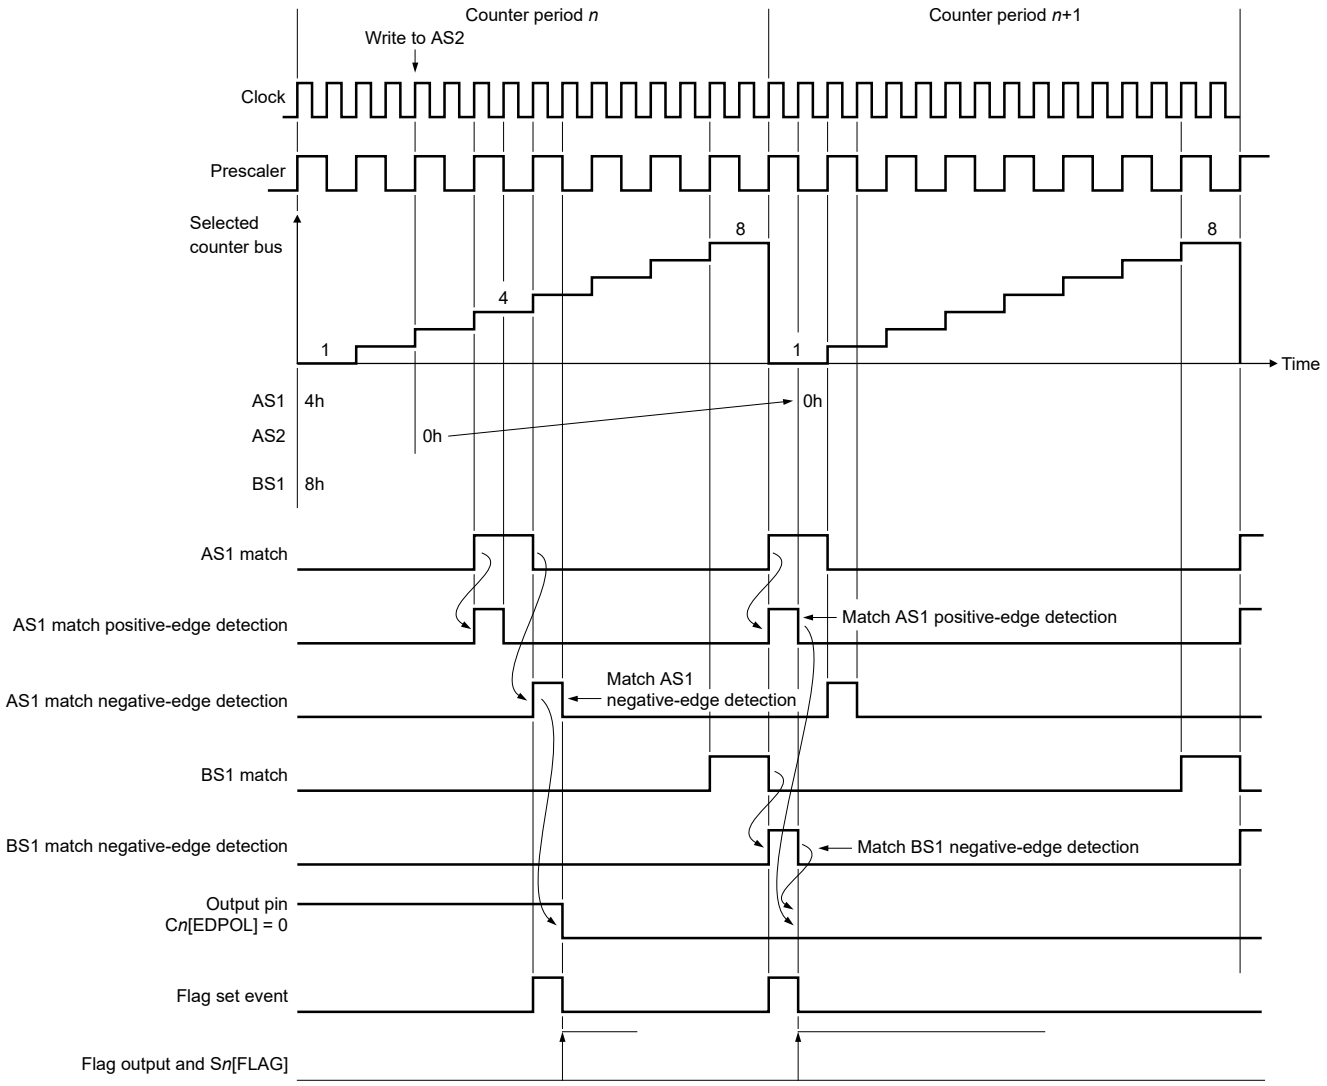

Figure 330. Timing example: 0% duty cycle

60.6.3.18.8 Active output disabled

Timing example: active output disabled illustrates the operation of the OPWMB mode with an emphasis on the assertion of the output-disable signal. The output disable forces a transition in the output pin to the value of C*n*[EDPOL]. The deassertion of the output-disable signal allows the output pin to transition at the following AS1 or BS1 match. The output disable does not modify the behavior of S*n*[FLAG]. A delay of one system clock cycle exists between the assertion of the output-disable signal and the transition of the output pin to C*n*[EDPOL].

60.6.3.18.9 Timing example: active output disabled

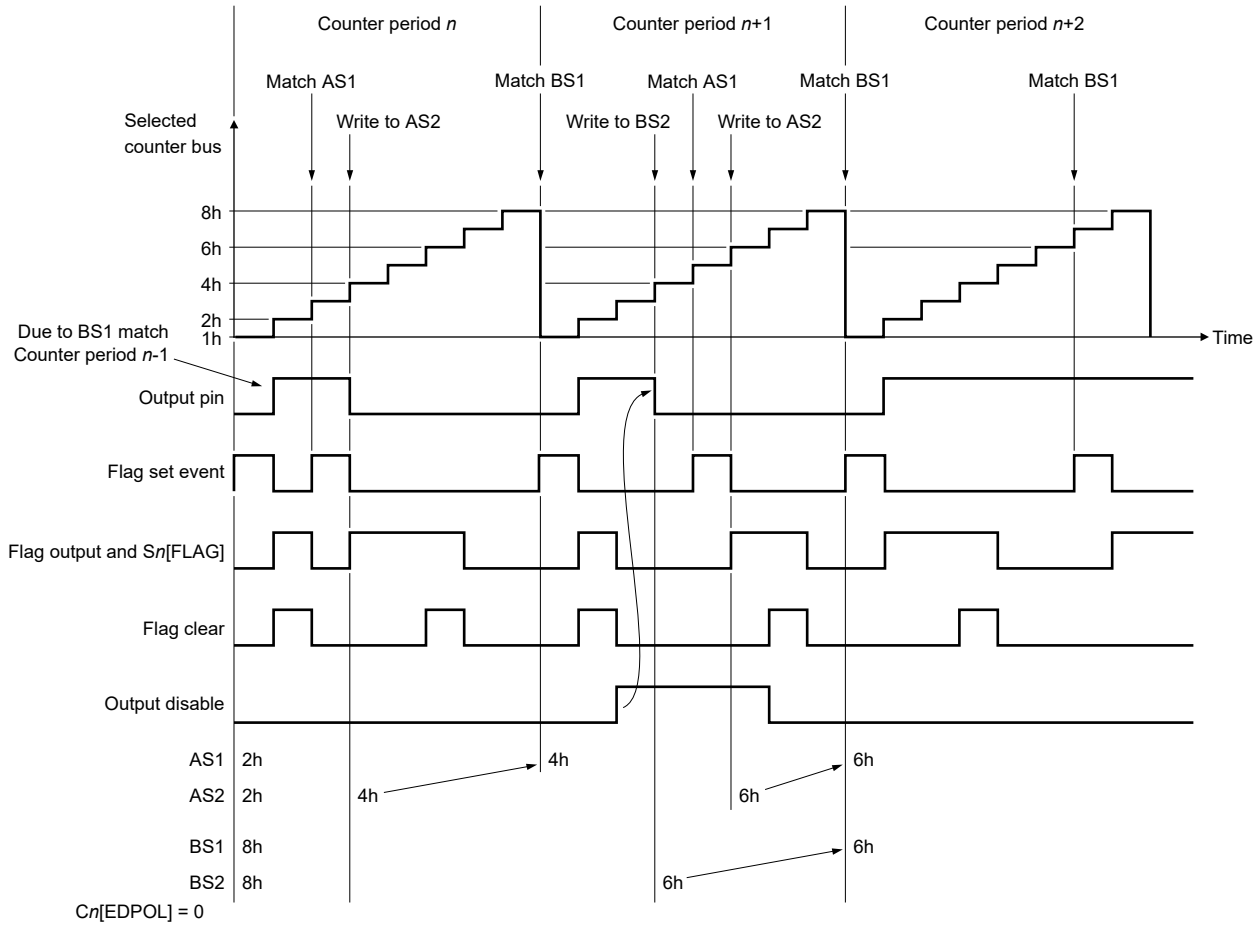

Figure 331. Timing example: active output disabled

60.6.3.18.10 Changing from 100% to 0% duty cycle

Timing example: 100% to 0% duty cycle illustrates a waveform changing from 100% to 0% duty cycle. In this example, BS1 has the same value as the period of the external selected timebase. If you write a value smaller than 8h to BS1, you cannot achieve a 0% duty cycle by only changing AS1. Because BS1 matches have precedence over AS1 matches, the output pin transitions to the complement of C*n*[EDPOL] at a BS1 match. For another example, if you write 9h to BS1, a BS1 match does not occur, and the UC generates a 0% duty-cycle signal.

60.6.3.18.11 Timing example: 100% to 0% duty cycle

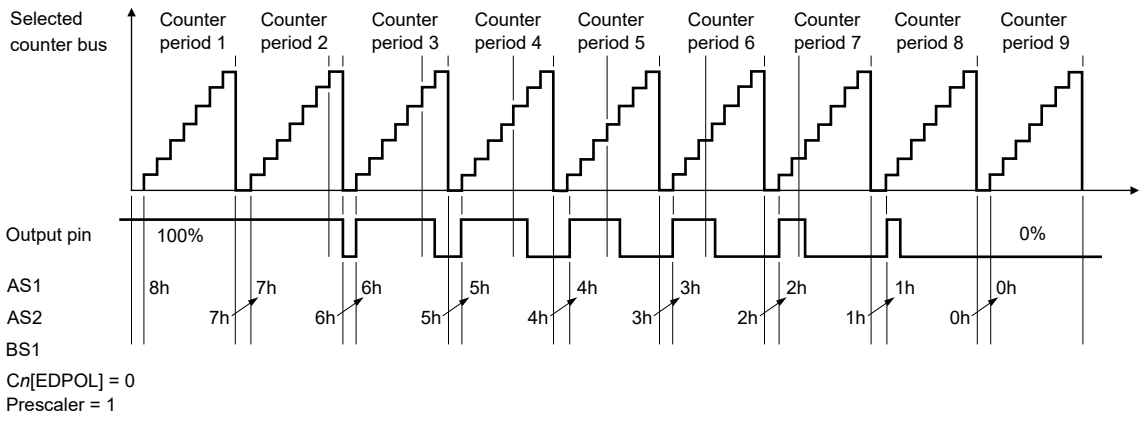

Figure 332. Timing example: 100% to 0% duty cycle

60.6.3.19 Output PWM with Trigger (OPWMT) mode

60.6.3.19.1 Overview

In this mode, the UC generates PWM pulses where the period does not change while the UC outputs the signal, but the duty cycle changes. When the duty cycle changes, it must not create glitches. The mode supports multiple UCs executing in the same mode and sharing a common timebase. Each UC can have a fixed PWM leading-edge position with respect to the other UCs. It can also generate a trigger signal at any point in the period. eMIOS can output this trigger signal to initiate activity in other parts of the chip—for example, to start ADC conversions.

You must select an external counter, driven in either MC Up or MCB Up mode (see Modulus Counter Buffered (MCB) mode), from one of the counter buses.

AS1 in OPWMT mode, AS2 in OPWMT mode, and BS1 and BS2 in OPWMT mode describe the configuration and behavior of the individual shadow registers in this mode.

To account for the shift in the AS1-defined leading edge of the waveform, the BS1-defined trailing edge may roll over into the next period. This means that a match against BS1 does not have to be qualified by a match in AS1. This also means that if you incorrectly write a value less than AS1 to BS1, the output persists over a period boundary until the UC encounters the BS1 value.

This mode provides a buffered update of the trailing edge by updating BS1 with BS2 contents only at a match of AS1.

The positive edges of the AS1, BS1, and AS2 match signals drive the output pin and flag transitions. See Timing example: matches and flags for details on positive-edge matches.

The UC sets the input capture flag (S*n*[FLAG]) only at an AS2 match. An AS1, BS1, or BS2 match has no effect on the flag.

When the UC enters OPWMT mode, it drives the complement of C*n*[EDPOL] on the output flip-flop.

Timing example: OPWMT illustrates the UC running in OPWMT mode with trigger-event generation and duty-cycle update after the next-period update.

60.6.3.19.2 Timing example: OPWMT

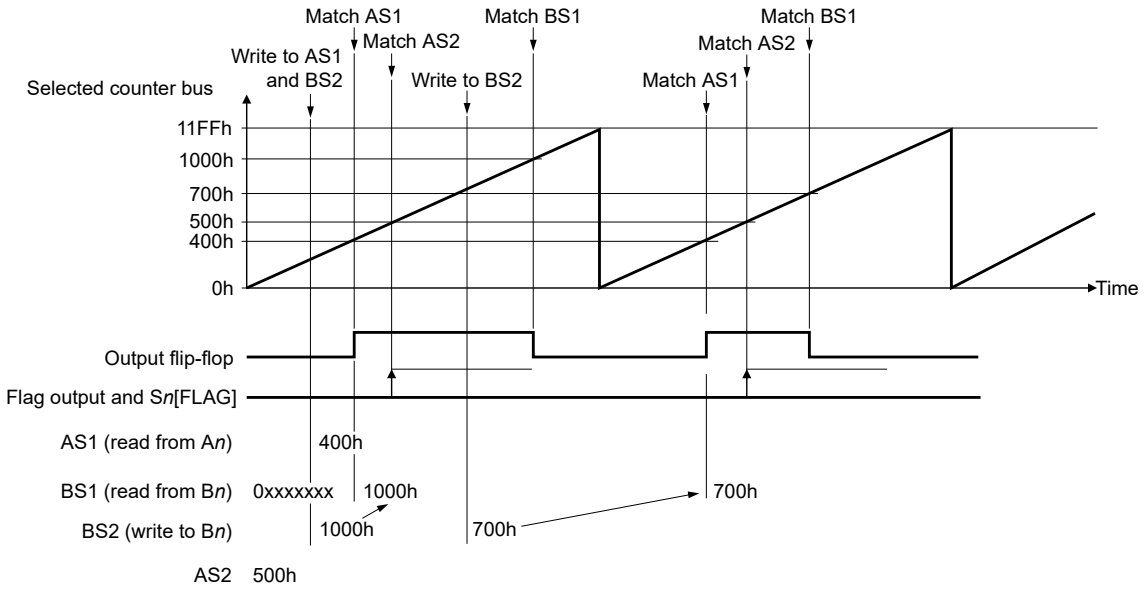

Figure 333. Timing example: OPWMT

60.6.3.19.3 AS1 in OPWMT mode

AS1 defines the leading edge of the PWM pulse output, and therefore the beginning of the PWM period. Using this fact, you can ensure that, when using a shared timebase, the leading edges of multiple UCs in OPWMT mode occur at specific times with respect to the other UCs. You can also introduce a fixed offset for each UC, which is particularly useful in the generation of lighting control signals. For this application, to reduce or eliminate noise generation, you can shift the PWM pulse of each UC with respect to the selected timebase by adjusting the AS1 value for each channel. The value you write to AS1 must be within the range of the selected timebase. Shadow registers (AS1, AS2, BS1, and BS2) loaded with 0h do not produce matches if the channel driving the timebase is in MCB mode.

AS1 is not buffered, because the shift of a PWM channel must not change while the UC generates the PWM signal. If you modify AS1, it updates immediately and one PWM pulse could be lost.

The UC compares AS1 to the selected timebase. When a match on AS1 occurs, the UC drives C*n*[EDPOL] on the output flip-flop. When a match occurs on comparator B, the UC drives the complement of C*n*[EDPOL] on the output flip-flop.

60.6.3.19.4 AS2 in OPWMT mode

AS2 defines the generation of a trigger event within the PWM period. The value you write to AS2 must be within the range of the selected timebase—otherwise the UC does not generate a trigger. A match on the comparator asserts the input-capture flag, but the match has no effect on the PWM output signal generation. The typical setup to obtain a trigger with a flag is to enable DMA and drive the DMA acknowledgement or DMA completion input high.

AS2 is not buffered, and therefore the UC updates it immediately. If the UC is running when you make a change, this could cause either of the following:

- The loss of one trigger event
- The generation of two trigger events within the same period

You access AS2 by reading or writing ALTA*n*[ALTA].

60.6.3.19.5 BS1 and BS2 in OPWMT mode

You access BS1 and BS2 using B*n*[B]:

- When you read B*n*[B], you read BS1.
- When you write to B*n*[B], you write to BS2.

BS1 defines the trailing edge of the PWM pulse output, and therefore the duty cycle of the PWM signal. To synchronize the BS1 update with the PWM signal and to ensure a correct output pulse generation, the BS2→BS1 transfer occurs at every AS1 match. This behavior is the same as in OPWM mode with next-period update.

Output Update Disable (OUDIS) affects transfers between BS2 and BS1 only.

60.6.3.19.6 Force match

At any time, Force Match A (C*n*[FORCMA]) and Force Match B (C*n*[FORCMB]) allow you to force the output flip-flop to the level corresponding to a match on AS1 or BS1, respectively. Similarly to a BS1 match, Force Match B changes the internal counter to 1h. The force-match operations do not set the input-capture flag (S*n*[FLAG]). Any match resulting from writing 1 to FORCMA or FORCMB has priority over any simultaneous match regarding output pin transitions. BS2→BS1 transfer at an A match is not inhibited by writing 1 simultaneously to both FORCMA or FORCMB. If you write 1 to both FORCMA and FORCMB simultaneously, the output pin acquires the complement of C*n*[EDPOL], as if AS1 and BS1 had the same value. FORCMA assertion causes the UC to process the BS2→BS1 transfer as a regular A match comparison and not due to FORCMA assertion, regardless of FORCMB assertion. If subsequent matches occur on comparators AS1 and B, the UC continues to generate PWM pulses, regardless of the state of S*n*[FLAG].

60.6.3.19.7 Duty cycle

To achieve 0% duty cycle, you must write the same value to AS1 and BS2. When a simultaneous match on comparators A and B occurs, the UC drives the complement of C*n*[EDPOL] on the output flip-flop at every period.

To achieve 100% duty cycle, you must write a value to BS1 that is greater than the maximum value of the selected timebase. The maximum counter value for the timebase is FF_FFFEh for a 24-bit counter and FFFEh for a 16-bit counter. When a match on comparator AS1 occurs, the UC drives C*n*[EDPOL] on the output flip-flop at every period. The match at comparator A still triggers the BS2→BS1 transfer.

Timing example: 0% duty cycle illustrates the UC running in OPWMT mode with trigger-event generation and a 0% duty cycle.

Timing example: 100% duty cycle illustrates the UC running in OPWMT mode with trigger-event generation and a 100% duty cycle.

60.6.3.19.8 Timing example: 0% duty cycle

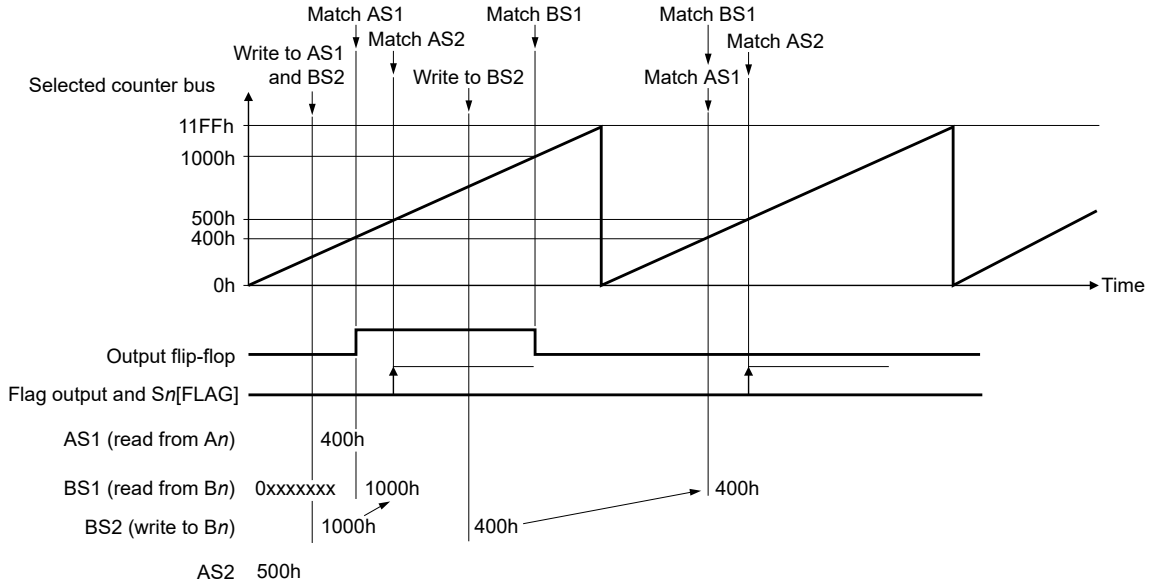

Figure 334. Timing example: 0% duty cycle

60.6.3.19.9 Timing example: 100% duty cycle

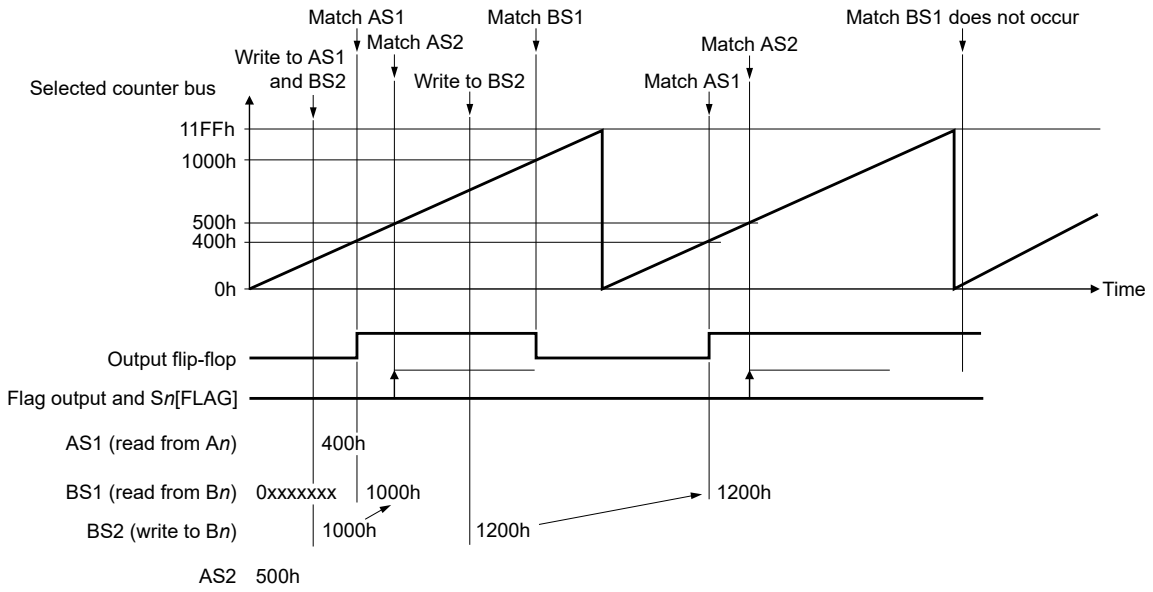

Figure 335. Timing example: 100% duty cycle

60.6.3.19.10 Output disable

As with other UC modes, OPWMT mode implements the output-disable function. When C*n*[ODIS] = 1, assertion of the output-disable input causes the UC to drive C*n*[EDPOL] on the output. Other than the fixed output, the UC continues to operate normally. When the output-disable signal deasserts, the UC returns to full normal operation.

60.6.3.20 Programmable input filter (PIF)

60.6.3.20.1 Overview

The PIF specifies the minimum input pulse width, in clock cycles, that can pass through the filter. It supports bypass operation (C*n*[IF]), with the input signal synchronized before arriving at the digital filter, or from 2 to 16 clock cycles in powers of 2.

60.6.3.20.2 Counter

The PIF is a 5-bit programmable up counter. The selected clock source increments the up counter after the number of clock cycles specified by the input filter (C*n*[IF]0.

The system clock synchronizes the input signal. When this signal changes state, the counter begins incrementing. As long as the new signal state is stable, the counter continues incrementing. If the counter overflows, eMIOS validates the new signal value. In this case, it transmits the value as a pulse edge to the edge detector. If the opposite edge appears on the signal before validation (overflow), eMIOS resets the counter. At the next transition, the counter starts incrementing again. A glitch does not occur on the edge detector for any pulse shorter than the full range of the masked counter.

Neither Freeze state nor deasserted GTBE disables the filter.

60.6.3.20.3 UC PIF logic

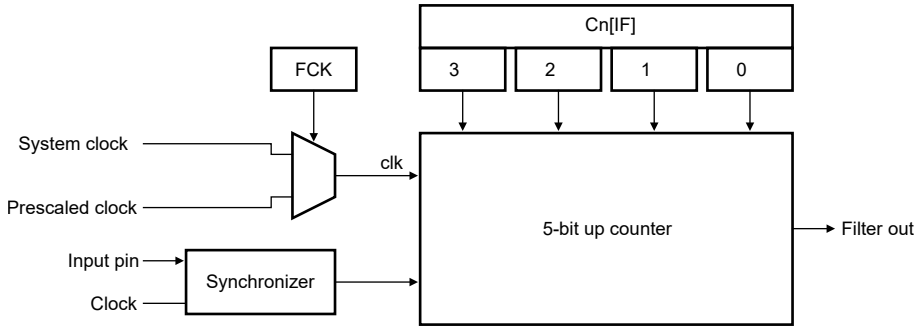

Figure 336. UC PIF logic

60.6.3.20.4 Timing example: UC PIF at 4 cycles

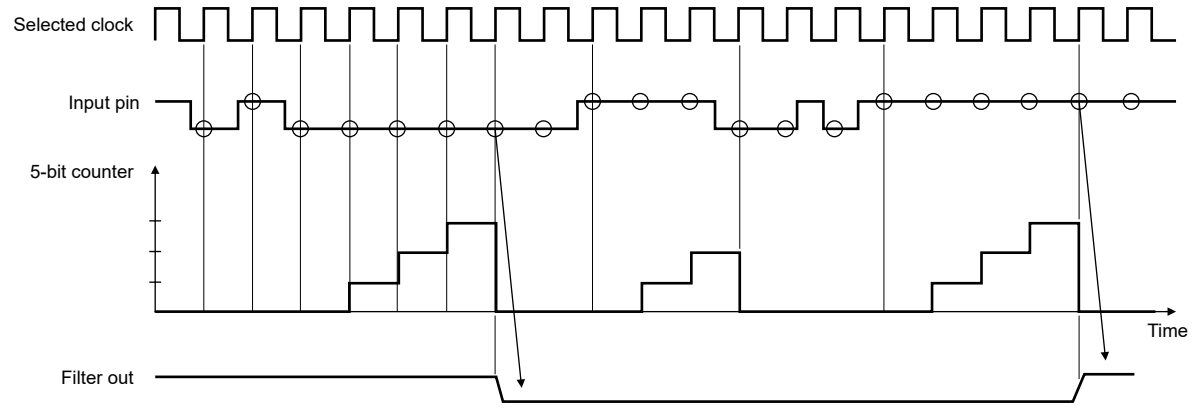

Figure 337. Timing example: UC PIF at 4 cycles

60.6.3.21 UC clock prescaler (CP)

eMIOS divides the GCP output signal by the UC CP (C*n*[UCPRE] + 1) to generate a clock enable for the UC internal counter. See Global clock prescaler (GCP). You enable the UC CP by writing 1 to C*n*[UCPREN]. If you disable the CP (write 0 to the same field), eMIOS stops the UC internal counter.

To ensure safe operation and avoid glitches, you must perform the following steps to change the UC CP:

1. Disable the GCP (write 0 to MCR[GPREN]).
2. Disable the UC CP (write 0 to C*n*[UCPREN]).
3. Specify the new prescaler value (write CP – 1 to C*n*[GPRE].
4. Enable the UC CP (write 1 to C*n*[UCPREN]).
5. Enable the GCP (write 1 to MCR[GPREN]).

60.6.4 Peripheral bus interface unit (BIU)

The BIU provides the interface between the IIB and the peripheral bus, which allows communication among all submodules and the IP interface. The BIU supports 8-, 16-, and 32-bit accesses performed over a 32-bit data bus in a single clock cycle.

60.6.5 Global clock prescaler (GCP)

eMIOS divides the system clock by the GCP (MCR[GPRE] + 1) and routes the resulting prescaled clock output to the channel CPs. You enable the GCP by writing 1 to MCR[GPREN]. If you disable the GCP (write 0 to the same field), eMIOS clears the prescaler counter and stops the prescaler clock.

To ensure safe operation and avoid glitches, you must perform the following steps to change the GCP:

1. Disable the GCP (write 0 to MCR[GPREN]).
2. Specify the new prescaler value (write GCP – 1 to MCR[GPRE].
3. Enable the GCP (write 1 to MCR[GPREN]).

60.6.6 Freeze and chip Debug mode

60.6.6.1 Enter and exit Freeze state

When the chip is in Debug mode (the chip Debug signal is asserted), you can freeze individual UCs. For the effects of Freeze state on eMIOS functions, see Freeze effects.

To put a channel in Freeze state, you must meet all of the following conditions:

- The chip must assert Debug.
- Prepare eMIOS for the Freeze state (write 1 to MCR[FRZ]).
- Enable Freeze for each channel you want to freeze:
  - Write 1 to C*n*[FREN].

A channel exits Freeze state when any of the following conditions occur:

- The chip deasserts Debug.
- You take eMIOS out of the Freeze state (write 0 to MCR[FRZ]).
- You disable Freeze for the channel:
  - write 0 to C*n*[FREN].

60.6.6.2 Freeze effects

Function	Effects of freeze
GCP	No effect
UC	• Halts counter, capture, and compare operation. • Freezes UC in its current state. • Makes all registers accessible. • In output modes, force match remains operational, allowing software to force the output to the desired level. • In input modes, the UC ignores input events. • When eMIOS exits Freeze state then UC operations resume, but they may be inconsistent until the UC reenters GPIO mode.
STAC	No effect
BIU	No effect

60.7 Initialization information

When initializing eMIOS, take the following considerations into account.

For eMIOS behavior on reset, see Reset.

Before changing the UC operating mode, you must:

1. Put the UC in GPIO mode (write 0b or 1b to C*n*[MODE]).
2. Write the correct values for the next operating mode to A*n* and B*n*.
3. Put the UC in the new operating mode (write the appropriate value to C*n*[MODE]).

If you change a UC from one mode to another without performing this procedure, the first operation cycle of the selected timebase can be random; that is, matches can occur in random time because you did not update A*n* and B*n* with correct values before the timebase matches the previous contents of either register.

NOTE

To to avoid causing an unexpected interrupt or DMA request when changing from GPIO to MCB mode, you must use the procedure described in Changing to MCB mode.

When you enable interrupts, any interrupt service routine must clear the flag before exiting.

60.8 Application information

60.8.1 Overview

All output operation modes can generate correlated output signals. You can disable updates of the output signals for each UC (OUDIS).

To guarantee that incrementing of the internal counters of correlated channels occurs in the same clock cycle, you must configure the internal CPs before enabling the GCP. If you configure the internal CPs after enabling the GCP, the internal counters may increment in the same ratio, but at different clock cycles.

You should drive the Output Disable Input signals with the flag signals of some UCs running in SAIC mode. When an output disable condition happens, the interrupt service routine must process the output channels before processing the channels running SAIC. This sequence avoids glitches in the output pins.

60.8.2 Timebase generation

In the MC and OPWFM modes with internal clock sources, you can modify the internal counter rate by configuring the CP ratio. Timebase with the fastest prescaler ratio illustrates a timebase with a prescaler ratio of one.

NOTE

The buffered modes, MCB and OPWFMB, behave differently.

If the prescaler ratio is greater than one or you select an external clock, the internal counter behaves in one of four different ways depending on the channel mode:

- In MC mode with Clear on Match Start and External Clock: Timebase generation with clear on match start and external clock.
- In MC mode with Clear on Match Start and Internal Clock source: Timebase generation with clear on match start and internal clock.
- In MC mode with Clear on Match End: Timebase generation with clear on match end.
- In OPWFM mode: Timebase generation with clear on match start and internal clock. The internal counter clears at the start of the match signal, skips the next prescaled clock edge, and then increments in the subsequent prescaled clock edge.

60.8.3 Timebase with the fastest prescaler ratio

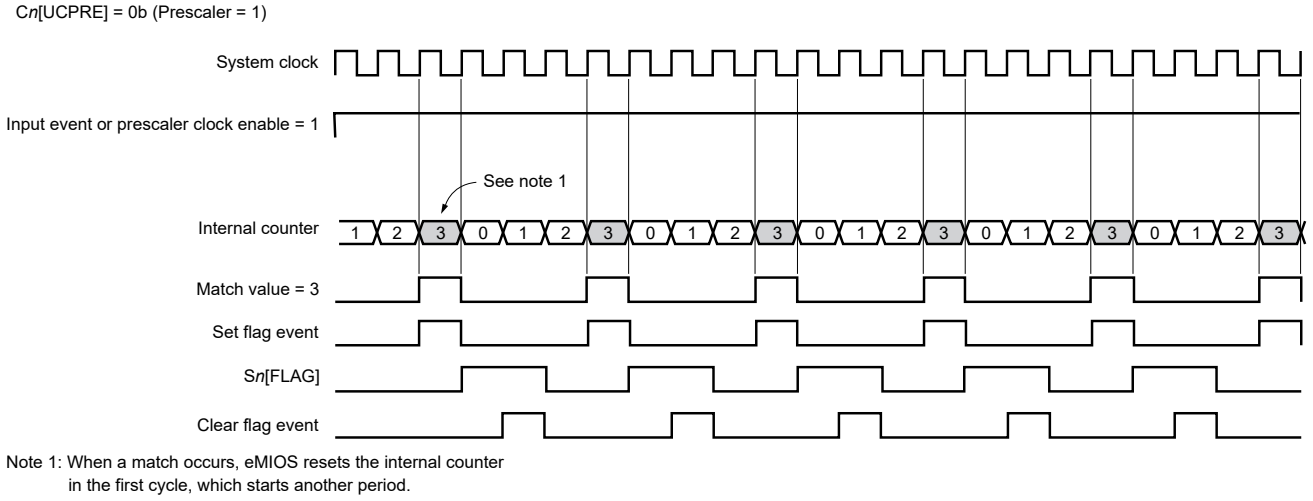

Figure 338. Timebase with fastest prescaler ratio

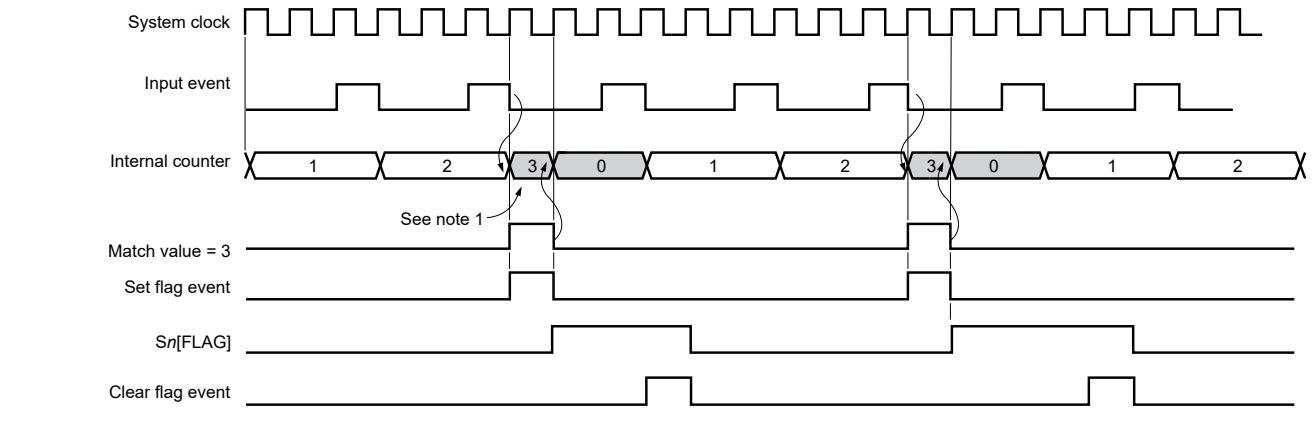
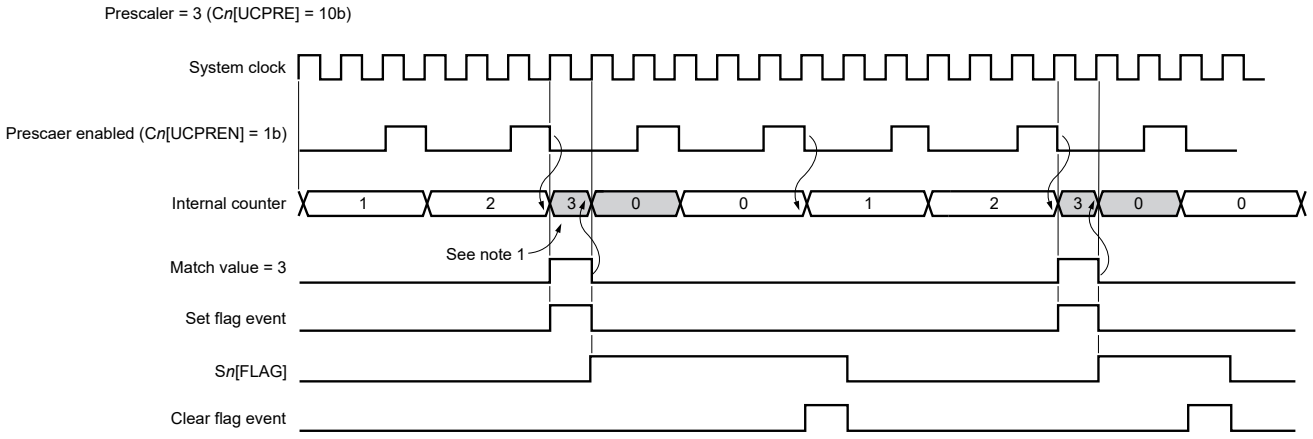
60.8.4 Timebase generation with clear on match start and external clock



Note 1: When a match occurs, eMIOS resets the internal counter in the first clock cycle.
The counter starts counting at the next edge of the prescaler clock enable.

Figure 339. Timebase generation with clear on match start and external clock

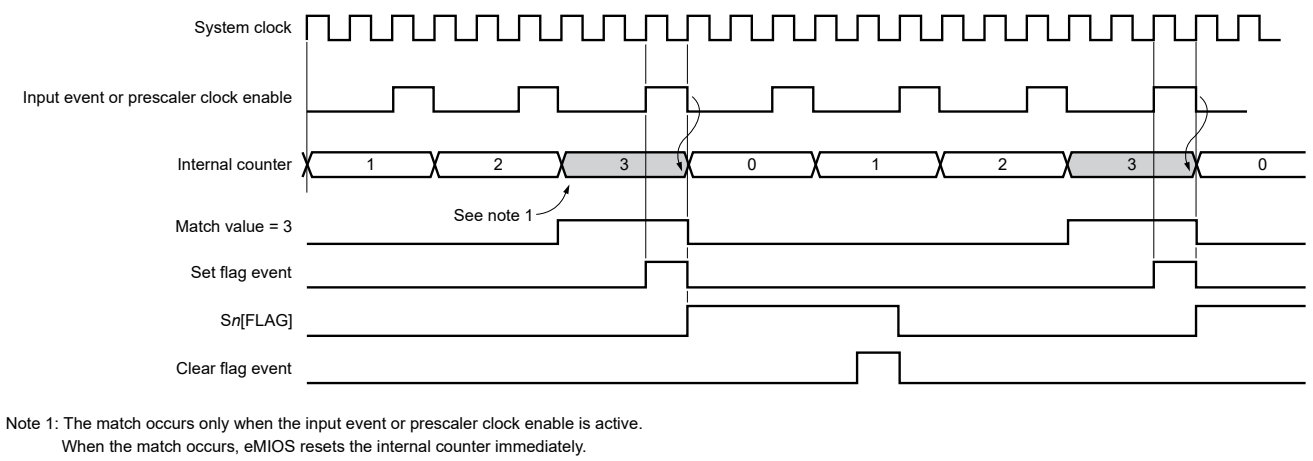
60.8.5 Timebase generation with clear on match start and internal clock



Note 1: When a match occurs, eMIOS clears the internal counter in the first clock cycle.
The counter starts counting again only after the second edge of the prescaled clock.

Figure 340. Timebase generation with clear on match start and internal clock

60.8.6 Timebase generation with clear on match end



Note 1: The match occurs only when the input event or prescaler clock enable is active.
When the match occurs, eMIOS resets the internal counter immediately.

Figure 341. Timebase generation with clear on match end

60.8.7 Coherent accesses

Reading A*n*[A] again in the same period as the last read of B*n*[B] results in incoherent results if the last read of B*n*[B] occurred after a disabled BS2→BS1 transfer.

60.8.8 Initializing channels and modes

Perform the following basic steps for output mode startup. This procedure assumes the channels are initially in GPIO mode:

1. Disable the GPC (write 0 to MCR[GPREN]).
2. For each timebase UC:
    a. Disable the CP (write 0 to C*n*[UCPREN]).
    b. Write an initial value to the internal counter (CNT*n*[C]).
    c. Write initial values to A*n*[A] and B*n*[B].
    d. Configure the UC for MC or MCB Up mode (write the appropriate value to C*n*[MODE]).
    e. Select the CP ratio (C*n*[UCPRE]).
    f. Enable the CP (write 1 to C*n*[UCPREN]).
3. For each output UC:
    a. Disable the CP (write 0 to C*n*[UCPREN]).
    b. Write initial values to A*n*[A] and B*n*[B].
    c. Select the timebase input (C*n*[BSL]).
    d. Specify the output mode (write the appropriate value to C*n*[MODE]).
    e. Select the same CP ratio as the timebase UC (C*n*[UCPRE]).
    f. Enable the CP (write 1 to C*n*[UCPREN]).
4. Enable the GPC (write 1 to MCR[GPREN]).
5. Enable GBTE (write 1 to MCR[GBTE]).

The timebase channel and the output channel may be the same for some applications such as in OPWFM or OPWFMB mode, or whenever the output channel drives the timebase itself.

You may configure flags at any time.

60.9 Memory maps and registers

60.9.1 Overall address map organization

All address locations not explicitly mentioned in this table are reserved. When you access an absent register, absent channel, or reserved address space, the transfer terminates with an error.

Table 340. Overall address map organization

Base address (hex)	Description
0	Module Configuration (MCR)
4	Global Flag (GFLAG)
8	Output Update Disable (OUDIS)
C	Disable Channel (UCDIS)
20	Channels 0–7
120	Channels 8–15
220	Channels 16–23

60.9.2 UC memory overview

Table 341. UC memory overview

Offset from UC *n* base address (hex)	Description
0	UC A n (A0 - A23)
4	UC B n (B0 - B23)
8	UC Counter n (CNT0 - CNT23)
C	UC Control n (C0 - C23)
10	UC Status n (S0 - S23)
14	Alternate Address n (ALTA0 - ALTA23)
18	UC Control 2 n (C2_0 - C2_23)
1C–1F	Reserved

60.9.3 AS1, AS2, BS1, and BS2 shadow registers

When you use eMIOS UC modes, you rely heavily on four shadow registers:

- AS1
- AS2
- BS1
- BS2

You use A*n*[A], B*n*[B], and ALTA*n*[ALTA] to access these shadow registers:

- Each instance of A*n*[A] has a separate associated instance of AS1 and AS2. In some UC modes, you also use ALTA*n*[ALTA] to access AS2.
- Each instance of B*n*[B] has a separate associated instance of BS1 and BS2.

See Relationship between A*n*, B*n*, ALTA*n*, and shadow registers.

Each UC mode uses the AS1-AS2 and BS1-BS2 shadow register pairs for various match and capture functions, as described in Unified channels (UC).

A reset clears all shadow registers.

Assignment of values for A*n*[A], B*n*[B], and ALTA*n*[ALTA] describes how you write to and read from the shadow registers for all operation modes. Values not listed are reserved. For more information, see Unified channels (UC).

60.9.4 Relationship between A*n*, B*n*, ALTA*n*, and shadow registers

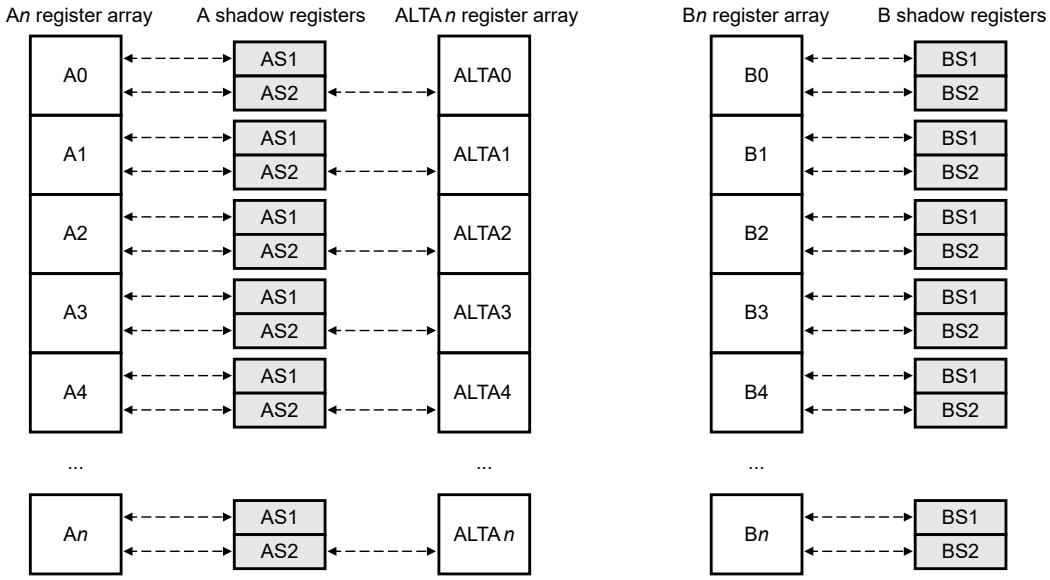


Figure 342. Relationship between A*n*, B*n*, ALTA*n*, and shadow registers

60.9.5 Assignment of values for A*n*[A], B*n*[B], and ALTA*n*[ALTA]

This table describes how you write to and read from the following registers for all operation modes:

- UC A n (A0 - A23)
- UC B n (B0 - B23)
- Alternate Address n (ALTA0 - ALTA23)

Values not listed are reserved. For more information, see Unified channels (UC).

Table 342. Assignment of values for A*n*[A], B*n*[B], and ALTA*n*[ALTA]

Operation mode	Register access					
	A*n*		B*n*		ALTA*n*	
	Write	Read	Write	Read	Write	Read
GPIO	AS1 and AS2[1]	AS1	BS1 and BS2[2]	BS1	AS2	AS2

Table continues on the next page...

Table 342. Assignment of values for A*n*[A], B*n*[B], and ALTA*n*[ALTA] (continued)

Operation mode	Register access					
	A*n*		B*n*		ALTA*n*	
	Write	Read	Write	Read	Write	Read
SAIC[3]	—	AS2	BS2	BS2	—	—
SAOC[3]	AS2	AS1	BS2	BS2	—	—
IPWM	—	AS2	—	BS1	—	—
IPM	—	AS2	—	BS1	—	—
DAOC	AS2	AS1	BS2	BS1	—	—
PEA	AS1	AS2	—	BS1	—	—
PEC[3]	AS1	AS1	BS1	BS1	—	AS2
WPTA	AS1	AS1	BS1	BS1	—	AS2
MC[3]	AS2	AS1	BS2	BS2	—	—
OPWFM	AS2	AS1	BS2	BS1	—	—
OPWMC	AS2	AS1	BS2	BS1	—	—
OPWM	AS2	AS1	BS2	BS1	—	—
OPWMT	AS1	AS1	BS2	BS1	AS2	AS2
MCB[3]	AS2	AS1	BS2	BS1	—	—
OPWFMB	AS2	AS1	BS2	BS1	—	—
OPWMCB	AS2	AS1	BS2	BS1	—	—
OPWMB	AS2	AS1	BS2	BS1	—	—

1. This operation writes the same value to AS1 and AS2.
2. This operation writes the same value to BS1 and BS2.
3. These modes do not require UC B n (B0 - B23), but you can still use it to access BS2.

60.9.6 eMIOS register descriptions

All control registers are 32 bits wide. Data fields are 16 bits wide. There are 24 UCs, as mapped in Counter buses, channels, and timebase sources.

60.9.6.1 eMIOS memory map

eMIOS_0 base address: 4008_8000h

eMIOS_1 base address: 4008_C000h

eMIOS_2 base address: 4009_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Module Configuration (MCR)	32	RW	0000_0000h

60.9.6.2 Module Configuration (MCR)

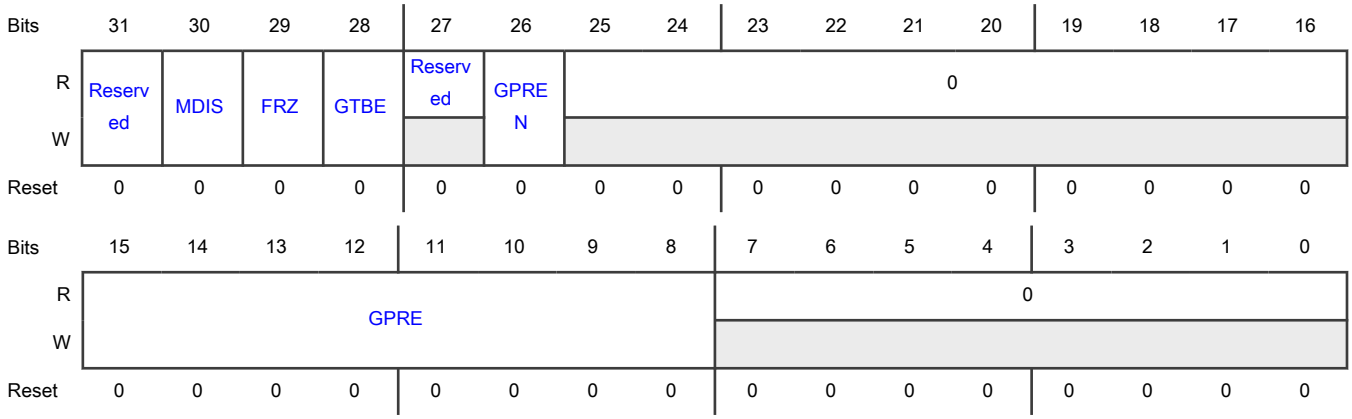
Offset

Register	Offset
MCR	0h

Function

Configures eMIOS operation.

Diagram



Fields

Field	Function
31 —	Reserved Write only the reset value to this field.
30 MDIS	Module Disable Disables eMIOS by stopping the clock. When you disable eMIOS, its clock stops, it consumes less power, and you can access only the following registers: • Module Configuration (MCR) • Output Update Disable (OUDIS) • Disable Channel (UCDIS) 0b - Enable 1b - Disable
29 FRZ	Freeze Prepares eMIOS to enter Freeze state (see Freeze and chip Debug mode). eMIOS does not enter Freeze state until both of the following conditions occur: • The chip asserts Debug mode. • You enable Freeze for each UC (write 1 to C*n*[FREN]). A channel remains frozen until one or more of the following occur: • You force eMIOS to exit the Freeze state (write 0 to FRZ). • The chip deasserts Debug mode. • You disable Freeze for that UC (write 0 to C*n*[FREN]). 0b - Exit Freeze state 1b - Enter Freeze state
28	Global Timebase Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
GTBE	Asserts the GTBE_OUT signal. If GTBE_OUT is connected to the GTBE_IN input of one or more eMIOS instances, asserting the signal turns on the internal counters of those eMIOS instances simultaneously. **NOTE** The GTBE_IN input enables (asserted) or disables (deasserted) the internal counters. 0b - Deassert GTBE_OUT 1b - Assert GTBE_OUT
27 —	Reserved
26 GPREN	Global Prescaler Enable Enables the global prescaler counter. Disabling the global prescaler clears the prescaler counter and stops the prescaler clock. 0b - Disable 1b - Enable
25-16 —	Reserved
15-8 GPRE	Global Prescaler Specifies the global clock prescaler. Write the desired clock divide ratio minus 1. For example, for a divide ratio of 8, write 111b. The prescaler can range from 1 (0b) to 256 (11111111b).
7-0 —	Reserved

60.9.6.3 Global Flag (GFLAG)

Offset

Register	Offset
GFLAG	4h

Function

Groups the flag fields from all channels into one register to improve interrupt handling.

For UCs, each field mirrors the corresponding channel flag (S*n*[FLAG]).

60.9.6.4 Output Update Disable (OUDIS)

Offset

Register	Offset
OUDIS	8h

Function

Disables transfers from AS2 to AS1 and BS2 to BS1 on a per-channel basis. This applies to any channel operating in MC, MCB, or any output mode that writes to AS2 and BS2.

When a field is 0, transfers on that channel occur immediately or in the next period, depending on the operation mode. Unless that mode's description states otherwise, the transfer occurs immediately.

60.9.6.6 UC A n (A0 - A23)

Offset

For n = 0 to 23:

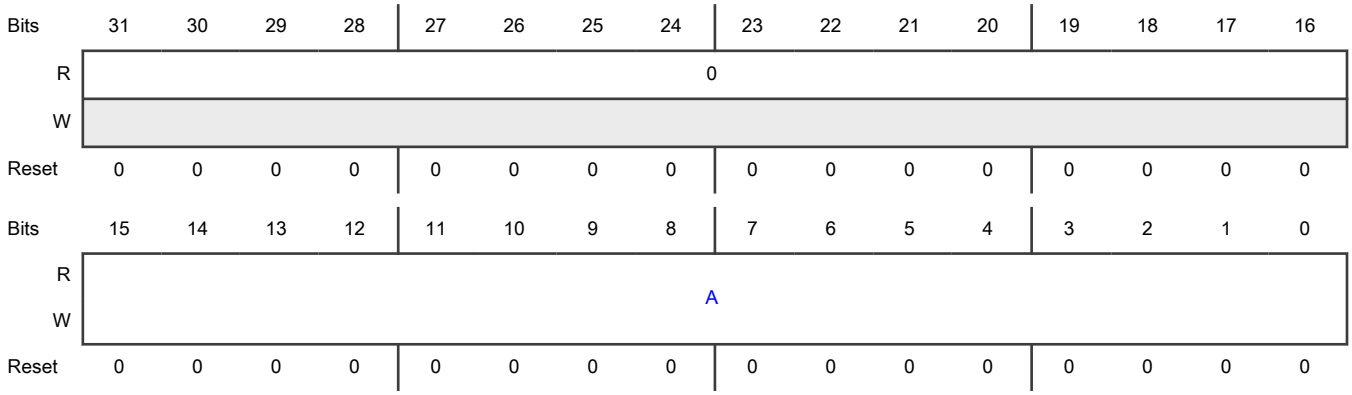
Register	Offset
An	20h + (n × 20h)

Function

Accesses the AS1 and AS2 shadow registers for each UC, depending on the selected UC mode. See AS1, AS2, BS1, and BS2 shadow registers.

For information about how you write to and read from A*n*, B*n*, and ALTA*n* for all UC modes, see Assignment of values for A*n*[A], B*n*[B], and ALTA*n*[ALTA].

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 A	A See the register description.

60.9.6.7 UC B n (B0 - B23)

Offset

For n = 0 to 23:

Register	Offset
Bn	24h + (n × 20h)

Function

Accesses the BS1 and BS2 shadow registers for each UC, depending on the selected UC mode. See AS1, AS2, BS1, and BS2 shadow registers.

For information about how you write to and read from A*n*, B*n*, and ALTA*n* for all UC modes, see Assignment of values for A*n*[A], B*n*[B], and ALTA*n*[ALTA].

60.9.6.8 UC Counter n (CNT0 - CNT23)

Offset

Register	Offset
CNT0	28h
CNT1	48h
CNT2	68h
CNT3	88h
CNT4	A8h
CNT5	C8h
CNT6	E8h
CNT7	108h
CNT8	128h
CNT16	228h
CNT22	2E8h
CNT23	308h

Function

Indicates the value of the UC internal counter.

When eMIOS is in GPIO mode or the UC is frozen, this register is read-write. For all other modes, this register is read-only. When entering some UC modes, eMIOS automatically clears this register. See Unified channels (UC) for details.

The following modes use the UC counter:

- Output Pulse Width and Frequency Modulation Buffered (OPWFMB) mode
- Center Aligned Output PWM with Dead Time Insertion Buffered (OPWMCB) mode
- Pulse Edge Counting (PEC) mode
- Modulus Counter (MC) mode
- Modulus Counter Buffered (MCB) mode

All other modes not in this list do not use the internal counter.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
eMIOS_0	CNT0–CNT8 CNT16 CNT22–CNT23	—
eMIOS_1	CNT0 CNT8 CNT16 CNT22–CNT23	CNT1–CNT7
eMIOS_2	CNT0 CNT8 CNT16 CNT22–CNT23	CNT1–CNT7

15-0 C	Internal Counter Value Indicates the value of the internal counter.

60.9.6.9 UC Control n (C0 - C23)

Offset

For n = 0 to 23:

Register	Offset
Cn	2Ch + (n × 20h)

Function

Controls UC operation.

Table 343. MODE field values

UC mode	MODE (binary)
GPIO (input)	000_0000
GPIO (output)	000_0001
SAIC	000_0010
SAIC with edge capturing	100_0010
SAOC	000_0011
IPWM	000_0100
IPM	000_0101

Table continues on the next page...

Table 343. MODE field values (continued)

UC mode	MODE (binary)
DAOC (with FLAG = 1 on B match)	000_0110
DAOC (with FLAG = 1 on A and B match)	000_0111
PEC (continuous)	000_1010
PEC (single shot)	000_1011
Reserved	000_1111
MC (up counter with clear on match start)	001_000p[1]
MC (up counter with clear on match end)	001_001p[1]
MC (up/down counter)	001_01pp[1]
Reserved	010_0100–010_0101
OPWMT	010_0110
Reserved	010_0111–100_1111
MCB (up counter)	101_000p[1]
Reserved	101_001p
MCB (up or down counter)	101_01pp[1]
OPWFMB	101_10p0[1]
Reserved	101_10p1
OPWMCB (with trailing edge dead time)	101_11p0[1]
OPWMCB (with leading edge dead time)	101_11p1[1]
OPWMB	110_00p0[1]
Reserved	110_0001–111_1111

1. p = Adjust parameters for the mode of operation. See Unified channels (UC) for details.

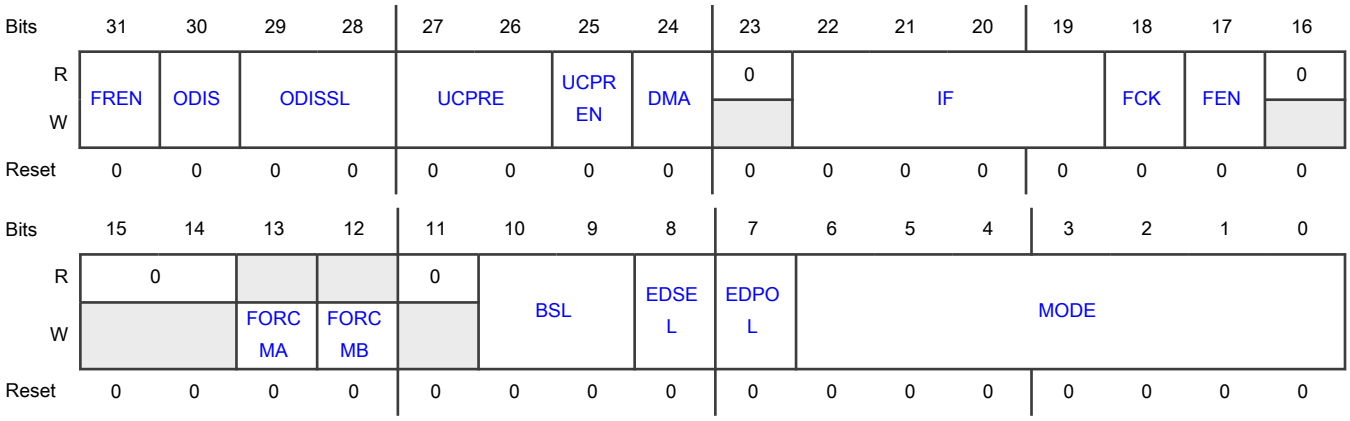
Table 344. Edge Polarity (EDPOL) settings

For these modes:	EDPOL does this:	and EDPOL values mean:
Input	Selects which edge triggers the internal counter, an input capture, or the input capture flag. If EDPOL does not appear in the UC mode description, it has no effect on UC operation.	0b - Trigger on a falling edge 1b - Trigger on a rising edge
Output	Selects the logic level on the output pin.	0b - A match on comparator A deasserts the output flip-flop, while a match on comparator B sets it 1b - A match on comparator A asserts the output flip-flop, while a match on comparator B clears it

Table 345. Edge Select (EDSEL) settings

For these modes:	EDSEL does this:	and EDSEL values mean:
Input	Selects whether the internal counter is triggered by both edges of a pulse or by a single edge as defined by EDPOL. If EDSEL does not appear in the UC mode description, it has no effect on UC operation.	0b - Single-edge triggering on edge specified in EDPOL 1b - Both-edges triggering
GPIO in	Selects whether an edge asserts the input capture flag (S*n*[FLAG]).	0b - Sets S*n*[FLAG] on the edge specified in EDPOL 1b - Does not set S*n*[FLAG]
SAOC	Selects the behavior of the output flip-flop at each match.	0b - Drive the EDPOL value on the output flip-flop 1b - Toggle output flip-flop

Diagram



Fields

Field	Function
31 FREN	Freeze Enable Enables putting the UC in Freeze state. See Freeze and chip Debug mode. 0b - Disable 1b - Enable
30 ODIS	Output Disable Disables the output pin when running any of the output modes except GPIO. When you assert ODIS: • If the selected Output Disable Input signal asserts, the output pin reflects: — For OPWFMB and OPWMB modes, EDPOL (see Output Pulse Width and Frequency Modulation Buffered (OPWFMB) mode and Output PWM Buffered (OPWMB) mode).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	— For all other modes, the complement of EDPOL, but the UC continues to operate normally—it continues to generate flags and matches. • If the selected Output Disable Input signal deasserts, the output pin operates normally. 0b - Enables output pin (the output pin operates normally) 1b - Disables output pin
29-28 ODISSL	Output Disable Select Selects one of four output disable input signals. 00b - 0 01b - 1 10b - 2 11b - 3
27-26 UCPRE	Prescaler Selects the clock divider value for the UC internal prescaler. **NOTE** The two least-significant bits of C2_*n*[UCEXTPRE] mirror UCPRE. Any write to UCPRE also affects UCEXTPRE. 00b - 1 01b - 2 10b - 3 11b - 4
25 UCPREN	Prescaler Enable Enables the prescaler counter. 0b - Disable (no clock) 1b - Enable
24 DMA	Direct Memory Access Selects whether the input capture flag (S*n*[FLAG]) or overrun (S*n*[OVR]) triggers an interrupt or DMA request. 0b - Interrupt request 1b - DMA request
23 —	Reserved
22-19	Input Filter

Table continues on the next page...

Table continued from the previous page...

Field	Function
IF	Selects the minimum input pulse width, in filter clock cycles, that can pass through the input filter. This field does not apply to output modes. The filter latency—the difference in time between the input and the response—is three clock edges. 0000b - Bypassed; the input signal is synchronized before arriving at the digital filter 0001b - 2 cycles 0010b - 4 cycles 0100b - 8 cycles 1000b - 16 cycles All other values are reserved.
18 FCK	Filter Clock Select Selects the clock source for the programmable input filter. 0b - Prescaled clock 1b - eMIOS module clock
17 FEN	Flag Enable Enables the input capture flag (S*n*[FLAG]) to generate an interrupt request or a DMA request, as selected in DMA. 0b - Disable 1b - Enable
16-14 —	Reserved
13 FORCMA	Force Match A For output modes, asserting Force Match A causes the comparator to report a successful comparison on comparator A regardless of whether a comparison actually occurred. It does not set the input capture flag (S*n*[FLAG]). This field always reads 0. This bit is meaningful for every output operation mode that uses comparator A. Otherwise it has no effect. 0b - No effect 1b - Force a match at comparator A
12 FORCMB	Force Match B For output modes, asserting Force Match B causes the comparator to report a successful comparison on comparator B regardless of whether a comparison actually occurred. It does not set the input capture flag (S*n*[FLAG] does not become 1). This field always reads 0. This field applies only if the UC is in one of the following output modes. • Single Action Output Capture (SAOC) mode • Double Action Output Compare (DAOC) mode

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• Output Pulse Width and Frequency Modulation Buffered (OPWFMB) mode • Center Aligned Output PWM with Dead Time Insertion Buffered (OPWMCB) mode • Output PWM Buffered (OPWMB) mode • Output PWM with Trigger (OPWMT) mode This field has no effect in all other modes. 0b - No effect 1b - Force a match at comparator B
11 —	Reserved
10-9 BSL	Bus Select Selects one of the counter buses or the internal counter for the UC. Not all chips support all counter buses. See the chip-specific eMIOS information for details. 00b - • Channels 0-22: counter bus A • Channel 23: reserved 01b - • Channels 1-7: counter bus B • Channels 9-15: counter bus C • Channels 17-23: counter bus D • Channels 25-31: counter bus E • Channels 0, 8, 16, 24: reserved 10b - • Channels 0-21, 23: counter bus F • Channel 22: reserved 11b - Internal counter for all channels
8 EDSEL	Edge Selection Controls several functions as shown in Table 345.
7 EDPOL	Edge Polarity Controls several functions as shown in Table 344.
6-0 MODE	Mode Selection Selects the UC mode as shown in Table 343.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE If you write a reserved value to this field, the results are unpredictable. When you change the value of MODE, you must first enter GPIO mode to reset the UC's internal functions. Failure to do this can result in invalid and unexpected output compare or input capture results or incorrectly set input capture flags (S*n*[FLAG]).

60.9.6.10 UC Status n (S0 - S23)

Offset

For n = 0 to 23:

Register	Offset
Sn	30h + (n × 20h)

Function

Indicates the status of the UC input-output signals and the overflow condition of the internal counter.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No overflow 1b - Return OVFL to 0
14-3 —	Reserved
2 UCIN	UC Input Pin Indicates the input pin state after the input pin has been filtered and synchronized. 0b - Negated 1b - Asserted
1 UCOUT	UC Output Pin Indicates the output pin state. 0b - Negated 1b - Asserted
0 FLAG	Flag Indicates that an input capture or a match event in the comparators has occurred. **NOTE** This field behaves differently for read and write operations. When reading 0b - No event 1b - Event has occurred When writing 0b - No event 1b - Clear the flag (FLAG returns to 0)

60.9.6.11 Alternate Address n (ALTA0 - ALTA23)

Offset

For n = 0 to 23:

Register	Offset
ALTAn	34h + (n × 20h)

Function

Provides an alternate address to access AS2 shadow registers in these restricted modes:

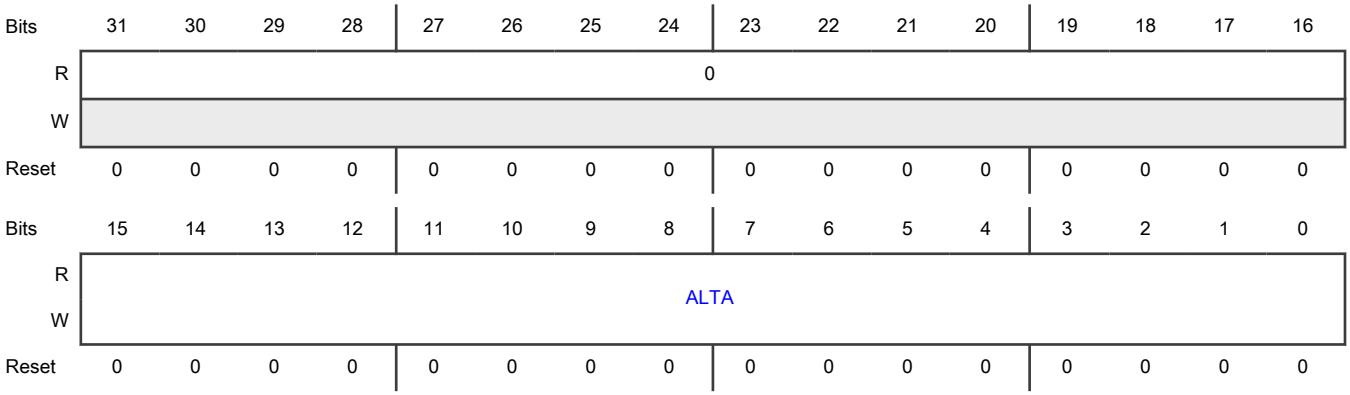
- General-Purpose Input and Output (GPIO) mode

- Pulse Edge Counting (PEC) mode
- Output PWM with Trigger (OPWMT) mode

In these modes, you can use A*n*[A] together with with ALTA*n*[ALTA] to access both AS1 and AS2. Assignment of values for A*n*[A], B*n*[B], and ALTA*n*[ALTA] summarizes the ALTA*n* writing and reading accesses for all ALTA*n* operation modes.

In modes that do not require this register, any write access is ignored and any read access returns unspecified data.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 ALTA	Alternate Address See the register description.

60.9.6.12 UC Control 2 n (C2_0 - C2_23)

Offset

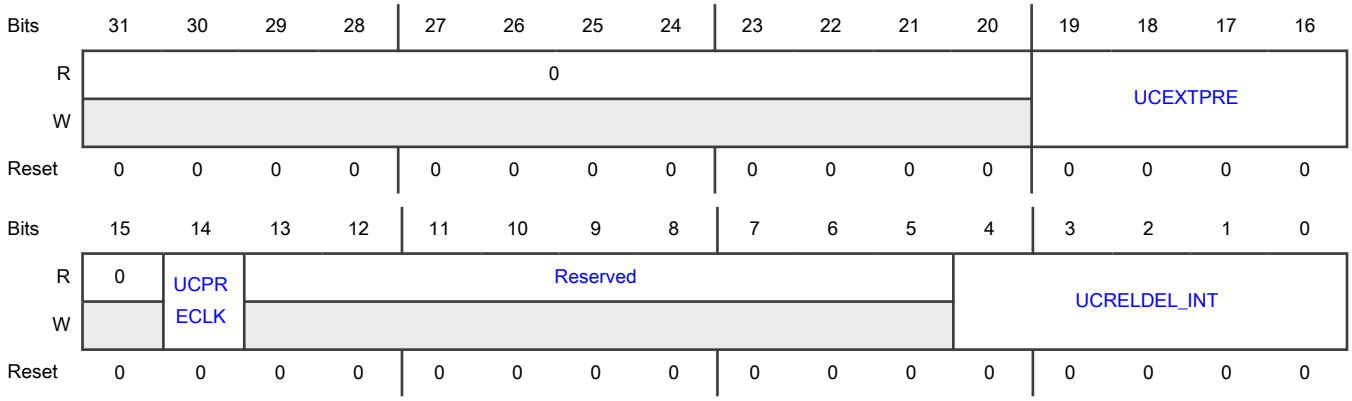
For n = 0 to 23:

Register	Offset
C2_n	38h + (n × 20h)

Function

Provides additional controls for the UC.

Diagram



Fields

Field	Function
31-20 —	Reserved
19-16 UCEXTPRE	Extended Prescaler Specifies the clock divider for the internal UC prescaler. Write the desired divider value minus 1. For example, for a divider of 1, write 0. **NOTE** The two least-significant bits of UCEXTPRE mirror C*n*[UCPRE]. Any write operation to UCEXTPRE also affects UCPRE.
15 —	Reserved
14 UCPRECLK	Prescaler Clock Source Selects the clock source for the internal prescaler. 0b - Prescaled clock 1b - eMIOS module clock
13-5 —	Reserved
4-0 UCRELDEL_INT	Reload Signal Output Delay Interval Specifies the delay interval, in counter bus reload events, between each assertion of AS1-BS1 reload in MC and MCB modes. 00000b - Every event 00001b - Every 2nd event 00010b - Every 3rd event

Table continues on the next page...

NOTE

You must clear triggers to BCTU after TRGMUX programming using TRGCFG_n[TRG_FLAG] bit.

61.2 Introduction

BCTU accepts ADC conversion-request trigger inputs and routes those requests to one or more ADCs.

BCTU accepts the following trigger sources:

- Hardware triggers (outputs from on-chip timer modules)
- Software triggers through the SFTRGRn register

BCTU maps each trigger input to a Trigger Configuration (TRGCFG_0 - TRGCFG_71) register, which specifies the target ADC channel and other control data for the requested conversion.

You can configure a list of ADC channels, the CL, that processes a sequence of conversions in response to a single trigger input. See the Conversion list (CL) section.

BCTU stores each ADC conversion result for CPU access or routing to memory through DMA.

If the same ADC is targeted by multiple triggers, priority logic selects the next trigger to process from all active trigger inputs. See Priority of simultaneous triggers.

BCTU inputs are active-high signals. That is, a logic 1 asserts the trigger input.

61.3 Features

BCTU supports:

- 72 trigger inputs, configured with the Trigger Configuration (TRGCFG_0 - TRGCFG_71) registers
- Trigger outputs to 3 ADCs
- One priority selection logic block per ADC
- Selection multiplexers to select one trigger at a time for each ADC
- A CL of 32 ADC channels
- A trigger grouping block to latch the hardware triggers. BCTU clears these triggers when the ADC sends an acknowledgement for conversion completion.

61.4 Block diagram

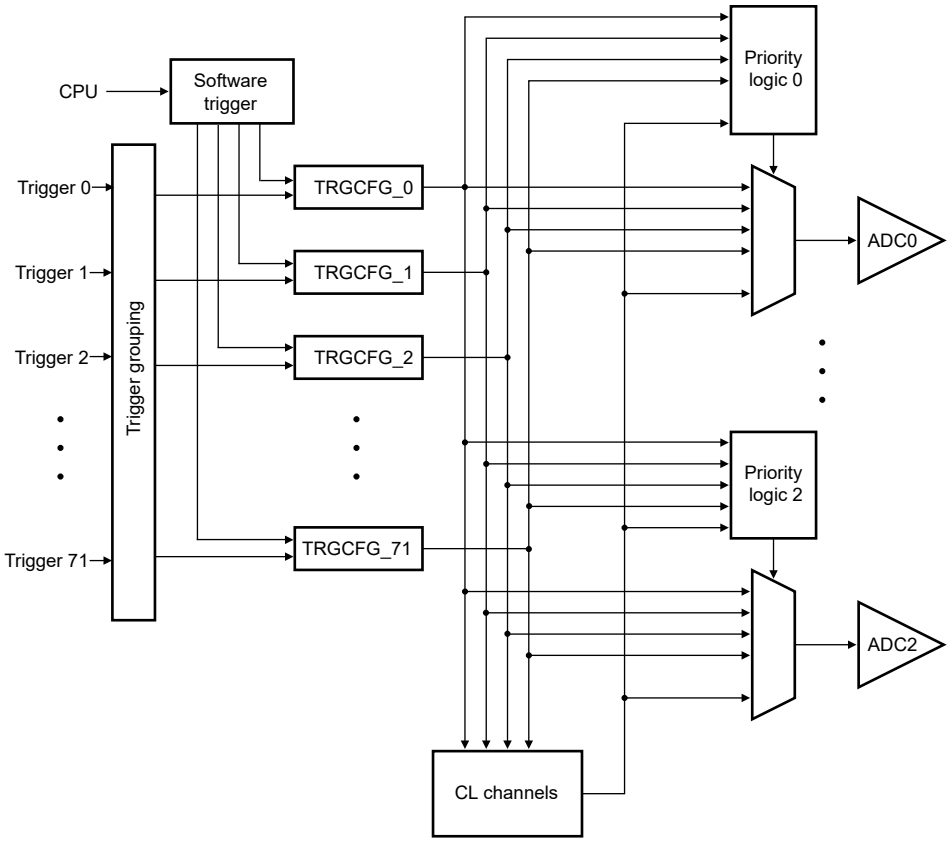

Figure 343. BCTU block diagram

61.5 Interaction with other peripherals

BCTU works together with timer and ADC modules on the chip. Use the Trigger Configuration registers (TRGCFG_*n*) to map BCTU triggers to ADC inputs. When a timer output asserts a BCTU trigger, BCTU passes the trigger to an ADC input and stores

the trigger assertion until the corresponding ADC begins the requested conversion. When the ADC completes the conversion, BCTU asserts a trigger clear signal to clear both the internally stored trigger and the external trigger source if they are still asserted. Implementation illustrates the modules that interact with BCTU.

NOTE

A timer trigger can remain active until the corresponding ADC initiates conversion. Therefore, another match may occur in the timer before the ADC conversion begins. BCTU does not detect this trigger overrun. Your application must look for and respond to such conditions.

61.6 Implementation

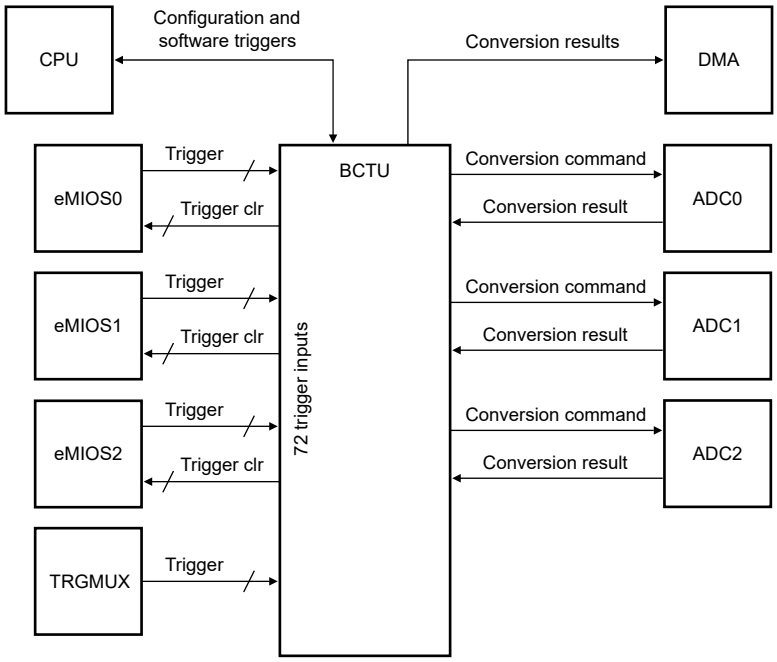

Figure 344. Implementation

61.7 Module Disable (Low Power state)

Module Disable (MCR[MDIS]) stops the BCTU clock, resulting in reduced power consumption.

When you disable BCTU (write 1 to MDIS), it:

- Waits for the completion of any in-progress conversions before stopping the clock.
- Ignores all trigger inputs.
- Does not trigger any ADC conversion requests.
- Maintains any asserted trigger inputs, which you can clear if necessary.

When you re-enable BCTU (write 0 to MDIS) and Global Triggers are enabled (MCR[GTRGEN]), BCTU processes all active asserted trigger inputs and sends conversion requests to ADCs according to the priority scheme.

61.8 Software reset

You can reinitialize all BCTU registers to their reset values with Software Reset (MCR[Software_Reset]).

Software reset does not clear any active trigger inputs, but it does put the ADC interface into the Reset state. Therefore, to avoid data incoherency, you must terminate any BCTU-triggered conversions or wait until they are complete before asserting software reset.

61.9 Triggers

61.9.1 Overview

BCTU prioritizes ADC trigger inputs based on the input number: the lower the number, the higher the priority associated with it. Therefore, trigger 0 is the highest priority trigger and trigger 71 is the lowest priority. The trigger input priority scheme determines which trigger takes precedence when more than one trigger occurs at the same time, or when the triggered ADC is busy with a conversion. Therefore, there are two possible scenarios for the trigger priority selection:

- When there are no ongoing conversions
- When a triggered ADC is executing a conversion

BCTU supports two types of trigger sources:

- Hardware triggers from timer modules
- Software triggers (SFTRGR*n*)

61.9.2 Hardware triggers

To request an ADC conversion through the BCTU, a timer module such as eMIOS asserts its output signal, which is connected to a BCTU trigger input. When BCTU detects the asserted trigger, it routes that request to the ADCs selected in the corresponding Trigger Configuration (TRGCFG_*n*[ADC_SEL*m*]). The trigger remains asserted until the requested conversion begins, at which time BCTU clears the trigger. If the timer asserts the trigger input when the trigger is already set, BCTU ignores the new trigger. If BCTU receives a new trigger input at the same time it is clearing the trigger, then the trigger remains asserted and BCTU initiates a new conversion.

If you configure the trigger for CL, trigger assertion begins a sequence of conversions controlled by the CL Channel Address (LISTCHR_0 - LISTCHR_15) registers. In this event, BCTU clears the trigger when the last conversion in the CL begins.

NOTE

Any new trigger input participates in the trigger priority selection scheme and therefore may not trigger the next conversion.

61.9.3 Software triggers

You assert a software trigger by writing 1 to the corresponding field of the appropriate Software Trigger (SFTRGR*n*) register. Similar to the hardware triggers, BCTU changes the software trigger field to 0 when the requested conversion begins. If you write 1 to the software trigger field while the conversion is still in progress, BCTU ignores the request. If you write 1 to the field at the same time BCTU is attempting to clear the trigger (change the field to 0), the trigger remains asserted and BCTU triggers a new conversion following the trigger priority criteria.

61.9.4 Configure all triggers

Global Trigger Enable (MCR[GTRGEN]) allows you to configure the BCTU trigger inputs and then activate them all at one time.

To configure and then activate all BCTU triggers:

1. Clear any currently active and asserted trigger inputs (write 0 to TRGFG_*n*[TRG_FLAG]), which also causes BCTU to assert trigger clear to the trigger sources.
2. Disable Global Triggers (MCR[GTRGEN]). This action deactivates all trigger inputs and prevents BCTU from generating any ADC conversion requests.
3. Configure the individual trigger inputs (see Configure individual triggers).

4. Enable Global Triggers (MCR[GTRGEN]). This action activates all individually enabled triggers at the same time.

61.9.5 Configure individual triggers

Using Trigger Configuration (TRGCFG_0 - TRGCFG_71), for each trigger:

- Enable the trigger (TRIGEN).
- Specify the target ADC (ADC_SEL*n*).
- Specify the ADC channel (CHANNEL_VALUE_OR_LADDR).
- Specify whether the trigger initiates a single conversion or a CL (TRS).
- For a CL trigger, specify a pointer to the CL element (TRGCFG_x[CHANNEL_VALUE_OR_LADDR]).

61.9.6 Reconfigure triggers on-the-fly

NOTE

Reconfigure BCTU triggers only when the individual trigger is not active (TRG_FLAG). If TRG_FLAG is 1, the requested conversion is still in progress and it is not safe to modify the trigger configuration.

To reconfigure a trigger on-the-fly (while BCTU is in full operation):

1. Disable the trigger (TRIGEN) to prevent it from requesting a new conversion.
2. Check the current state of the trigger (TRG_FLAG) to be sure no conversion or CL is in progress.
3. When any in-progress conversion or CL completes (TRG_FLAG == 0), clear the trigger source by writing 1 to TRG_FLAG. This action ensures that only trigger inputs that assert after you reconfigure and re-enable the trigger are able to request a new conversion or CL.
4. Reconfigure the trigger (see Configure individual triggers).
5. Enable the trigger (TRIGEN).

61.9.7 Enable software triggers

To allow software triggers (SFTRGR*n*[SFTRG*m*]) to request conversions, you must enable Global Trigger Enable (MCR[GTRGEN]). If you disable Global Trigger Enable, software triggers do not initiate a conversion but asserted triggers remain asserted. However, when you enable Global Trigger Enable, any asserted software triggers initiate conversions following the priority scheme of lowest to highest trigger number.

Software triggers operate regardless of individual Trigger Enable (TRGCFG_x[TRIGEN]). That is, writing 1 to any Software Trigger (SFTRGR*n*[SFTRG*m*]) initiates a conversion (following the priority scheme) regardless of the value of Trigger Enable. This software trigger independence supports the elimination of conflict between software and hardware triggers.

61.9.8 Trigger timing

There are four clock cycles from assertion of a BCTU trigger input to assertion of the trigger output to the ADC. For single conversions, BCTU asserts Trigger Clear back to the trigger source simultaneous to asserting the trigger to the ADC.

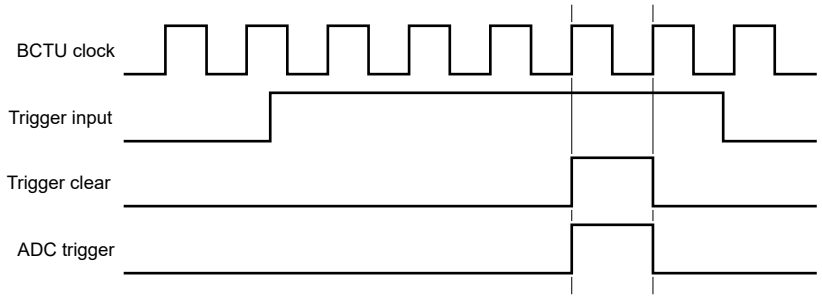

Figure 345. Trigger timing

61.9.9 Priority of simultaneous triggers

When more than one trigger input asserts a conversion request to the same ADC at the same time—that is, in the same BCTU clock cycle—BCTU employs a priority scheme to determine which asserted trigger to process next. BCTU prioritizes trigger inputs based on the trigger number. The lowest number, trigger 0, has the highest priority, and the highest number, trigger 71, has the lowest priority.

If two triggers assert in the same clock cycle, BCTU gives priority to the lower numbered trigger. For example, if trigger 0 and trigger 1 both assert in the same cycle, BCTU selects trigger 0 for trigger generation. Trigger 1 remains active (pending) until the conversion requested by trigger 0 completes. See Simultaneous trigger priority management.

If trigger 0 asserts again before the next trigger selection opportunity at the end of the current conversion, then BCTU selects it again and trigger 1 remains asserted (pending) during the next ADC conversion time frame.

As illustrated in Trigger timing, BCTU requires four clock cycles to transmit a conversion request to an ADC if that ADC is not already executing a conversion. However, if the ADC is busy at the time of trigger assertion, BCTU requires only three clock cycles to generate the conversion request for a subsequent conversion.

Triggers that assert in the same clock cycle but target different ADCs are not in conflict, and BCTU processes both triggers at the same time.

61.9.10 Simultaneous trigger priority management

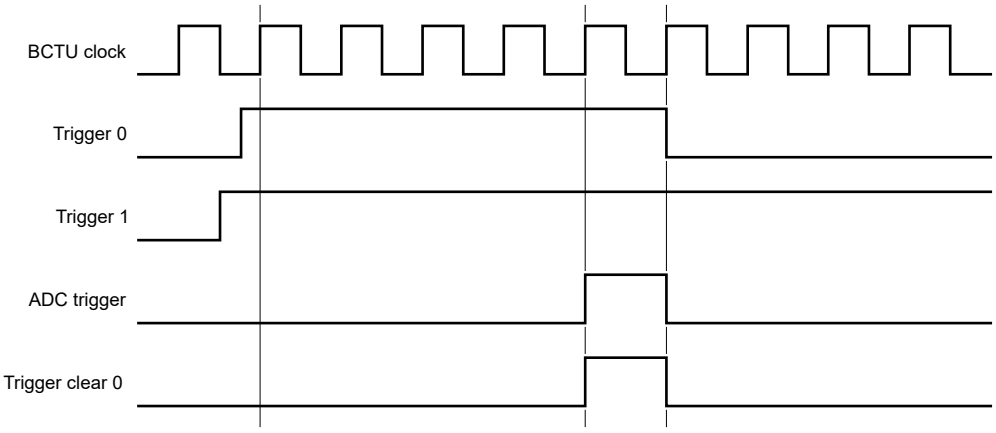

Figure 346. Simultaneous trigger priority management

61.9.11 Trigger management when ADC is busy

When a trigger input asserts a conversion request to an ADC that is already processing a conversion requested by a different trigger, the new trigger remains active (pending) until the conversion in progress completes. This behavior is the same as if the two triggers had been simultaneous (occurred in the same clock cycle). When the in-progress conversion completes, the pending trigger then competes for priority with any other active trigger for that ADC.

61.10 Conversion list (CL)

61.10.1 CL overview

A CL executes a sequence of conversions on one or more target ADCs. See CL architecture and operation. It also stores information from the last conversion executed in a sequence except for the target ADC, which is stored in ADC Select n (TRGCFG_*m*[ADC_SEL*n*]).

If the Channel or CL Address (TRGCFG_x[CHANNEL_VALUE_OR_LADDR]) points to a CL element containing one or more entries:

1. The trigger initiates a sequence of conversions starting with the target CL element.
2. The sequence executes until the LAST channel (LISTCHR_*n*[LAST_y] is 1), and stops after that channel is converted.

When you configure the CL element for Next Channel Wait For Trigger (write 1 to LISTCHR_*n*[NEXT_CH_WAIT_ON_TRIG_y]):

1. BCTU clears the trigger source.
2. CL execution pauses after the current conversion is completed.
3. CL execution resumes when the same trigger asserts again.

BCTU determines trigger priority before executing any CL. See Priority of simultaneous triggers.

61.10.2 CL architecture and operation

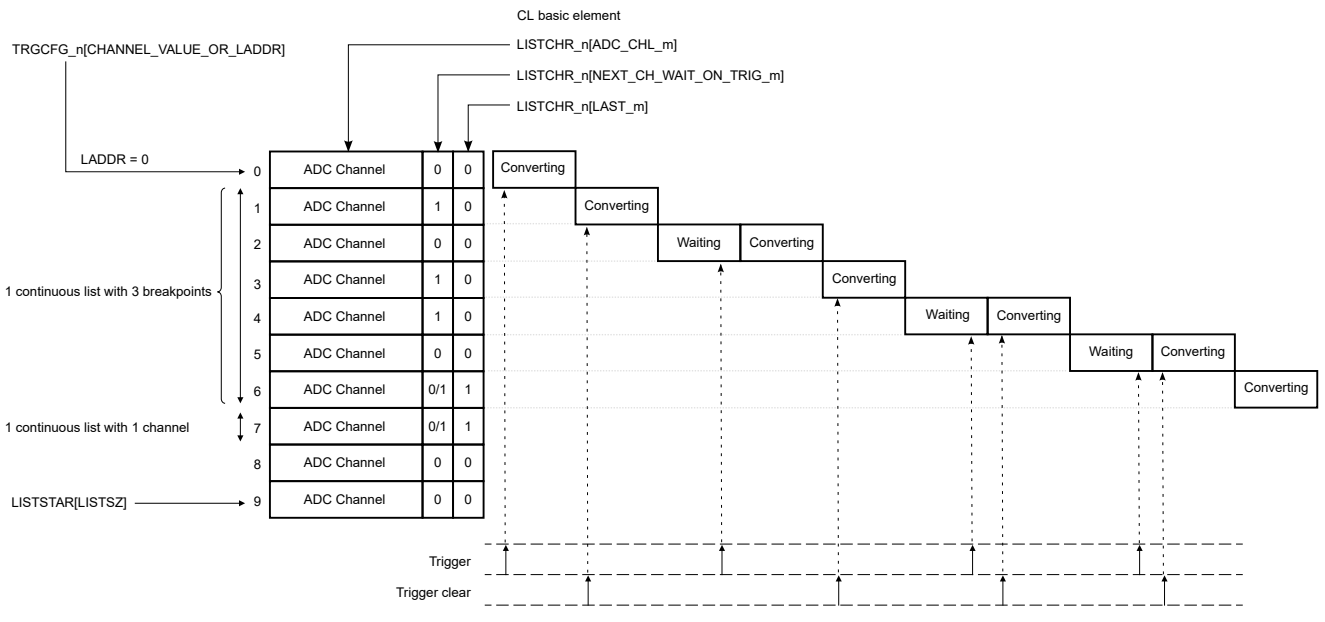

Figure 347. CL architecture and operation

61.10.3 CL channel rules

CL conversion obeys the following rules:

- The sequence of conversions executes until the Last Channel (LISTCHR_*n*[LAST_y] is 1).
- A CL conversion sequence precludes other conversions on the same ADC. If the CL is waiting (LISTCHR_*n*[NEXT_CH_WAIT_ON_TRIG_y] is 1), BCTU cannot route a non-CL conversion to that ADC (although that ADC remains available for normal and injected conversions).
- Two or more triggers for different ADCs may point to the same CL. This CL can drive parallel execution on the selected ADCs.
- If the Channel or CL Address (TRGCFG_x[CHANNEL_VALUE_OR_LADDR]) does not point to a valid list address, BCTU uses address 0 by default.
- When the CL pointer reaches the last available list address (LISTSTAR[LISTSZ] minus 1), the pointer wraps to list address 0.
- You can select more than one ADC per trigger using the ADC Select n (TRGCFG_x[ADC_SELn]) fields, but selecting more than one ADC is valid only for multiple parallel CL operation. If you select more than one ADC for a single-conversion trigger, BCTU ignores the trigger.

61.11 ADC conversion results access

61.11.1 Overview

The value of DATA_DEST determines access to ADC results.

- DATA_DEST = 000: ADC results are available in the ADC data registers.
- DATA_DEST = 001: ADC results are available in FIFO 1 Result Data (FIFO Result Data (FIFO1DR - FIFO2DR)). See Route conversion data to FIFO.
- DATA_DEST = 010: ADC results are available in FIFO 2 Result Data (FIFO Result Data (FIFO1DR - FIFO2DR)). See Route conversion data to FIFO.

You can access ADC results using flags and interrupt requests (see Access on interrupt request) or DMA (see Access on DMA request). Interrupt requests are based on Module Status (MSR) flags. ADC*n*DR provides the following information, with one register used for each ADC:

- The conversion results
- The channel that was used for the conversion
- The trigger input that initiated the conversion
- Whether a CL element generated the conversion
- Whether the data was the last conversion of a CL

61.11.2 Access on interrupt request

If interrupts are enabled for ADC*n* Result Data (MCR[IEN*n*] is 1) and DMAs are disabled for ADC*n* Result Data (MCR[DMA*n*] is 0), BCTU generates an interrupt request for each available conversion data in ADC*n*DR. Because BCTU executes conversions on different ADCs in parallel, conversion results may be available on multiple ADCs at the same time. New Data (MSR[NDATAn] is 1) indicates that new conversion data is available in the corresponding ADC Data Result (ADC*n*DR). To clear the New Data flag, write 1 to MSR[NDATAn_CLR].

61.11.3 Access on DMA request

If you enable DMA requests (MCR[DMA*n*]):

- You must select one channel for DMA per ADC.
- New conversion result data (ADC*n*DR) generates a DMA request.

- The DMA controller deasserts the DMA request and writes 1 to MSR[NDATAn_CLR] to clear the flag.

When an ADC generates New Data (MSR[NDATAn]), BCTU processes the DMA request. See Clear a DMA request.

61.11.4 Clear an interrupt request

BCTU clears an interrupt request when:

- The number of valid entries is less than or equal to the FIFOn Watermark Level (FIFOWM[WM_FIFO*n*]).
- You write 1 to FIFO Watermark Interrupt Status (FIFOERR[WM_INT_FIFO*n*]).

61.11.5 Clear a DMA request

BCTU clears a DMA request when:

- The number of valid entries is less than or equal to the FIFOn Watermark Level (FIFOWM[WM_FIFO*n*]).
- The DMA controller sends acknowledgment to BCTU.

61.11.6 Clear an error-generated interrupt request

Clear an interrupt generated because of an error condition by writing 1 to the appropriate error flag:

- FIFOERR[OVR_ERR_FIFO1]
- FIFOERR[UNDR_ERR_FIFO1]
- FIFOERR[OVR_ERR_FIFO2]
- FIFOERR[UNDR_ERR_FIFO2]

61.11.7 Conversion data overrun

If new ADC conversion data becomes available before you read the previous data (ADC*n*DR), then BCTU indicates a data overrun (MSR[DATAOVRn] is 1).

If you enable interrupts for the ADC (MCR[IEN*n*]), a data overrun also generates an interrupt request, regardless of the DMA request configuration.

To clear a data overrun (MSR[DATAOVRn]), write 1 to Data Overrun Clear (MSR[DATAOVRn_CLR]). See Clear an error-generated interrupt request.

61.11.8 Route conversion data to FIFO

BCTU allows you to route multiple ADC conversion results to one of 2 internal data FIFOs. Any trigger source can route results to an available FIFO based on the trigger index. Each FIFO has a dedicated counter (FIFOCNTR[CNTR_FIFO*n*]) to indicate the number of entries in the FIFO.

Each FIFO also has its own result data register (FIFO*n*DR) that contains the following information about the last conversion result routed to the FIFO.

- ADC result data
- Trigger source index
- ADC number
- ADC channel number

61.11.9 Read ADC result from FIFO

Each FIFO has DMA and interrupt interfaces. The DMA interface reads data. The interrupt interface indicates watermark and error conditions:

- An overrun error (FIFOERR[OVR_ERR_FIFO*n*]) occurs when you attempt to write data to an already full FIFO.
- An underrun error (FIFOERR[UNDR_ERR_FIFO*n*]) occurs when you attempt to read data from an empty FIFO.
- BCTU asserts a Watermark interrupt request if the number of valid FIFO entries exceeds the watermark level (FIFOWM[WM_FIFO*n*]).

You can read a FIFO:

- by enabling DMA requests (FIFOCR[DMA_EN_FIFO*n*])
- by polling the FIFO Full status (FIFOSR[FULL_FIFO*n*])

See Configuration of DMA and interrupt behavior.

61.11.10 Configuration of DMA and interrupt behavior

Table 348. Configuration of DMA and interrupt behavior

FIFOCR[DMA_EN_FIFO*n*]	FIFOCR[IEN_FIFO*n*]	Condition
0	0	No DMA request; no interrupt request
0	1	Interrupt request when FIFO exceeds watermark level; interrupt request on error
1	0	DMA request when FIFO exceeds watermark level
1	1	DMA request when FIFO exceeds watermark level; interrupt request on error

61.12 Multiple parallel conversions (MPC)

61.12.1 Overview

The MPC mechanism allows you to execute a series of simultaneous ADC conversions by selecting more than one ADC for any CL-configured trigger.

61.12.2 Configure MPC

To configure a CL to perform MPC:

1. Select CL for the trigger resolution (write 1 to TRGCFG_*m*[TRS]).
2. Select more than one ADC for the trigger (TRGCFG_*m*[ADC_SEL*n*]).
3. Specify the CL address for the first CL element (TRGCFG_*m*[CHANNEL_VALUE_OR_LADDR]).

61.12.3 CL address selection for MPC

When the trigger input for the CL asserts, BCTU uses the Channel or List Address (CHANNEL_VALUE_OR_LADDR) as an index into the CL for the lowest numbered ADC selected (ADC_SEL*n*), and each subsequent element of the CL for each remaining selected ADC. The set of selected ADC channels perform their conversions in parallel. When that set of conversions is complete, the next set of CL elements determine the next set of ADC channels to perform parallel conversions, as illustrated in:

- Example: MPC with two ADCs
- Example: MPC with three ADCs

61.12.4 Example: MPC with two ADCs

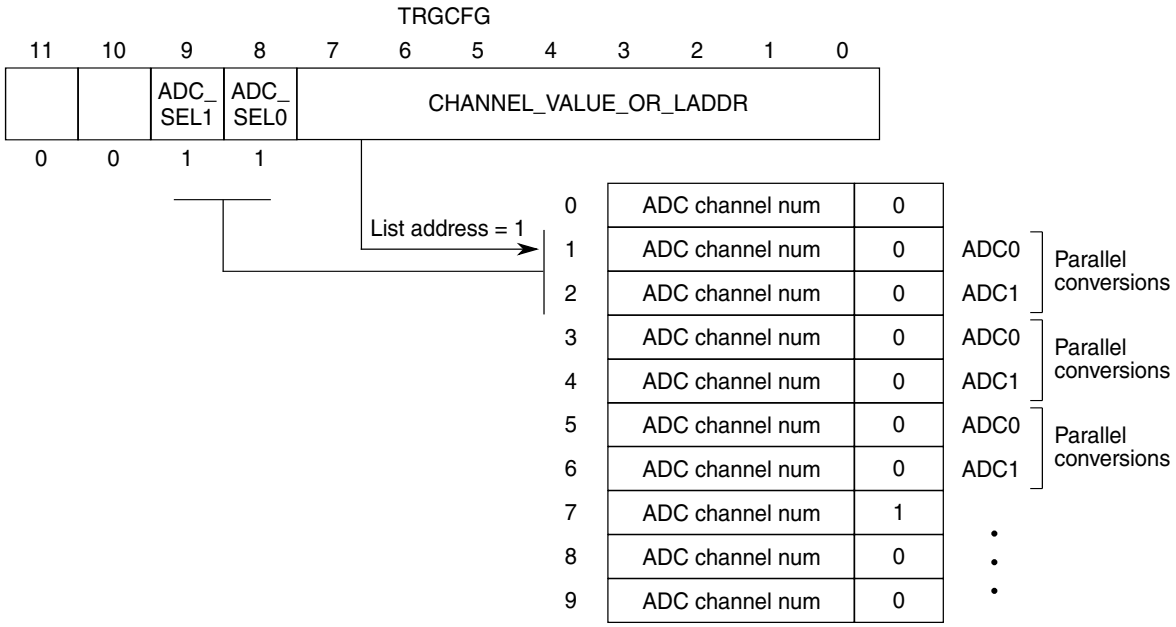

Figure 348. Example: MPC with two ADCs

61.12.5 Example: MPC with three ADCs

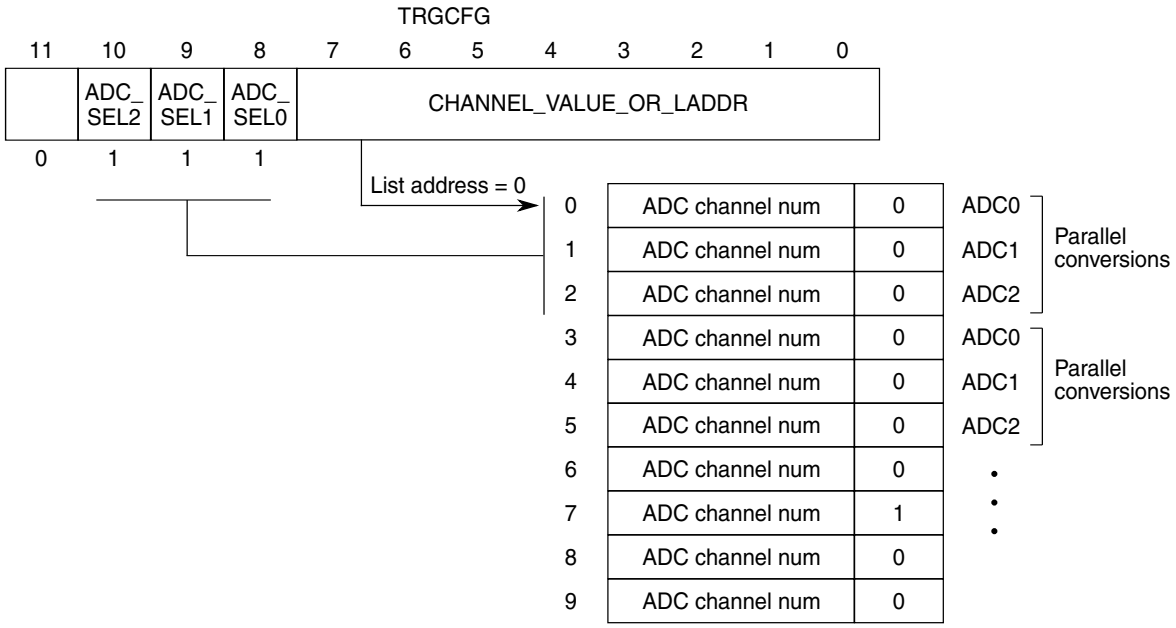

Figure 349. Example: MPC with three ADCs

61.12.6 MPC priority rules

MPC follows the same priority rules as for single conversions, which is based on the trigger input number: the lower the trigger, the higher the priority. However, MPC cannot start until all ADCs selected for the CL are available; that is, they are not currenlty

engaged in conversion. For example, if a trigger input asserts for a CL using ADC0 and ADC1, BCTU does not initiate the CL until ADC0 and ADC1 are both available.

Also, if ADC0 is available but there is a higher priority trigger for ADC1, the MPC does not start. If trigger inputs assert for two MPCs that have at least one ADC in common, the lower trigger number has higher priority. A priority conflict occurs only when separate requested CLs have at least one ADC in common. If the MPCs use different ADCs, there is no conflict and the MPCs execute at the same time.

61.13 Interrupts and DMA requests

Table 349. Interrupts and DMA requests

Event	Enable interrupt	Enable DMA request	Description
Trigger Flag	MCR[TRGEN]	—	Interrupt request on assertion of Trigger Flag (MSR[TRGF])
ADC Data Ready	MCR[IEN*n*]	MCR[DMA*n*]	Interrupt or DMA request when ADC result data is available (ADC*n*DR)
CL Last	MCR[LIST_IEN]	—	Interrupt request when the last conversion of any CL executes
FIFO Watermark	FIFOCR[IEN_FIFO*n*]	FIFOCR[DMA_EN_FIFO*n*]	Interrupt or DMA request when the number of valid FIFO entries exceeds the FIFO

61.14 BCTU register descriptions

All BCTU registers are 32 bits wide. 8-bit write operations are allowed. The BCTU module does not include any coherence mechanism, so application software must ensure coherency.

NOTE

- You must always write 0 to reserved writable registers and fields. Read accesses of reserved registers and fields do not return meaningful data.
- For registers with write protection, if protection is active and you attempt to write to those registers, register content is unaffected and BCTU issues a transfer error.

6 —	Reserved
5 LIST_IEN	CL Interrupt Enable Enables an interrupt request for the last conversion in a CL (both ADC*n*DR[LIST] and ADC*n*DR[LAST] are 1). 0b - Disable 1b - Enable
4-3 —	Reserved
2-0 IENn	Interrupt Enable For ADCnDR Enables an interrupt request when BCTU writes a new conversion result to ADC Data (ADC*n*DR). Also enables an interrupt request on an overrun in ADC*n*DR, which indicates the previous data has been overwritten by a new conversion result. See also MSR[NDATA*n*] and MSR[DATAOVR*n*]]. Enabling ADC*n*DR DMA (DMA*n* field) disables the interrupt for new data in ADC*n*DR, but the interrupt for ADC*n*DR data overrun remains enabled. 0b - Disable 1b - Enable

61.14.3 Module Status (MSR)

Offset

Register	Offset
MSR	8h

Function

Indicates the status of various BCTU functions, including:

- Whether conversion data is available for each ADC
- CL operation, such as the last conversion command executed in a CL
- Whether BCTU triggered any of the ADCs

All flag fields become 0 upon assertion of a low-power (software) or clock-stop (hardware) request. You can turn off individual flags by writing 1 to the field.

Fields

Field	Function
31 LOOP	Loop Specifies that the current trigger executes in a loop; that is, the triggered conversion repeats until you disable Loop. Each loop-triggered conversion wins the priority evaluation among all pending triggers, and executes only if it is the highest-priority triggered conversion at the moment the conversion starts. 0b - Disable 1b - Enable
30-28 DATA_DEST	Data Destination Specifies the destination for storing the conversion results. You can route each ADC's conversion result to either of the following: • ADC-specific data registers • One of the available FIFOs BCTU routes conversion results to different destinations based on the trigger index that requested the conversion. You cannot duplicate the same data in more than one destination. 000b - ADC-specific data registers 001b - FIFO1 010b - FIFO2 011b - Reserved All other values are reserved.
27-24 —	Reserved
23-16 —	Reserved
15 TRIGEN	Trigger Enable Enables hardware input triggers to initiate ADC conversions. This field does not affect software triggers. 0b - Disable 1b - Enable
14 TRG_FLAG	Trigger Flag Indicates the trigger input is asserted and an ADC conversion is in progress. When the conversion completes, BCTU changes this field to 0. Writing 1 to this field causes the input trigger event to clear when the in-progress conversion completes, and prevents this trigger from initiating a new ADC conversion until the input trigger is asserted again. **NOTE** This field behaves differently for read and write operations. When reading

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No ongoing ADC conversion initiated 1b - Ongoing ADC conversion initiated When writing 0b - No action 1b - Changes to 0
13 TRS	Trigger Resolution Selects single conversion or CL conversions. 0b - Single conversion 1b - CL conversions
12-11 —	Reserved
10-8 ADC_SELn	ADC Select n Selects ADC *n* for conversion. 0b - Deselects 1b - Selects
7 —	Reserved
6-0 CHANNEL_VALUE_OR_LADDR	Channel or CL Address Depending on the value of TRS: • 0: Specifies the ADC channel for conversion • 1: Specifies the address of the first CL position to execute

61.14.5 Write Protection (WRPROT)

Offset

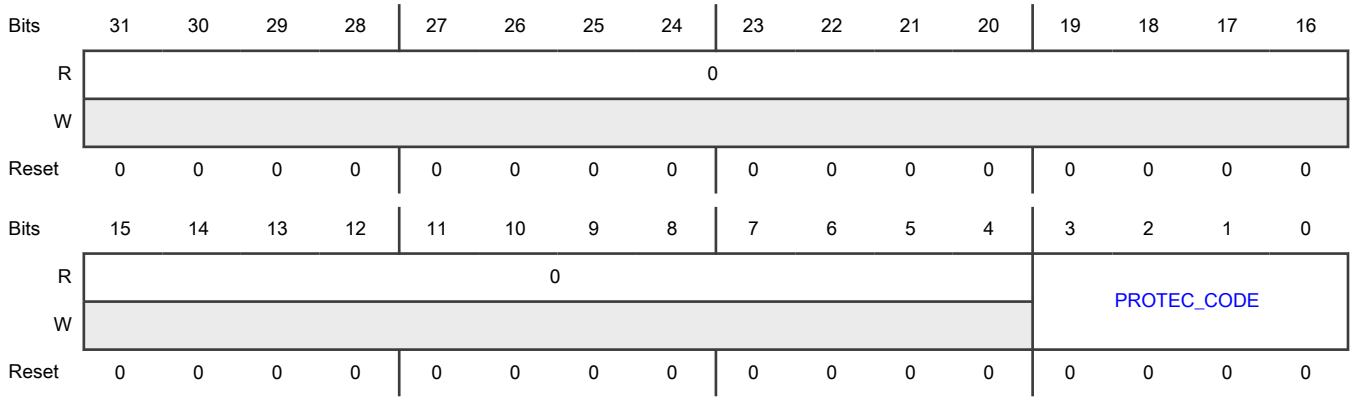
Register	Offset
WRPROT	228h

Function

Enables write protection at reset exit. To allow writes to protected registers, you must write a special code into PROTEC_CODE. There are two codes to remove protection: one that permanently disables the protection; one that disables protection during one write cycle to a protected register, after which the protection code returns to the initial (protected) value of 0000b.

Access: User read/write

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 PROTEC_CODE	Protection Code Controls the protection of write-protected registers. **NOTE** You can write this field only in Normal mode (MCR[MDIS] is 0). 0000b - Enable protection 1001b - Disable protection for one write cycle 1010b - Disable protection permanently

61.14.6 Software Trigger 1 (SFTRGR1)

Offset

Register	Offset
SFTRGR1	22Ch

Function

Allows you to trigger conversions on the associated triggers.

To use a software trigger, you must first disable the corresponding hardware trigger (TRGCFG_x[TRIGEN]).

BCTU writes 0 to a software trigger field on completion of the triggered conversion.

Access: User read/write; this register is write protected by Write Protection (WRPROT). If protection is enabled, writes to this register generate a transfer error and do not modify its content.

61.14.7 Software Trigger 2 (SFTRGR2)

Offset

Register	Offset
SFTRGR2	230h

Function

Allows you to trigger conversions on the associated triggers.

To use a software trigger, you must first disable the corresponding hardware trigger (TRGCFG_*n*[TRIGEN]).

BCTU writes 0 to a software trigger field on completion of the triggered conversion.

Access: User read/write; this register is write protected by Write Protection (WRPROT). If protection is enabled, writes to this register generate a transfer error and do not modify its content.

61.14.9 ADCn Result Data (ADC0DR - ADC2DR)

Offset

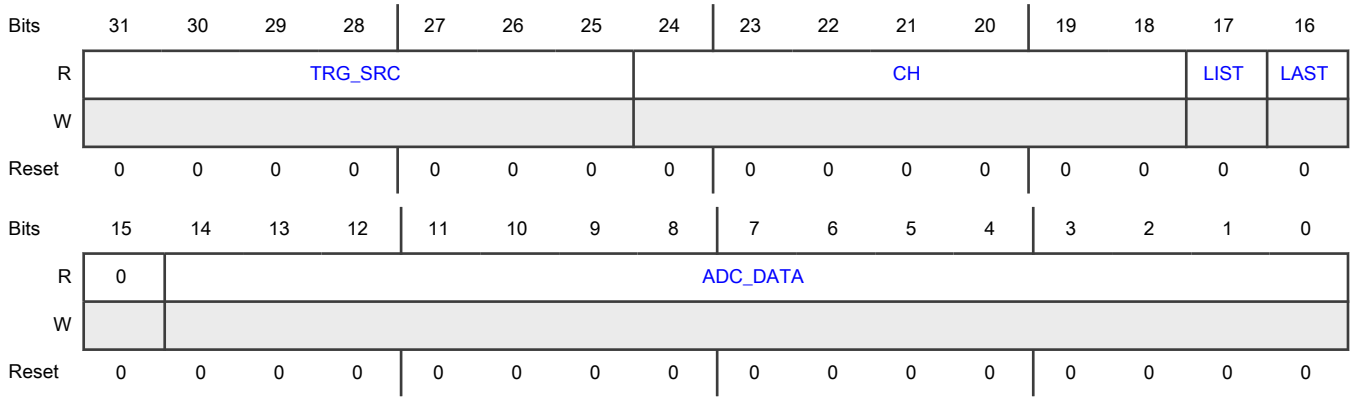
Register	Offset
ADC0DR	23Ch
ADC1DR	240h
ADC2DR	244h

Function

Provides ADC conversion result data. Also indicates the ADC channel used in that conversion, the trigger source that initiated it, and whether conversion was initiated from a CL.

Access: User read

Diagram



Fields

Field	Function
31-25 TRG_SRC	Trigger Source Contains the trigger number used to trigger the conversion.
24-18 CH	Channel Contains the ADC channel used for the conversion.
17 LIST	List Indicates whether the conversion was part of a CL or a single conversion trigger. 0b - Single conversion 1b - CL
16 LAST	Last For CL conversions, indicates this conversion result is the last conversion of the CL. 0b - Not the last conversion of a CL, or not a CL conversion 1b - Last conversion of a CL
15 —	Reserved
14-0 ADC_DATA	ADC Data Contains the data from the conversion.

61.14.10 CL Size Status (LISTSTAR)

Offset

Register	Offset
LISTSTAR	24Ch

Function

Indicates the size of the CL. Each element of the CL contains the channel number used in one conversion.

Access: User read

61.14.12 FIFO Result Data (FIFO1DR - FIFO2DR)

Offset

Register	Offset
FIFO1DR	450h
FIFO2DR	454h

Function

Contains the ADC conversion result and information about the conversion:

- ADC channel
- Trigger source
- ADC number

Access: User read

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

7-4 —	Reserved
3-0 WM_FIFO1	FIFO1 Watermark Level Specifies the watermark level for FIFO1.

61.14.15 FIFO Error/Status (FIFOERR)

Offset

Register	Offset
FIFOERR	468h

Function

Allows you to clear FIFO error and status flags. Each FIFO has its own error and status flags that can be configured to generate an interrupt. FIFO Status (FIFOSR) maintains the status of these flags. BCTU writes a 1 to these flags, and you must then clear them using FIFOERR.

Access: User read/write

Chapter 62
Trigger MUX (TRGMUX)

62.1 Chip-specific TRGMUX information

62.1.1 TRGMUX input output configuration and instances

This chip has one instance of TRGMUX module.

The device supports the triggering scheme between peripherals. For the supported trigger sources and destination, see the TRGMUX connectivity file attached to this document.

This device has 16 pads (SIUL2) mapped from TRGMUX inputs and TRGMUX outputs are mapped to the eMIOS channels, hence two timers channels can use a single pin of the device to do input capture.

While using TRGMUX, below points need to be taken care:

- User must ensure the minimum pulse of 100 ns on SIUL2 pads when using them as trigger source on TRGMUX.
- Pulses which are visible on pads depends on the pad type. Different pad supports different frequencies. For more details on pad types and their respective bandwidth, see section "IO signal table" in "Signal Multiplexing" chapter.
- End of conversion (EOC) signals of ADC modules are mapped on TRGMUX inputs as trigger sources. The EOC signal is asserted after ADC conversion regardless whether conversion is signaled by polling flags, interrupt or DMA transfer. The signal shall not be used to start injected conversion on same ADC channel as it will overwrite current result register.
- The minimum pulse length requirement is 1.5X of destination clock, so that it gets properly sampled at the destination IP connected to TRGMUX outputs, otherwise there are chances of missing the triggers generated from source. For example, the trigger generated from PAD for ADC conversion should be kept high/low for at least 1.5X of ADC clock so that it gets sampled in ADC clock domain. To ensure this, pulse strechers have been placed before some of the hardware modules mapped on TRGMUX outputs.
- Some PADS are being shared by both ADC and TRGMUX. It is recommended that trigger initiated from such PADS should not be used to trigger a conversion on the ADC channel mapped on same PAD. Failing to do this will cause congestion on same PAD.
- Out of all the pads mapped on TRGMUX, first four pads have glitch filters. For details, see the TRGMUX connectivity file attached to this document. The trigger pulse width should honour the pulse width requirement as per Glitch Filter specifications. The same signal can be observed at output pin if the pulse width of the input data signal is more than 400ns and no output signal should be observed if the pulse width of the input data signal is less than 20ns. A signal with a pulse width that is between 20ns and 400 ns should not be applied as the behavior is not guaranteed.
- Trigger outputs are grouped peripheral-wise and have a common lock bit based on TRGMUX REGx. For instance, normal_trigger, injected_trigger and external_sync of ADC_0 are grouped onto TRGMUX_REG0 and have a common lock bit.

62.1.2 Pulse strechers in TRGMUX

TRGMUX has some hardware modules on its input side running at faster clock than some of the IPs present on output side. For instance, eMIOS reload outputs running at 160 MHz can trigger LPI2C trigger input clocked at 40 MHz, in that case there is a high chance that trigger from eMIOS will be missed. Following Pulse strechers are added for the IPs on output side of TRGMUX.

Table 350. Pulse strechers in TRGMUX

Evaluation Parameter	ADC_0/1/2 external trigger to sync the start pulse	BCTU trigger 23/47/71	FlexIO trigger input_0/1/2/3[1]	LPI2C_0 Trigger input	LPSPI_0/1/2 Trigger input	CM7_0/1/2/3 RXEV
IP expects	Synchronized single cycle pulse	Synchronized pulse	IP requirement is to have 2 cycle pulse of flexio_clk	IP requirement is to have 2 cycle pulse of lpi2c_clk	IP requirement is to have 2 cycle pulse of lpspi_clk	Single cycle pulse
Frequency	CORE_CLK	CORE_CLK	CORE_CLK	AIPS_SLOW_CLK	LPSPI_0 - PLAT_AIPS_CLK LPSPI_1/2/3 - AIPS_SLOW_CLK	CORE_CLK
Inside IP	Used as combo signal	Flopped inside IP and clear after ADC conversion completed	Synchronized inside IP	Synchronized inside IP	Synchronized inside IP	-
At SoC	Since it an ASYNC signal and IP required synchronized single cycle pulse, so a pulse stretcher is added to convert pulse from any frequency domain into a signle cycle pulse of CORE_CLK	Since slow IP such as LPCMP or from PAD can also trigger BCTU and BCTU wants that trigger should clear after the ADC conversion. So a pulse stretcher is added which convert any size of pulse to a single cycle pulse of BCTU clock (CORE_CLK)	Pulse stretcher is added to convert any pulse into a two cyle pulse of FLEXIO_CLK	Pulse stretcher is added to convert any pulse into a two cyle pulse of LPI2C_CLK	Pulse stretcher is added to convert any pulse into a two cyle pulse of LPSPI_CLK	Pulse stretcher is added to convert any pulse into a single cyle pulse of CORE_CLK
Output slot at which pulse stretcher is added	2, 6, 10	24, 25, 26	64, 65, 66, 67	84	88, 92, 96	156, 157

1. These pulse stretchers are available in MWCT2D17S variant only.

NOTE

The trigger outputs which have pulse stretcher before them, there should be atleast a gap of 5 cycle of destination clock for back to back trigger.

62.1.3 Trigger monitor

A trigger monitor is added before the TRGMUX inputs ADC12_0_EOC, ADC12_1_EOC and ADC12_2_EOC. You can configure the UDR registers in SIUL2 to select which trigger needs to propagate to the above TRGMUX inputs. By default after coming out of reset, all the enables are 0. Hence no trigger will be coming to these 3 TRGMUX inputs.

NOTE

Trigger monitor is not present in MWCT2D17S.

62.2 Introduction

The trigger multiplexer (TRGMUX) module allows software to configure the trigger inputs for various peripherals.

62.3 Features

The TRGMUX module allows software to select the trigger source for peripherals. The block diagram below shows the trigger selection logic of the TRGMUX module.

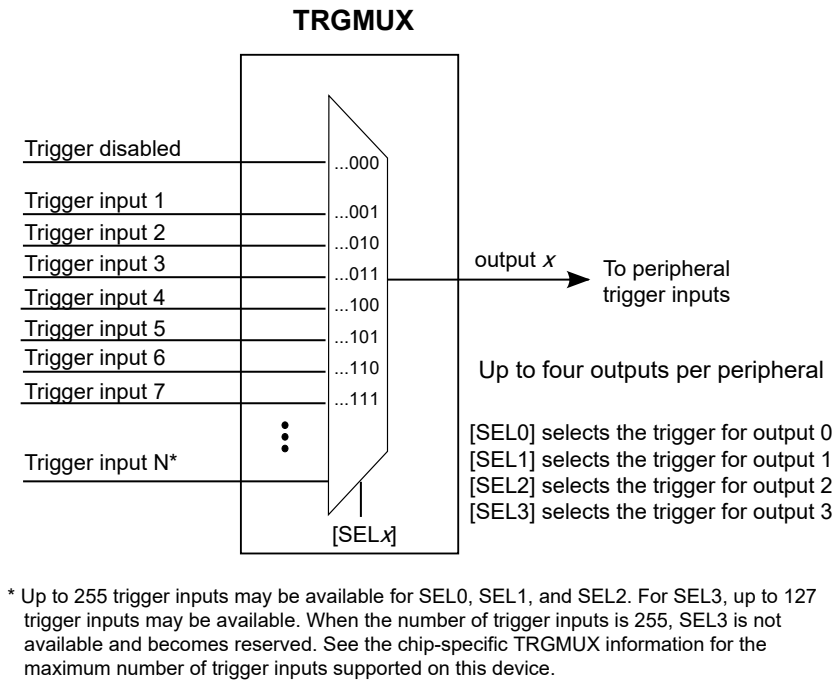

Figure 350. TRGMUX block diagram

Each peripheral has its own dedicated TRGMUX register. See each peripheral's TRGMUX register for details.

62.4 Memory map and register definition

The TRGMUX registers contain fields for selecting trigger sources for peripheral modules.

TRGMUX registers can be written only in supervisor mode.

62.4.1 TRGMUX register descriptions

62.4.1.1 TRGMUX memory map

Table 351. Select Bit Fields

Field	Description
SELx	This read/write field is used to configure the MUX select for the peripheral trigger inputs. 0000_0000 - (0x00) LOGIC 0 (VSS) 0000_0001 - (0x01) LOGIC 1 (VDD) 0000_0010 - (0x02) ADC12_0_EOC (ADC 0 end of conversion) 0000_0011 - (0x03) ADC12_1_EOC (ADC 1 end of conversion) 0000_0100 - (0x04) ADC12_2_EOC (ADC 2 end of conversion) 0000_0101 - (0x05) LPCMP_0_COUT output (LPCMP_0 comparison output (COUT)) 0000_0110 - (0x06) LPCMP_1_COUT output (LPCMP_1 comparison output (COUT)) 0000_0111 - (0x07) LPCMP_2_COUT output (LPCMP_2 comparison output (COUT)) 0000_1000 - (0x08) eDMA_eDMA_0 DONE (dma channel 0 transfer done) 0000_1001 - (0x09) eDMA_eDMA_1 DONE (dma channel 1 transfer done) 0000_1010 - (0x0A) eDMA_eDMA_16 DONE (dma channel 16 transfer done) 0000_1011 - (0x0B) eDMA_eDMA_17 DONE (dma channel 17 transfer done) 0000_1100 - (0x0C) eMIOS_0_RELOAD_OUT_CH[23] (eMIOS_0 channel 23 reload output) 0000_1101 - (0x0D) eMIOS_0_RELOAD_OUT_CH[22] (eMIOS_0 channel 22 reload output) 0000_1110 - (0x0E) eMIOS_0_RELOAD_OUT_CH[8] (eMIOS_0 channel 8 reload output) 0000_1111 - (0x0F) eMIOS_0_RELOAD_OUT_CH[0] (eMIOS_0 channel 0 reload output) 0001_0000 - (0x10) eMIOS_0_IPP_DO_eMIOS_CH[0] (eMIOS_0 channel 0 output) 0001_0001 - (0x11) eMIOS_0_IPP_DO_eMIOS_CH[1] (eMIOS_0 channel 1 output) 0001_0010 - (0x12) eMIOS_0_IPP_DO_eMIOS_CH[2] (eMIOS_0 channel 2 output) 0001_0011 - (0x13) eMIOS_0_IPP_DO_eMIOS_CH[3] (eMIOS_0 channel 3 output) 0001_0100 - (0x14) eMIOS_0_IPP_DO_eMIOS_CH[4] (eMIOS_0 channel 4 output) 0001_0101 - (0x15) eMIOS_0_IPP_DO_eMIOS_CH[5] (eMIOS_0 channel 5 output) 0001_0110 - (0x16) eMIOS_0_IPP_DO_eMIOS_CH[6] (eMIOS_0 channel 6 output) 0001_0111 - (0x17) eMIOS_0_IPP_DO_eMIOS_CH[7] (eMIOS_0 channel 7 output) 0001_1000 - (0x18) eMIOS_0_IPP_DO_eMIOS_CH[8] (eMIOS_0 channel 8 output) 0001_1001 - (0x19) eMIOS_0_IPP_DO_eMIOS_CH[9] (eMIOS_0 channel 9 output) 0001_1010 - (0x1A) eMIOS_0_IPP_DO_eMIOS_CH[10] (eMIOS_0 channel 10 output) 0001_1011 - (0x1B) eMIOS_0_IPP_DO_eMIOS_CH[11] (eMIOS_0 channel 11 output) 0001_1100 - (0x1C) eMIOS_0_IPP_DO_eMIOS_CH[12] (eMIOS_0 channel 12 output) 0001_1101 - (0x1D) eMIOS_0_IPP_DO_eMIOS_CH[13] (eMIOS_0 channel 13 output) 0001_1110 - (0x1E) eMIOS_0_IPP_DO_eMIOS_CH[14] (eMIOS_0 channel 14 output) 0001_1111 - (0x1F) eMIOS_0_IPP_DO_eMIOS_CH[15] (eMIOS_0 channel 15 output)

62.4.1.2 TRGMUX ADC12_0 Register (ADC12_0)

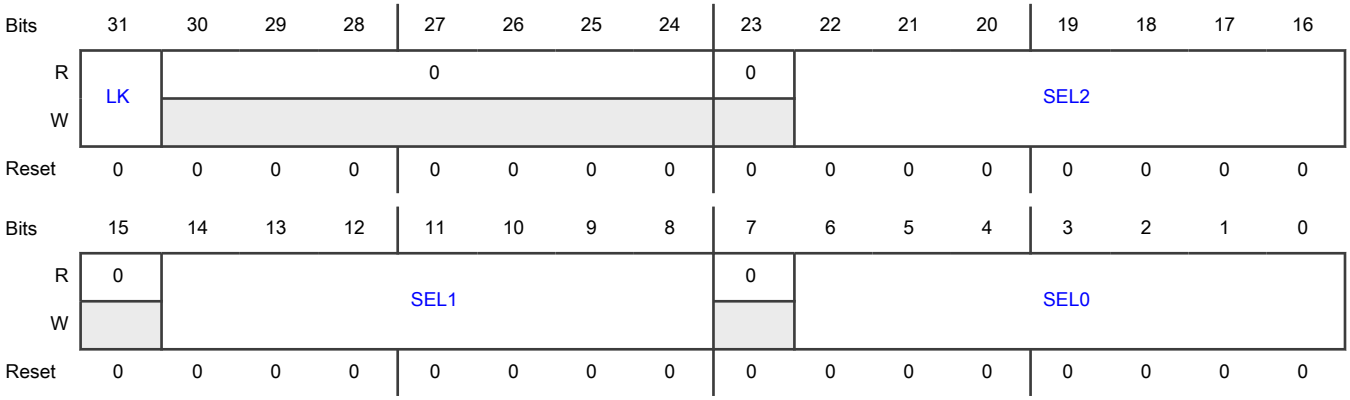
Offset

Register	Offset
ADC12_0	0h

Function

This register is for the ADC12_0 module.

Diagram



Fields

Field	Function
31	TRGMUX register lock.

Table continues on the next page...

Table continued from the previous page...

Field	Function
LK	This bit shows whether the register can be written or not. The LK bit can only be written once after any system reset. Once LK is set, the SELx bits in this TRGMUX register cannot be changed until the next system reset clears LK. 0b - Register can be written. 1b - Register cannot be written until the next system Reset.
30-24 —	This read-only bit field is reserved and always has the value 0.
23 —	This read-only bit field is reserved and always has the value 0.
22-16 SEL2	Trigger MUX Input 2 Source Select This read/write bit field is used to configure the MUX select for peripheral trigger input 2. For the field setting definitions, see Memory map and register definition.
15 —	This read-only bit field is reserved and always has the value 0.
14-8 SEL1	Trigger MUX Input 1 Source Select This read/write bit field is used to configure the MUX select for peripheral trigger input 1. For the field setting definitions, see Memory map and register definition.
7 —	This read-only bit field is reserved and always has the value 0.
6-0 SEL0	Trigger MUX Input 0 Source Select This read/write bit field is used to configure the MUX select for peripheral trigger input 0. For the field setting definitions, see Memory map and register definition.

62.4.1.3 TRGMUX ADC12_1 Register (ADC12_1)

Offset

Register	Offset
ADC12_1	4h

Function

This register is for the ADC12_1 module.

Diagram

Chapter 63
Software Watchdog Timer (SWT)

63.1 Chip-specific SWT information

63.1.1 SWT instances and configuration

This chip supports up to two instances of SWT, one for each Cortex-M7 core.

Table 352. SWT instances

Instance	MWCT2D16S/MWCT2D17S	MWCT2015S/MWCT2016S
SWT_0	Yes	Yes
SWT_1	Yes	No

Table 353. SWT configuration

Instance	Core	Reset type	Clock Source	SWT_MIN_TO (100µs)	SWT_TO_RST (25ms)
SWT_0[1]	Cortex-M7_0	Functional Reset - RAM retention	SIRC (32K)	3	320h
SWT_1	Cortex-M7_1	Functional Reset - RAM retention	SIRC (32K)	3	320h

1. SWT_0 supports operation in STANDBY mode.

NOTE

When using SWT as a wakeup source from standby, software should ensure proper value of timeout such that SWT timeout doesn't get expired again (after wakeup till standby exit is completed). The timeout should be programmed to a value greater than the time till standby exit is complete (sum of standby exit time and the time till software disables padkeeping).

NOTE

The "Reset only the SWT" feature using SWT_RRR[RRF] is supported only when SWT reset reaction is demoted to interrupt within MC_RGM.

Protect SWT from service by non-core masters

You must program protection for the SWT registers so that only core masters can service SWT.

When an SWT timeout takes place, the logic generating a reset to the system runs off the slow internal RC oscillator (32KHz). It could therefore take the SWT almost 31.25µs to reset the system, after timeout, leaving more time for runaway code to execute. The register interface clock of SWT is running from AIPS_SLOW_CLK, see Clocking chapter for more details. The register interface clock is responsible for generating the abort for invalid access while the counter clock is responsible for generating the SWT reset request. Since there is a synchronization happening between the register interface clock and counter clock domains before generating the SWT reset request, thus the generation of the reset request can take a number of register interface clock cycles after an invalid access is done.

63.2 Introduction

The Software Watchdog Timer (SWT) is a 32-bit window watchdog timer that enables the system to recover from situations such as:

- Software trapped in a loop
- A bus transaction failing to terminate

In regular operation, SWT requires periodic execution of a watchdog servicing operation. The servicing operation resets the timer to a specified timeout period. If this servicing action does not occur before the timer expires, SWT generates an interrupt or a hardware reset request.

You can configure SWT to generate a reset request or an interrupt on the initial timeout. SWT always generates a reset request on a second consecutive timeout.

63.3 Features

SWT has the following features:

- 32-bit countdown timer
- Selection of regular or window servicing
- Selection of reset request or interrupt on an initial timeout
- Selection of fixed or keyed service sequence
- Master access protection
- Hard and soft configuration lock bits

63.4 Initialize the SWT

To initialize the SWT, you must do the following:

- Select the clock source (if there are more than one possible sources).
- Set the timeout period.
- Control timeout behavior. There are two options:
  - Select reset request on timeout, or
  - Select interrupt on initial timeout.

You must intialize all registers before enabling SWT (CR[WEN]). You can initialize the registers in any sequence.

63.4.1 Select the clock source

See the chip-specific SWT information to find the clock source that drives the countdown timer.

63.4.2 Set the timeout period

When you enable SWT, it loads the greater of the specified watchdog timeout period or the minimum timeout period into an internal 32-bit countdown timer every time you perform a valid service operation.

To set the watchdog timeout period:

- Write the desired timeout period to TO[WTO].

The minimum timeout period is 3 clock cycles.

63.4.3 Control timeout behavior

SWT can respond to a timeout in one of two ways:

- Generate an immediate reset request on any timeout.
- Generate an interrupt and load the countdown timer on an inital timeout, then generate a reset request on a subsequent timeout.

63.4.3.1 Select reset request on timeout

To configure SWT to generate an immediate reset request on any timeout:

- Write 0 to CR[ITR].

63.4.3.2 Select interrupt on initial timeout

To configure SWT to generate an interrupt on an initial timeout:

- Write 1 to CR[ITR].

In this configuration, on the initial timeout:

- SWT loads the countdown timer with the timeout period (TO[WTO]).
- SWT indicates the interrupt with the timeout interrupt flag (IR[TIF]).
- If a second consecutive timeout occurs before writing the service sequence for the first timeout, SWT generates a reset request.

You clear the interrupt flag by writing 1 to IR[TIF].

63.4.4 Configure locking and unlocking

You can lock the SWT configuration with either a hard lock or a soft lock. When either lock is in effect, CR, TO, WN, and SK are read-only.

63.4.4.1 Enable the hard lock

To enable the hard lock:

- Write 1 to CR[HLK].

Hard lock is disabled only by a reset.

63.4.4.2 Enable the soft lock

To enable the soft lock:

- Write 1 to CR[SLK].

63.4.4.3 Unlock the soft lock

To unlock the soft lock:

1. Write C520h to SR[WSC].
2. Write D928h to SR[WSC].

This unlock sequence:

- Ignores service sequence writes.
- Recognizes the unlock sequence regardless of previous writes.
- Recognizes the unlock sequence regardless of the time between writes.
- Does not require CR[WEN] to be 1.

You can write this unlock sequence at any time.

NOTE

It is possible for a keyed service sequence to unlock soft lock. See Avoid soft unlock for the procedure to handle this situation.

63.4.4.4 Avoid soft unlock

When SWT operates in keyed sequence service, the sequence of service keys generated by the pseudorandom generator includes the unlock keys for soft lock. If one or more service routines use both unlock keys in the proper order, 0xC520 followed at any future time by 0xD928, SWT unlocks soft lock (CR[SLK] = 0). The unlock sequence logic ignores any service keys other than the unlock keys, so the unlock keys don't have to be inserted consecutively. If the second unlock key is also the second key of a service operation, unlock occurs before the service operation completes.

To avoid unlock:

If the service routine writes a key value of C520h to SR[WSC] as a key of the service operation, then do the following:

1. Complete the service operation.
2. Complete the unlock sequence by writing the second unlock key, D928h, to SR[WSC].
3. Reinitiate the soft lock (CR[SLK] = 1).

63.4.5 Select behavior on an invalid access

SWT can respond to an invalid access one of two ways:

- Generate a bus error.
- Generate a bus error and, if SWT is enabled, a reset request.

To select how SWT responds to an invalid access:

- Write the appropriate value to CR[RIA].

63.5 Enable the SWT

To enable the SWT:

- Write 1 to CR[WEN].

63.6 Initiate service operations

When enabled, SWT requires periodic execution of a servicing operation.

SWT can operate in one of the following service sequence modes:

- Fixed service sequence
- Keyed service sequence

63.6.1 Initiate a fixed service sequence

To initiate the fixed service sequence:

1. Select the fixed servicing mode (write 00b to CR[SMD]).
2. Write A602h to SR[WSC].
3. Write B480h to SR[WSC].

There is no timing requirement between the two writes. The service sequence logic ignores unlock-sequence writes.

63.6.2 Initiate a keyed service sequence

To initiate the keyed service sequence:

1. Select the keyed servicing mode (write 01b to CR[SMD]).
2. Read the initial service key from SK[SK].
3. Calculate the next service key using the provided equation.

4. Write that service key to SR[WSC].
5. Repeat steps 2 through 4 one time.

See Service key generation for information about service keys.

63.6.3 Select window service mode

In window service mode, you must write the service sequence only when the watchdog timer is less than the window start value (WN[WST]). If you write the service sequence outside of this window, the access is invalid and generates a bus error or reset request depending on the Reset on Invalid Access setting (CR[RIA]).

For example, if the timeout period is 5000 and the window start value is 1000, you must write the service sequence during the last 20% of the timeout period.

Synchronization logic in SWT causes a slight delay in the opening of the window. This delay can be up to three system clock cycles plus four counter clock cycles.

To select window service mode:

- Write 1 to (CR[WND].

63.7 Reset only the SWT

When a timeout triggers a reset request and the application does not require a system reset, you can make the SWT instance reset itself rather than the whole system.

To make a timeout reset request trigger only an SWT reset (rather than the whole system), write 1 to the Reset Request Flag (RRR[RRF]).

This action causes SWT to:

- Clear the reset request.
- If an interrupt request also occurred, clear the interrupt request (IR[TIF]).
- Reset and restart the SWT.

For systems with multiple SWT instances, this feature allows you to reset an individual SWT instance, avoiding the widespread impact of a system reset.

63.8 Test SWT operation

When you disable SWT, it loads the current countdown timer into CO[CNT]. When you enable SWT, it clears this register. You can use CO[CNT] to perform a software self-test of SWT.

To test SWT operation:

1. Enable the SWT (CR[WEN] = 1).
2. Do not service SWT for a fixed period of time that is less than the timeout value.
3. Disable the SWT (CR[WEN] = 0).
4. Read the value in CO[CNT] to determine whether the internal countdown timer is working properly.

NOTE

The value shown in CO[CNT] can lag behind the actual internal timer up to six system clock cycles plus eight counter clock cycles.

63.9 Functional description

63.9.1 Behavior in different chip modes

SWT supports the chip modes of operation as follows:

Chip mode	SWT behavior
Normal	When SWT is enabled (CR[WEN] = 1), the SWT timer counts down continuously.
Debug	If CR[FRZ] = 1, SWT stops the timer; otherwise, the timer continues to run.
Stop or Standby	If CR[STP] = 1, SWT stops the timer; otherwise, the timer continues to run.

63.9.2 Register access latency

Accesses to SWT registers occur with no peripheral bus wait states. The peripheral bus bridge may add 1 or more system wait states. However, due to synchronization logic in the SWT design, recognition of the service sequence or configuration changes may require up to three system clock cycles plus seven counter clock cycles.

63.9.3 Service key generation

SWT generates service keys with the pseudorandom key generator defined by the following equation.

$$SK_{n+1} = (17 \times SK_n + 3) \bmod 2^{16}$$

Figure 351. Pseudorandom key generator

This algorithm generates a sequence of 2^{16} different key values before repeating. In keyed service sequence mode, each time you write a valid key to SR[WSC], SWT updates SK[SK] with the next key.

For example, if the previous service key (SK[SK]) is 100h, then the next service sequence keys are 1103h followed by 2136h.

63.10 SWT register descriptions

The SWT programming model allows only 32-bit (word) accesses.

Any of the following attempted accesses are invalid:

- Non-32-bit accesses
- Writes to read-only registers
- Writes of incorrect values to SR when SWT is enabled
- Accesses to reserved addresses
- Accesses by masters without permission

You control how SWT responds to an invalid access with CR[RIA].

Chapter 64
System Timer Module (STM)

64.1 Chip-specific STM information

64.1.1 STM instances and configuration

This chip has up to two instances of STM, one for each Cortex-M7 core. The STM counter increments at the STM module clock frequency divided by a pre-scaled value.

Table 354. STM instances

Instance	MWCT2D16S/MWCT2D17S	MWCT2015S/MWCT2016S
STM_0	Yes	Yes
STM_1	Yes	No

Table 355. STM configuration

Instance	Description	Number of Channels	Number of Registers (32-bit)
STM_0	Intended for Cortex-M7_0 core	4	14
STM_1	Intended for Cortex-M7_1 core	4	14

64.2 Introduction

The System Timer Module (STM) supports commonly required system and application software timing functions. STM includes a 32-bit count-up timer and four 32-bit compare channels with a separate interrupt source for each channel. The timer is driven by the STM module clock divided by an 8-bit prescale value (1 to 256).

64.3 Features

STM has the following features:

- One 32-bit count-up timer with an 8-bit prescaler
- Four 32-bit compare channels
- An independent interrupt source for each channel
- Ability to stop the timer in Debug mode

64.4 Block diagram

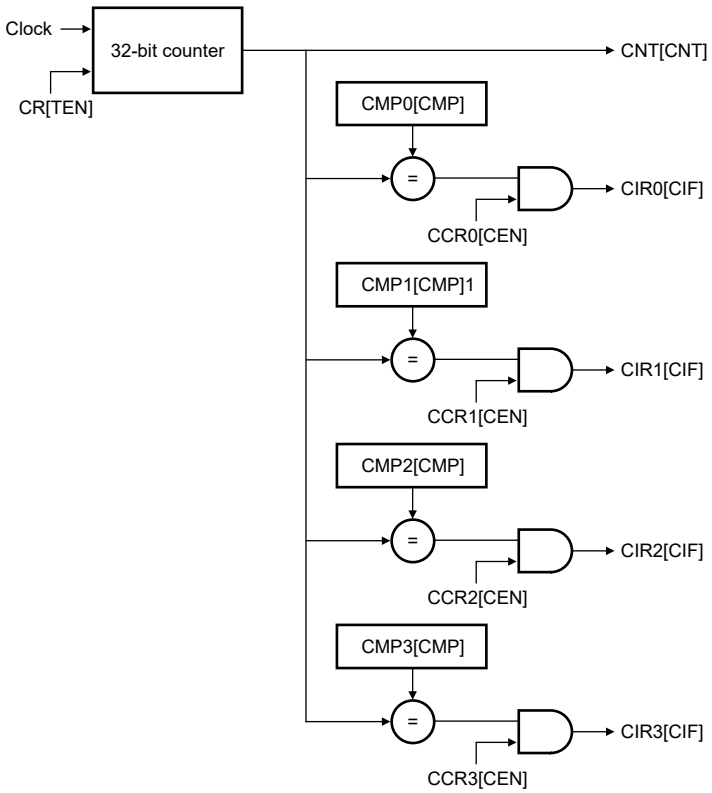

Figure 352. Block diagram

64.5 Functional description

64.5.1 Count-up timer

STM has one 32-bit count-up timer that serves as the time base for four compare channels. When enabled, the counter increments at the module clock frequency divided by a prescaler value in the range from 1 to 256. When enabled in Normal mode, the timer increments continuously. The counter rolls over at FFFF_FFFFh to 0000_0000h with no restrictions at this boundary.

64.5.2 Compare channels

STM has four identical compare channels. Each channel includes a channel control register (CCR*n*), a channel interrupt register (CCR*n*), and a channel compare register (CMP*n*). When the channel is enabled and its channel compare value matches the timer count, STM sets the channel interrupt flag and generates an IRQ on that channel.

64.5.3 Behavior in different chip modes

STM supports the chip modes of operation as follows:

Chip mode	STM behavior
Normal	When the timer is enabled (CR[TEN] = 1), the timer counts up continuously.
Debug	If CR[FRZ] = 1, STM stops the timer. Otherwise, when the timer is enabled (CR[TEN] = 1), the timer counts up continuously.

64.6 Application information

64.6.1 Configure the timer

1. Set the initial timer count (CNT[CNT]).
2. Specify STM behavior in chip Debug mode (CNT[FRZ]).
3. Set the counter prescaler (CR[CPS]).
4. Start the timer (CR[TEN]).

64.6.2 Configure the compare channels

For each compare channel:

1. Set the channel compare value (CMP*n*[CMP]).
2. Enable the compare channel (CCR*n*[CEN]).

64.6.3 Respond to compare channel events

For each compare channel:

1. Check the channel interrupt flag (CIR*n*[CIF]).
2. If the channel interrupt flag is set, respond to the interrupt request.
3. When the channel interrupt has been handled, clear the channel interrupt flag (CIR*n*[CIF]).

64.7 STM register descriptions

The STM programming model allows only 32-bit (word) accesses. An attempted reference using a different size or to a reserved address generates a bus error termination.

64.8 Glossary

IRQ	Interrupt request

Chapter 65
Periodic Interrupt Timer (PIT)

65.1 Chip-specific PIT information

65.1.1 PIT instances and configuration

This chip has up to two instances of the PIT each with 4 PIT timers/channels, each channel being 32 bits in length.

Table 356. PIT instances

Instance	MWCT2D17S	MWCT2016S	MWCT2015S
PIT_0	Yes	Yes	Yes
PIT_1	Yes	Yes	Yes

Table 357. PIT instances and features

Feature	PIT_0	PIT_1
Real time interrupt (RTI)	Yes (32-bit)[1]	No
Lifetime Timer	Yes	No
Timer chaining to create a 64-bit timer	Yes	No
Number of 32-bit timer channels	4	4
Timer value unchanged by a non-destructive reset	No	No

1. The RTI on PIT_0 supports operation in STANDBY mode

The RTI shall be possible to set the timer resolution to 1us independently to other timers. The interrupt can be generated by programming LDVAL0, LDVAL1, LDVAL2 and LDVAL3 to 48 in case of 48 MHz FIRC as system clock and 40 in case of 40 MHz system clock to generate an interrupt after 1us.

65.1.2 Input Output

All the PIT instances are capable of generating periodic triggers. PIT triggers are routed to motor control IPs such as eMIOS, LCU, BCTU, ADC etc. via TRGMUX. See the TRGMUX connectivity file attached to this document for details.

65.2 Introduction

The following sections show the PIT's:

- Block diagram
- Features

65.2.1 Block diagram

The following figure shows the block diagram of PIT_RTI module.

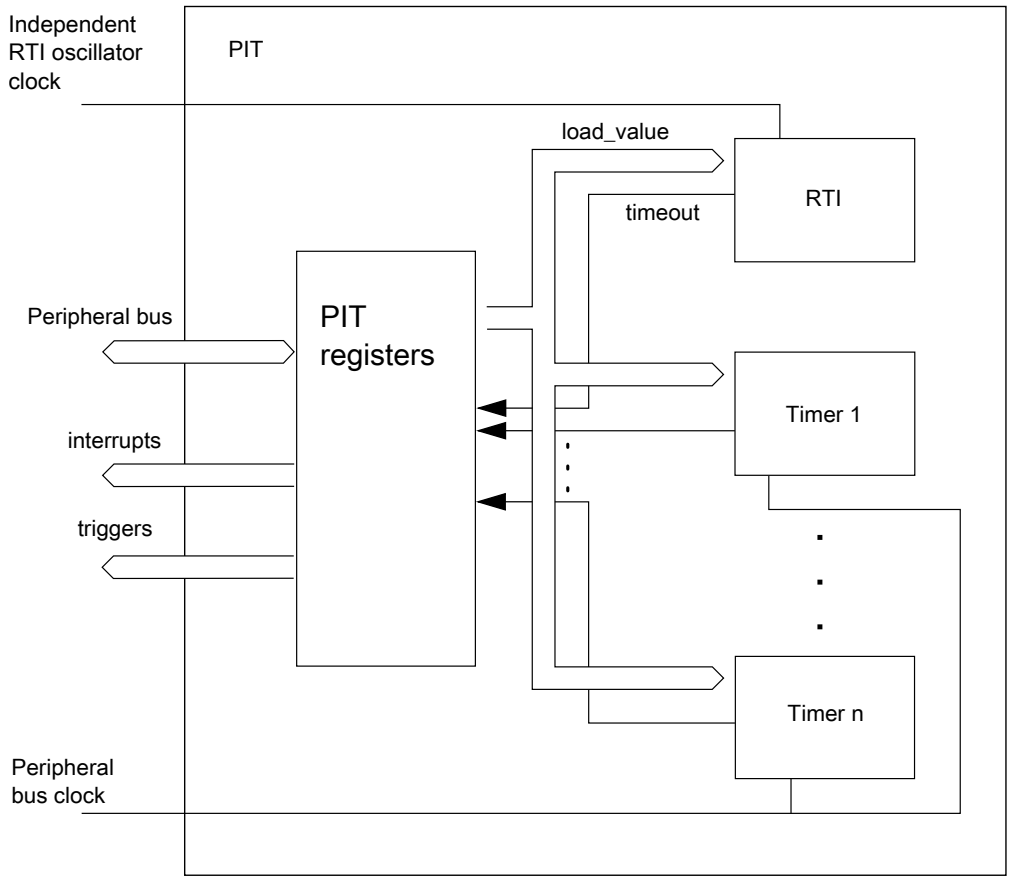

Figure 353. Block diagram of PIT_RTI

65.2.2 Features

The key features of the module are:

- One RTI timer to wakeup the CPU
- Ability of timers to generate trigger pulses
- Ability of timers to generate interrupts
- Maskable interrupts
- Option to raise RTI interrupt, even when the bus clock is switched off
- Power saving with a separate input clock for the RTI timer. All other timers share a common core clock.
- Independent timeout periods for each timer
- All the timers use a downcounter

65.3 Modes of operation

This subsection briefly describes all operating modes supported by PIT.

- Run mode

  All functional parts of the PIT are running during normal Run mode.

65.4 Functional description

This section provides the functional description of the module.

65.4.1 General operation

This section provides detailed information on the internal operation of the module. Each timer can be used to generate trigger pulses and interrupts, and each interrupt is available on a separate interrupt line. Additionally, the RTI timer can be used to wake up the processor.

65.4.1.1 Timers/RTI

The timers generate triggers at periodic intervals, when enabled. The timers load the start values as specified in their LDVAL registers, count down to 0 and then load the respective start values again. Each time a timer reaches 0, it generates a trigger pulse and sets the interrupt flag.

All interrupts can be enabled or masked by setting TCTRLn[TIE]. A new interrupt can be generated only after the previous one is cleared. Because in the case of the RTI, clearing the interrupt crosses clock domains, a minimum load value of 32 must be maintained.

If desired, the current counter value of the timer can be read via the CVAL registers. The value of the RTI counter can be delayed considerably, as it is synchronized to the bus clock from the RTI clock domain.

The counter period can be restarted by first disabling and then enabling the timer with TCTRLn[TEN]. See the following figure.

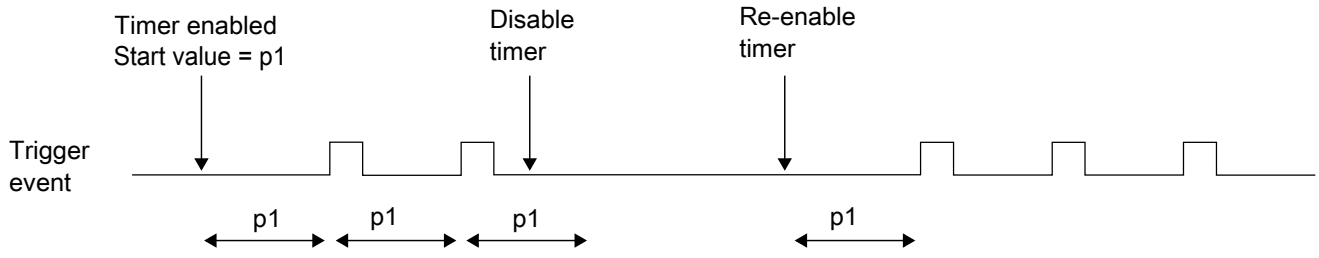

Figure 354. Stopping and starting a timer

The counter period of a running timer can be modified by first disabling the timer, setting a new load value, and then enabling the timer again. See the following figure.

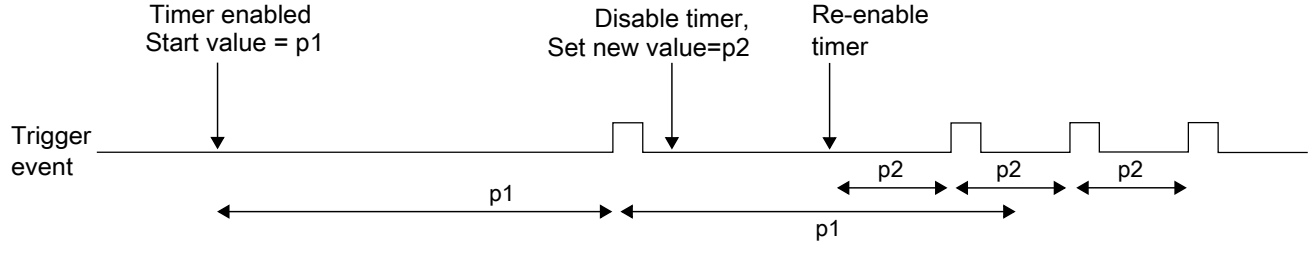

Figure 355. Modifying running timer period

It is also possible to change the counter period without restarting the timer, by writing LDVAL with the new load value. This value then loads after the next trigger event. See the following figure.

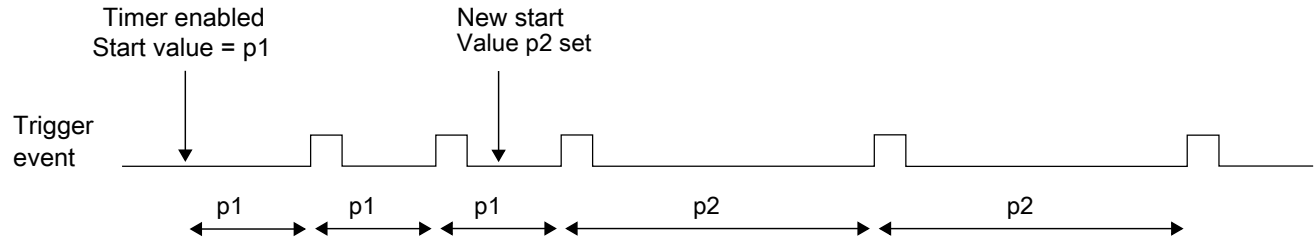

Figure 356. Dynamically setting a new load value

NOTE

- If MCR[FRZ] is written as 1 and when the timer is nearing 0 (CVALn =0x0), the debug mode command may not make it to the IP before the timer expires and generates a trigger.
- Debug Mode will be ignored if CVALn =0x0, but the trigger will remain asserted until the mode is removed. The user is recommended to exit Debug mode and then clear the interrupt TFLGn[TIF].
- If the timers are to be freezed for debug, sufficient time must be ensured for the IP to react.

65.4.1.2 Debug mode

In the Debug mode, the timers are frozen based on MCR[FRZ]. This is intended to aid software development, allowing the developer to halt the processor, investigate the current state of the system, for example, the timer values, and then continue the operation.

65.4.2 Interrupts

All the timers support interrupt generation. The RTI is typically used for system wakeup, but can be used for interrupt generation as well.

Timer interrupts can be enabled by setting TCTRLn[TIE].

TFLGn[TIF] are set to 1 when a timeout occurs on the associated timer, and are cleared to 0 by writing a 1 to the corresponding TFLGn[TIF].

The PIT_RTI generates an RTI when the selected interrupt time period elapses. The RTI is disabled locally by setting TCTCRLn[TIE] to zero. The real-time interrupt flag (TIF) is set to 1 when a timeout occurs, and is cleared by writing a 1 to the corresponding TFLGn[TIF]. The flag is set regardless of whether the interrupt is enabled.

The RTI can be used for periodic wakeup from a STANDBY mode. It can also be used to generate a general-purpose interrupt.

65.4.3 Chained timers

When a timer has chain mode enabled, it counts after the previous timer has expired. So if timer n-1 counts down to 0, counter n decrements the value by one. This allows to chain some of the timers together to form a longer timer. The first timer (timer 0) cannot be chained to any other timer. The same applies to RTI. See Example configuration for chained timers for details.

65.5 Initialization and application information

In the example configuration:

- The PIT clock has a frequency of 50 MHz.
- The RTI clock has a frequency of 10 MHz.
- The RTI creates a wakeup interrupt every 500 ms.
- Timer 1 creates an interrupt every 5.12 ms.
- Timer 3 creates a trigger event every 30 ms.

The PIT module must be activated by writing a 0 to MCR[MDIS].

The 50 MHz clock frequency equates to a clock period of 20 ns and the 10 MHz frequency equates to a clock period of 100 ns. Therefore, the RTI timer needs to trigger every 500 ms/100 ns = 5,000,000 cycles. Timer 1 needs to trigger every 5.12 ms/20 ns = 256,000 cycles and Timer 3 every 30 ms/20 ns = 1,500,000 cycles. The value for the LDVAL register trigger is calculated as:

LDVAL trigger = (period / clock period) -1

This means RTI LDVAL is written with 004C4B3F hex; LDVAL1 and LDVAL3 must be written with 0x0003E7FF and 0x0016E35F, respectively.

To generate the wakeup interrupt, the interrupt line must be enabled by writing 1 to the RTI TIE bit in the TCTRL register. To start the RTI, the TEN in the RTI TCTRL register must also be set.

The interrupt for Timer 1 is enabled by setting TCTRL1[TIE]. The timer is started by writing 1 to TCTRL1[TEN].

Timer 3 shall be used only for triggering. Therefore, Timer 3 is started by writing a 1 to TCTRL3[TEN]. But, TCTRL3[TIE] stays at 0.

The following example code matches the described setup:

```
// turn on PIT
PIT_MCR = 0x00;
```

```
// RTI
PIT_RTI_LDVAL = 0x004C4B3F; // setup RTI for 5000000 cycles
PIT_RTI_TCTRL = PIT_TIE; // let RTI generate interrupts
PIT_RTI_TCTRL |= PIT_TEN; // start RTI
```

```
// Timer 1
PIT_LDVAL1 = 0x0003E7FF; // setup timer 1 for 256000 cycles
PIT_TCTRL1 = TIE; // enable Timer 1 interrupts
PIT_TCTRL1 |= TEN; // start Timer 1
```

```
// Timer 3
PIT_LDVAL3 = 0x0016E35F; // setup timer 3 for 1500000 cycles
PIT_TCTRL3 |= TEN; // start Timer 3
```

65.6 Example configuration for chained timers

In the example configuration:

- The PIT clock has a frequency of 100 MHz.
- Timers 1 and 2 are available.
- An interrupt is raised every 1 minute.

The PIT module needs to be activated by writing a 0 to MCR[MDIS].

The 100 MHz clock frequency equates to a clock period of 10 ns, so the PIT needs to count for 6000 million cycles, which is more than a single timer can do. So, Timer 1 is set up to trigger every 6 s (600 million cycles). Timer 2 is chained to Timer 1 and programmed to trigger 10 times.

The value for the LDVAL register trigger is calculated as number of cycles-1, so LDVAL1 receives the value 0x23C345FF and LDVAL2 receives the value 0x00000009.

The interrupt for Timer 2 is enabled by setting TCTRL2[TIE], the Chain mode is activated by setting TCTRL2[CHN], and the timer is started by writing a 1 to TCTRL2[TEN].

TCTRL1[TEN] needs to be set, and TCTRL1[CHN] and TCTRL1[TIE] are cleared.

The following example code matches the described setup:

```
// turn on PIT
PIT_MCR = 0x00;
```

```
// Timer 2
PIT_LDVAL2 = 0x00000009; // setup Timer 2 for 10 counts
PIT_TCTRL2 = TIE; // enable Timer 2 interrupt
PIT_TCTRL2 |= CHN; // chain Timer 2 to Timer 1
PIT_TCTRL2 |= TEN; // start Timer 2
```

```
// Timer 1
PIT_LDVAL1 = 0x23C345FF; // setup Timer 1 for 600 000 000 cycles
PIT_TCTRL1 = TEN; // start Timer 1
```

65.7 Example configuration for the Lifetime Timer

To configure the Lifetime Timer, channels 0 and 1 need to be chained together.

First, the PIT module needs to be activated by writing a 0 to the MDIS bit in the CTRL register, and then the LDVAL registers need to be set to the maximum value.

The following example code matches the described setup:

```
// turn on PIT
PIT_MCR = 0x00;
```

```
// Timer 1
PIT_LDVAL1 = 0xFFFFFFFF; // setup timer 1 for maximum counting period
PIT_TCTRL1 = 0x0; // disable timer 1 interrupts
PIT_TCTRL1 |= CHN; // chain timer 1 to timer 0
PIT_TCTRL1 |= TEN; // start timer 1
```

```
// Timer 0
PIT_LDVAL0 = 0xFFFFFFFF; // setup timer 0 for maximum counting period
PIT_TCTRL0 = TEN; // start timer 0
```

To access the Lifetime Timer, read first LTMR64H and then LTMR64L.

```
current_uptime = PIT_LTMR64H<<32;
current_uptime = current_uptime + PIT_LTMR64L;
```

65.8 PIT register descriptions

This section provides a detailed description of all registers accessible in the PIT_RTI module.

- See the chip-specific PIT information for the number of PIT channels used in this MCU.
- The RTI registers should be programmed only when the RTI clock is running.

NOTE

When a chip has more than one instance of the PIT, the different instances might have different feature and register sets. Please see the configuration information.

Fields

Field	Function
31-0 LTH	Life Timer value Shows the timer value of timer 1. If this register is read at a time t1, LTMR64L shows the value of timer 0 at time t1.

65.8.4 PIT Lower Lifetime Timer Register (LTMR64L)

Offset

Register	Offset
LTMR64L	E4h

Function

This register is intended for applications that chain timer 0 and timer 1 to build a 64-bit Lifetime Timer.

To use LTMR64H and LTMR64L, timer 0 and timer 1 need to be chained. To obtain the correct value, first read LTMR64H and then LTMR64L. The value for the LTMR64H register is set to CVAL1 register at the time of the first access and the value of the LTMR64L register is set to CVAL0 register at first access. Therefore, the application is not affected by the carry-over effects of the running counter.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported

Field	Function
31-0 LTL	Life Timer value Shows the value of timer 0 at the time LTMR64H was last read. It will only update if LTMR64H is read.

65.8.5 RTI Timer Load Value Sync Status Register (RTI_LDVAL_STAT)

Offset

Register	Offset
RTI_LDVAL_STAT	ECh

Function

These registers gives the RTI timer load synchronization status. In the case of the RTI timer load, it will take several cycles until this value is synchronized into the RTI clock domain. This register gives the status of the new value loaded in the RTI timer load register.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
PIT_0	RTI_LDVAL_STAT	—
PIT_1	—	RTI_LDVAL_STAT

0 RT_STAT	RTI Timer Load Value Sync Status RTI timer load value loaded in RTI_LDVAL register. **NOTE** Any attempt to write will clear this field. 0b - RTI_LDVAL register not loaded. 1b - RTI_LDVAL register updated with new value.

65.8.6 Timer Load Value Register (RTI_LDVAL)

Offset

Register	Offset
RTI_LDVAL	F0h

Function

These registers select the timeout period for the timer interrupts. In the case of the RTI, it will take several cycles until this value is synchronized into the RTI clock domain. For all other timers, the value change is visible immediately. The synchronization mechanism allows 0 wait states in this case.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 TSV	Timer Start Value Sets the timer start value. The timer counts till it reaches 0; then it generates an interrupt and loads the register value again. Writing a new value to this register does not restart the timer; instead the value loads after the timer expires. To abort the current cycle and start a timer period with a new value, the timer must be disabled and enabled again. **NOTE** The RTI timer must not be set to a value lower than 32 cycles, otherwise interrupts may be lost, as it takes several cycles to clear the RTI interrupt. For the other timers, this limit does not apply; however, there are practical limits because the processor requires several cycles to service an interrupt.

65.8.7 Current Timer Value Register (RTI_CVAL)

Offset

Register	Offset
RTI_CVAL	F4h

Function

These registers indicate the current timer position. For the RTI timers, they show a value that is several cycles old because it originates from a potentially different clock domain.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
PIT_0	RTI_CVAL	—
PIT_1	—	RTI_CVAL
PIT_2	—	RTI_CVAL

0 TIF	Timer Interrupt Flag Sets to 1 at the end of the timer period. Writing 1 to this flag clears it and writing 0 has no effect. If enabled, or, when TCTRLn[TIE] = 1, TIF causes an interrupt request. 0b - Timeout has not yet occurred. 1b - Timeout has occurred.

65.9 Glossary

RTI Real-time interrupt

Chapter 66
Real Time Clock (RTC)

66.1 Chip-specific RTC information

66.1.1 RTC instances and configuration

The chip contains one instance of RTC (Real Time Clock) timer and API (Autonomous Periodic Interrupt) timer, where both can perform 32-bit comparisons.

The RTC is present in always ON domain, hence available in RUN mode as well as in STANDBY mode. Both RTC and API timers can generate interrupts as well as wakeup from low power modes.

RTC supports a resolution of 1µs with high speed internal oscillator clock (1/48MHz (FIRC) * 48 (RTC counter) = 1µs)

This chip supports seamless RTC operation across functional reset with the clock sources SIRC and SXOSC.

NOTE

SXOSC is not present in MWCT2015S, thus RTC will run from SIRC clock.

API has the capability to change the Timer compare value (APIVAL) independently without stopping the timer.

API can also be used in conjunction with the Comparator module. In STANDBY mode configuration, the API is configured to generate a START / NEXT type signal to inform the Comparator module that a 'compare' must be carried out.

66.3 Introduction

The Real-Time Clock (RTC) is a free-running counter used for time keeping applications. The RTC can be configured to generate an interrupt at a pre-defined interval independent of the mode of operation (run mode or low power mode). If in a low power mode, the RTC interval is reached, the RTC first generates a wakeup and then asserts the interrupt request. The RTC also supports an API function used to generate a periodic wakeup request to exit a low-power mode or an interrupt request.

66.3.1 Features

RTC features include:

- 32-bit counter
- Selectable counter clock sources (IRCs and OSCs)
  - Clock source 0
  - Clock source 1
  - Clock source 2
  - Clock source 3
- Optional 512 prescaler and optional 32 prescaler to run the 32 bit counter.
- RTC interrupt with interrupt enable.
- Counter runs in all modes of operation.
- RTC counter is reset when the counter is disabled by software and by reset to RTC block.
- Autonomous periodic interrupt support includes:
  - 32-bit compare value to support range of wakeup intervals/interrupts
  - API logic has a separate enable to support changing compare value while RTC is running
  - API interrupt with interrupt enable
  - Operates in all modes

— API compare value can be modified while RTC is running

- Optional interrupt for RTC match, API match, and RTC rollover.

66.3.2 Block diagram

The following figure shows Clock gating for RTC clocks.

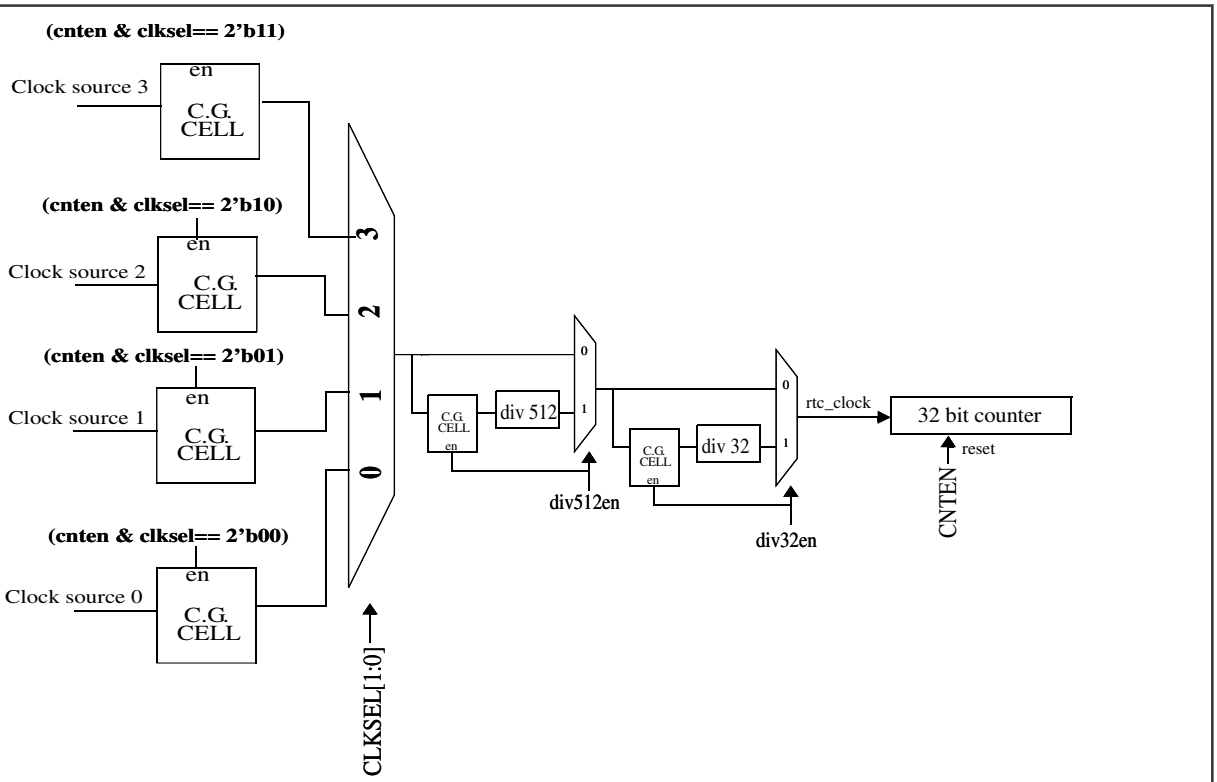

Figure 357. Clock gating for RTC clocks

The following figure shows the block diagram of RTC.

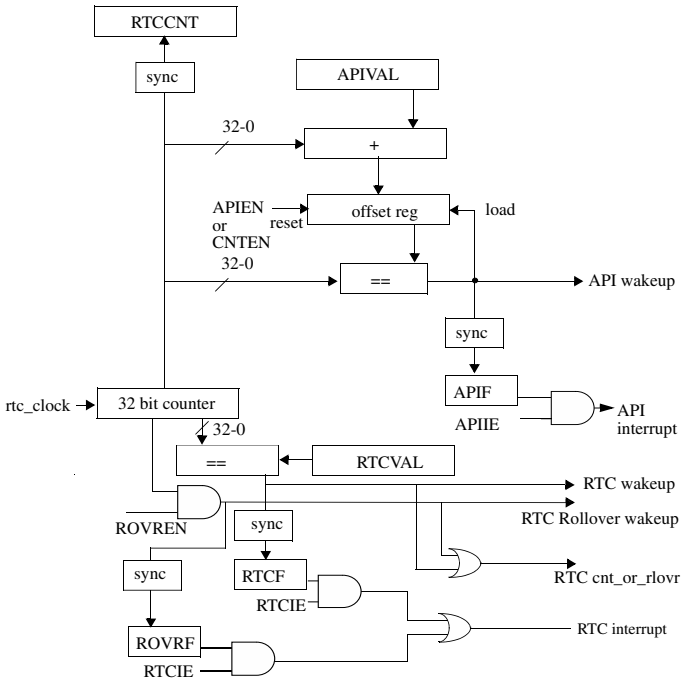

Figure 358. Block diagram

66.3.3 Modes of operation

66.3.3.1 Functional mode

There are two functional modes of operation for RTC: normal operation and low-power mode. In normal operation, all RTC registers can be read or written . The RTC/API and associated interrupts are optionally enabled. In low-power mode, the bus interface is disabled. The RTC/API is enabled (if enabled prior to entry into low-power mode).

66.3.3.2 Debug mode

On entering into the debug mode, the RTC counter freezes on the last valid count if the FRZEN is set. On exit from debug mode, counter continues from the frozen value.

66.4 Functional description

66.4.1 RTC

The RTC consists of a 32-bit free running counter enabled with the CNTEN bit (CNTEN, when negated, asynchronously resets the counter and synchronously enables the counter when enabled). After disabling CNTEN, RTCVAL, APIVAL, needs to be written again for desired functionality. The value of the counter may be read via the RTC Counter register (RTCCNT) register. Note that because of clock synchronization, the RTC Counter register (RTCCNT) value may represent a previous counter value. The difference between the counter and the read value depends on the ratio of counter clock and bus clock. Maximum possible difference between the two is 6 count values.

The clock source to the counter is selected with the CLKSEL field, which gives four options for clocking the RTC/API. The four clock sources are assumed to be on these:Clock source 0, Clock source 1, Clock source 2, and Clock source 3. The output of the clock mux can be optionally divided by a combination of 512 and 32 to give various count periods for different clock sources. Note that the CNTEN bit should be disabled when the RTC/API clock source is switched.

When the RTC Counter register (RTCCNT) counter value for counter bits 31-0 match the 32-bit value in the RTCVAL field, then the RTCF interrupt flag bit is set (after proper clock synchronization). If the RTCIE interrupt enable bit is set, then the RTC interrupt request is generated. RTC Compare value register (RTCVAL) register can be written only when INV_RTC bit is clear. Initially INV_RTC=0, and hence RTC Compare value register (RTCVAL) can be written once and hence INV_RTC gets set. This bit can now be cleared only by enabling the RTC counter. After the counter is enabled, RTC Compare value register (RTCVAL) can be written anytime, until RTC is disabled again. RTC Compare value register (RTCVAL) is first synchronized to the RTC clock domain, therefore, if RTC Compare value register (RTCVAL) is updated at the point where a counter match is due to happen in the next 2-3 RTC clocks because of previous RTC Compare value register (RTCVAL), the RTCF flag is set. However, if the RTC Compare value register (RTCVAL) is updated at the point where no counter match is due as per the previous RTC Compare value register (RTCVAL), the RTCF flag is set when the counter matches the new RTC Compare value register (RTCVAL). If there is a match when in the low-power mode, then the RTC first generates a wakeup request to force a wakeup to run mode,and then the RTCF flag is set.

If RTC Compare value register (RTCVAL) is updated just after counter match, new RTC Compare value register (RTCVAL) value should not be within next 6 RTC counter values.

A rollover wakeup and/or interrupt can be generated when the RTC transitions from a count of 0xFFFF_FFFF to 0x0000_0000. The rollover flag is enabled by setting the ROVREN bit. If RTCIE is enabled, an interrupt request is generated for an RTC counter rollover. If system is in low power mode, RTC counter rollover with this bit causes a wakeup from the low-power mode.

Both rollover wakeup and RTC wakeup gets asynchronously de-asserted with disabling of CNTEN.

All the flags and counter values are synchronized with the Bus clock. It is assumed that the Bus clock and RTC clock selected through CLKSEL follows the below relation:

Bus clock >= (1.5 * RTC clock)/(div_factor)

- if both DIV32EN and DIV512EN bits are disabled, div_factor = 1
- if DIV32EN=1 and DIV512EN=0, div_factor = 32
- if DIV32EN=0 and DIV512EN=1, div_factor = 512
- if both DIV32EN and DIV512EN bits are enabled, div_factor = 512*32 = 16384

In case, RTC wakeup's are used as a wakeup source, Bus clock should be disabled after enabling the required wakeup and ensuring sufficient time gap (few Bus clock or RTC clock cycles, whichever is slower) between Bus clock disabling and wakeup event.

66.4.2 API functional description

Setting APIEN bit enables the autonomous interrupt function. The 32-bit APIVAL field selects the time interval for triggering an interrupt and/or wakeup event. Because the RTC is a free-running counter, the APIVAL is added to the current count to calculate an offset. When the counter reaches the offset count, an interrupt and/or wakeup request is generated. Then the offset value is recalculated and again re-triggers a new request when the new value is reached. API function is enabled only when CNTEN and APIEN bits are asserted and APIVAL is non-zero. Also, APIVAL can be updated anytime. After APIVAL is updated, the first API interrupt is generated according to the previous value. From the second interrupt onwards, the API interrupt is generated with the new APIVAL. When a compare is reached, the APIF interrupt flag bit is set (after proper clock synchronization). If the APIIE interrupt enable bit is set, then the API interrupt request is generated. If there is a match while being in the low-power mode, then the API first generates a wakeup request to force a wakeup into normal operation, and then the APIF flag is set.

When the CNTEN is de-asserted, the API function is reset , though wakeup API is not asynchronously de-asserted with CNTEN. If APIEN is disabled when counter matches the offset, APIF can be missed.

66.5 Recommended programming flow

1. Program RTCVAL register with the value greater than 4 if RTCF related functionality is required.
2. Program APIVAL register with the value greater than 4 if API functionality is required.
3. Program all fields (as required) of RTC Control register (RTCC) register with CNTEN=1. After setting CNTEN field, counter starts running and RTC/API functionality will be active as per the configurations.

4. If RTCVAL or APIVAL needs to be updated during run, check corresponding INV_RTC or INV_API bit is cleared before writing and do meet all the restrictions of the corresponding register.
5. If CLKSEL or DIV32EN or DIV512EN needs to be updated, first update RTC Control register (RTCC) register with CNTEN=0 (when all INV_RTC or INV_API are 0) keeping other field values same. Wait for minimum 3 RTC clock cycles so that CNTEN will be synchronized to RTC clock domain. Then write the RTC Control register (RTCC) register with new configuration required with CNTEN=1.

66.6 RTC register descriptions

The RTC registers are listed in this section.

NOTE

Address offset - 0x18h should not be accessed by application as corresponding feature/s are not available. Therefore, transfer error will not be generated at this offset.

NOTE

XFR error will be generated when RTCSUPV is accessed in user mode, any other register is accessed in user mode when SUPV bit is set, write attempt is made for RTCCNT register and any register accessed out of address range.

66.6.1 RTC memory map

RTC base address: 4028_8000h

Offset	Register	Width (In bits)	Access	Reset value
0h	RTC Supervisor control register (RTCSUPV)	32	RW	8000_0000h
4h	RTC Control register (RTCC)	32	RW	0000_0000h
8h	RTC Status register (RTCS)	32	W1C	0000_0000h
Ch	RTC Counter register (RTCCNT)	32	RO	0000_0000h
10h	API Compare value register (APIVAL)	32	RW	0000_0000h
14h	RTC Compare value register (RTCVAL)	32	RW	0000_0000h

66.6.2 RTC Supervisor control register (RTCSUPV)

Offset

Register	Offset
RTCSUPV	0h

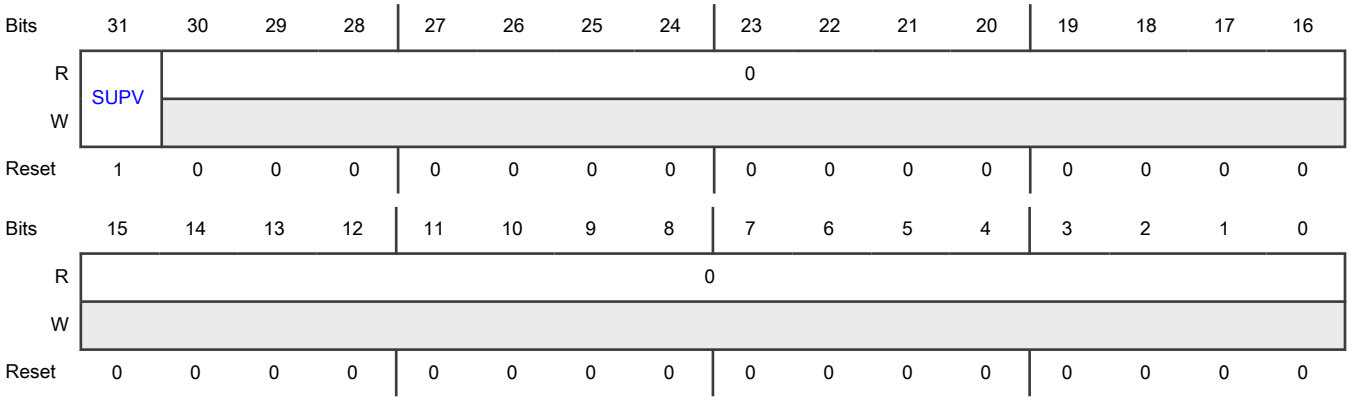
Function

The RTCSUPV register contains the SUPV bit that determines whether other registers are accessible in supervisor mode or user mode.

NOTE

You can access this register only in Supervisor mode, and you must write a value only to the SUPV field of the register.

Diagram



Fields

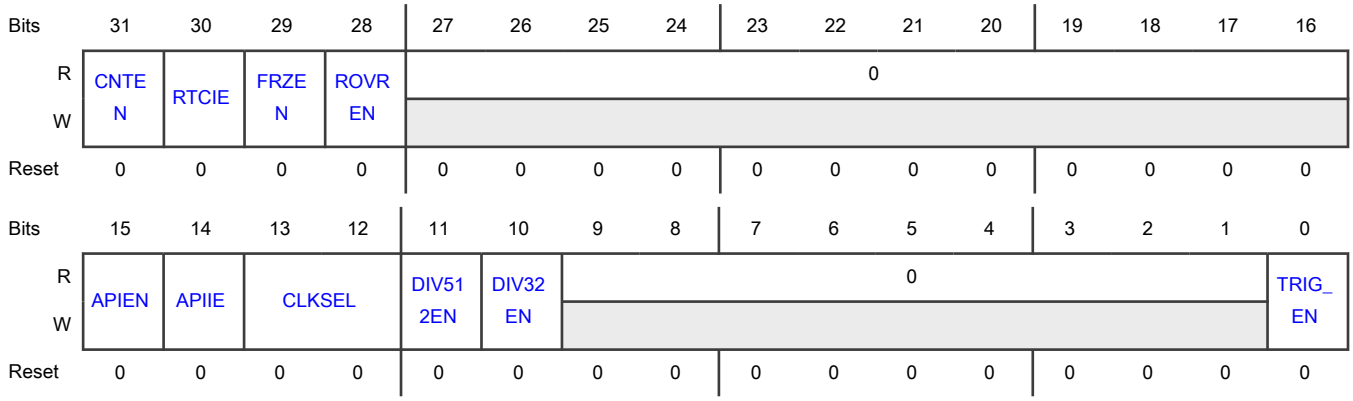
Field	Function
31 SUPV	RTC Supervisor Bit. 0b - All registers are accessible in both user as well as supervisor mode. 1b - All other registers are accessible in the supervisor mode only.
30-0 —	Reserved

66.6.3 RTC Control register (RTCC)

Offset

Register	Offset
RTCC	4h

Diagram



Fields

Field	Function
31 CNTEN	Counter Enable The CNTEN bit enables the RTC counter. Setting CNTEN bit to 0b has the effect of asynchronously resetting (synchronous reset negation) all the RTC and API logic. This allows RTC configuration and clock source selection to be updated without causing synchronization issues. **NOTE** CNTEN should be disabled when INV_RTC, INV_API are cleared. 0b - Counter disabled 1b - Counter enabled
30 RTCIE	RTC Interrupt Enable. The RTCIE bit enables interrupts requests to the system if RTCF is asserted. 0b - RTC interrupts disabled. 1b - RTC interrupts enabled.
29 FRZEN	Freeze Enable Bit The counter freezes on entering the debug mode on the last valid count value if the FRZEN bit is set. After passing of the debug mode counter starts from the frozen value. This bit should not be changed when debug mode is enabled. 0b - Counter does not freeze in debug mode. 1b - Counter freezes in debug mode.
28 ROVREN	Counter Roll Over wakeup/Interrupt Enable. The ROVREN bit enables wakeup and interrupt requests when the RTC has rolled over from 0xFFFF_FFFF to 0x0000_0000. The RTCIE bit must also be set in order to generate an interrupt from a counter rollover. 0b - RTC rollover wakeup/interrupt disabled 1b - RTC rollover wakeup/interrupt enabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
27-16 —	Reserved
15 APIEN	Autonomous Periodic Interrupt Enable. The APIEN bit enables the autonomous periodic interrupt function. Setting this bit to 0b, asynchronously disables API wakeup output of RTC as well. 0b - API disabled. 1b - API enabled.
14 APIIE	API Interrupt Enable. The APIIE bit enables interrupts requests to the system if APIF is asserted. 0b - API interrupts disabled. 1b - API interrupts enabled.
13-12 CLKSEL	Clock select The CLKSEL[1:0] bits select the clock source for the RTC. CLKSEL may only be updated when CNTEN is 0. The user should ensure that oscillator is enabled before selecting it as a clock source for RTC. **NOTE** Refer the RTC clocking section in the Clocking chapter of this document. 00b - Clock source 0 01b - Clock source 1 10b - Clock source 2 11b - Clock source 3
11 DIV512EN	Divide by 512 enable The DIV512EN bit enables the 512 clock divider. DIV512EN may only be updated when CNTEN is 0. 0b - Divide by 512 is disabled. 1b - Divide by 512 is enabled.
10 DIV32EN	Divide by 32 enable. The DIV32EN bit enables the 32 clock divider. DIV32EN may only be updated when CNTEN is 0. 0b - Divide by 32 is disabled 1b - Divide by 32 is enabled
9-1 —	Reserved
0 TRIG_EN	Trigger enable for Analog Comparator

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This bit (TRIG_EN) when set will de-assert the wakeup_api on the next RTC clock (required for ACMP when bus clock is disabled). **NOTE** If API wakeup is asserted with TRIG_EN set, and bus clock enabled, setting of RTCS[APIF] may be missed.

66.6.4 RTC Status register (RTCS)

Offset

Register	Offset
RTCS	8h

Function

NOTE

W1C has priority over setting of the RTCF, APIF and ROVRF bits, in case both clearing and setting occurs at the same time.

18 INV_RTC	Invalid RTC write This bit returns value 1 after a value is written to the RTCVAL register and the synchronization process is in progress. During this synchronization period, any attempt to write to the RTCVAL register again is ignored. Synchronization will complete only when CNTEN is set.
17 INV_API	Invalid APIVAL write This bit returns value 1 after a value is written to the APIVAL register and the synchronization process is in progress. During this synchronization period, any attempt to write to the APIVAL register again is ignored. Synchronization will complete only when CNTEN is set.
16 —	Reserved
15-14 —	Reserved
13 APIF	API Interrupt Flag. The APIF bit indicates that the RTC counter has reached the counter value matching API offset value. APIF is cleared by writing a 1 to APIF. Writing a 0 to APIF has no effect. 0b - Counter is not equal to API offset value. 1b - Counter matches the API offset value.
12-11 —	Reserved
10 ROVRF	Counter Roll Over Interrupt Flag. The ROVRF bit indicates that the RTC has rolled over from 0xFFFF_FFFF to 0x0000_0000. ROVRF is cleared by writing a 1 to ROVRF. 0b - RTC has not rolled over 1b - RTC has rolled over
9-0 —	Reserved

66.6.5 RTC Counter register (RTCCNT)

Fields

Field	Function
31-0 RTCCNT	RTC Counter Value Because of clock synchronization, the RTCCNT value may represent a previous counter value.

66.6.6 API Compare value register (APIVAL)

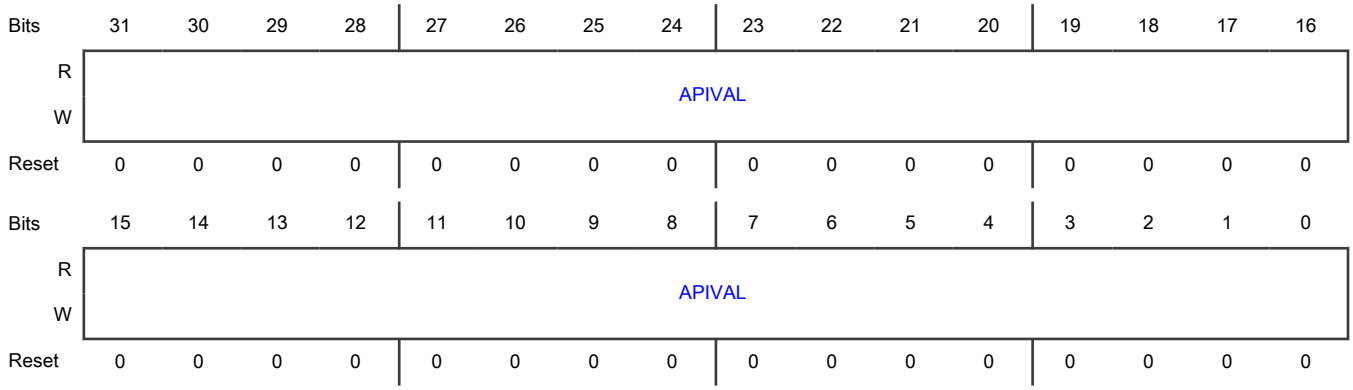
Offset

Register	Offset
APIVAL	10h

Function

The APIVAL offset bits are compared to the RTC counter bits and if a match occurs, an interrupt/wakeup request is asserted.

Diagram



Fields

Field	Function
31-0 APIVAL	API Compare Value. APIVAL bits are added to the current count to calculate an offset. The APIVAL offset bits are compared to the RTC counter bits and if a match occurs, an interrupt/wakeup request is asserted. **NOTE** API functionality is active only when APIVAL is non zero. The first API interrupt takes two more cycles because of synchronization of APIVAL to RTC clock. After that, interrupts are periodic in nature and it takes APIVAL+1 cycles. The Minimum supported value of APIVAL is 4. This is because of synchronization.

66.6.7 RTC Compare value register (RTCVAL)

Offset

Register	Offset
RTCVAL	14h

Function

The RTCVAL bits are compared to the RTC counter bits and if a match occurs, RTCF is set. The minimum value of RTCVAL should be 4.

LPSPI2	4x32 bit	4x32 bit	4
LPSPI3	4x32 bit	4x32 bit	4
LPSPI4	4x32 bit	4x32 bit	4
LPSPI5	4x32 bit	4x32 bit	4

- For supported data rates see table Peripheral data rates
- Low leakage and Wait modes are not supported in this device.

The number of chip selects that each LPSPI instance supports varies. Because of that, in the Configuration Register 1 (CFGR1), the Peripheral Chip Select (PCS) field and the Peripheral Chip Select Polarity (PCSPOL) field also vary. See the next 2 tables.

67.1.2 LPSPI HREQ considerations for MWCT2D17S

It is recommended that the HREQ pin (when PCS[1] is used as HREQ) should get de-asserted before the completion of frame transfer. In case if the HREQ state is still asserted and LPSPI returns to idle state after frame transfer completion, the HREQ state is internally latched and the next data is written to the transmit FIFO without waiting for the next HREQ assertion.

This limitation is present only while using PCS[1] as HREQ and HREQ remains asserted throughout frame transfer. In case of using trigger input as HREQ, there is no issue.

67.2 Overview

LPSPI is a low-power Serial Peripheral Interface (SPI) module that supports an efficient interface to an SPI bus, either as a master and/or as a slave. The SPI bus is a synchronous serial communication interface used in embedded systems, typically to perform short distance communications between microcontrollers and peripheral devices, on printed circuit boards. Typical applications include interfacing to Secure Digital cards and LCD displays.

67.2.1 Block diagram

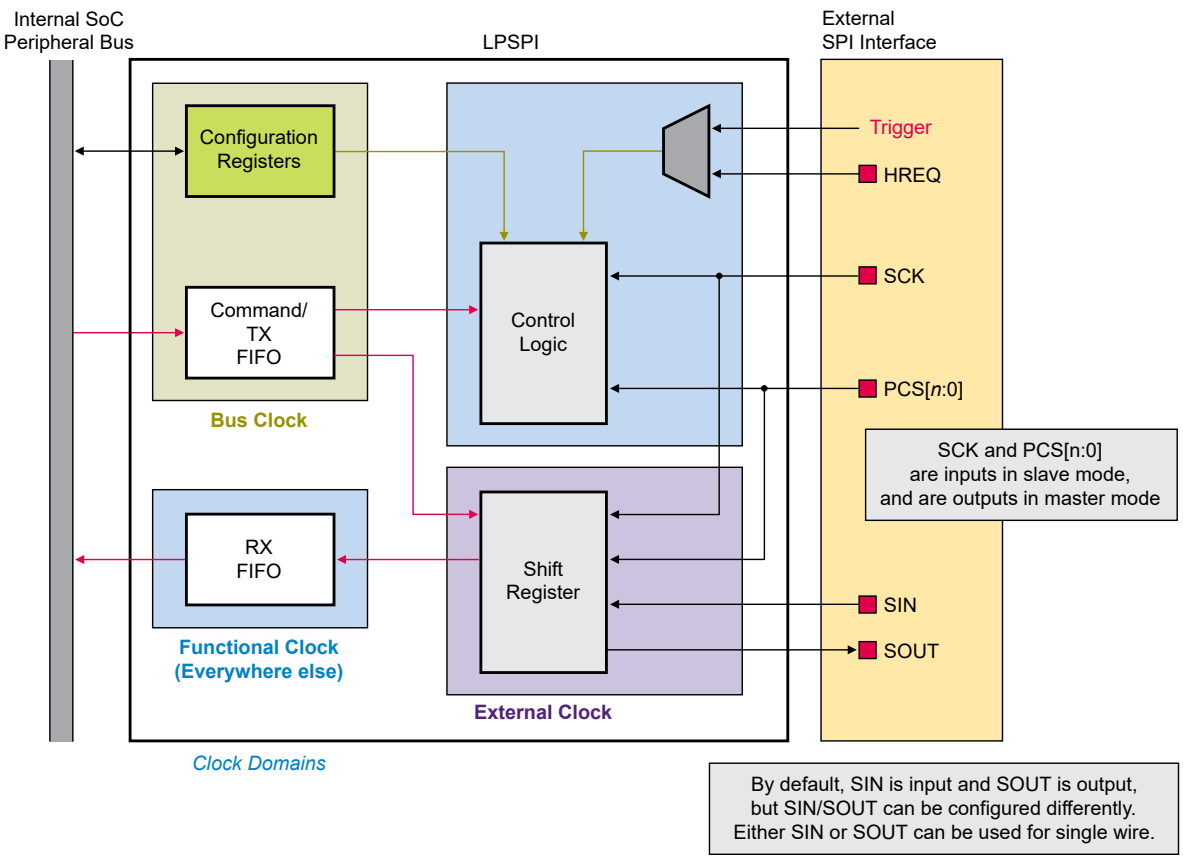

Figure 359. Block diagram

67.2.2 Features

LPSPI supports:

- Uses little CPU overhead, with DMA offloading of FIFO register accesses
- Supports DMA accesses and generates a DMA request
- Word size of 32 bits
- Configurable clock polarity and clock phase
- Master operation supporting up to 8 peripheral chip selects
- Slave operation
- Command/transmit FIFO of 4 words
- Receive FIFO of 4 words
- Flexible timing parameters in Master mode, including SCK frequency, duty cycle, and delays between PCS and SCK edges
- Continuous transfer option to keep the PCS asserted across multiple frames
- Full duplex transfers supporting 1-bit transmit and receive on each clock edge
- Half duplex transfers supporting 1-bit transmit or receive on each clock edge

- Half duplex transfers supporting 2-bit transmit or receive on each clock edge
- Half duplex transfers supporting 4-bit transmit or receive on each clock edge
- Half duplex transfers supporting 8-bit transmit or receive on each clock edge
- Host request can be used to control the start of a SPI bus transfer
- Receive data match logic supporting wakeup on data match

67.3 Functional description

67.3.1 Master mode

67.3.1.1 Transmit and Command FIFO commands

The transmit and command FIFO is a combined FIFO that includes both transmit data words and command words.

- Transmit data words are stored to the transmit/command FIFO, by writing the Transmit Data (TDR).
- Command words are stored to the transmit/command FIFO, by writing the Transmit Command (TCR).

When a command word is at the top of the transmit/command FIFO, the actions that can occur depend upon whether the LPSPI module is either busy or between frames. See Continuous Transfer bit, TCR[CONT] and Continuing Command bit, TCR[CONTC]

Table 362. Possible actions when a command word is at the top of the transmit/command FIFO

Condition	Action
If LPSPI is between frames	then the command word is pulled from the FIFO, and that command word controls all subsequent transfers.
If LPSPI is busy and the Continuing Command bit (TCR[CONTC]) is cleared	then the SPI frame completes at the end of the existing word, ignoring the FRAMESZ configuration. The command word is then pulled from the FIFO and that command word controls all subsequent transfers (or until the next update to the command word). Note that a command word with TCR[CONTC] = 0 always terminates (stop) the existing transfer regardless of the previous TCR[CONT] value.
If LPSPI is busy and the existing TCR[CONT] bit is set and the new TCR[CONTC] value is set	then the command word must be updated at the frame boundary. The command word is pulled from the FIFO during the last SCK pulse of the existing frame (based on the FRAMESZ configuration), and the frame continues using the new command value for the rest of the frame (or until the next update to the command word). When TCR[CONTC] is set, only the lower 24-bits of the command word are updated. If the command word is updated at a word boundary, then the transfer halts (stops) after that word. Essentially the TCR[CONTC] bit is ignored when not at a frame boundary, so the frame ends prematurely.

About TCR[CONT] and TCR[CONTC]:

- TCR[CONT] = 1 is used to keep PCS asserted at end of frame, allowing the transfer to continue.
- TCR[CONTC] = 1 is used to indicate that this command word should not terminate the existing frame, and the transfer can continue using the new command word.

TCR[CONTC] = 1 is restricted in the sense that the new command must load on a frame boundary, and the only way for a transfer to continue from a frame boundary, is when the previous command has TCR[CONT] = 1.

The current state of the existing command word is read from Transmit Command (TCR). It requires at least 3 LPSPI functional clock cycles for TCR to update after TCR is written (assuming an empty FIFO) and LPSPI must be enabled (CR[MEN] bit is set).

Writing the TCR does not initiate a SPI bus transfer, unless the TCR[TXMSK] = 1. When the TCR[TXMSK] bit is set, a new command word is not be loaded until the end of the existing frame (based on FRAMESZ configuration); at the end of the transfer, the TCR[TXMSK] bit clears.

In master mode, the LPSPI command word in TCR controls SPI attributes (using bits and fields in registers).

Table 363. LPSPI Command Word in Master mode

Transmit Command (TCR)		Description	Can this field be modified during a data transfer?
Field	Name		
CPOL	Clock Polarity	Configures the polarity of the SCK pin. Any change of CPOL value will cause a transition on the SCK pin.	N
CPHA	Clock Phase	Configures the clock phase of the transfer.	N
PRESCALE	Prescaler Value	Configures a prescaler used to divide the LPSPI functional clock, to generate the timing parameters of the SPI bus transfer. Changing PRESCALE in conjunction with PCS enables the LPSPI module to connect to different slave devices at different frequencies.	N
PCS	Peripheral Chip Select	Configures which PCS asserts for the transfer; the polarity of PCS is static and configured by CFGR1[PCSPOL]. If CFGR1[PCSCFG] = 1. then PCS[3:2] should not be selected.	N
LSBF	LSB First	Configures if LSB (bit 0) or MSB (bit 31 for a 32-bit word) is transmitted or received first.	Y
BYSW	Byte Swap	Enables byte swap on each 32-bit word when transmitting and receiving data. Byte swapping can be useful when interfacing to devices that organize data as big-endian.	Y
CONT	Continuous Transfer	Configures for a continuous transfer that keeps PCS asserted between frames (as configured by FRAMESZ). A new command word is required to cause PCS to negate. Also supports changing the command word at the frame size boundaries.	Y
CONTC	Continuing Command	Indicates that this is a new command word for the existing continuous transfer. The CONTC bit when set must only be written to the transmit/ command FIFO on a frame boundary.	Y
RXMSK	Receive Data Mask	Masks the receive data and does not store the masked receive data to the receive FIFO or perform receive data matching. Useful for half-duplex transfers or to configure which fields are compared during receive data matching.	Y
TXMSK	Transmit Data Mask	Masks the transmit data, so that masked transmit data is not pulled from transmit FIFO, and the output data pin is tristated (unless configured by CFGR1[OUTCFG]). Useful for half-duplex transfers.	Y
WIDTH	Transfer Width	Configures the number of bits shifted on each SCK pulse. • 1-bit transfers support traditional SPI bus transfers in either half-duplex or full-duplex data formats. • 2-bit and 4-bit half-duplex transfers are useful for interfacing to QuadSPI memory devices, and at least one bit (TCR[TXMSK] or TCR[RXMSK]) must also be set.	Y

Table continues on the next page...

Table 363. LPSPI Command Word in Master mode (continued)

Transmit Command (TCR)		Description	Can this field be modified during a data transfer?
Field	Name		
		• 8-bit half-duplex transfers are useful for interfacing to OctelSPI memory devices, and at least one bit (TCR[TXMSK] or TCR[RXMSK]) must also be set.	
FRAMESZ	Frame Size	Configures the frame size in number of bits equal to (FRAMESZ + 1). • The minimum frame size is 8 bits, or 16 bits for an 8-bit transfer. • If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32-bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately. • If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO will contain the remainder bits. For example, a 72-bit transfer will consist of 3 words: the 1st and 2nd words are 32-bit, and the 3rd word is 8-bit.	Y

SPI bus transfers:

- LPSPI initiates a SPI bus transfer when all conditions are true:
  - Data is written to the transmit FIFO
  - And the HREQ pin is asserted (or the HREQ function is disabled)
  - And LPSPI is enabled
- To perform the SPI bus transfer, LPSPI uses the attributes configured in Transmit Command (TCR) and uses the timing parameters in Clock Configuration (CCR).
- The SPI bus transfer ends after the FRAMESZ configuration is reached (provided CONT=0), or at the end of a word when a new transmit command word is at the top of the transmit/command FIFO. When LPSPI is disabled, the SPI bus transfers end after the transmit FIFO is empty and LPSPI is idle.
- The HREQ input is only checked when PCS is negated.

Circular FIFO: The transmit/command FIFO also supports a Circular FIFO feature, which enables the LPSPI master to (periodically) repeat a short data transfer that fits within the transmit/command FIFO, without requiring additional FIFO accesses. When the circular FIFO is enabled (CFGR0[CIRFIFO] = 1), the current state of the FIFO read pointer is saved and the status flags do not update. After the transmit/command FIFO is considered empty and LPSPI is idle, the FIFO read pointer is restored with the saved version, so the contents of the transmit/command FIFO are not permanently pulled from the FIFO while circular FIFO mode is enabled.

67.3.1.2 Receive FIFO and Data Match

The receive FIFO stores receive data during SPI bus transfers. When TCR[RXMSK] = 1, the receive data is discarded instead of being stored in the receive FIFO.

- The receive data is written to the receive FIFO when the last bit of the word is sampled.
- If the transmit FIFO is empty during a multiple word or continuous transfer, then the receive data is written to the receive FIFO before the transfer stalls (assuming CFGR1[NOSTALL] is clear) while waiting for new transmit data or command word to be written.

Receive data supports a receive data match function that can match received data against one of two words in the DMR0 and DMR1 registers or against a masked data word. The receive data match function can also be configured to compare only the first one or two received data words since the start of the frame.

- Received data that is already discarded due to the TCR[RXMSK] bit cannot cause the data match to set, and delays the receive data match on the first received data word, until all discarded data is received.
- The receive data match function can also be configured to discard all received data until a data match is detected, using the CFGR0[RDMO] bit.
- After a receive data match, to allow all subsequent data to be received, clear the CFGR0[RDMO] bit, then clear the SR[DMF] bit.

67.3.1.3 Timing parameters

The timing parameters that are used for all SPI bus transfers are relative to the LPSPI functional clock divided by the PRESCALE configuration. Although the Clock Configuration (CCR) cannot be changed when the LPSPI module is busy, to support interfacing to different slave devices at different frequencies, the TCR[PRESCALE] configuration can be changed between SPI bus transfers using the Transmit Command Register (TCR).

NOTE

The minimum value below is the minimum counter value, but the clock configuration register values must also satisfy the datasheet specs based on the LPSPI functional clock frequency and prescaler value.

Table 364. LPSPI timing parameters

Clock Configuration (CCR) Clock Configuration 1 (CCR1)		Description	Min	Max
Field	Name			
SCKSET	SCK Setup Phase	Configures the SCK setup phase to (SCKSET + 1) cycles. The setup phase is the SCK high period when either CPHA = 0, CPOL = 1 or CPHA = 1, CPOL = 0, otherwise is it the SCK low period. The SCK period is defined as (SCKSET + SCKHLD + 2) and the duty cycle is the difference between SCKSET and SCKHLD.	0 (1 cycle)	255 (256 cycles)
SCKHLD	SCK Hold Phase	Configures the SCK hold phase to (SCKHLD + 1) cycles. The hold phase is the SCK low period when either CPHA = 0, CPOL = 1 or CPHA = 1, CPOL = 0, otherwise it is the SCK high period. The SCK period is defined as (SCKSET + SCKHLD + 2) and the duty cycle is the difference between SCKSET and SCKHLD.	0 (1 cycle)	255 (256 cycles)
PCSPCS	PCS to PCS Delay	Configures the minimum delay between PCS negation and the next PCS assertion to (PCSPCS + PCSPCS + 2) cycles. When the command word is updated between transfers, there is a minimum of (PCSPCS + 1) cycles between the command word update and any change on PCS pins.	0 (2 cycles)	255 (512 cycles)
SCKSCK	SCK to SCK Delay	Configures the delay during a continuous transfer between the last SCK edge of a frame and the first SCK edge of the continuing frame to (SCKSCK +	0 (1 cycle)	255 (256 cycles)

Table continues on the next page...

Table 364. LPSPI timing parameters (continued)

Clock Configuration (CCR) Clock Configuration 1 (CCR1)		Description	Min	Max
Field	Name			
		1) cycles. This is useful when the external slave requires a large delay between different words of an SPI bus transfer.		
PCSSCK	PCS-to-SCK Delay	Configures the minimum delay between PCS assertion and the first SCK edge to (PCSSCK + 1) cycles.	0 (1 cycle)	255 (256 cycles)
SCKPCS	SCK-to-PCS Delay	Configures the minimum delay between the last SCK edge and the PCS assertion to (SCKPCS + 1) cycles.	0 (1 cycle)	255 (256 cycles)

This figure shows the timing settings controlled by TCR[CPHA], TCR[CPOL], CCR[SCKPCS], CCR[PCSSCK], CCR1[SCKSET], and CCR1[SCKHLD].

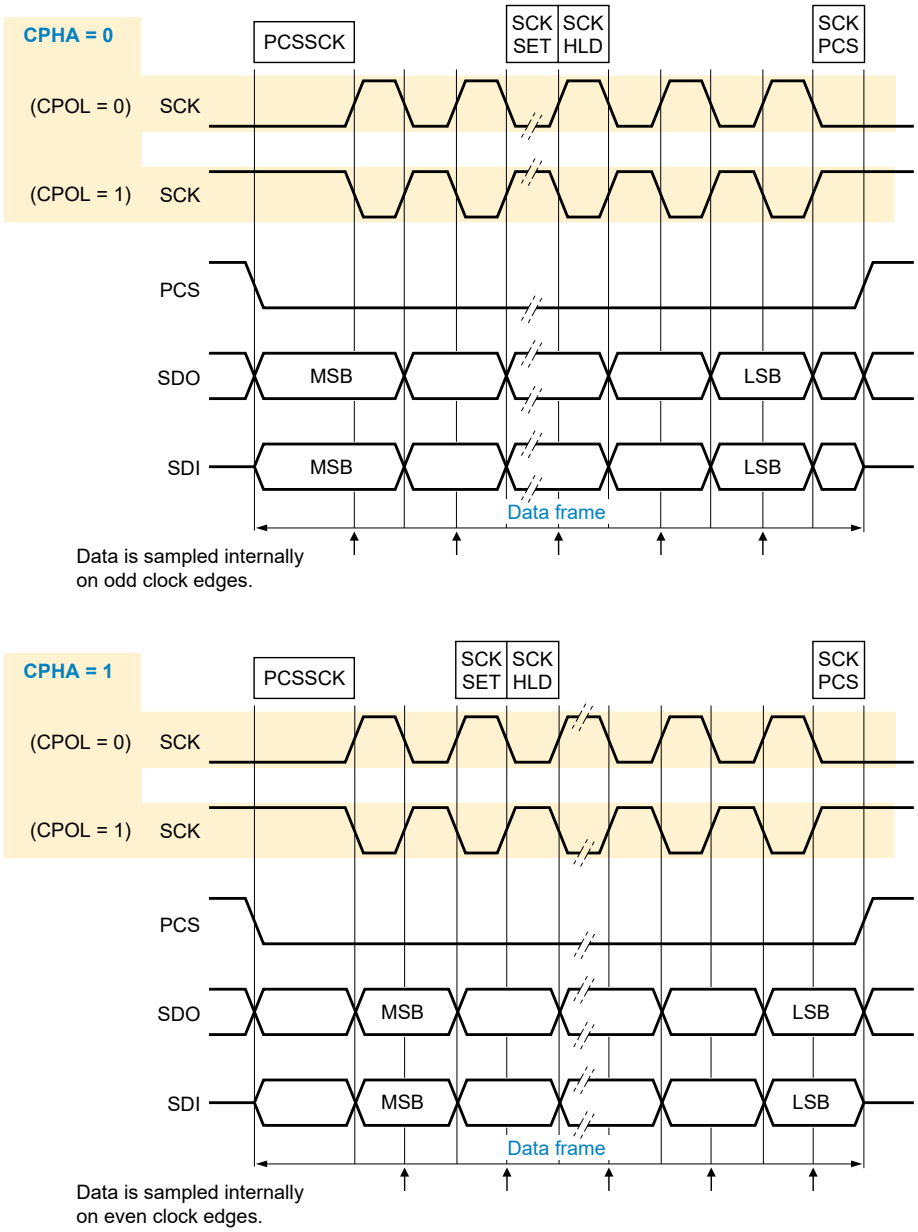

Figure 360. Clock Phase (TCR[CPHA]) timing diagram example

67.3.1.4 Pin configuration

- To swap directions or support half-duplex transfers on the same pin, the SIN and SOUT pins can be configured using CFGR1[PINCFG].
- To determine if an output data pin (like SOUT) tristates when PCS is negated, or if the output data pin simply retains the last value, use CFGR1[PCSCFG].
- When configuring for half-duplex transfers the output data pins must be configured to tristate when PCS is negated; use CFGR1[OUTCFG] CFGR1[OUTCFG].
- When performing half-duplex 2-bit transfers, CFGR1[PCSCFG] can be set to any value.
- When performing half-duplex 4-bit transfers, CFGR1[PCSCFG] must equal 0x1.

67.3.1.5 Clock loopback

Configure the LPSPI master to use either the output clock or a loopback clock to sample the receive data (for example, SIN). Use one of these these clocks to sample the input data:

- The SCK output clock directly
- A delayed version of the SCK output clock

The delayed version of the SCK is chosen by the SCK pin output delay, plus the SCK pin input delay, and is configured by setting CFGR1[SAMPLE]. Enabling the loopback version of the SCK can improve the setup time of the input data from the slave.

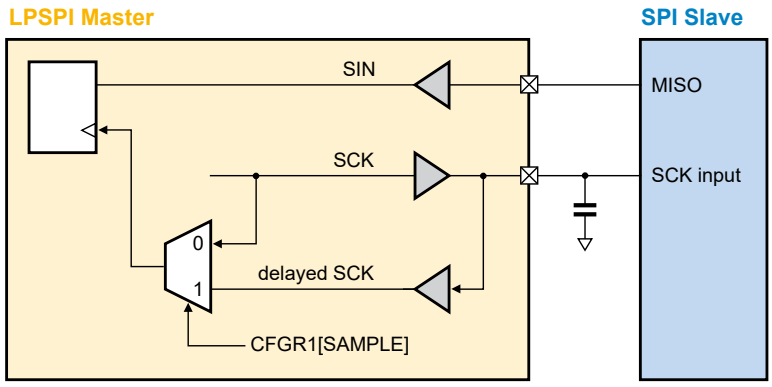

Figure 361. Clock loopback

See the chip data sheet for the specific input setup time in master loopback mode.

67.3.2 Slave mode

LPSPI slave mode:

- Uses the same shift register and logic that master mode uses
- Does not use the Clock Configuration Register (CCR)
- During SPI bus transfers, requires that the Transmit Command (TCR) register remain static (unchanging)

67.3.2.1 Transmit and Command FIFO commands

Before enabling LPSPI in slave mode, initialize the Transmit Command (TCR) register, although the TCR register does not update until after LPSPI is enabled. After being enabled, the TCR register should only be changed if LPSPI is idle. In slave mode, the LPSPI command word in TCR controls SPI attributes. Before the PCS input asserts, the transmit FIFO must be filled with transmit data, or the transmit error flag sets.

Table 365. LPSPI Command Word in Slave mode

Transmit Command (TCR)		Description
Field	Name	
CPOL	Clock Polarity	Configures the polarity of the external SCK input.
CPHA	Clock Phase	Configures the clock phase of transfer.
PRESCALE	Prescaler Value	Configures the LPSPI functional clock prescaler.

Table continues on the next page...

Table 365. LPSPI Command Word in Slave mode (continued)

Transmit Command (TCR)		Description
Field	Name	
PCS	Peripheral Chip Select	Configures which PCS is used, the polarity of PCS is static and configured by CFGR1[PCSPOL]. If CFGR1[PCSCFG] is not equal to zero, then PCS[3:2] pins should not be selected.
LSBF	LSB First	Configures if LSB (bit 0) or MSB (bit 31 for a 32-bit word) is transmitted or received first.
BYSW	Byte Swap	Enables byte swap on each 32-bit word when transmitting and receiving data. Byte swapping can be useful when interfacing to devices that organize data as big-endian.
CONT	Continuous Transfer	When Continuous Transfer is set in slave mode and after the first FRAMESZ bits are transferred, the LPSPI will passthrough and transmit the received data until the next PCS negation. Whatever is shifted in on the receive data is shifted out as transmit data as if there was a 32-bit shift register.
CONTC	Continuing Command	When Continuing Command is set in slave mode and after the first FRAMESZ bits are transferred, then RXMSK will be considered set and TXMSK will be considered clear until the next PCS negation. CONTC can be used to flip the direction of a transfer after the first FRAMESZ bits.
RXMSK	Receive Data Mask	Masks the receive data and does not store the masked receive data to the receive FIFO or perform receive data matching. Useful for half-duplex transfers or to configure which fields are compared during receive data matching.
TXMSK	Transmit Data Mask	Masks the transmit data, so that the masked transmit data is not pulled from transmit FIFO, and the output data pin is tristated (unless configured by CFGR1[OUTCFG]). Useful for half-duplex transfers.
WIDTH	Transfer Width	Configures the number of bits shifted on each SCK pulse. • 1-bit transfers support traditional SPI bus transfers in either half-duplex or full-duplex data formats. • 2-bit and 4-bit half-duplex transfers are useful for interfacing to QuadSPI memory devices, and at least one bit (Transmit Data Mask (TCR[TXMSK] or Receive Data Mask TCR[RXMSK]) must also be set. • 8-bit half-duplex transfers are useful for interfacing to OctelSPI memory devices, and at least one bit (Transmit Data Mask (TCR[TXMSK] or Receive Data Mask TCR[RXMSK]) must also be set.
FRAMESZ	Frame Size	Configures the frame size in number of bits equal to (FRAMESZ + 1). • The minimum frame size is 8 bits, or 16 bits for an 8-bit parallel transfer. • If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32-bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately. • If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO will contain the remainder bits. For example, a 72-bit transfer will consist of 3 words: the 1st and 2nd words are 32-bit, and the 3rd word is 8-bit.

67.3.2.2 Receive FIFO and data match

The receive FIFO stores receive data during SPI bus transfers. When TCR[RXMSK] = 1, the received data is discarded instead of storing the received data in the receive FIFO.

Receive data supports a receive data match function that can match received data against one of two words in the DMR0 and DMR1 registers or against a masked data word. The data match function can also be configured to compare only the first one or two received data words since the start of the frame.

- Received data that is already discarded because TCR[RXMSK] = 1 cannot cause the data match to set, and delays the match on the first received data word, until all discarded data is received.
- The receiver match function can also be configured to discard all received data until a data match is detected, using the CFGR0[RDMO] bit.
- After a receive data match, to allow all subsequent data to be received, first clear the CFGR0[RDMO] bit, then clear the SR[DMF] bit.

67.3.2.3 Partial Received Word

When the PCS negates and the receive shift register has shifted in a partial word, the receive shift register can be configured to discard the partial word or to store it in the receive FIFO. This is controlled by the CFGR1[PARTIAL] configuration bit.

A partial word is defined as less than FRAMESZ bits (when FRAMESZ is equal or less than 32 bits, or it is the last word in a multi-word frame) or less than 32 bits (when FRAMESZ is greater than 32 bits and not the last word in a multi-word frame).

A single bit frame is not supported. A partial received word of 1 bit is fine, but a partial received frame of 1 bit is not supported.

67.3.2.4 Clocked interface

The LPSPI module supports interfacing to external masters that provide only clock and data pins (PCS is not required). This interface requires:

- Using Clock Phase TCR[CPHA] = 1 (data is changed on the leading edge of SCK and captured on the following edge)
- Configuring the PCS input to be always asserted (CFGR1[PCSPOLn] = 1). For example, to configure PCS[0] to be always asserted, set PCSPOL[0] = 1, and do not configure PCS[0] in the pin muxing. The chip-level drives PCS to a certain value (ideally 1), CFGR1[PCSPOLn] could be used to invert that value.
- Setting CFGR1[AUTOPCS] = 1 (Automatic PCS generation is enabled). When CFGR1[AUTOPCS] = 1, a minimum of 4 LPSPI functional clock cycles (divided by PRESCALE configuration) is required between the last SCK edge of one word and the first SCK edge of the next word.

67.3.3 Low power modes

Table 366. Low power modes

Chip mode	LPSPI operation
Run	Normal operation

67.3.4 Debug mode

Table 367. Debug mode

Chip mode	LPSPI operation
Debug (the core is in Debug/ Halted mode)	Can continue operating in Debug mode, if the CR[DBGEN] = 1.

67.3.5 Interrupts and DMA Requests

The next table lists the slave mode sources (status flags) that can generate LPSPI interrupts and LPSPI slave transmit/receive DMA requests.

Table 368. LPSPI Interrupts and DMA Requests

Status (SR)		Description	Can generate		
Status Flag	Name		Interrupt?	DMA Request?	Low Power Wakeup?
TDF	Transmit Data Flag	Data can be written to transmit FIFO, as configured by the Transmit FIFO Watermark FCR[TXWATER]	Y	TX	Y
RDF	Receive Data Flag	Data can be read from the receive FIFO, as configured by the Receive FIFO Watermark FCR[RXWATER]	Y	RX	Y
WCF	Word Complete Flag	Word is complete, the last bit of the word has been sampled	Y	N	Y
FCF	Frame Complete Flag	Frame is complete, and PCS has negated	Y	N	Y
TCF	Transfer Complete Flag	Transfer is complete, PCS has negated, and the transmit/command FIFO is empty	Y	N	Y
TEF	Transmit Error Flag	Indicates a transmit/command FIFO underrun. In master mode when CFGR1[NOSTALL] = 0 (transfers stall when transmit FIFO is empty), the Transmit Error Flag bit cannot set.	Y	N	Y
REF	Receive Error Flag	Receive error flag, indicates a receive FIFO overflow. In master mode when CFGR1[NOSTALL] = 0 (transfers stall when receive FIFO is full), the Receive Error Flag bit cannot set.	Y	N	Y
DMF	Data Match Flag	Indicates that the received data has matched the configured data match value	Y	N	Y
MBF	Module Busy Flag	LPSPI is busy performing a SPI bus transfer	N	N	N

67.3.6 Clocks

Table 369. LPSPI Clocks

LPSPI Functional clock	• The LPSPI functional clock is asynchronous to the bus clock. • If the LPSPI functional clock remains enabled in low power modes, then LPSPI can perform SPI bus transfers and low power wakeups, in both master and slave modes.

Table continues on the next page...

Table 369. LPSPI Clocks (continued)

	• The LPSPI divides the functional clock by a prescaler; the resulting frequency must be at least 2 times faster than the SPI external clock frequency (SCK).
External clock	• The LPSPI shift register is clocked directly by the SCK clock. • How the SCK clock is generated or supplied depends upon the mode (master or slave): — In master mode: the SCK clock is generated internally. — In slave mode: the SCK clock is supplied externally.
Bus clock	The bus clock is only used for bus accesses to the LPSPI control and configuration registers. The bus clock frequency must be high enough to support the data bandwidth requirements of the LPSPI registers, including the FIFOs.

For chip-specific clocking information, see the Clocking chapter.

67.3.7 Resets

Table 370. Resets

Chip reset	Resets the LPSPI logic and registers to their default state.
Software reset	• Resets the LPSPI logic and registers to their default state, except for the Control Register. • The LPSPI software reset is in the Control Register CR[RST].
FIFO resets	• Resets the transmit/command FIFO and the receive FIFO. • The Reset Transmit FIFO field, CR[RTF] and the Reset Receive FIFO field, CR[RRF] are write-only bits. • After being reset, a FIFO is empty.

67.3.8 Peripheral Triggers

The connection of the LPSPI peripheral triggers to other peripherals depend upon the specific device being used.

Table 371. LPSPI Triggers

Trigger	Description	Notes
Frame Output Trigger	The frame output trigger: • asserts at the end of each frame (when PCS negates) • remains asserted for one cycle of LPSPI functional clock divided by the PRESCALE configuration	LPSPI generates 2 output triggers that can be connected to other peripherals on the device.
Word Output Trigger	The word output trigger: • asserts at the end of each received word • remains asserted for one cycle of LPSPI functional clock divided by the PRESCALE configuration	
Input Trigger	To control the start of a LPSPI bus transfer, the LPSPI input trigger can be selected instead of the HREQ input.	

Table continues on the next page...

Table 371. LPSPI Triggers (continued)

Trigger	Description	Notes
	• The LPSPI input trigger is synchronized, and must assert for at least 2 cycles of the LPSPI functional clock divided by the PRESCALE configuration, so that the input trigger can be detected. • When the LPSPI module is busy, the HREQ input (and therefore the LPSPI input trigger) is ignored. • Both HREQ and the LPSPI input trigger are ignored when the module is busy. They are used to start a new transfer when the module is idle.	

67.4 Signal descriptions

Table 372. Signals

Signal	Name	Description	I/O
SCK	Serial clock	• Input in slave mode • Output in master mode	I/O
PCS[0]	Peripheral Chip Select	• Input in slave mode • Output in master mode	I/O
PCS[1] / HREQ	Peripheral Chip Select or Host Request	Host Request pin is selected when CFGR0[HREN] = 1 and CFGR0[HRSEL] = 0 • Input in either slave mode or when used as master Host Request • Output in either master mode or when used as slave Host Request	I/O
PCS[2] / DATA[2]	Peripheral Chip Select or data pin 2 during parallel data transfers	When CFGR1[PCSCFG] = 0: • Input in slave mode • Output in master mode When CFGR1[PCSCFG] = 1: • Input in half-duplex parallel data receive transfers • Output in half-duplex parallel data transmit transfers	I/O
PCS[3] / DATA[3]	Peripheral Chip Select or data pin 3 during parallel data transfers	When CFGR1[PCSCFG] = 0: • Input in slave mode • Output in master mode When CFGR1[PCSCFG] = 1: • Input in half-duplex parallel data receive transfers	I/O

Table continues on the next page...

Table 372. Signals (continued)

Signal	Name	Description	I/O
		• Output in half-duplex parallel data transmit transfers	
PCS[4] / DATA[4]	Peripheral Chip Select or data pin 4 during parallel data transfers	When CFGR1[PCSCFG] = 0: • Input in slave mode • Output in master mode When CFGR1[PCSCFG] = 11b: • Input in half-duplex parallel data receive transfers • Output in half-duplex parallel data transmit transfers	I/O
PCS[5] / DATA[5]	Peripheral Chip Select or data pin 5 during parallel data transfers	When CFGR1[PCSCFG] = 0: • Input in slave mode • Output in master mode When CFGR1[PCSCFG] = 11b: • Input in half-duplex parallel data receive transfers • Output in half-duplex parallel data transmit transfers	I/O
PCS[6] / DATA[6]	Peripheral Chip Select or data pin 6 during parallel data transfers	When CFGR1[PCSCFG] = 0: • Input in slave mode • Output in master mode When CFGR1[PCSCFG] = 11b: • Input in half-duplex parallel data receive transfers • Output in half-duplex parallel data transmit transfers	I/O
PCS[7] / DATA[7]	Peripheral Chip Select or data pin 7 during parallel data transfers	When CFGR1[PCSCFG] = 0: • Input in slave mode • Output in master mode When CFGR1[PCSCFG] = 11b: • Input in half-duplex parallel data receive transfers • Output in half-duplex parallel data transmit transfers	I/O
SOUT / DATA[0]	Serial Data Output	Can be configured as serial data input signal	I/O

Table continues on the next page...

Table 372. Signals (continued)

Signal	Name	Description	I/O
		• Used as data pin 0 in half-duplex parallel data transfers	
SIN / DATA[1]	Serial Data Input	Can be configured as serial data output signal • Used as data pin 1 in half-duplex parallel data transfers	I/O

67.5 Memory map and registers

NOTE

Writing a Read-Only (RO) register or reading a Write-Only (WO) register can cause bus errors. LPSPI does not check if programmed values in the registers are correct, so application software must take care to write valid values only.

67.5.1 LPSPI register descriptions

67.5.1.1 LPSPI memory map

LPSPI_0 base address: 4035_8000h

LPSPI_1 base address: 4035_C000h

LPSPI_2 base address: 4036_0000h

LPSPI_3 base address: 4036_4000h

LPSPI_4 base address: 404B_C000h

LPSPI_5 base address: 404C_0000h

Offset	Register	Width (In bits)	Access	Reset value

600h - 7FCh	Receive Data Burst (RDBR0 - RDBR127)	32	RO	0000_0000h

67.5.1.2 Version ID (VERID)

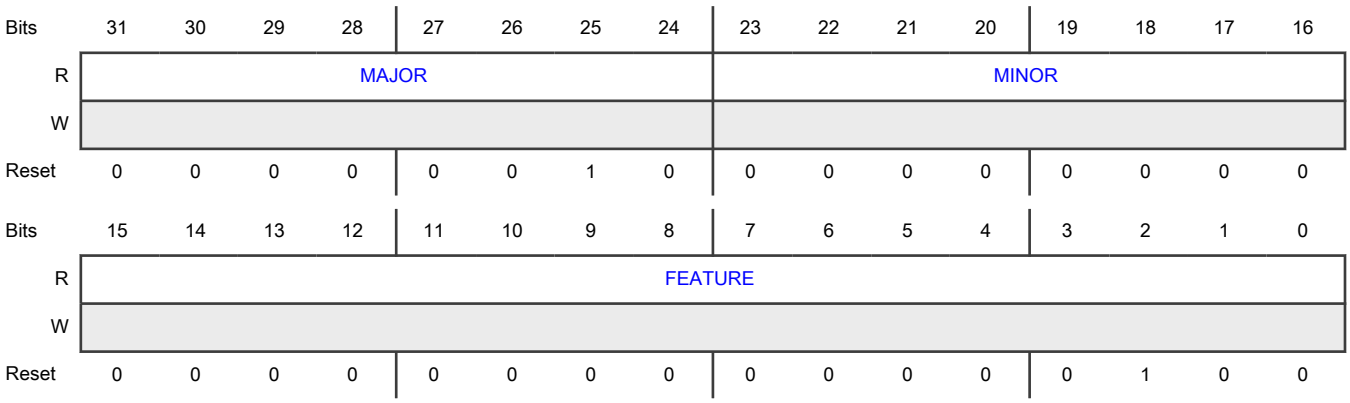
Offset

Register	Offset
VERID	0h

Function

Contains version numbers for the module design and feature set.

Diagram



Fields

Field	Function
31-24 MAJOR	Major Version Number Returns the major version number for the module specification. Read-only field.
23-16 MINOR	Minor Version Number Returns the minor version number for the module specification. Read-only field.
15-0 FEATURE	Module Identification Number Returns the feature set number. Read-only field. 0000_0000_0000_0100b - Standard feature set supporting a 32-bit shift register.

67.5.1.3 Parameter (PARAM)

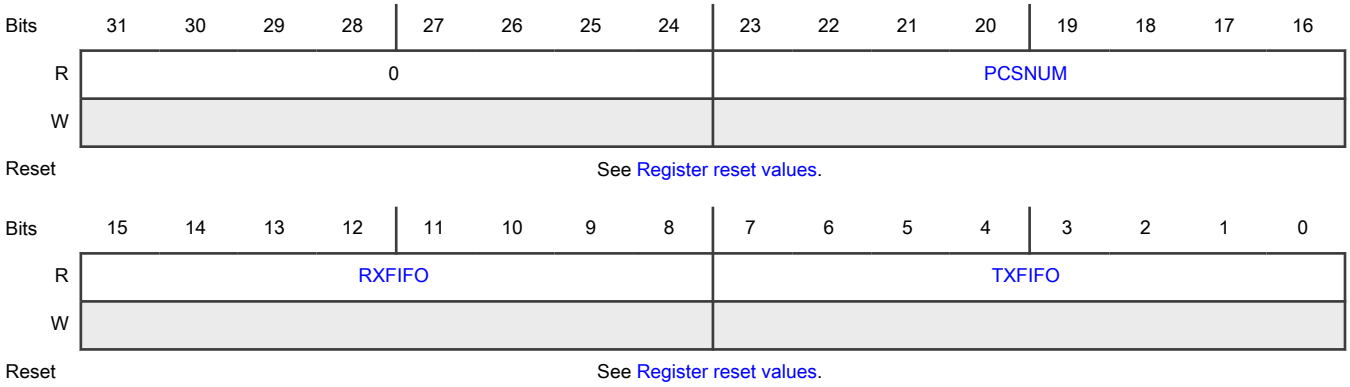
Offset

Register	Offset
PARAM	4h

Function

Contains parameter values that were implemented in the module.

Diagram



Register reset values

Register	Reset value
PARAM	LPSPI_0: 0008_0202h LPSPI_1: 0006_0202h LPSPI_2–LPSPI_5: 0004_0202h

Fields

Field	Function
31-24 —	Reserved
23-16 PCSNUM	PCS Number Sets the number of PCS pins supported by the peripheral.
15-8 RXFIFO	Receive FIFO Size Indicates the maximum number of words in the receive FIFO, which is 2^{RXFIFO}.
7-0 TXFIFO	Transmit FIFO Size Indicates the maximum number of words in the transmit FIFO, which is 2^{TXFIFO}.

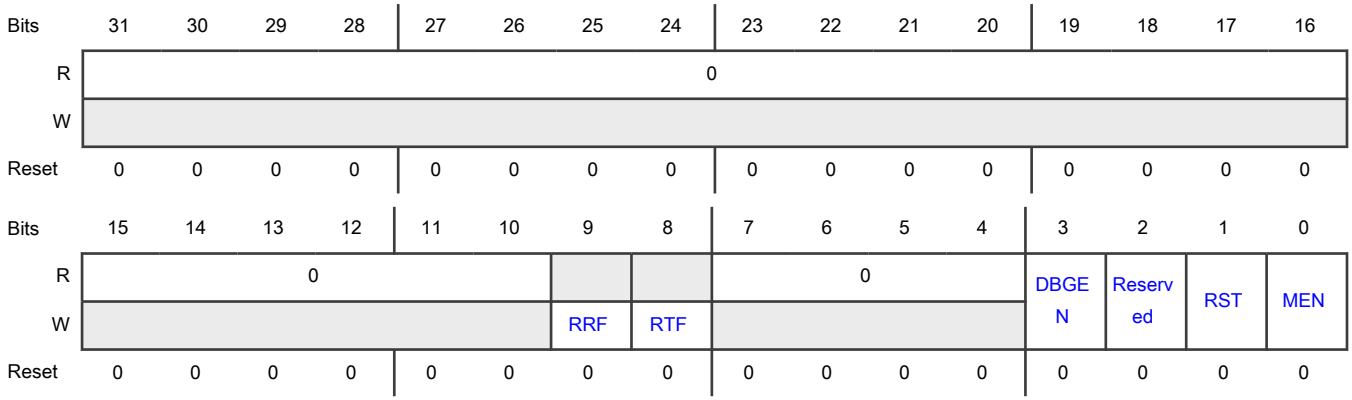
67.5.1.4 Control (CR)

Offset

Register	Offset
CR	10h

Function
Contains fields associated with the module operation.

Diagram



Fields

Field	Function
31-10 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
9 RRF	Reset Receive FIFO 0b - No effect 1b - Reset the Receive FIFO. The register bit always reads zero.
8 RTF	Reset Transmit FIFO 0b - No effect 1b - Reset the Transmit FIFO. The register bit always reads zero.
7-4 —	Reserved
3 DBGEN	Debug Enable Enables or disables the LPSPI module in debug mode. Debug Enable bit should be updated only when the LPSPI module is disabled. 0b - LPSPI module is disabled when the CPU is halted. When LPSPI is disabled, the PCS will be negated once the transmit FIFO is empty regardless of the state of TCR register. 1b - LPSPI module is enabled in debug mode
2 —	Reserved
1 RST	Software Reset Reset all internal logic and registers, except the Control Register. RST remains set until cleared by software. The reset takes effect immediately and remains asserted until negated by software. There is no minimum delay required before clearing the software reset. 0b - Module is not reset 1b - Module is reset
0 MEN	Module Enable 0b - Module is disabled 1b - Module is enabled

67.5.1.5 Status (SR)

Offset

Register	Offset
SR	14h

Function
Contains the status of data flow.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W			W1C	W1C	W1C	W1C	W1C	W1C								
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Fields

Field	Function
31-25 —	Reserved
24 MBF	Module Busy Flag In Master mode, MBF asserts when there is data to transmit and LPSPI is able to transmit (eg: HREQ asserted, etc). It negates after the PCS negates and the LPSPI master has waited half the DBT time with no new data to transmit. Slave mode asserts MBF when LPSPI is enabled and PCS is asserted. 0b - LPSPI is idle 1b - LPSPI is busy
23-14 —	Reserved
13 DMF	Data Match Flag Indicates that the received data has matched the DMR0[MATCH0] and/or DMR1[MATCH1] fields (as configured by CFGR1[MATCFG]. 0b - Have not received matching data 1b - Have received matching data
12 REF	Receive Error Flag The Receive Error Flag sets when the Receiver FIFO overflows. When the Receive Error Flag is set, it is recommended to first end the transfer, empty the Receive FIFO, clear the Receive Error Flag and then restart the transfer from the beginning. 0b - Receive FIFO has not overflowed 1b - Receive FIFO has overflowed
11 TEF	Transmit Error Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
	The Transmit Error Flag sets when the Transmit FIFO underruns. When the Transmit Error Flag is set, it is recommended to first end the transfer, clear the Transmit Error Flag and then restart the transfer from the beginning. 0b - Transmit FIFO underrun has not occurred 1b - Transmit FIFO underrun has occurred
10 TCF	Transfer Complete Flag In Master mode when LPSPI returns to idle state with the transmit FIFO empty, the Transfer Complete Flag sets. 0b - All transfers have not completed 1b - All transfers have completed
9 FCF	Frame Complete Flag The Frame Complete Flag sets at the end of each frame transfer, when the PCS negates. 0b - Frame transfer has not completed 1b - Frame transfer has completed
8 WCF	Word Complete Flag The Word Complete Flag sets when the last bit of a received word is sampled. 0b - Transfer of a received word has not yet completed 1b - Transfer of a received word has completed
7-2 —	Reserved
1 RDF	Receive Data Flag The Receive Data Flag is set whenever the number of words in the receive FIFO is greater than the value in FCR[RXWATER]. 0b - Receive Data is not ready 1b - Receive data is ready
0 TDF	Transmit Data Flag The Transmit Data Flag is set whenever the number of words in the transmit FIFO is equal or less than the value in FCR[TXWATER]. 0b - Transmit data not requested 1b - Transmit data is requested

67.5.1.6 Interrupt Enable (IER)

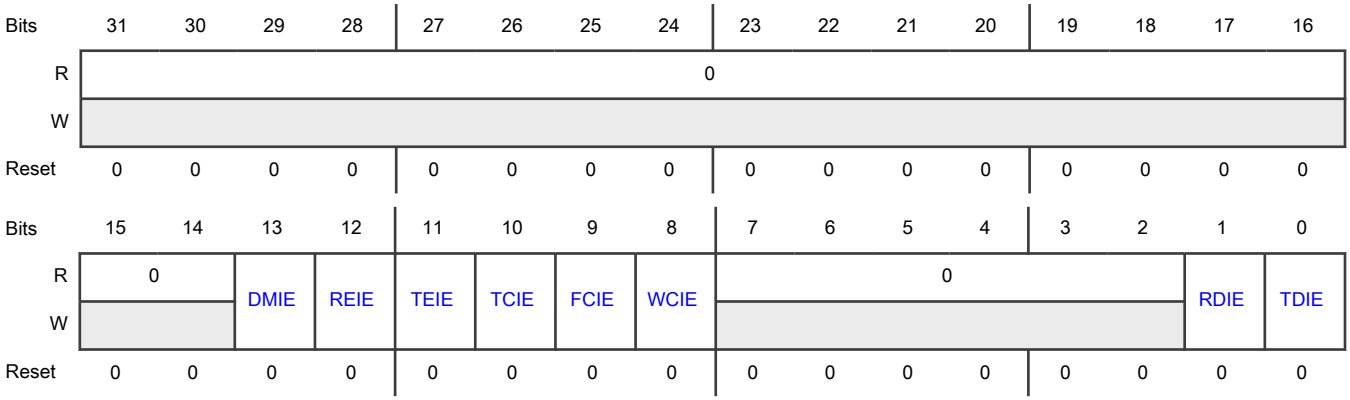
Offset

Register	Offset
IER	18h

Function

Enables interrupts based on data flow and errors.

Diagram



Fields

Field	Function
31-14 —	Reserved
13 DMIE	Data Match Interrupt Enable 0b - Disabled 1b - Enabled
12 REIE	Receive Error Interrupt Enable 0b - Disabled 1b - Enabled
11 TEIE	Transmit Error Interrupt Enable 0b - Disabled 1b - Enabled
10 TCIE	Transfer Complete Interrupt Enable 0b - Disabled 1b - Enabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
9 FCIE	Frame Complete Interrupt Enable 0b - Disabled 1b - Enabled
8 WCIE	Word Complete Interrupt Enable 0b - Disabled 1b - Enabled
7-2 —	Reserved
1 RDIE	Receive Data Interrupt Enable 0b - Disabled 1b - Enabled
0 TDIE	Transmit Data Interrupt Enable 0b - Disabled 1b - Enabled

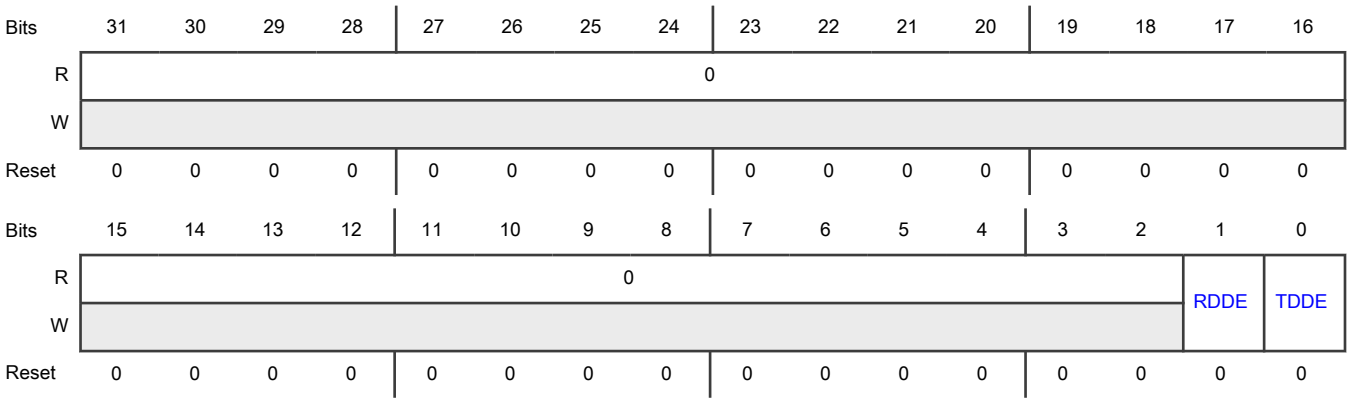
67.5.1.7 DMA Enable (DER)

Offset

Register	Offset
DER	1Ch

Function
Enables DMA data flow.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 RDDE	Receive Data DMA Enable 0b - DMA request is disabled 1b - DMA request is enabled
0 TDDE	Transmit Data DMA Enable 0b - DMA request is disabled 1b - DMA request is enabled

67.5.1.8 Configuration 0 (CFGR0)

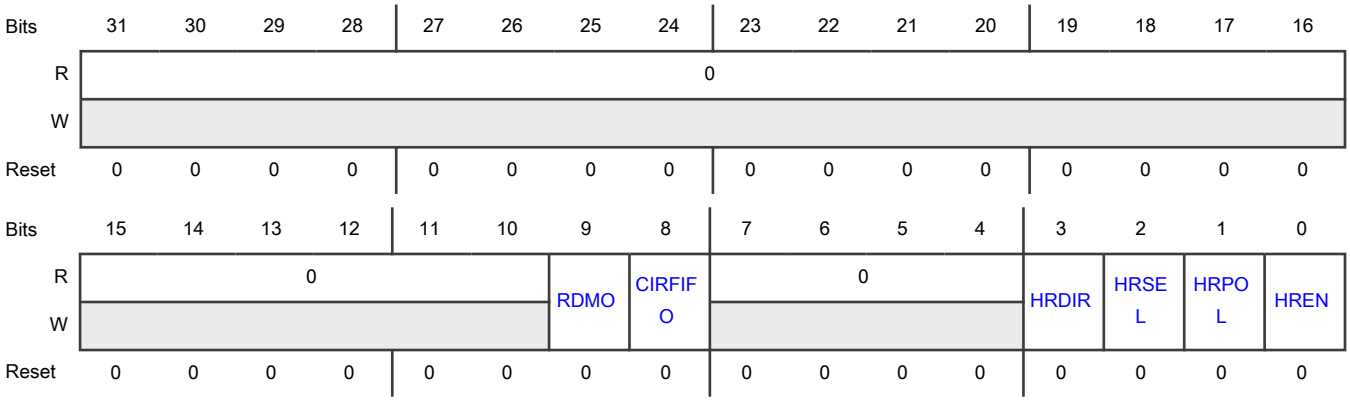
Offset

Register	Offset
CFGR0	20h

Function

Includes additional fields to configure LPSPI including Circular FIFO Enable and Receive Data Match Only.

Diagram



Fields

Field	Function
31-10 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
9 RDMO	Receive Data Match Only When RDMO is enabled, all received data that does not cause the Data Match Flag (SR[DMF]) to set is discarded. • Set the RDMO bit when LPSPI is idle and SR[DMF] = 0. • After SR[DMF] = 1, the RDMO bit configuration is ignored. • When disabling RDMO and to ensure that no receive data is lost, before clearing SR[DMF], first clear RDMO. 0b - Received data is stored in the receive FIFO as in normal operations 1b - Received data is discarded unless the SR[DMF] = 1
8 CIRFIFO	Circular FIFO Enable When enabled, the transmit FIFO read pointer is saved to a temporary register. The transmit FIFO is emptied as it normally is, but after LPSPI is idle and the transmit FIFO is empty, then the read pointer value is restored from the temporary register. This restoring of the read pointer causes the contents of the transmit FIFO to be cycled through repeatedly. **NOTE** The read pointer is restored for as long as the CIRFIFO is set. Writing additional words to the FIFO after setting CIRFIFO adds them to the end of the FIFO, up to the size of the transmit FIFO. 0b - Circular FIFO is disabled 1b - Circular FIFO is enabled
7-4 —	Reserved
3 HRDIR	Host Request Direction Configures the direction of the HREQ pin. The HREQ pin should only be configured as output in Slave mode. The HREQ pin direction is input for Master mode. 0b - HREQ pin is configured as input 1b - HREQ pin is configured as output
2 HRSEL	Host Request Select Selects the source of the host request input. When the host request function is enabled with the HREQ pin, the PCS[1] function is disabled. 0b - Host request input is the HREQ pin 1b - Host request input is the input trigger
1 HRPOL	Host Request Polarity Configures the polarity of the host request pin or trigger.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - HREQ pin or input trigger is active high 1b - HREQ pin or input trigger is active low
0 HREN	Host Request Enable When enabled in Master mode, LPSPI only starts a new SPI bus transfer if the host request input is asserted. When LPSPI is busy, the host request input is ignored. When enabled in Slave mode, the HREQ output pin asserts when data is available to be transmitted. 0b - Host request is disabled 1b - Host request is enabled

67.5.1.9 Configuration 1 (CFGR1)

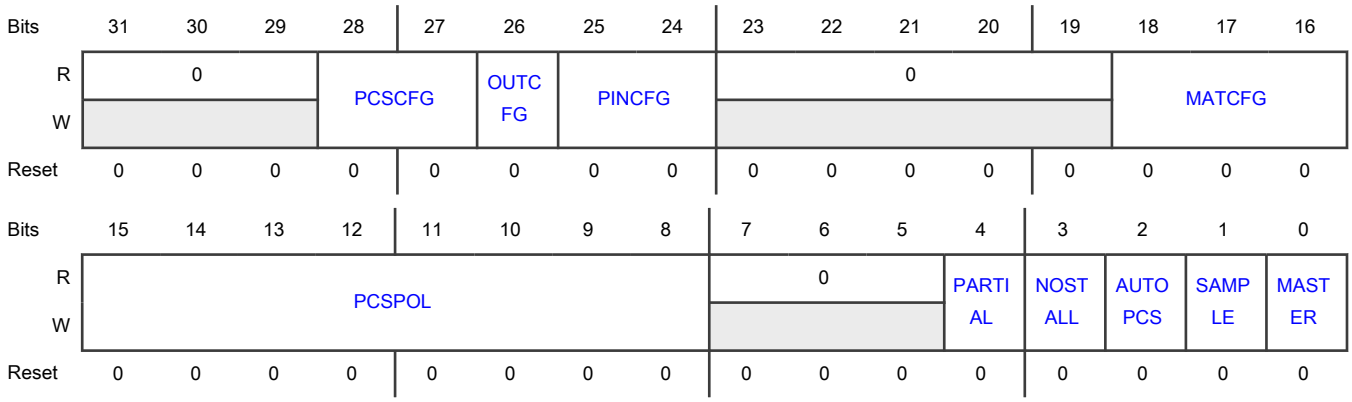
Offset

Register	Offset
CFGR1	24h

Function

CFGR1 should only be written when LPSPI is disabled.

Diagram



Fields

Field	Function
31-29 —	Reserved
28-27	Peripheral Chip Select Configuration

Table continued from the previous page...

<table>
<tr><th>Field</th><th>Function</th></tr>
<tr><td>PCSCFG</td><td>When performing parallel transfers, PCSCFG must be configured to enable the desired transfer.

NOTE
This field is not supported in every instance. The following table includes only supported registers.

<table>
<tr><th>Instance</th><th>Field supported in</th><th>Field not supported in</th></tr>
<tr><td>LPSPI_0</td><td>CFGR1</td><td>—</td></tr>
<tr><td>LPSPI_1</td><td>CFGR1[27]</td><td>CFGR1[28]</td></tr>

</table>
00b - PCS[7:2] are configured for chip select function
01b - PCS[3:2] are configured for half-duplex 4-bit transfers (PCS[3:2] = DATA[3:2])
11b - PCS[7:2] are configured for half-duplex 4-bit and 8-bit transfers (PCS[7:2] = DATA[7:2])</td></tr>
<tr><td>26
OUTCFG</td><td>Output Configuration
Configures if the output data is tristated between accesses (PCS is negated). If performing half-duplex transfers, the Output Configuration bit must be set.
0b - Output data retains last value when chip select is negated
1b - Output data is tristated when chip select is negated</td></tr>
<tr><td>25-24
PINCFG</td><td>Pin Configuration
Configures which pins are used for input and output data during serial transfers. When performing parallel transfers, the Pin Configuration field is ignored.
00b - SIN is used for input data and SOUT is used for output data
01b - SIN is used for both input and output data, only half-duplex serial transfers are supported
10b - SOUT is used for both input and output data, only half-duplex serial transfers are supported
11b - SOUT is used for input data and SIN is used for output data</td></tr>
<tr><td>23-19
—</td><td>Reserved</td></tr>
<tr><td>18-16</td><td>Match Configuration
Configures the condition that causes the DMF to set.</td></tr>
</table>

Table continues on the next page...

Table continued from the previous page...

<table>
<tr><th>Field</th><th>Function</th></tr>
<tr><td>MATCFG</td><td>

NOTE

Syntax: * is boolean AND, + is boolean OR

000b - Match is disabled

001b - Reserved

010b - Match is enabled is 1st data word is MATCH0 or MATCH1. Match is enabled, if 1st data word equals MATCH0 OR MATCH1, that is (*1st data word* = MATCH0 + MATCH1)

011b - Match is enabled on any data word equal MATCH0 or MATCH1. Match is enabled, if any data word equals MATCH0 OR MATCH1, that is (*any data word* = MATCH0 + MATCH1)

100b - Match is enabled on data match sequence. Match is enabled, if 1st data word equals MATCH0 AND 2nd data word equals MATCH1, that is [(*1st data word* = MATCH0) * (*2nd data word* = MATCH1)]

101b - Match is enabled on data match sequence. Match is enabled, if any data word equals MATCH0 AND the next data word equals MATCH1, that is [(*any data word* = MATCH0) * (*next data word* = MATCH1)]

110b - Match is enabled. Match is enabled, if (1st data word AND MATCH1) equals (MATCH0 AND MATCH1), that is [(*1st data word* * MATCH1) = (MATCH0 * MATCH1)]

111b - Match is enabled. Match is enabled, if (any data word AND MATCH1) equals (MATCH0 AND MATCH1), that is [(*any data word* * MATCH1) = (MATCH0 * MATCH1)]

</td></tr>
<tr><td>15-8
PCSPOL</td><td>

Peripheral Chip Select Polarity

Configures the polarity of each Peripheral Chip Select pin. Each PCSPOL bit position (let's call it *n*) corresponds to a PCS[*n*] pin. For example, PCSPOL[0] is chip select 0 (at PCS[0] pin), and PCSPOL[1] is chip select 1 (at PCS[1] pin). If a PCSPOL bit:

- = 0, then the PCS[*n*] pin is active low.
- = 1, then the PCS[*n*] pin is active high.

NOTE

The entire PCSPOL field is not fully supported in every LPSPI module instance. Refer to the chip-specific information for LPSPI.

NOTE

This field is not supported in every instance. The following table includes only supported registers.

<table>
<tr><th>Instance</th><th>Field supported in</th><th>Field not supported in</th></tr>
<tr><td>LPSPI_0</td><td>CFGR1</td><td>—</td></tr>
<tr><td>LPSPI_1</td><td>CFGR1[13–8]</td><td>CFGR1[15–14]</td></tr>
<tr><td>LPSPI_2</td><td>CFGR1[11–8]</td><td>CFGR1[15–12]</td></tr>
</table>

</td></tr>
</table>

Table continues on the next page...

Table continued from the previous page...

Field	Function
	<table><tr><th>Instance</th><th>Field supported in</th><th>Field not supported in</th></tr><tr><td>LPSPI_3</td><td>CFGR1[11–8]</td><td>CFGR1[15–12]</td></tr><tr><td>LPSPI_4</td><td>CFGR1[11–8]</td><td>CFGR1[15–12]</td></tr><tr><td>LPSPI_5</td><td>CFGR1[11–8]</td><td>CFGR1[15–12]</td></tr></table>
7-5 ——	Reserved
4 PARTIAL	Partial Enable In Slave mode, when PCS negates then any partially received word can be either discarded or stored in the receive FIFO. 0b - Partial words in the receive shift register when PCS negates are discarded. 1b - Partial words in the receive shift register when PCS negates are stored in the receive FIFO.
3 NOSTALL	No Stall In Master mode, LPSPI stalls transfers when the transmit FIFO is empty or when the receive FIFO is full, ensuring that no transmit FIFO underrun or receive FIFO overrun can occur. Setting the No Stall bit disables this functionality. 0b - Transfers stall when the transmit FIFO is empty or the receive FIFO is full 1b - Transfers do not stall, allowing transmit FIFO underruns or receive FIFO overruns to occur
2 AUTOPCS	Automatic PCS For correct operations, the LPSPI slave normally requires the PCS to negate between frames. Setting the AUTOPCS bit causes LPSPI to generate an internal PCS signal at the end of each transfer word when the Clock Phase bit TCR[CPHA] = 1. • When the Automatic PCS bit is set, the SCK must remain idle for at least 4 LPSPI functional clock cycles (divided by the Prescaler Value TCR[PRESCALE] configuration) between each word, to ensure correct operations • In Master mode, the Automatic PCS bit is ignored 0b - Automatic PCS generation is disabled 1b - Automatic PCS generation is enabled
1 SAMPLE	Sample Point When set, the LPSPI master samples the input data on a delayed loopback SCK clock edge, which improves the setup time when sampling data. • The input data setup time in Master mode with delayed SCK edge is equal to the input data setup time in Slave mode

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• In Slave mode, the SAMPLE bit is ignored 0b - Input data is sampled on SCK edge 1b - Input data is sampled on delayed SCK edge
0 MASTER	Master Mode Configures LPSPI in Master or Slave mode. The Master Mode bit directly controls the direction of the SCK and PCS pins. 0b - Slave mode 1b - Master mode

67.5.1.10 Data Match 0 (DMR0)

Offset

Register	Offset
DMR0	30h

Function

For the Data Match register to be available, set CFGR0[RDMO] = 1. Do not change the value stored in DMR0 while CFGR0[RDMO] is enabled.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-24 SCKSCK	SCK Inter-Frame Delay In Master mode: • Configures the delay from the last SCK pulse of a frame and the first SCK pulse of the following frame, in a continuous transfer. • The delay is equal to (SCKSCK + 1) cycles of the LPSPI functional clock divided by the Prescaler Value TCR[PRESCALE] configuration. • The minimum delay is 1 cycle. **NOTE** For backwards compatibility, writing CCR[DBT] updates CCR1[SCKSCK] with the value written.
23-16 PCSPCS	PCS to PCS delay In Master mode: • Configures the delay from the PCS negation to the next PCS assertion. • The delay is equal to (PCSPCS + PCSPCS + 2) cycles of the LPSPI functional clock divided by the Prescaler Value TCR[PRESCALE] configuration. • The minimum delay is 2 cycles. • Half of the delay (PCSPCS + 1) occurs before PCS assertion and the other half of the delay (PCSPCS + 1) occurs after PCS negation. If the command word is updated between 2 transfers, then the command word is updated half-way between the PCS negation of the last transfer and PCS assertion of the next transfer. • The command word sets which PCS signal is used, the polarity/phase of the SCK signal, and the Prescaler Value.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE For backwards compatibility, writing CCR[DBT] updates CCR1[PCSPCS] with (DBT/2) rounded up.
15-8 SCKHLD	SCK Hold In Master mode, the SCK Hold configures the hold phase of the SCK pin. • The hold phase is the delay between the SCK edge that samples the receive data and the SCK edge that drives the transmit data. • This is the SCK low period for CPHA=0, CPOL=1 and CPHA=1, CPOL =0 and the SCK high period for CPHA=0, CPOL=0 and CPHA=1, CPOL=1. • The SCK hold phase delay is equal to (SCKHLD + 1) cycles of the LPSPI functional clock divided by the Prescaler Value TCR[PRESCALE] configuration. • The minimum delay is 1 cycle. • The SCK period is equal to (SCKSET + SCKHLD + 2) cycles of the LPSPI functional clock divided by the Prescaler Value TCR[PRESCALE] configuration. • The SCK duty cycle is based on the difference between SCKSET and SCKHLD, configure both fields to the same value for 50/50 duty cycle. See Figure 360. **NOTE** For backwards compatibility, writing CCR[SCKDIV] updates CCR1[SCKHLD] with (SCKDIV/2) rounded down.
7-0 SCKSET	SCK Setup In Master mode, the SCK Setup configures the setup phase of the SCK pin. • The setup phase is the delay between the SCK edge that drives the transmit data and the SCK edge that samples the receive data. • This is the SCK high period for CPHA=0, CPOL=1 and CPHA=1, CPOL =0 and the SCK low period for CPHA=0, CPOL=0 and CPHA=1, CPOL=1. • The SCK setup phase delay is equal to (SCKSET + 1) cycles of the LPSPI functional clock divided by the Prescaler Value TCR[PRESCALE] configuration. • The minimum delay is 1 cycle. • The SCK period is equal to (SCKSET + SCKHLD + 2) cycles of the LPSPI functional clock divided by the Prescaler Value TCR[PRESCALE] configuration. • The SCK duty cycle is based on the difference between SCKSET and SCKHLD, configure both fields to the same value for 50/50 duty cycle. See Figure 360.

67.5.1.16 Transmit Command (TCR)

Offset

Register	Offset
TCR	60h

Function

Writes to either the Transmit Command Register or Transmit Data Register pushes the data into the transmit FIFO, in the order that the data are written. The Command Register should only be written using 32-bit writes. Command Register writes are tagged and cause the command register to update, after that entry reaches the top of the FIFO. This allows changes to the command word and the transmit data itself to be interleaved. That is, the writes to the two registers can be interleaved (write command word, then data word, then command word, and so on). Changing the command word causes all subsequent SPI bus transfers to be performed using the new command word.

- **In Master mode,** writing a new command word does not initiate a new transfer, unless TXMSK is set. Transfers are initiated by transmit data in the transmit FIFO, or by a new command word (with TXMSK set). Hardware clears TXMSK when the PCS negates.
- **In Master mode,** if the command word is changed before an existing frame has completed, then the existing frame terminates and the command word then updates. The command word can be changed during a continuous transfer, if CONTC of the new command word is set and the command word is written on a frame size boundary.
- **In Slave mode,** the command word should be changed only when LPSPI is idle and there is no SPI bus transfer.

Avoid register reading problems: Reading the Transmit Command Register returns the current state of the command register. Reading the Transmit Command Register at the same time that the Transmit Command Register is loaded from the transmit FIFO, can return an incorrect Transmit Command Register value. It is recommended:

- Read the Transmit Command Register when the transmit FIFO is empty,
- Read the Transmit Command Register more than once and then compare the returned values.

Field	Function
	0b - Byte swap is disabled 1b - Byte swap is enabled
21 CONT	Continuous Transfer • In Master mode, CONT keeps the PCS asserted at the end of the frame size, until a command word is received that starts a new frame. • In Slave mode, when CONT is enabled, LPSPI only transmits the first FRAMESZ bits; after which LPSPI transmits received data (assuming a 32-bit shift register) until the next PCS negation. 0b - Continuous transfer is disabled 1b - Continuous transfer is enabled
20 CONTC	Continuing Command In Master mode, the CONTC bit allows the command word to be changed within a continuous transfer. • The initial command word must enable continuous transfer (CONT = 1), • the continuing command must set this bit (CONTC = 1), • and the continuing command word must be loaded on a frame size boundary. For example, if the continuous transfer has a frame size of 64-bits, then a continuing command word must be loaded on a 64-bit boundary. In Slave mode, the Continuing Command bit modifies the internal RXMSK/TXMSK configuration after the first FRAMESZ bits and until the PCS negation. • Receive data is discarded after the first FRAMESZ bits, if CONT is also set this does not block the transmission of received data. • Transmit data is not masked after the first FRAMESZ bits, this allows the first FRAMESZ bits to be received and a response transmitted. 0b - Command word for start of new transfer 1b - Command word for continuing transfer
19 RXMSK	Receive Data Mask When set, receive data is masked (receive data is not stored in receive FIFO). 0b - Normal transfer 1b - Receive data is masked
18 TXMSK	Transmit Data Mask When set, transmit data is masked (no data is loaded from transmit FIFO and output pin is tristated). In Master mode, the TXMSK bit initiates a new transfer which cannot be aborted by another command word; the TXMSK bit is cleared by hardware at the end of the transfer. 0b - Normal transfer 1b - Mask transmit data

Field	Function
15-12 —	Reserved
11-0 FRAMESZ	Frame Size Configures the frame size in number of bits equal to (FRAMESZ + 1). • The minimum frame size is 8 bits, or 16 bits for an 8-bit transfer • If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32-bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately. • If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO contains the remainder bits. For example, a 72-bit transfer consists of 3 words: the 1st and 2nd words are 32 bits, and the 3rd word is 8 bits.

67.5.1.17 Transmit Data (TDR)

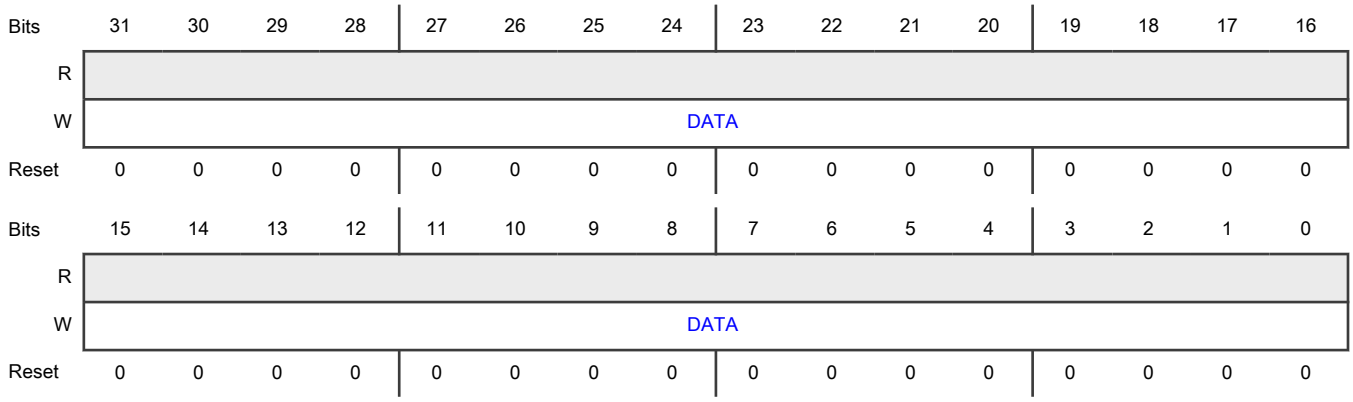
Offset

Register	Offset
TDR	64h

Function

Writes to either the Transmit Command Register or Transmit Data Register push the data into the transmit FIFO, in the order that the data was written. The Data Register can be written using 32-bit, 16-bit, or 8-bit writes, but each write pushes data into the FIFO with zero pushed in unwritten bytes.

Diagram



Fields

Field	Function
31-0 DATA	Transmit Data Both 8-bit and 16-bit writes of transmit data zero-extend the data written and push the data into the transmit FIFO. To zero-extend 8-bit and 16-bit writes (to 32 bits), means that the higher order (most significant) empty parts of the 8-bit and 16-bit writes are filled with zeroes.

Chapter 68
Low Power Inter-Integrated Circuit (LPI2C)

68.1 Chip-specific LPI2C information

68.1.1 LPI2C instances and configuration

This chip has two instances of LPI2C: LPI2C_0 and LPI2C_1.

Table 373. LPI2C configuration

Instances	TX FIFO Size	RX FIFO Size	SMBus[1]	Slave Mode Enable
LPI2C_0	4x11 bit	4x8 bit	Yes	Yes
LPI2C_1	4x11 bit	4x8 bit	Yes	Yes

1. System Management Bus

- LPI2C slave mode operation supports up to high speed mode = 3.4MHz (3.4 Mbps data rate; effective data rate reduces according to I2C protocol).
- LPI2C master mode operation supports up to fast Mode = 400KHz (400 kbps data rate; effective data rate reduces according to I2C protocol).
- The LPI2C module includes SMBus (System Management Bus) support and DMA support.
- LPI2C RX FIFO is 8-bit and TX FIFO is 11-bit (8bit data + 3bit command)
- LPI2C supports fast data communication as per I2C standard v3.0.

68.2 Overview

The LPI2C is a low power Inter-Integrated Circuit (I2C) module that supports an efficient interface to an I^2C bus as a master and/or as a slave.

- Implements logic support for standard-mode, fast-mode, fast-mode plus and ultra-fast modes of operation.
- Uses little CPU overhead, with DMA offloading of FIFO register accesses.

The LPI2C module also complies with the System Management Bus (SMBus) Specification, version 3. The SMBus is a single-ended simple two-wire bus, which is typically used for low bandwidth communications.

NOTE

The I^2C (Inter-Integrated Circuit) serial bus is multi-master, multi-slave, packet-switched, and single-ended, and is often used to attach microcontroller ICs to lower-speed peripheral ICs.

68.2.1 Block diagram

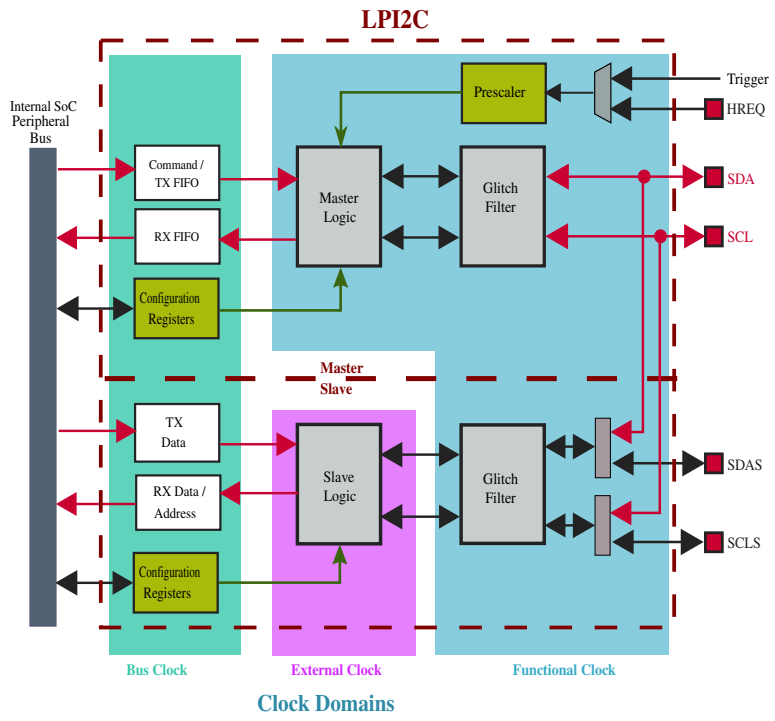

Figure 362. LPI2C block diagram

68.2.2 Features

The LPI2C supports:

- Standard, Fast, Fast+ and Ultra Fast modes are supported
- High speed mode (HS) in slave mode
- Multi-master support, including synchronization and arbitration. Multi-master means any number of master nodes can be present. Additionally, master and slave roles may be changed between messages (after a STOP is sent).
- Clock stretching: Sometimes multiple I2C nodes may be driving the lines at the same time. If any I2C node is driving a line low, then that line will be low. I2C nodes that are starting to transmit a logical one (by letting the line float high) can detect that the line is low, and thereby know that another I2C node is active at the same time.
  - When node detection is used on the SCL line, it is called *clock stretching*, and clock stretching is used as a I2C flow control mechanism.
  - When node detection is used on the SDA line, it is called *arbitration*, and arbitration ensures that there is only one I2C node transmitter at a time.
- General call, 7-bit and 10-bit addressing
- Software reset, START byte and Device ID (also require software support)

The LPI2C master supports:

- Command/transmit FIFO of 4 words (8-bit transmit data + 3-bit command).
- Receive FIFO of 4 words (8-bit receive data).
- Command FIFO will wait for idle I2C bus before initiating transfer
- Command FIFO can initiate (repeated) START and STOP conditions and one or more master-receiver transfers

- STOP condition can be generated from command FIFO, or generated automatically when the transmit FIFO is empty
- Host request input to control the start time of an I2C bus transfer
- Flexible receive data match can generate interrupt on data match and/or discard unwanted data
- Flag and optional interrupt to signal Repeated START condition, STOP condition, loss of arbitration, unexpected NACK, and command word errors
- Supports configurable bus idle timeout and pin-stuck-low timeout

The LPI2C slave supports:

- Separate I2C slave registers to minimize software overhead because of master/slave switching
- Support for 7-bit or 10-bit addressing, address range, SMBus alert and general call address
- Transmit data register that supports interrupt or DMA requests
- Receive data register that supports interrupt or DMA requests
- Software-controllable ACK or NACK, with optional clock stretching on ACK/NACK bit
- Configurable clock stretching, to avoid transmit FIFO underrun and receive FIFO overrun errors
- Flag and optional interrupt at end of packet, STOP condition, or bit error detection

68.3 Functional description

68.3.1 Master Mode

The LPI2C master logic operates independently from the slave logic to perform all master mode transfers on the I2C bus.

Transmit and Command FIFO commands

The transmit FIFO stores command data to initiate the various I2C operations. The following operations can be initiated through commands in the transmit FIFO:

- START or Repeated START condition with address byte and expecting ACK or NACK.
- Transmit data (this is the default for zero extended byte writes to the transmit FIFO).
- Receive 1-256 bytes of data (can also be configured to discard receive data and not store in receive FIFO).
- STOP condition (can also be configured to send STOP condition when transmit FIFO is empty).

Multiple transmit and receive commands can be inserted between the START condition and STOP conditon; transmit and receive commands must not be interleaved (to comply with the I2C specification). The receive data command and the receive data and discard commands can be interleaved, to ensure that only the desired received data is stored in the receive FIFO (or compared with the data match logic).

The LPI2C master automatically transmits a NACK on the last byte of a receive data command unless the next command in the FIFO is also a receive data command. A NACK is also automatically transmitted if the transmit FIFO is empty when a receive data command completes.

The LPI2C master supports 10-bit addressing through a (repeated) START condition, followed by a transmit data byte containing the second address byte, followed by any number of data bytes with the master-transmit data.

A START or Repeated START condition that is expecting a NACK (for example,HS-mode master code) must be followed by a STOP or (repeated) START condition.

Master operations

Whenever the LPI2C is enabled, it monitors the I2C bus to detect when the I2C bus is idle (MSR[BBF]). The I2C bus is no longer considered idle if either SCL or SDA are low, and the I2C bus becomes idle if a STOP condition is detected or if a bus idle timeout

is detected (as configured by MCFGR2[BUSIDLE]). After the I2C bus is idle, the transmit FIFO is not empty, and the host request is either asserted or disabled, then the LPI2C master initiates a transfer on the I2C bus. This involves the following steps:

- Wait the bus idle time equal to (MCCR0[CLKLO] + 1) multiplied by the prescaler (MCFGR1[PRESCALE]).
- Transmit a START condition and address byte using the timing configuration in Master Clock Configuration 0 (MCCR0); if a high speed mode transfer is configured, then the timing configuration from Master Clock Configuration 1 (MCCR1) is used instead.
- Perform master-transmit or master-receive transfers, as configured by the transmit FIFO.
- Transmit NACK on the last byte of a master-receive transfer, unless the next command in the transmit FIFO is also a receive data command and the transmit FIFO is not empty.
- Transmit a Repeated START or STOP condition as configured by the transmit FIFO and/or MCFGR1[AUTOSTOP]. A repeated START can change which timing configuration register is used.

When the LPI2C master is disabled (either due to MCR[MEN] being clear or automatically due to mode entry), the LPI2C continues to empty the transmit FIFO until a STOP condition is transmitted. However, the LPI2C will no longer stall the I2C bus waiting for the transmit or receive FIFO, and after the transmit FIFO is empty, the LPI2C generates a STOP condition automatically.

The LPI2C master can stall the I2C bus under certain conditions; this results in SCL pulled low continuously on the first bit of a byte, until the condition is removed:

- LPI2C master is enabled and busy, the transmit FIFO is empty, and MCFGR1[AUTOSTOP] is clear.
- LPI2C master is enabled and receiving data, receive data is not being discarded (due to command or receive data match), and the receive FIFO is full.

Receive FIFO and Data Matching

The receive FIFO is used to store receive data during master-receiver transfers. Receive data can also be configured to discard receive data instead of storing in the receive FIFO; this is configured by the command word in the transmit FIFO.

Receive data supports a receive data match function that can match received data against one of two bytes or against a masked data byte. The data match function can also be configured to compare only the first one or two received data words since the last (repeated) START condition. Receive data that is already discarded due to the command word cannot cause the data match to set, and delaya the match on the first received data word until after the discarded data is received. The receiver match function can also be configured to discard all receive data until a data match is detected, using the MCFGR0[RDMO] control bit. When clearing the MCFGR0[RDMO] control bit following a data match, clear MCFGR0[RDMO] before clearing MSR[DMF], to allow all subsequent data to be received.

Timing Parameters

The following timing parameters can be configured by the LPI2C master. Parameters are configured separately for high speed mode (Master Clock Configuration 1 (MCCR1)) and other modes (Master Clock Configuration 0 (MCCR0)). This allows the high speed mode master code to be sent using the regular timing parameters, and then switch to the high speed mode timing (following a repeated START) until the next STOP condition.

The LPI2C master timing parameters in LPI2C functional clock cycles are configured as follows. They must be configured to meet the I2C timing specification for the required mode.

Table 374. Timing Parameters

I2C Specification Timing Parameter	I2C Specification Timing Symbol	LPI2C Timing Parameter (LPI2C functional clock cycles)
SCL clock period	tSCL	(CLKHI + CLKLO + 2 + SCL_LATENCY) x (2 ^ PRESCALE)
hold time (repeated) START condition	tHD:STA	(SETHOLD +1) x (2 ^ PRESCALE)

Table continues on the next page...

Table 374. Timing Parameters (continued)

I2C Specification Timing Parameter	I2C Specification Timing Symbol	LPI2C Timing Parameter (LPI2C functional clock cycles)
LOW period of the SCL clock	tLOW	(CLKLO + 1) x (2 ^ PRESCALE)
HIGH period of the SCL clock	tHIGH	(CLKHI + 1 + SCL_LATENCY) x (2 ^ PRESCALE)
setup time for a repeated START condition or STOP condition	tSU:STA, tSU:STO	(SETHOLD + 1 + SCL_LATENCY) x (2 ^ PRESCALE)
data hold time	tHD:DAT	(DATAVD + 1) x (2 ^ PRESCALE)
data setup time	tSU:DAT	(SDA_LATENCY + 1) x (2 ^ PRESCALE)
bus free time between a STOP and START condition	tBUF	(CLKLO + 1 + SDA_LATENCY) x (2 ^ PRESCALE)
data valid time, data valid acknowledge time	tVD:DAT, tVD:ACK	(DATAVD + 1) x (2 ^ PRESCALE)

The latency parameters are defined in the following table, these parameters assume the risetime is less than one LPI2C functional clock cycle. The risetime depends on a number of factors, including the I/O propagation delay, the I2C bus loading and the external pull-up resistor sizing. A larger rise time increasea the number of cycles that the signal takes to propagate through the synchronizer (and glitch filter), which increases the latency.

Table 375. Synchronization Latency

Timing Parameter	Timing Definition
SCL_LATENCY	ROUNDDOWN ((2 + FILTSCL + SCL_RISETIME) / (2 ^ PRESCALE))
SDA_LATENCY	ROUNDDOWN ((2 + FILTSDA + SDA_RISETIME) / (2 ^ PRESCALE))

The following timing restrictions must be enforced to avoid unexpected START or STOP conditions on the I2C bus, or to avoid unexpected START or STOP conditions detected by the LPI2C master. The timing restrictions can be summarized as **SDA cannot change when SCL is high outside of a transmitted (repeated) START or STOP condition**.

Table 376. LPI2C Timing Parameter Restrictions

Timing Parameter	Minimum	Maximum	Comment
CLKLO	0x03	-	Also: CLKLO x (2 ^ PRESCALE) > SCL_LATENCY
CLKHI	0x01	-	Configure CLKHI to meet the duty cycle requirements in the I2C specification
SETHOLD	0x02	-	Also: SETHOLD x (2 ^ PRESCALE) > SDA_LATENCY
DATAVD	0x01	CLKLO - SDA_LATENCY - 1	Configure DATAVD to meet the data hold requirement in the I2C specification
FILTSCL	0x00	[CLKLO x (2 ^ PRESCALE)] - 3	FILTSCL and FILTSDA are the only parameters not multiplied by (2 ^ PRESCALE)

Table continues on the next page...

Table 376. LPI2C Timing Parameter Restrictions (continued)

Timing Parameter	Minimum	Maximum	Comment
FILTSDA	FILTSCL	[CLKLO x (2 ^ PRESCALE)] - 3	Configuring FILTSDA greater than FILTSCL can delay the SDA input to compensate for board level skew
BUSIDLE	(CLKLO+SETHOLD+2) x 2	-	Must also be greater than (CLKHI+1)

The timing parameters must be configured to meet the requirements of the I2C specification; this depends on the mode being supported and the LPI2C functional clock frequency. When switching between two modes using the different clock configuration registers (for example, Fast and HS-mode), the PRESCALE factor must remain constant between the modes. Some example timing configurations are provided below.

Table 377. LPI2C Example Timing Configurations

I2C Mode	Clock Frequency	Baud Rate	PRESCALE	FILTSCL / FILTSDA	SETHOLD	CLKLO	CLKHI	DATAVD
Fast	8 MHz	400 kbps	0x0	0x0/0x0	0x04	0x0B	0x05	0x02
Fast+	8 MHz	1 Mbps	0x0	0x0/0x0	0x02	0x03	0x01	0x01
Fast	48 MHz	400 kbps	0x0	0x1/0x1	0x1D	0x3E	0x35	0x0F
Fast	48 MHz	400 kbps	0x2	0x1/0x1	0x07	0x11	0x0B	0x03
Fast+	48 MHz	1 Mbps	0x2	0x1/0x1	0x03	0x06	0x04	0x04
HS-mode	48 MHz	3.2 Mbps	0x0	0x0/0x0	0x07	0x08	0x03	0x01
Fast	60 MHz	400 kbps	0x1	0x2/0x2	0x11	0x28	0x1F	0x08
Fast+	60 MHz	1 Mbps	0x1	0x2/0x2	0x07	0x0F	0x0B	0x01
HS-mode	60 MHz	3.33 Mbps	0x1	0x0/0x0	0x04	0x04	0x02	0x01

Error Conditions

The LPI2C master monitors for errors while it is active, the following conditions generates an error flag and block a new START condition from being sent, until the flag is cleared by software:

- A START or STOP condition is detected and is not generated by the LPI2C master (sets MSR[ALF]).
- Transmitting data on SDA and different values are being received (sets MSR[ALF]).
- NACK is detected when transmitting data, and MCFGR1[IGNACK] is clear (sets MSR[NDF]).
- NACK is detected and is expecting ACK for the address byte, and MCFGR1[IGNACK] is clear (sets MSR[NDF]).
- ACK is detected and is expecting NACK for the address byte, and MCFGR1[IGNACK] is clear (sets MSR[NDF]).
- Transmit FIFO is requesting to transmit or receive data without a START condition (sets MSR[FEF]).
- SCL (or SDA if MCFGR1[TIMECFG] is set) is low for (MCFGR2[TIMELOW] * 256) prescaler cycles without a pin transition (sets MSR[PLTF]).

Software must respond to the MSR[PLTF] flag to terminate the existing command either cleanly (by clearing MCR[MEN]), or abruptly (by setting MCR[RST]).

The MCFGR2[BUSIDLE] field can be used to force the I2C bus to be considered idle when SCL and SDA remain high for (BUSIDLE+1) prescaler cycles. The I2C bus is normally considered idle when the LPI2C master is first enabled, but when

BUSIDLE is configured greater than zero then SCL and/or SDA must be high for (BUSIDLE+1) prescaler cycles before the I2C bus is first considered idle.

Pin Configuration

- **Open-drain support:** The LPI2C master defaults to open-drain configuration of the SDA and SCL pins. Support for true open drain depends on the specific device, and requires the pins where LPI2C pins are muxed to support true open drain.
- **High Speed mode support:** Support for high speed mode also depends on the specific device, and requires the SCL pin to support the current source pull-up required in the I2C specification.
- **Ultra-Fast mode support:** The LPI2C master also supports the output-only push-pull function required for I2C ultra-fast mode using the SDA and SCL pins. Support for ultra-fast mode also requires the MCFGR1[IGNACK] bit to be set.
- **Push-pull 2-wire support:** A push-pull 2-wire configuration is also available to the LPI2C master that may support a partial high speed mode, if the LPI2C is the only master and all I2C pins on the bus are at the same voltage. This configures the SCL pin as push-pull for every clock except the 9th clock pulse, to allow high speed mode compatible slaves to perform clock stretching. In this mode, the SDA pin is tristated for master-receive data bits and master-transmit ACK/NACK bits, and is configured as push-pull at other times. To avoid the risk of contention when SDA is push-pull, the pin can be configured for open-drain operation, as part of the device-specific configuration.
- **Push-pull 4-wire support:** The push-pull 4-wire configuration separates the SCL input data and output data into separate pins, and separates the SDA input data and output data into separate pins. The SCL/SDA pins are used for input data; the SCLS/SDAS pins are used for output data, with configurable polarity. This simplifies external connections when connecting the LPI2C to the I2C bus through external level shifters or discrete components. When using this 4-wire configuration, the LPI2C master logic and LPI2C slave logic are not able to connect to separate I2C buses.

68.3.2 Slave Mode

To perform all slave mode transfers on the I2C bus, the LPI2C slave logic operates independently from the LPI2C master logic.

Address Matching

The LPI2C slave can be configured:

- To match one of two addresses, using either 7-bit or 10-bit addressing modes for each address
- To match a range of addresses in either 7-bit or 10-bit addressing modes
- To match the General Call Address, and generate appropriate flags
- To match the SMBus Alert Address, and generate appropriate flags
- To detect the high speed mode master code, and to disable the digital filters and output valid delay time until the next STOP condition is detected

After a valid address is matched, the LPI2C slave automatically performs slave-transmit or slave-receive transfers until:

- A NACK is detected (unless SCFGR1[IGNACK] is set)
- A bit error is detected (the LPI2C slave is driving SDA, but a different value is sampled)
- A (repeated) START or STOP condition is detected

Transmit and Receive Data

- The Transmit and Receive Data registers are double-buffered and only update during a slave-transmit and slave-receive transfer, respectively.
- The slave address *that was received* can be configured to be read from either the Receive Data register (for example, when using DMA to transfer data), or from the Address Status register.
- The Transmit Data register can be configured to only request data after a slave-transmit transfer is detected, or to request new data whenever the Transmit Data register is empty.

- The Transmit Data register should only be written when the Transmit Data flag is set.
- The Receive Data register should only be read when the Received Data flag is set (or the Address Valid flag is set and SCFGR1[RXCFG] = 1).
- The Address Status register should only be read when the Address Valid flag is set.

Clock Stretching

The LPI2C slave supports many configurable options for when clock stretching is performed. The following conditions can be configured to perform clock stretching:

- During the 9th clock pulse of the address byte and the Address Valid flag is set.
- During the 9th clock pulse of a slave-transmit transfer and the Transmit Data flag is set.
- During the 9th clock pulse of a slave-receive transfer and the Receive Data flag is set.
- During the 8th clock pulse of an address byte or a slave-receive transfer and the Transmit ACK flag is set. In high speed mode, this is disabled.
- Clock stretching can also be extended for CLKHOLD cycles, to allow additional setup time to sample the SDA pin externally. In high speed mode, this is disabled.

Unless extended by the CLKHOLD configuration, clock stretching extends for one peripheral bus clock cycle after SDA updates when clock stretching is enabled.

Timing Parameters

The LPI2C slave can configure the following timing parameters. These parameters are disabled when SCR[FILTEN] is clear, when SCR[FILTDZ] is set in Doze mode, and when LPI2C slave detects high speed mode. When disabled, the LPI2C slave is clocked directly from the I2C bus, and may not satisfy all timing requirements of the I2C specification (such as SDA minimum hold time in Standard/Fast mode).

- SDA data valid time from SCL negation to SDA update
- SCL hold time when clock stretching is enabled to increase setup time when sampling SDA externally
- SCL glitch filter time
- SDA glitch filter time

The LPI2C slave imposes the following restrictions on the timing parameters.

- FILTSDA must be configured to greater than or equal to FILTSCL (unless compensating for board level skew between SDA and SCL).
- DATAVD must be configured less than the minimum SCL low period.

Error Conditions

The LPI2C slave can detect the following error conditions:

- Bit error flag sets when the LPI2C slave is driving SDA, but samples a different value than what is expected.
- FIFO error flag sets due to a transmit data underrun or a receive data overrun. To eliminate the possibility of underrun and overrun occurring, enable clock stretching.
- FIFO error flag also sets due to an address overrun when SCFGR1[RXCFG] is set, otherwise an address overrun is not flagged. To eliminate the possibility of overrun occurring, enable clock stretching.

The LPI2C slave does not implement a timeout due to SCL and/or SDA being stuck low. If this detection is required, then the LPI2C master logic should be used and so software can reset the LPI2C slave when this condition is detected.

68.3.3 Low power modes

Table 378. LPI2C low power modes

Mode	LPI2C Operation
Run	Normal operations
Stop	Can continue operating in Stop mode if the Doze Enable bit is clear (MCR[DOZEN] = 0) and LPI2C uses an external or internal clock source that remains operating during Stop mode.

68.3.4 Debug mode

Table 379. LPI2C Debug mode

Mode	LPI2C Operation
Debug	Can continue operating in Debug mode if the Debug Enable bit is set (MCR[DBGEN] = 1).

68.3.5 Interrupts and DMA requests

Depending on the specific device, interrupts and DMA requests can be combined in some ways:

- The LPI2C master and slave interrupts may be combined
- The LPI2C master and slave transmit DMA requests may be combined
- The LPI2C master and slave receive DMA requests may be combined

Master mode

The next table lists the master mode sources that can generate LPI2C master interrupts and LPI2C master transmit/receive DMA requests.

Table 380. Master Interrupts and DMA Requests

Master Status (MSR)		Description	Can generate		
Flag	Name		Interrupt?	DMA Request?	Low Power Wakeup?
TDF	Transmit Data Flag	Data can be written to Transmit FIFO, as configured by the Transmit FIFO Watermark MFCR[TXWATER]	Y	TX	Y
RDF	Receive Data Flag	Data can be read from the Receive FIFO, as configured by the Receive FIFO Watermark MFCR[RXWATER]	Y	RX	Y
EPF	End Packet Flag	Master has transmitted a Repeated START or STOP condition	Y	N	Y
SDF	STOP Detect Flag	Master has transmitted a STOP condition	Y	N	Y

Table continues on the next page...

Table 380. Master Interrupts and DMA Requests (continued)

Master Status (MSR)		Description	Can generate		
Flag	Name		Interrupt?	DMA Request?	Low Power Wakeup?
NDF	NACK Detect Flag	• During an address byte, the master expected an ACK but detected a NACK • During an address byte, the master expected a NACK but detected an ACK • During a master-transmitter data byte, the master detected a NACK	Y	N	Y
ALF	Arbitration Lost Flag	• The master lost arbitration due to a START/STOP condition detected at the wrong time • Or the master was transmitting data but received different data than the data that was transmitted	Y	N	Y
FEF	FIFO Error Flag	The master is expecting a START condition in the Command FIFO, but the next entry in the Command FIFO is not a START condition	Y	N	Y
PLTF	Pin Low Timeout Flag	Pin low timeout is enabled and SCL (or SDA if configured) is low for longer than the configured timeout	Y	N	Y
DMF	Data Match Flag	The received data matches the configured data match, but the received data is not discarded due to a command FIFO entry	Y	N	Y
MBF	Master Busy Flag	LPI2C master is busy transmitting/receiving data	N	N	N
BBF	Bus Busy Flag	LPI2C master is enabled and activity is detected on the I2C bus, but a STOP condition has not been detected and a bus idle timeout (if enabled) has not occurred.	N	N	N

Slave mode

The next table lists the slave mode sources that can generate LPI2C slave interrupts and the LPI2C slave transmit/receive DMA requests.

Table 381. Slave Interrupts and DMA Requests

Slave Status (SSR)		Description	Can generate		
Flag	Name		Interrupt?	DMA Request?	Low Power Wakeup?
TDF	Transmit Data Flag	Data can be written to the Slave Transmit Data (STDR)	Y	TX	Y

Table continues on the next page...

Table 381. Slave Interrupts and DMA Requests (continued)

Slave Status (SSR)		Description	Can generate		
Flag	Name		Interrupt?	DMA Request?	Low Power Wakeup?
RDF	Receive Data Flag	Data can be read from the Slave Receive Data (SRDR)	Y	RX	Y
AVF	Address Valid Flag	Address can be read from the Slave Address Status (SASR)	Y	RX	Y
TAF	Transmit ACK Flag	ACK/NACK can be written to the Slave Transmit ACK (STAR)	Y	N	Y
RSF	Repeated Start Flag	Slave has detected an address match followed by a Repeated START condition	Y	N	Y
SDF	STOP Detect Flag	Slave has detected an address match followed by a STOP condition	Y	N	Y
BEF	Bit Error Flag	Slave was transmitting data, but received different data than what was transmitted	Y	N	Y
FEF	FIFO Error Flag	• Transmit data underrun • Receive data overrun • Address status overrun (when Receive Data Configuration SCFGR1[RXCFG] = 1). FEF flag can only set when clock stretching is disabled.	Y	N	Y
AM0F	Address Match 0 Flag	Slave detected an address match with SAMR[ADDR0] field	Y	N	N
AM1F	Address Match 1 Flag	Slave detected an address match with SAMR[ADDR1] field or using an address range	Y	N	N
GCF	General Call Flag	Slave detected an address match with the General Call address	Y	N	N
SARF	SMBus Alert Response Flag	Slave detected an address match with the SMBus Alert address	Y	N	N
SBF	Slave Busy Flag	LPI2C slave is busy receiving an address byte or is transmitting/receiving data	N	N	N
BBF	Bus Busy Flag	LPI2C slave is enabled and a START condition is detected on I2C bus, but a STOP condition has not been detected	N	N	N

68.3.6 Clocks

Table 382. LPI2C clocks

LPI2C Functional clock	The LPI2C functional clock is asynchronous to the bus clock and can remain enabled in low power modes to support I2C bus transfers by the LPI2C master. The functional clock is also used by the LPI2C slave to support digital filter and data hold time configurations. The LPI2C master divides the functional clock by a prescaler and the resulting frequency must be at least 8 times faster than the I2C bus bandwidth.
External clock	The LPI2C slave logic is clocked directly from the external pins SCL and SDA (or SCLS and SDAS if master and slave are implemented on separate pins). This allows the LPI2C slave to remain operational, even when the LPI2C functional clock is disabled. **NOTE** The LPI2C slave digital filter must be disabled if the LPI2C functional clock is disabled, and this can affect compliance with some of the timing parameters of the I2C specification, such as the data hold time.
Bus clock	The bus clock is only used for bus accesses to the control and configuration registers. The bus clock frequency must be sufficient to support the data bandwidth requirements of the LPI2C master and slave registers.

For device-specific clocking information, refer to the Clocking chapter.

68.3.7 Resets

Table 383. LPI2C Resets

Chip reset	The logic and registers for the LPI2C master and slave are reset to their default state on a chip reset.
Software reset	• The LPI2C master implements a software reset bit in its Control Register. The MCR[RST] bit resets all master logic and registers to their default state, except for the MCR register itself. • The LPI2C slave implements a software reset bit in its Control Register. The SCR[RST] bit resets all slave logic and registers to their default state, except for the SCR register itself.
FIFO reset	• The LPI2C master implements write-only control bits that reset the transmit FIFO (MCR[RTF]) and receive FIFO (MCR[RRF]). After a FIFO is reset, that FIFO is empty. • The LPI2C slave implements write-only control bits that reset the transmit data register (SCR[RTF] and receive data register (SCR[RRF]). After a data register is reset, that data register is empty.

68.3.8 Peripheral Triggers

The connection of the LPI2C peripheral triggers to other peripherals depend upon the specific device being used.

Table 384. LPI2C Triggers

Trigger	Description
Master Output Trigger	The LPI2C master generates an output trigger that can be connected to other peripherals on the device. The master output trigger asserts on both a Repeated START or STOP condition, and the master output trigger remains asserted for one cycle of the LPI2C functional clock divided by the prescaler.

Table continues on the next page...

Table 384. LPI2C Triggers (continued)

Trigger	Description
Slave Output Trigger	The LPI2C slave generates an output trigger that can be connected to other peripherals on the device. The slave output trigger asserts on both a Repeated START or STOP condition that occurs after a slave address match, and the slave output trigger remains asserted until the next slave SCL pin negation.
Input Trigger	To control the start of a LPI2C bus transfer, the LPI2C input trigger can be selected instead of the HREQ input. The input trigger is synchronized and to be detected, the input trigger must assert for at least 2 cycles of the LPI2C functional clock divided by the PRESCALE configuration. When the LPI2C is busy, the HREQ input (and therefore the input trigger) is ignored.

68.4 Signal descriptions

Table 385. Signals

Signal	Name	2-Wire Scheme	4-Wire Scheme	I/O
SCL	LPI2C clock line	SCL	In 4-wire mode, this is the SCL input pin.	I/O
SDA	LPI2C data line	SDA	In 4-wire mode, this is the SDA input pin.	I/O
SCLS	Secondary I2C clock line	Not used	In 4-wire mode, this is the SCLS output pin. If LPI2C master/slave are configured to use separate pins, then this is the LPI2C slave SCL pin.	I/O
SDAS	Secondary I2C data line	Not used	In 4-wire mode, this is the SDAS output pin. If LPI2C master/slave are configured to use separate pins, then this is the LPI2C slave SDA pin.	I/O
HREQ	Host request	If host request is asserted and the I2C bus is idle, then it initiates an LPI2C master transfer. HREQ is an additional pin separate from the 2-wire or 4-wire scheme.		I

The I^2C 2-wire serial bus diagram shows the 2 signal connection.

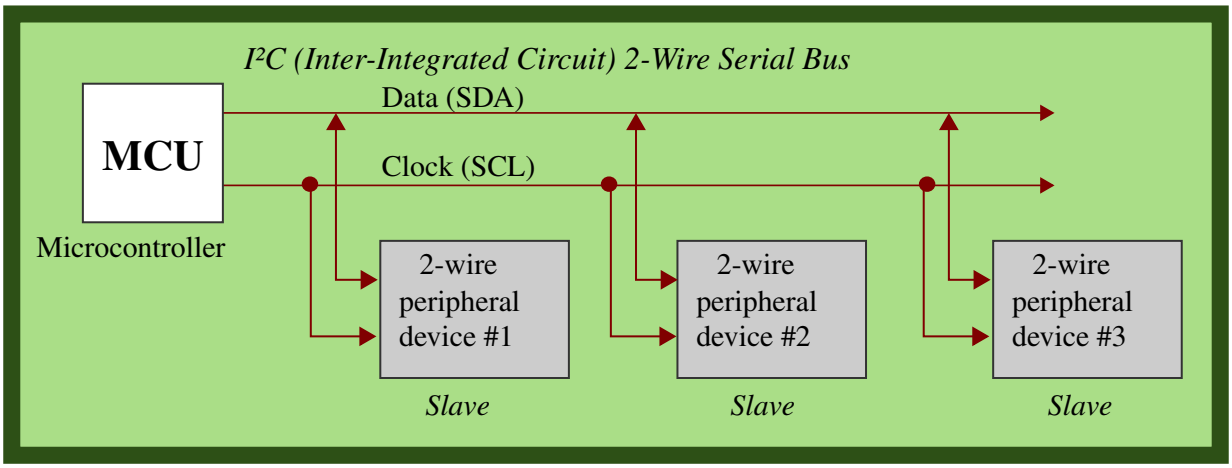

Figure 363. I²C 2-wire serial bus

The I²C 4-wire serial bus diagram shows a possible 4 signal connection.

68.5 Memory Map and Registers

NOTE

Writing a Read-Only (RO) register or reading a Write-Only (WO) register can cause bus errors. This module will not check if programmed values in the registers are correct; the application software must ensure that valid programmed values are being written.

Table continues on the next page...

Table continued from the previous page...

Field	Function
RST	Resets all internal master logic and registers, except the Master Control (MCR) register. RST remains set until cleared by software. The reset takes effect immediately and remains asserted until negated by software. There is no minimum delay required before clearing the software reset. 0b - Master logic is not reset 1b - Master logic is reset
0 MEN	Master Enable Enables the Master logic. 0b - Master logic is disabled 1b - Master logic is enabled

68.5.1.5 Master Status (MSR)

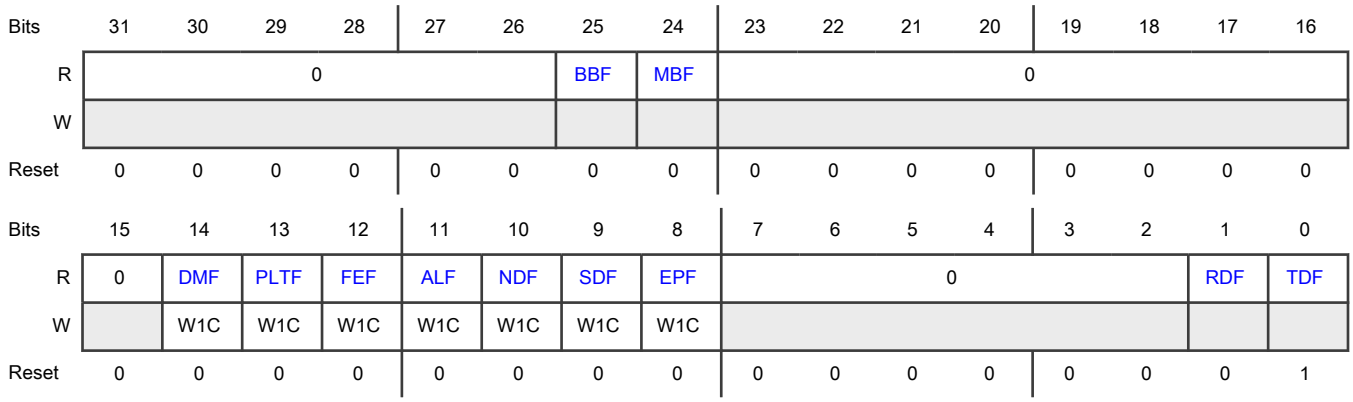
Offset

Register	Offset
MSR	14h

Function

MSR contains status flags for transmit and receive data; Start and Stop conditions; and bus and master busy or idle status.

Diagram



Fields

Field	Function
31-26 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
25 BBF	Bus Busy Flag Indicates that the I2C bus is busy. 0b - I2C Bus is idle 1b - I2C Bus is busy
24 MBF	Master Busy Flag Indicates that the I2C Master is busy. 0b - I2C Master is idle 1b - I2C Master is busy
23-16 —	Reserved
15 —	Reserved
14 DMF	Data Match Flag Indicates that the received data has matched the MDMR[MATCH0] and/or MDMR[MATCH1] fields (as configured by MCFGR1[MATCFG]. Received data *that is discarded due to CMD field* does not cause DMF to set. 0b - Have not received matching data 1b - Have received matching data
13 PLTF	Pin Low Timeout Flag Sets when the SCL and/or SDA input is low for more than PINLOW cycles (Pin Low Timeout, MCFGR3[PINLOW]), even when the LPI2C master is idle. • Software is responsible for resolving the pin low condition. • PLTF cannot be cleared as long as the pin low timeout continues. • Before the LPI2C can initiate a START condition, the PLTF must be cleared. 0b - Pin low timeout has not occurred or is disabled 1b - Pin low timeout has occurred
12 FEF	FIFO Error Flag Detects an attempt to send or receive data without first generating a (repeated) START condition. This can occur if the transmit FIFO underflows when MCFGR1[AUTOSTOP] = 1. When FEF is set, the LPI2C master sends a STOP condition (if busy), and does not initiate a new START condition until FEF has been cleared. 0b - No error 1b - Master sending or receiving data without a START condition

Table continues on the next page...

Table continued from the previous page...

Field	Function
11 ALF	Arbitration Lost Flag Set if either of these conditions exist: • The LPI2C master transmits a logic one and detects a logic zero on the I2C bus • The LPI2C master detects a START or STOP condition while the LPI2C master is transmitting data When ALF sets, the LPI2C master releases the I2C bus (goes idle), and the LPI2C master does not initiate a new START condition until the ALF has been cleared. 0b - Master has not lost arbitration 1b - Master has lost arbitration
10 NDF	NACK Detect Flag Set if the LPI2C master detects a NACK it was not expecting when transmitting an address or data. When set, the master does not initiate a new START condition until NDF has been cleared. If a NACK is expected for a given address (as configured by the command word), then the NDF sets if a NACK is not generated. When NDF is set, the LPI2C master automatically transmits a STOP condition if MCFGR1[AUTOSTOP] = 1, or the transmit FIFO is not empty. 0b - Unexpected NACK was not detected 1b - Unexpected NACK was detected
9 SDF	STOP Detect Flag Set when the LPI2C master generates a STOP condition. 0b - Master has not generated a STOP condition 1b - Master has generated a STOP condition
8 EPF	End Packet Flag Set when the LPI2C master generates either a repeated START condition or a STOP condition. Does not set when the master first generates a START condition. 0b - Master has not generated a STOP or Repeated START condition 1b - Master has generated a STOP or Repeated START condition
7-2 —	Reserved
1 RDF	Receive Data Flag RDF sets whenever the number of words in the receive FIFO is greater than MFCR[RXWATER]. 0b - Receive Data is not ready 1b - Receive data is ready
0 TDF	Transmit Data Flag TDF sets whenever the number of words in the transmit FIFO is equal or less than MFCR[TXWATER].

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Transmit data is not requested 1b - Transmit data is requested

68.5.1.6 Master Interrupt Enable (MIER)

Offset

Register	Offset
MIER	18h

Function

MIER contains transmit and receive data interrupt enables; Start, Stop, and Nack detect interrupt enables; and DMA interrupt enables.

68.5.1.8 Master Configuration 0 (MCFGR0)

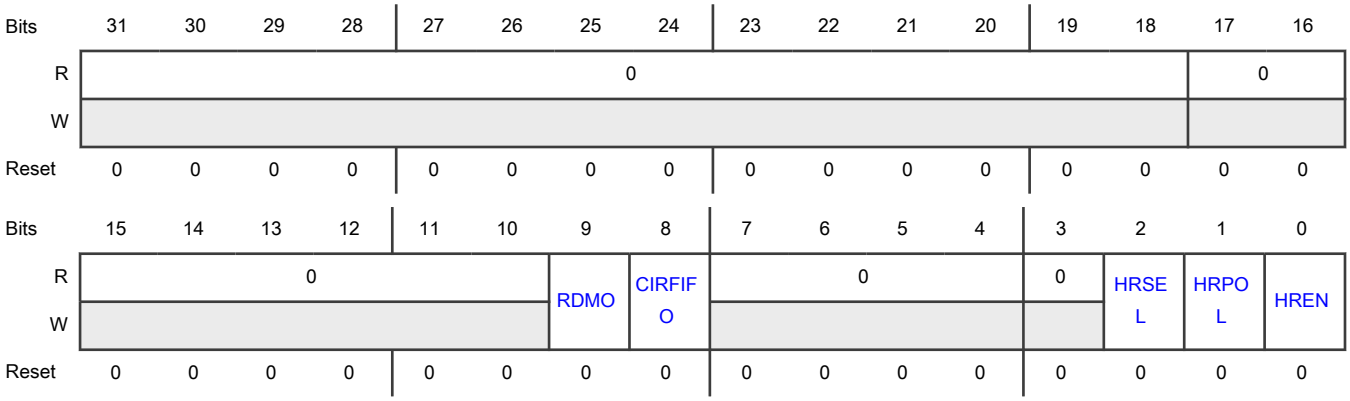
Offset

Register	Offset
MCFGR0	20h

Function

MCFGR0 contains host settings and other receive and transfer settings.

Diagram



Fields

Field	Function
31-18 —	Reserved
17-16 —	Reserved
15-10 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
9 RDMO	Receive Data Match Only When enabled, all received data that does not cause the Data Match Flag (MSR[DMF]) to set is discarded. After MSR[DMF] is set, the RDMO configuration is ignored. When disabling RDMO, clear RDMO before clearing MSR[DMF], to ensure that no receive data is lost. 0b - Received data is stored in the receive FIFO 1b - Received data is discarded unless the the Data Match Flag (MSR[DMF]) is set
8 CIRFIFO	Circular FIFO Enable When enabled, the transmit FIFO read pointer is saved to a temporary register. The transmit FIFO empties as normal, but after the LPI2C master is idle and the transmit FIFO is empty, then the read pointer value will be restored from the temporary register. This causes the contents of the transmit FIFO to be cycled through repeatedly. If MCFGR1[AUTOSTOP] is set, then a STOP condition is sent whenever the transmit FIFO is empty and the read pointer is restored. 0b - Circular FIFO is disabled 1b - Circular FIFO is enabled
7-4 —	Reserved
3 —	Reserved
2 HRSEL	Host Request Select Selects the source of the host request input. When host request is enabled, HRSEL should remain static (the Host Request Select should not change). 0b - Host request input is pin HREQ 1b - Host request input is input trigger
1 HRPOL	Host Request Polarity Configures the polarity of the host request pin. When host request is enabled, HRPOL should remain static (Host Request Polarity should not change). 0b - Active low 1b - Active high
0 HREN	Host Request Enable When enabled, the LPI2C master only initiates a START condition if the host request input is asserted and the bus is idle. A repeated START is not affected by the host request. 0b - Host request input is disabled 1b - Host request input is enabled

68.5.1.9 Master Configuration 1 (MCFGR1)

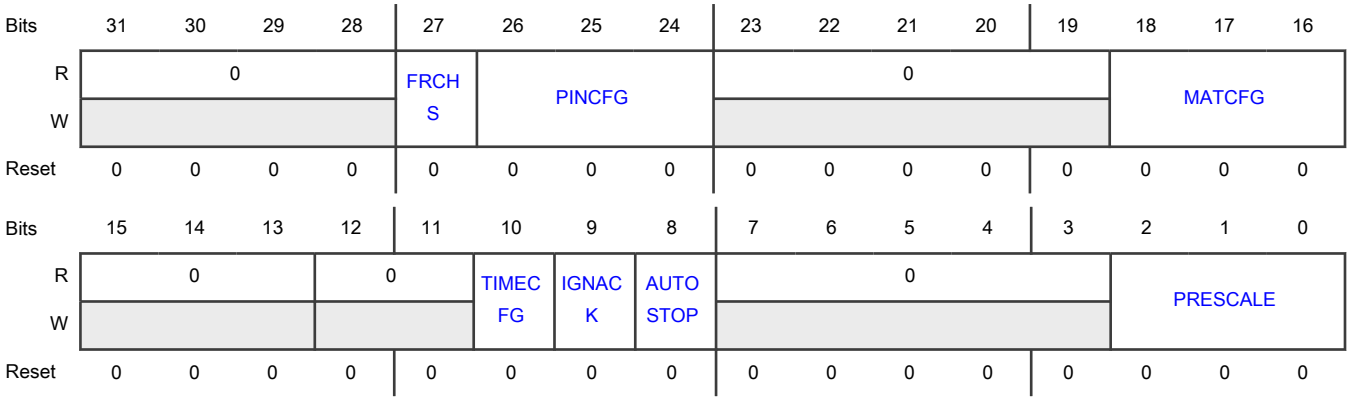
Offset

Register	Offset
MCFGR1	24h

Function

The MCFGR1 should only be written when the I2C Master is disabled.

Diagram



Fields

Field	Function
31-28 —	Reserved
27 FRCHS	Force HS-mode When set, forces the LPI2C pin state into HS-mode. Setting this does not impact the digital filter configuration or digital timing parameters. 0b - No effect 1b - LPI2C pin state forced into HS-mode.
26-24 PINCFG	Pin Configuration Configures the pin mode for LPI2C.

Table 386. 2-pin / 4-pin pin configurations for masters and slaves

PINCFG	SCL / SDA pins	SCLS / SDAS pins
000	Bi-directional open drain for master and slave	Not used

68.5.1.13 Master Clock Configuration 0 (MCCR0)

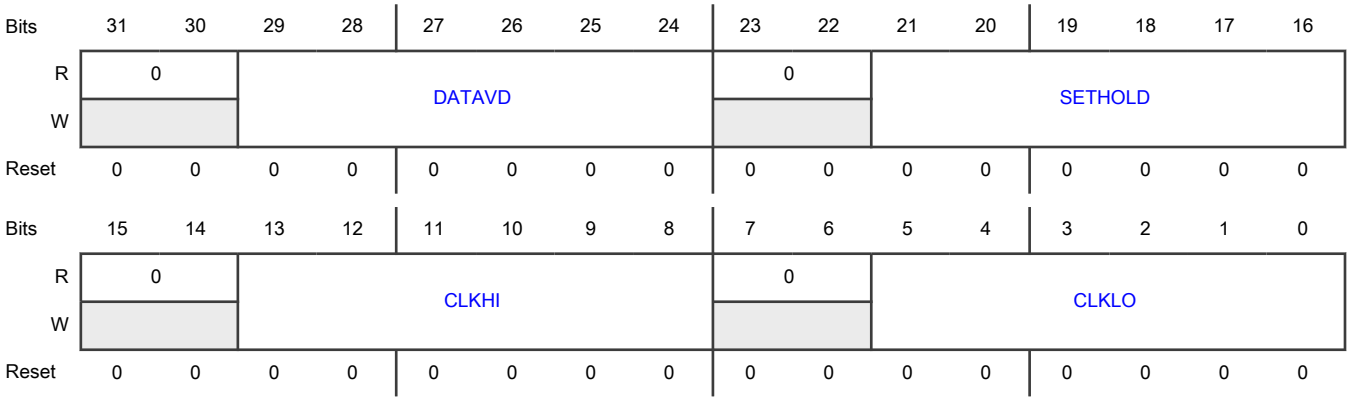
Offset

Register	Offset
MCCR0	48h

Function

The MCCR0 cannot be changed when the I2C master is enabled and is used for standard, fast, fast-mode plus and ultra-fast transfers.

Diagram



Fields

Field	Function
31-30 —	Reserved
29-24 DATAVD	Data Valid Delay Minimum number of cycles (minus one) that is used as the data hold time for SDA. Must be configured less than the minimum SCL low period.
23-22	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
21-16 SETHOLD	Setup Hold Delay Minimum number of cycles (minus one) that is used by the master for these conditions: • Hold time for a START • Setup and hold time for a repeated START • Setup time for a STOP The setup time is extended by the time it takes to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to (2 + FILTSCL) / 2^PRESCALE cycles.
15-14 —	Reserved
13-8 CLKHI	Clock High Period Minimum number of cycles (minus one) that the SCL clock is driven high by the master. The SCL high time is extended by the time it takes to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to (2 + FILTSCL) / 2^PRESCALE cycles.
7-6 —	Reserved
5-0 CLKLO	Clock Low Period Minimum number of cycles (minus one) that the SCL clock is driven low by the master. The Clock Low Period value is also used for the minimum bus free time between a STOP and a START condition; this is extended by the time it takes to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to (2 + FILTSCL) / 2^PRESCALE cycles.

68.5.1.14 Master Clock Configuration 1 (MCCR1)

Offset

Register	Offset
MCCR1	50h

Function

The MCCR1 cannot be changed when the I2C master is enabled and is used for high speed mode transfers. The separate clock configuration for high speed mode allows arbitration to take place in Fast mode (with timing configured by Master Clock Configuration 0 (MCCR0)), before switching to high speed mode (with timing configured by MCCR1).

Diagram

25 BBF	Bus Busy Flag Indicates if an I2C bus is idle or busy. 0b - I2C Bus is idle 1b - I2C Bus is busy
24 SBF	Slave Busy Flag Indicates if an I2C slave is idle or busy. 0b - I2C Slave is idle 1b - I2C Slave is busy
23-16 —	Reserved
15	SMBus Alert Response Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
SARF	• SARF is cleared by reading the Slave Address Status (SASR) register • SARF cannot generate an asynchronous wakeup 0b - SMBus Alert Response is disabled or not detected 1b - SMBus Alert Response is enabled and detected
14 GCF	General Call Flag Indicates whether a slave has detected the General Call Address. • General Call Flag is cleared by reading the Slave Address Status (SASR) register • General Call Flag cannot generate an asynchronous wakeup 0b - Slave has not detected the General Call Address or the General Call Address is disabled 1b - Slave has detected the General Call Address
13 AM1F	Address Match 1 Flag Indicates that the received address has matched the ADDR1 field or ADDR0 to ADDR1 range as configured by SCFGR1[ADDRCFG]. • Address Match 1 Flag is cleared by reading the Slave Address Status (SASR) register • Address Match 1 Flag cannot generate an asynchronous wakeup 0b - Have not received an ADDR1 or ADDR0/ADDR1 range matching address 1b - Have received an ADDR1 or ADDR0/ADDR1 range matching address
12 AM0F	Address Match 0 Flag Indicates that the received address has matched the ADDR0 field as configured by SCFGR1[ADDRCFG]. • AM0F is cleared by reading the Slave Address Status (SASR) register • AM0F cannot generate an asynchronous wakeup 0b - Have not received an ADDR0 matching address 1b - Have received an ADDR0 matching address
11 FEF	FIFO Error Flag FEF can only be set when clock stretching is disabled. 0b - FIFO underflow or overflow was not detected 1b - FIFO underflow or overflow was detected
10 BEF	Bit Error Flag BEF sets if the LPI2C slave transmits a logic one and detects a logic zero on the I2C bus. The slave ignores the rest of the transfer until the next (repeated) START condition. 0b - Slave has not detected a bit error 1b - Slave has detected a bit error

Table continues on the next page...

Table continued from the previous page...

Field	Function
9 SDF	STOP Detect Flag SDF sets when the LPI2C slave detects a STOP condition and if the LPI2C slave matched the last address byte. 0b - Slave has not detected a STOP condition 1b - Slave has detected a STOP condition
8 RSF	Repeated Start Flag RSF sets when the LPI2C slave detects a repeated START condition and if the LPI2C slave matched the last address byte. The RSF does not set when the slave first detects a START condition. 0b - Slave has not detected a Repeated START condition 1b - Slave has detected a Repeated START condition
7-4 —	Reserved
3 TAF	Transmit ACK Flag TAF is cleared by writing to the Slave Transmit ACK (STAR) register. 0b - Transmit ACK/NACK is not required 1b - Transmit ACK/NACK is required
2 AVF	Address Valid Flag AVF is cleared by reading the Slave Address Status (SASR) register. When SCFGR1[RXCFG] = 1, SSR[AVF] is also cleared by reading the Slave Receive Data (SRDR) register. 0b - Address Status Register is not valid 1b - Address Status Register is valid
1 RDF	Receive Data Flag RDF is cleared by reading the Slave Receive Data (SRDR) register. When SCFGR1[RXCFG] = 1, RDF is not cleared when reading the Slave Receive Data (SRDR) register and if SSR[AVF] is set. 0b - Receive data is not ready 1b - Receive data is ready
0 TDF	Transmit Data Flag TDF is cleared by writing the to the Slave Transmit Data (STDR) register. When SCFGR1[TXCFG] = 0 and if a NACK or a Repeated START or STOP condition is detected, then TDF is also cleared. 0b - Transmit data not requested 1b - Transmit data is requested

68.5.1.21 Slave Interrupt Enable (SIER)

Offset

Register	Offset
SIER	118h

Function

SIER contains transmit and receive data interrupt enables; Start and Stop detect interrupt enables; and other slave interrupt enables.

68.5.1.22 Slave DMA Enable (SDER)

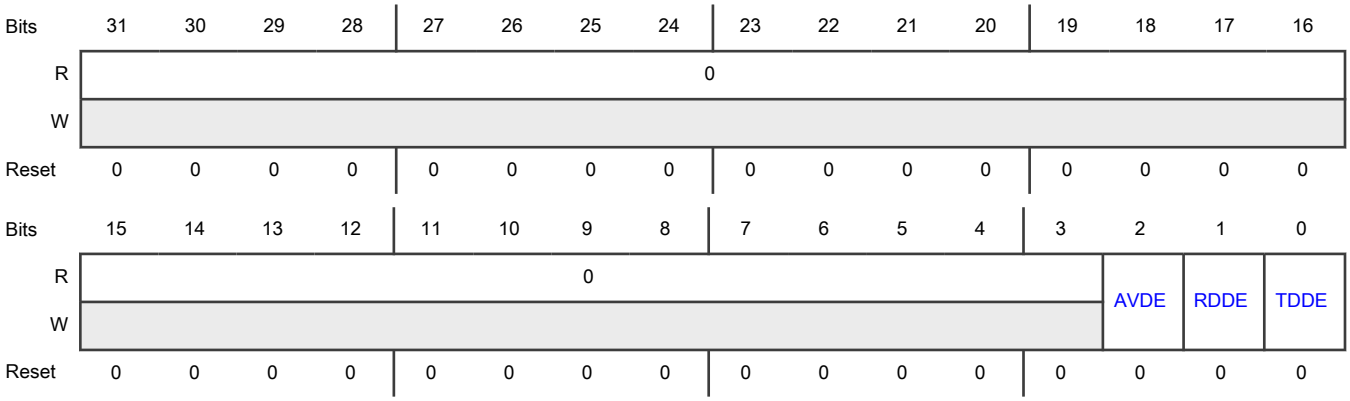
Offset

Register	Offset
SDER	11Ch

Function

SDER contains the transmit, request, and receive enables for DMA.

Diagram



Fields

Field	Function
31-3 —	Reserved
2 AVDE	Address Valid DMA Enable The Address Valid DMA request is shared with the Receive Data DMA request. If both Address Valid DMA request and Receive Data DMA request are enabled, then set SCFGR1[RXCFG] = 1, to allow the DMA to read the address from the Slave Receive Data (SRDR) register. 0b - DMA request is disabled 1b - DMA request is enabled
1 RDDE	Receive Data DMA Enable Enables receive data for DMA. 0b - DMA request is disabled 1b - DMA request is enabled
0 TDDE	Transmit Data DMA Enable Enables transmit data for DMA. 0b - DMA request is disabled 1b - DMA request is enabled

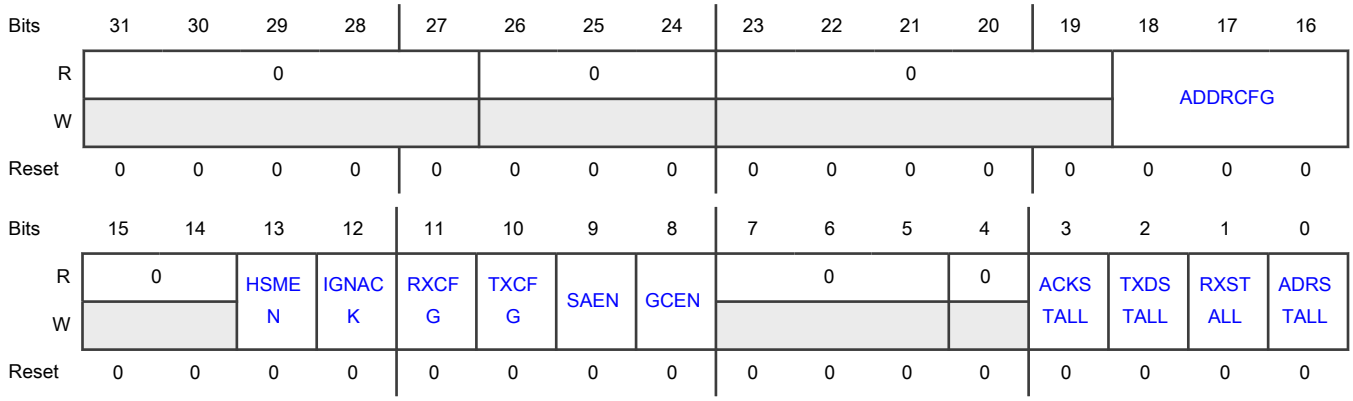
68.5.1.23 Slave Configuration 1 (SCFGR1)

Offset

Register	Offset
SCFGR1	124h

Function
The Slave Configuration Register 1 should only be written when the I2C Slave is disabled.

Diagram



Fields

Field	Function
31-27 —	Reserved
26-24 —	Reserved
23-19 —	Reserved
18-16 ADDRCFG	Address Configuration Configures the condition that causes an address to match. 000b - Address match 0 (7-bit) 001b - Address match 0 (10-bit) 010b - Address match 0 (7-bit) or Address match 1 (7-bit) 011b - Address match 0 (10-bit) or Address match 1 (10-bit) 100b - Address match 0 (7-bit) or Address match 1 (10-bit) 101b - Address match 0 (10-bit) or Address match 1 (7-bit) 110b - From Address match 0 (7-bit) to Address match 1 (7-bit) 111b - From Address match 0 (10-bit) to Address match 1 (10-bit)
15-14 —	Reserved
13 HSMEN	High Speed Mode Enable Enables detection of the High-Speed Mode master code of slave address 0000_1XX, but does not cause an address match on this code. When set and any HS-mode master code is detected, SCR[FILTEN] and SCFGR1[ACKSTALL] bits are ignored until the next STOP condition is detected.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disables detection of HS-mode master code 1b - Enables detection of HS-mode master code
12 IGNACK	Ignore NACK When Ignore NACK is set, the LPI2C slave continues transfers after a NACK is detected. Ignore NACK bit is required to be set in Ultra-Fast mode. 0b - Slave ends transfer when NACK is detected 1b - Slave does not end transfer when NACK detected
11 RXCFG	Receive Data Configuration 0b - Reading the Receive Data register returns received data and clears the Receive Data flag (MSR[RDF]). 1b - Reading the Receive Data register when the Address Valid flag (SSR[AVF])is set, returns the Address Status register and clear the Address Valid flag. Reading the Receive Data register when the Address Valid flag is clear, returns received data and clears the Receive Data flag (MSR[RDF]).
10 TXCFG	Transmit Flag Configuration The transmit data flag always asserts before a NACK is detected at the end of a slave-transmit transfer. This can cause an extra word to be written to the transmit data FIFO. • When TXCFG = 0, the Transmit Data register is automatically emptied when a slave-transmit transfer is detected. This causes the transmit data flag to assert whenever a slave-transmit transfer is detected, and causes the transmit data flag to negate at the end of the slave-transmit transfer. • When TXCFG = 1, the Transmit Data flag asserts whenever the Transmit Data register is empty, and the Transmit Data flag negates when the Transmit Data register is full. This allows the Transmit Data register to be filled before a slave-transmit transfer is detected, but can cause the Transmit Data register to be written before a NACK is detected on the last byte of a slave transmit transfer. 0b - Transmit Data Flag only asserts during a slave-transmit transfer when the Transmit Data register is empty 1b - Transmit Data Flag asserts whenever the Transmit Data register is empty
9 SAEN	SMBus Alert Enable Enables a match on an SMBus alert. 0b - Disables match on SMBus Alert 1b - Enables match on SMBus Alert
8 GCEN	General Call Enable Enables a general call address. 0b - General Call address is disabled 1b - General Call address is enabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
7-5 —	Reserved
4 —	Reserved
3 ACKSTALL	ACK SCL Stall Enables SCL clock stretching during slave-transmit address byte(s) and slave-receiver address and data byte(s), to allow software to write the Slave Transmit ACK (STAR) register before the ACK or NACK is transmitted. Clock stretching occurs when transmitting the 9th bit, and is therefore not compatible with high speed mode. When ACKSTALL is enabled, there is no need to set either RX SCL Stall (SCFGR1[RXSTALL]) or Address SCL Stall (SCFGR1[ADRSTALL]). When ACKSTALL is enabled and there is an address match on the first byte of a 10-bit address, SSR[AVF] sets allowing software to read the Received Address before writing to the Slave Transmit ACK (STAR) register. 0b - Clock stretching is disabled 1b - Clock stretching is enabled
2 TXDSTALL	TX Data SCL Stall Enables SCL clock stretching when the SSR[TDF] = 1 during a slave-transmit transfer. Clock stretching occurs following the 9th bit, and is therefore compatible with high speed mode. 0b - Clock stretching is disabled 1b - Clock stretching is enabled
1 RXSTALL	RX SCL Stall Enables SCL clock stretching when SSR[RDF] = 1 during a slave-receive transfer. Clock stretching occurs following the 9th bit, and is therefore compatible with high speed mode. 0b - Clock stretching is disabled 1b - Clock stretching is enabled
0 ADRSTALL	Address SCL Stall Enables SCL clock stretching when SSR[AVF] = 1. Clock stretching only occurs following the 9th bit, and is therefore compatible with high speed mode. 0b - Clock stretching is disabled 1b - Clock stretching is enabled

68.5.1.24 Slave Configuration 2 (SCFGR2)

Offset

Register	Offset
SCFGR2	128h

Function

The Slave Configuration Register 2 should only be written when the I2C Slave is disabled.

27-24 FILTSDA	Glitch Filter SDA Configures the I2C slave digital glitch filters for SDA input. • A configuration of 0 disables the glitch filter • Glitches equal to or less than FILTSDA cycles long are filtered out and ignored • The latency through the glitch filter is equal to FILTSDA+3 cycles, and must be configured to be less than the minimum SCL low or high period • The glitch filter cycle count is not affected by the PRESCALE configuration, and the glitch filter cycle count is disabled in high speed mode
23-20 —	Reserved
19-16 FILTSCL	Glitch Filter SCL Configures the I2C slave digital glitch filters for SCL input.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• A configuration of 0 disables the glitch filter • Glitches equal to or less than FILTSCL cycles long are filtered out and ignored • The latency through the glitch filter is equal to FILTSCL+3 cycles, and must be configured to be less than the minimum SCL low or high period • The glitch filter cycle count is not affected by the PRESCALE configuration, and the glitch filter cycle count is disabled in high speed mode
15-14 —	Reserved
13-8 DATAVD	Data Valid Delay Configures the SDA data valid delay time for the I2C slave, and is equal to FILTSCL+DATAVD+3 cycles. • The data valid delay must be configured to be less than the minimum SCL low period • The I2C slave data valid delay time is not affected by the PRESCALE configuration, and the I2C slave data valid delay time is disabled in high speed mode
7-4 —	Reserved
3-0 CLKHOLD	Clock Hold Time Configures the minimum clock hold time for the I2C slave, when clock stretching is enabled. • The minimum hold time is equal to CLKHOLD+3 cycles • The I2C slave clock hold time is not affected by the PRESCALE configuration, and the I2C slave clock hold time is disabled in high speed mode

68.5.1.25 Slave Address Match (SAMR)

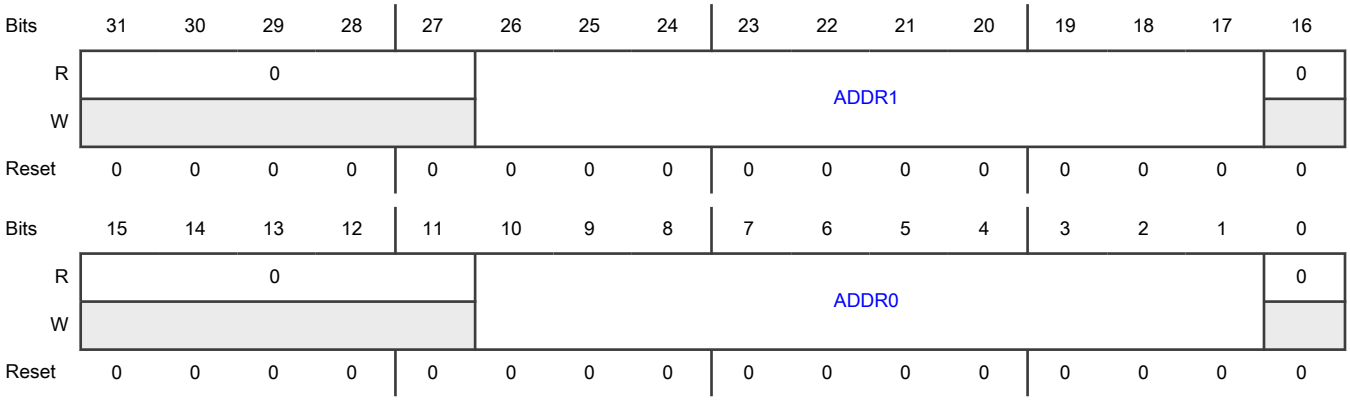
Offset

Register	Offset
SAMR	140h

Function

The SAMR should only be written when the I2C Slave is disabled.

Diagram



Fields

Field	Function
31-27 —	Reserved
26-17 ADDR1	Address 1 Value Compared against the received address to detect the Slave Address. • In 10-bit mode, the first address byte is compared to { 11110, ADDR1[26:25] } and the second address byte is compared to ADDR1[24:17] • In 7-bit mode, the address is compared to ADDR1[23:17]
16-11 —	Reserved
10-1 ADDR0	Address 0 Value Compared against the received address to detect the Slave Address. • In 10-bit mode, the first address byte is compared to { 11110, ADDR0[10:9] } and the second address byte is compared to ADDR0[8:1] • In 7-bit mode, the address is compared to ADDR0[7:1] •
0 —	Reserved

68.5.1.26 Slave Address Status (SASR)

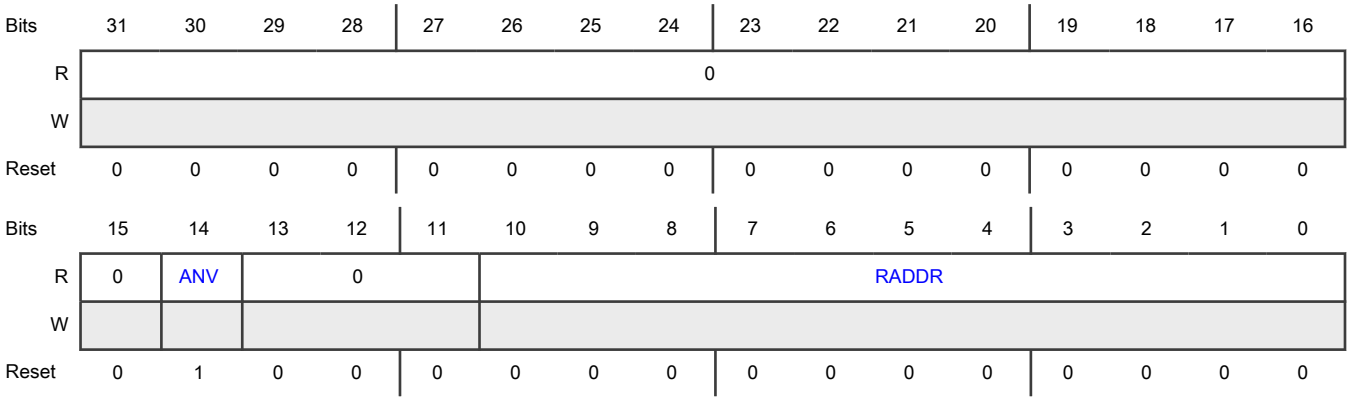
Offset

Register	Offset
SASR	150h

Function

SASR contains the read-only RADDR and ANV fields.

Diagram



Fields

Field	Function
31-15 —	Reserved
14 ANV	Address Not Valid 0b - Received Address (RADDR) is valid 1b - Received Address (RADDR) is not valid
13-11 —	Reserved
10-0 RADDR	Received Address The Received Address updates whenever the AMF is set; the AMF is cleared by reading the Slave Address Status register. • In 7-bit mode, the address byte is stored in RADDR[7:0] • In 10-bit mode, the first address byte is { 11110, RADDR[10:9], RADDR[0] } and the second address byte is RADDR[8:1]. The R/W bit is therefore always stored in RADDR[0] • When ACKSTALL is set, if the first address byte matches in 10-bit mode, then the first address byte is stored in RADDR[7:0] so software can read the Received Address before writing the Transmit ACK. The Received Address then updates with the full 10-bit address if the second address byte matches.

68.5.1.27 Slave Transmit ACK (STAR)

Offset

Register	Offset
STAR	154h

Function

STAR can only be written when the ACK SCL Stall bit is set (SCFGR1[ACKSTALL]).

- The SCFGR1[ACKSTALL] bit enables clock stretching during the ACK/NACK bit slot, and during this time, the STAR register can be written by software.
- The logic ensures that the clock stretching continues for at least 1 bus clock cycle after the STAR register is updated.
- This clock stretching time can be extended more using the Clock Hold Time field (SCFGR2[CLKHOLD]).

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	0															TXNACK
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-1 —	Reserved
0 TXNACK	Transmit NACK After receiving each word, software can transmit either an ACK (logic 0) or a NACK (logic 1); Transmit NACK selects which to use: ACK or NACK. • When SCFGR1[ACKSTALL] is set, a Transmit NACK must be written once for each matching address byte and each received word. ACKSTALL must be set, because that stalls the data transfer until software reads the received word (and decides whether to respond with an ACK or NACK). • To configure the default ACK/NACK, Transmit NACK can also be written when LPI2C Slave is disabled or idle. 0b - Write a Transmit ACK for each received word 1b - Write a Transmit NACK for each received word

68.5.1.28 Slave Transmit Data (STDR)

Offset

Register	Offset
STDR	160h

Function

Clock stretching (enabled or disabled) affects when the transmit data is transferred. The SCFGR1[TXDSTALL] bit enables clock stretching during the 1st data bit of a slave-transmit transfer.

- **If clock stretching is enabled (SCFGR1[TXDSTALL] = 1)**, then the transmit data transfer is stalled until the STDR is updated. Clock stretching is extended by at least 1 bus clock cycle after STDR is updated, and clock stretching can be delayed even more using the Clock Hold Time field (SCFGR2[CLKHOLD].
- **If clock stretching is disabled (SCFGR1[TXDSTALL] = 0)**, then the transmit data should be written before the start of the slave-transmit transfer; otherwise (that is, if the transmit data is not written before the start of the slave-transmit transfer), the FIFO Error Flag (SSR[FEF]) sets.

Chapter 69
Flexible I/O (FlexIO)

69.1 Chip-specific FlexIO information

69.1.1 FlexIO instances and configuration

The device contains one instance of FlexIO.

FlexIO is a highly configurable module providing a wide range of functionality including:

- Emulation of a variety of serial communication protocols like UART, I2C, SPI, SAI. It can work either as master or slave.
- Flexible 16-bit timers with support for a variety of trigger, reset, enable and disable conditions.

Table 387. FlexIO instances

Chip	Instance	No. of pins	No. of timers	No. of shift registers	No. of bits in counter
MWCT2016S, MWCT2D16S, MWCT2D17S,	FlexIO	32	8	8	16
MWCT2015S	FlexIO	16	8	8	16

Table 388. Data rate limitation

FlexIO operation	Data rate limitation
Master Tx	FlexIO_clk/4
Slave Tx	FlexIO_clk/10
Master Rx	FlexIO_clk/8
Slave Rx	FlexIO_clk/6

NOTE

FlexIO supports 32 bit accesses only.

NOTE

When I2S is emulated on FlexIO, you could observe a skew between bit-clock (BCLK) and frame sync pulse amounting to 1/2 of BCLK.

69.2 Overview

The FlexIO is a highly configurable module providing a wide range of functionality including:

- Emulation of a variety of serial/parallel communication protocols
- Flexible 16-bit timers with support for a variety of trigger, reset, enable and disable conditions
- Programmable logic blocks allowing the implementation of digital logic functions on-chip and configurable interaction of internal and external modules
- Programmable state machine for offloading basic system control functions from CPU

69.2.1 Block Diagram

The following diagram gives a high-level overview of the configuration of FlexIO timers and shifters.

The FlexIO uses shifters, timers and external triggers to shift data into or out of the FlexIO. The timing of the data shift is controlled by the timers, as shown in the block diagram. The timers can be configured to use generic timer functions, external triggers, or various other conditions to determine this control.

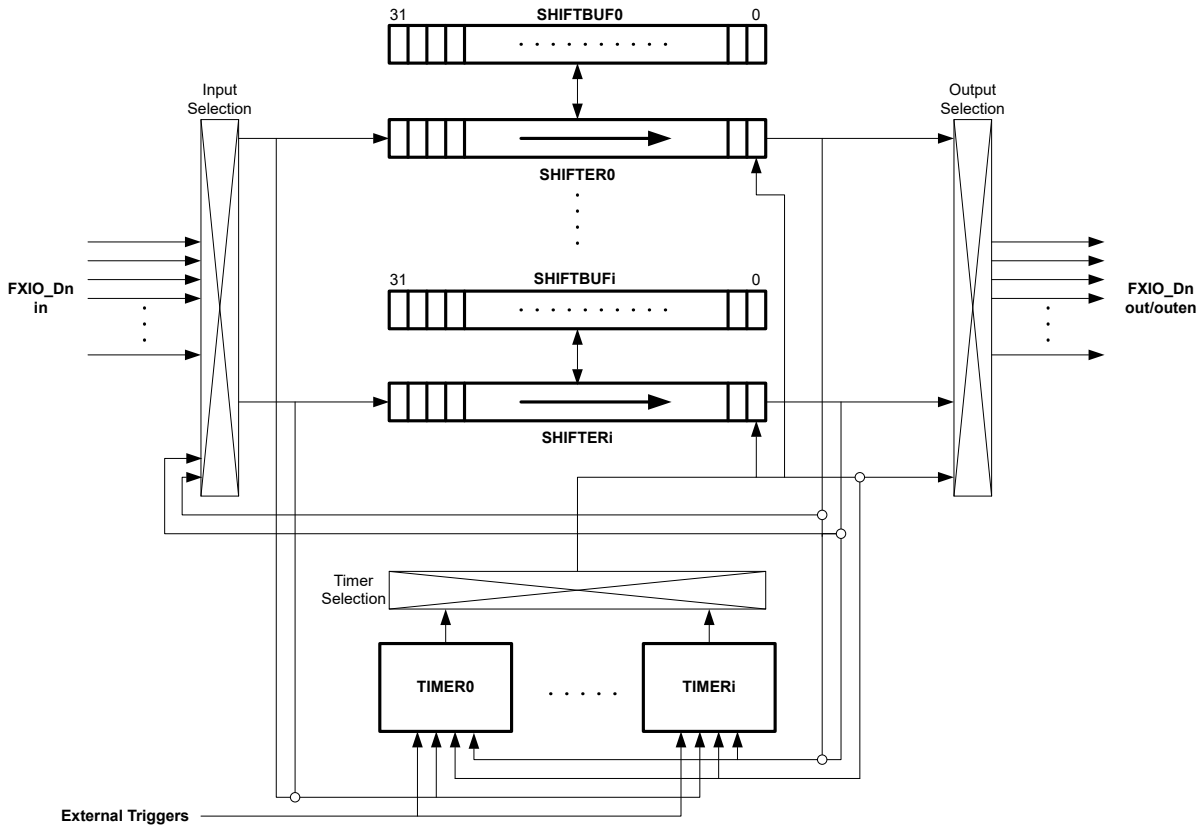

Figure 365. FlexIO block diagram

69.2.2 Features

The FlexIO module is capable of supporting a wide range of protocols including, but not limited to:

- UART
- I2C
- SPI
- I2S
- Camera IF
- Motorola 68K/Intel 8080 bus
- PWM/Waveform generation
- Input-capture (pulse edge interval measurement) - Example: SENT

The following key features are provided:

- Array of 32-bit shift registers with transmit, receive, data match, logic mode, and state modes
- Double buffered shifter operation for continuous data transfer

- Shifter concatenation to support large transfer sizes
- Automatic start/stop bit generation
- 1, 2, 4, 8, 16 or 32 multi-bit shift widths for parallel interface support
- Interrupt, DMA or polled transmit/receive operation
- Programmable baud rates independent of bus clock frequency
- Highly flexible 16-bit timers with support for a variety of internal or external trigger, reset, enable and disable conditions
- Programmable logic mode for integrating external digital logic functions on-chip or combining pin/shifter/timer functions to generate complex outputs
- Programmable state machine for offloading basic system control functions from CPU with support for up to 8 states, 8 outputs and 3 selectable inputs per state
- Integrated general purpose input/output registers and pin rising/falling edge interrupts to simplify software support

69.3 Functional description

69.3.1 Shifter operation

Shifters are responsible for buffering and shifting data into or out of the FlexIO. The timing of shift, load and store events are controlled by the Timer assigned to the Shifter via the SHIFTCTL[TIMSEL] register. The Shifters are designed to support either DMA, interrupt or polled operation. The following block diagram provides a detailed view of the Shifter microarchitecture.

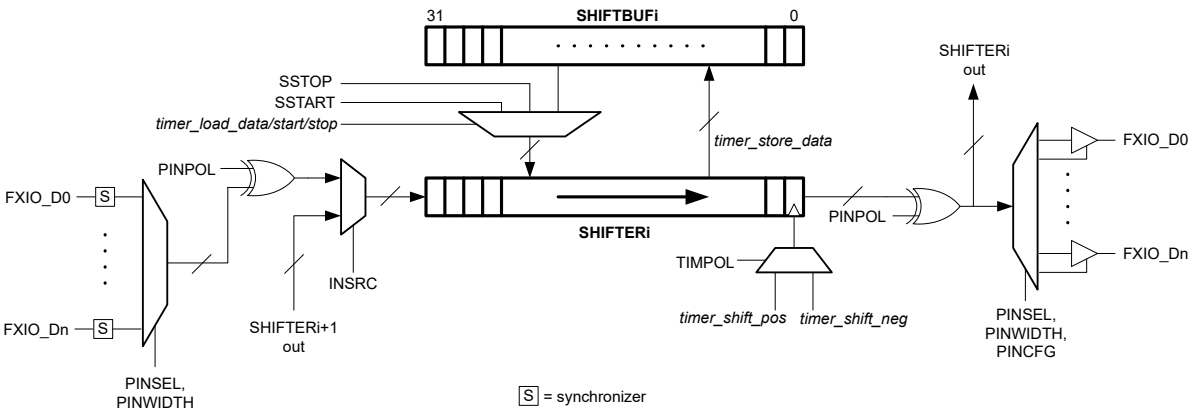

Figure 366. Shifter Microarchitecture

Transmit Mode

When configured for Transmit mode (SHIFTCTL[SMOD]=Transmit), the shifter loads data from the SHIFTBUF register and shift data out when a load event is signalled by the assigned Timer. An optional start/stop bit can also be automatically loaded before/ afterSHIFTBUFdata by configuring the SHIFTCFG[SSTART], TIMCFG[TSTART] or SHIFTCFG[SSTOP], TIMCFG[TSTOP] registers in the Shifter and Timer.

NOTE

The shifter immediately loads a stop bit when the Shifter is initially configured for Transmit mode if a stop bit is enabled.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when data has been loaded from the SHIFTBUF register into the Shifter or when the Shifter is initially configured into Transmit mode. The flag clears when new data has been written into the SHIFTBUF register or a logic 1 is written to this flag. In transmit mode, any write of the SHIFTBUF register clears the corresponding Shifter Status Flag. It does not matter what is writing or the state of the DMA/interrupt enables, the flag is cleared. How the flag is set/cleared for each mode is documented in the SSF register description.

The Shifter Error Flag (SHIFTERR[SEF]) and any enabled interrupts are set when an attempt to load data from an empty SHIFTBUF register occurs (buffer underrun). The flag can be cleared by writing it with logic 1.

Receive Mode

When configured for Receive mode (SHIFTCTL[SMOD]=Receive), the shifter shifts data in and store data into the SHIFTBUF register when a store event is signalled by the assigned Timer. Checking for a start/stop bit can be enabled before/after shifter data is sampled by configuring the SHIFTCFG[SSTART], TIMCFG[TSTART] or SHIFTCFG[SSTOP], TIMCFG[TSTOP] registers in the Shifter and Timer.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when data has been stored into the SHIFTBUF register from the Shifter. The flag clears when the data has been read from theSHIFTBUF register or a logic 1 is written to this flag. Any read of the SHIFTBUF register clears the corresponding Shifter Status Flag when Shifter is configured in Receive mode. It does not matter what is reading or the state of the DMA/interrupt enables, the flag is cleared. How the flag is set/clear for each mode is documented in the SSF register description.

The Shifter Error Flag (SHIFTERR[SEF]) and any enabled interrupts are set when an attempt to store data into a fullSHIFTBUF register occurs (buffer overrun) or when a mismatch occurs on a start/stop bit check. The flag can be cleared by writing it with logic 1.

Match Store Mode

When configured for Match Store mode (SHIFTCTL[SMOD]=Match Store), the shifter shifts data in, check for a match result and store matched data into the SHIFTBUF register when a store event is signalled by the assigned Timer. Checking for a start/stop bit can be enabled before/after shifter data is sampled by configuring the SHIFTCFG[SSTART], TIMCFG[TSTART] or SHIFTCFG[SSTOP], TIMCFG[TSTOP] registers in the Shifter and Timer. Up to 16-bits of data can be compared using SHIFTBUF[31:16] to configure the data to be matched and SHIFTBUF[15:0] to mask the match result.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when a match occurs and matched data has been stored into the SHIFTBUF register from the Shifter. The flag clears when the matched data has been read from the SHIFTBUF register or a logic 1 is written to this flag. Any read of the SHIFTBUF register clears the corresponding Shifter Status Flag when Shifter is configured in Match Store mode. It does not matter what is reading or the state of the DMA/interrupt enables, the flag is cleared. How the flag is set/clear for each mode is documented in the SSF register description.

The Shifter Error Flag (SHIFTERR[SEF]) and any enabled interrupts are set when an attempt to store matched data into a full SHIFTBUF register occurs (buffer overrun) or when a mismatch occurs on a start/stop bit check. The flag can be cleared by writing it with logic 1.

Match Continuous Mode

When configured for Match Continuous mode (SHIFTCTL[SMOD]=Match Continuous), the shifter shifts data in and continuously check for a match result whenever a shift event is signalled by the assigned Timer. Up to 16-bits of data can be compared using SHIFTBUF[31:16] to configure the data to be matched and SHIFTBUF[15:0] to mask the match result.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when a match occurs. The flag clears automatically as soon as there is no longer a match between Shifter data and SHIFTBUF register. **The flag cannot be cleared by reading the SHIFTBUF register.**

The Shifter Error Flag (SHIFTERR[SEF]) and any enabled interrupts are set when a match occurs. The flag clears when there is a read from the SHIFTBUF register or it written with logic 1.

State Mode

Using State mode enables the user to implement any state machine with up to 8 states, 8 outputs and 3 selectable inputs per state. This feature allows basic control functions to be offloaded from the CPU.

When configured for State mode (SHIFTCTL[SMOD]=State), the SHIFTBUF register is used to drive the output and compute next state values when the Shifter has been selected by the current state pointer (SHIFTSTATE[STATE]). The following diagram provides a detailed view of Shifter microarchitecture when configured for State mode.

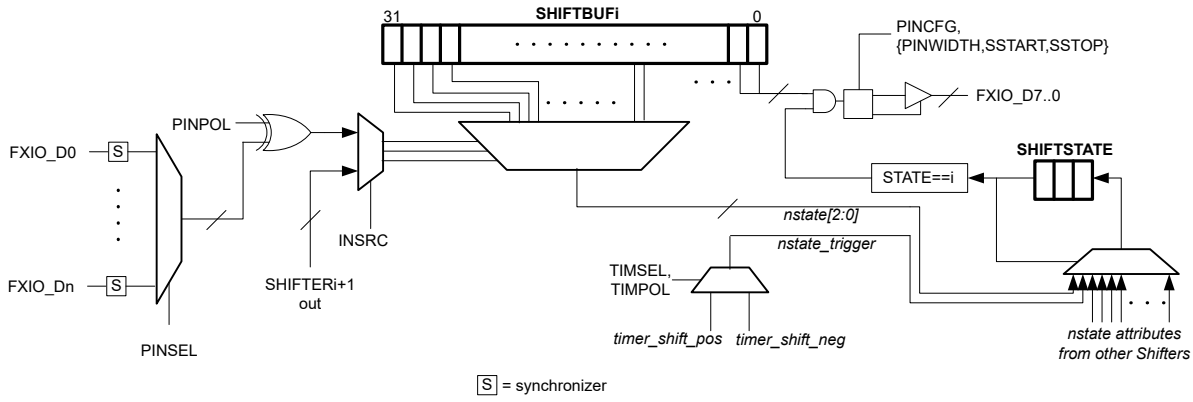

Figure 367. State Microarchitecture

When Shifter i has been selected by the current state pointer, output pins FXIO_D[7:0] are driven by SHIFTBUFi[31:24] using the configuration set by SHIFTCTLi[PINCFG]. When set, SHIFTCFGi{PWIDTH[3:0],SSTOP[1:0],SSTART[1:0]} are respectively used to disable the output drive on pins FXIO_D[7:0] for state machine applications which require less than 8 output pins.

The next state value is computed using the 3 input pins selected by SHIFTCTLi[PINSEL] together with SHIFTBUFi[23:0].

NOTE

Each state could potentially use a different set of 3 input pins.

The following table details how the next state value is computed when the current state pointer is pointing to Shifter i.

Table 389. Next State computation for SHIFTSTATE[STATE]=i

FXIO_D[PINSEL+2]	FXIO_D[PINSEL+1]	FXIO_D[PINSEL]	Next State Value
0	0	0	SHIFTBUFi[2:0]
0	0	1	SHIFTBUFi[5:3]
0	1	0	SHIFTBUFi[8:6]
0	1	1	SHIFTBUFi[11:9]
...	...	...	...
1	1	1	SHIFTBUFi[23:21]

Note that other shifters/timers could potentially be configured to drive the input pins of a given state, allowing the user to create complex combinations of shifters/timers as desired e.g. the output of a Shifter configured for logic mode could potentially be used to drive a state machine input.

The next state transition is triggered using the Timer output selected by SHIFTCTLi[TIMSEL] with polarity controlled by SHIFTCTLi[TIMPOL]. Note that each state could potentially use a different Timer to trigger each next state transition, allowing a variety of internal/external trigger sources and clocking configurations to be used (see Timer section for more detail).

The current state pointer defaults to Shifter 0 at reset, however it can be written by the user to select a different Shifter for the initial state. If the current state pointer selects a Shifter which is not configured for State mode, then outputs are not driven and a next state transition is never triggered.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set whenever the Shifter has been selected by the current state pointer. The flag clears when the current state pointer is updated to a different Shifter.

Logic Mode

Using logic mode enables the user to implement a small amount of programmable digital logic within a FlexIO Shifter.

When configured for Logic mode (SHIFTCTL[SMOD]=Logic), theSHIFTBUF register is used to implement a 5-input, 32-bit programmable logic look-up table. The following diagram provides a detailed view of Shifter microarchitecture when configured for Logic mode.

The SHIFTBUFi configures the lookup table for the 4 pin inputs and the SHIFTERi can optionally be used to configure a feedback or delayed pin source as the 5th input to the look up table.

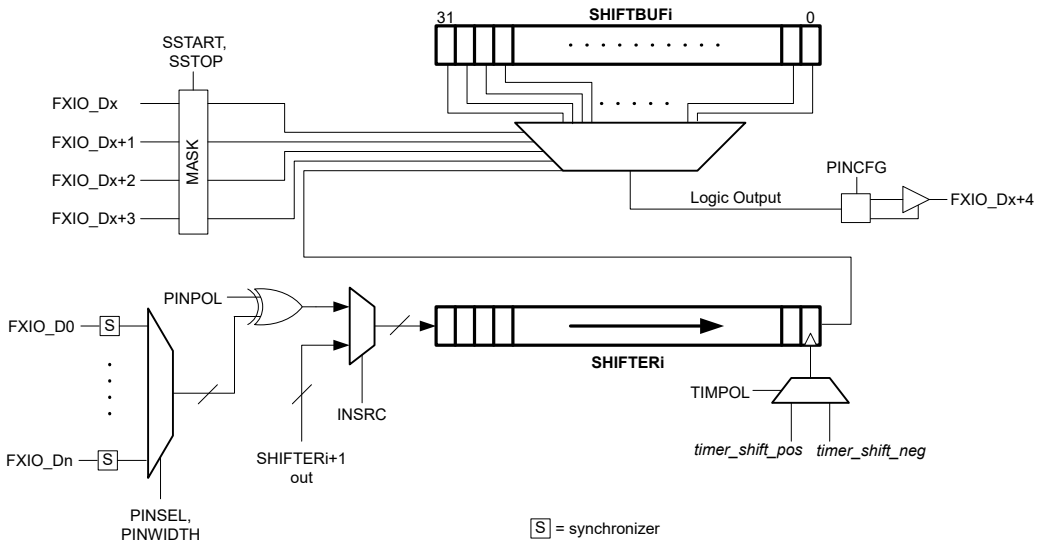

Figure 368. Logic Microarchitecture

The look-up table is driven using 4 pin inputs (maskable using SHIFTCFG[SSTOP] and SHIFTCFG[SSTART]) plus 1 input from the internal shifter and can be configured to drive an output pin using the SHIFTCTL[PINCFG] field. Pin inputs and outputs are fixed for each logic look-up table and are not selectable. The following table lists the logic output value selected by the look-up table for Shifter 'i'.

Table 390. Logic Look-up table for Shifter 'i'

SHIFTERi[0]	FXIO_D[x+3][1]	FXIO_D[x+2]	FXIO_D[x+1]	FXIO_D[x]	Logic Output to FXIO_D[x+4]
0	0	0	0	0	SHIFTBUFi[0]
0	0	0	0	1	SHIFTBUFi[1]
0	0	0	1	0	SHIFTBUFi[2]
0	0	0	1	1	SHIFTBUFi[3]
...	...	...	...	...	...
1	1	1	1	1	SHIFTBUFi[31]

1. for Shifter i=0...3, x=i

   for Shifter i=4...7, x=i+4

To minimize output glitches, SHIFTCFG[SSTOP] and SHIFTCFG[SSTART] can be used to mask unused input pins. When set, {SSTOP[1:0], SSTART[1:0]} mask FXIO_D[x+3]...FXIO_D[x] inputs respectively, so that any transitions on these pins does not cause the logic output to glitch.

Note that other shifters/timers could potentially be configured to drive the input pins of a given look-up table, allowing the user to concatenate look-up tables or create complex combinations of shifters/timers as desired.

SHIFTCFG[PWIDTH] controls the number of delay stages introduced by the internal shifter input (SHIFTERi[0]). For example, when configured for 1-bit shift (PWIDTH=0), the internal shifter introduces a 32 Shift clock delay before passing its input (selected by SHIFTCTL[PINSEL]) to the look-up table. When configured for 32-bit shift (PWIDTH=16...31), the internal shifter introduces a 1 Shift clock delay to its input.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set whenever the output pin allocated to the logic look-up table has a value of 1 (after being synchronized to the FlexIO clock). The flag clears when the output pin has a value of 0. This also allows the SSF flag to be used as a trigger to a Timer if desired.

The Shifter Error Flag (SHIFTERR[SEF]) and any enabled interrupts are set when the output pin allocated to the logic look-up table has asserted. The flag can be cleared by writing it with logic 1.

The logic mode input pins (including pins driven by other shifters/timers) are first synchronized to the FlexIO functional clock before they are input to the programmable logic look-up table.

69.3.2 Timer Operation

The FlexIO 16-bit timers control the loading, shifting and storing of the shift registers, the counters load the contents of the compare register and decrement down to zero on the FlexIO clock. They can perform generic timer functions such as generating a clock or select output or a PWM waveform. Timers can be configured to enable in response to a trigger, pin or shifter condition; decrement always or only on a trigger or pin edge; reset in response to a trigger or pin condition; and disable on a trigger or pin condition or on a timer compare. Timers can optionally include a start condition and/or stop condition.

Each timer operates independently, although a timer can be configured to enable or disable at the same time as the previous timer (eg: timer1 can enable or disable at the same time as timer 0) and a timer output can be used to trigger any other timer. The trigger used by each timer is configured independently and can be configured to be a timer output, shifter status flag, pin input or an external trigger input (refer to the chip-specific FlexIO information for details on the external trigger connections). The trigger configuration is separate from the pin configuration, which can be configured for input, output data or output enable.

The Timer Configuration Register (TIMCFGn) should be configured before setting the Timer Mode (TIMOD).

Timer 8-bit Baud Counter Mode

In 8-bit Baud Counter Mode, the 16-bit counter is divided into two 8-bit counters. The lower 8-bits are used to configure the baud rate of the shift clock and the upper 8-bits are used to configure the number of shift clock edges in the transfer. When the lower 8-bits decrement to zero, the timer output is toggled and the lower 8-bits reload from the compare register. The upper 8-bits decrement when the lower 8-bits equal zero and decrement.

Note that a timer reset event in 8-bit Baud Counter Mode only resets the lower 8-bit counter, the upper 8-bit counter is not affected and can decrement if the timer reset is configured to update the state of the timer output, and the timer output toggles as a result of the timer reset event.

A timer compare event occurs when the upper 8-bits equal zero and decrements. The timer status flag is set on a timer compare event.

Timer 8-bit High PWM Mode

In 8-bit High PWM Mode, the 16-bit counter is divided into two 8-bit counters. The lower 8-bits are used to configure the timer output high period and the upper 8-bits are used to configure the timer output low period. The lower 8-bits decrement when the output is high. When the lower 8-bits equal zero and decrement, the timer output is cleared and the lower 8-bits are reloaded from the compare register. The upper 8-bits decrement when the output is low. When the upper 8-bits equal zero and decrement, the timer output is set and the upper 8-bits are reloaded from the compare register.

A timer compare event occurs when the upper 8-bits equal zero and decrements. The timer status flag is set on a timer compare event.

Timer 16-bit Counter Mode

In 16-bit Counter Mode, the 16-bit counter can be used to configure either the baud rate of the shift clock (eg: TIMDEC[1:0] != 10 or 11) or the number of shift clock edges in the transfer (eg: TIMDEC[1:0] = 10 or 11). When the 16-bit counter equals zero and decrements, the timer output toggles and the counter reloads from the compare register.

A timer compare event occurs when the 16-bit counter equals zero and decrements. The timer status flag is set on a timer compare event.

Timer 16-bit Counter Disable Mode

In 16-bit Counter Disable Mode, the 16-bit counter can be used to configure either the baud rate of the shift clock (eg: TIMDEC[1:0] != 10 or 11) or the number of shift clock edges in the transfer (eg: TIMDEC[1:0] = 10 or 11). When the 16-bit counter equals zero and decrements, the timer output toggles and the counter reloads from the compare register.

A timer compare event occurs when the 16-bit counter equals zero and decrements. The timer status flag is set on a timer disable event.

Timer 8-bit Word Counter Mode

In 8-bit Word Counter Mode, the 16-bit counter is divided into two 8-bit counters. The lower 8-bits are used to configure the number of shift clock edges in each word and the upper 8-bits are used to configure the number number of words in the transfer. When the lower 8-bits decrement to zero, the timer output is toggled and the lower 8-bits reload from the compare register. The upper 8-bits only decrement when the lower 8-bits equal zero and decrement.

A timer compare event occurs when the lower 8-bits equal zero and decrements. The timer status flag is set when the upper 8-bits equal zero and decrements.

Timer 8-bit Low PWM Mode

In 8-bit Low PWM Mode, the 16-bit counter is divided into two 8-bit counters. The lower 8-bits are used to configure the timer output low period and the upper 8-bits are used to configure the timer output high period. The lower 8-bits decrement when the output is low. When the lower 8-bits equal zero and decrement, the timer output is set and the lower 8-bits are reloaded from the compare register. The upper 8-bits decrement when the output is high. When the upper 8-bits equal zero and decrement, the timer output is cleared and the upper 8-bits are reloaded from the compare register.

A timer compare event occurs when the upper 8-bits equal zero and decrements. The timer status flag is set on a timer compare event.

Timer 16-bit Input Capture Mode

In 16-bit Input Capture Mode, the 16-bit counter uses a fixed initial value of 0xFFFF to load the counter. Whenever a timer counter disable condition is detected (as configured by TIMDIS), the timer status flag is set and the inverted timer counter value is stored in the timer compare register, then the timer counter is immediately restarted from 0xFFFF. The timer output is always output on the FlexIO trigger outputs (which can also be used by other timers as an input trigger) and can also be output to a pin (PINCFG/PINPOL/PINSEL) or a shifter.

If the timer status flag is already set, then the input capture event is missed. When the 16-bit counter equals zero and decrements, the timer output toggles and the counter reloads with 0xFFFF. The timer output can be used to count the number of counter overflows between two input capture events. Input capture mode is not intended to be used to control shift registers, it is to enable software to count the number of bits in a variable length transfer or to monitor the period or frequency of an input.

A timer compare event occurs when the 16-bit counter equals zero and decrements. The timer status flag is set on a timer disable event. Whenever the status flag asserts, the inverted timer counter value is stored in the timer compare register.

Timer Enable and Start Bit

When the TIMOD is configured for the desired mode, and the condition configured by timer enable (TIMENA) is detected then the following events occur. When ONETIM is set, then the timer status flag must also be clear to generate a timer enable event, otherwise the timer enable event is blocked. This can be used to enforce software intervention after each timer iteration.

- Timer counter loads the current value of the compare Register and start decrementing as configured by TIMDEC.
- Timer output may update to its initial state depending on the TIMOUT configuration. Shifters that are controlled by this timer do not see this as a rising edge on the timer shift clock.
- Transmit shifters controlled by this timer either output their start bit value, or load the shift register from the shift buffer and output the first bit, as configured by SSTART.

If the Timer start bit is enabled, the timer counter reloads with the compare register on the first rising edge of the shift clock after the timer starts decrementing. If there is no falling edge on the shift clock before the first rising edge (for example, when TIMOUT=1), a shifter that is configured to shift on falling edge and load on the first shift does not load correctly.

Timer Decrement and Reset

The Timer then generates the timer output and timer shift clock depending on the TIMOD and TIMDEC fields. The shifter clock is either equal to the timer output (when TIMDEC != 10 or 11) or equal to the decrement clock (when TIMDEC = 10 or 11). When TIMDEC is configured to decrement from a pin or trigger, the timer decrements on both rising and falling edges.

If a Timer is configured to decrement on the FlexIO functional clock divided by 16 or 256 (when TIMDEC = 100 or 101), then a common prescaler that is shared by all Timers is used to generate the two divide ratios. This prescaler is reset when all Timers are either idle or configured to not use the prescaler (TIMDEC != 100 or 101).

When the Timer is configured to reset as configured in the TIMRST field then the Timer counter loads the current value of the compare register again. The timer output and timer shift clock can be configured to update on timer reset, as configured by TIMOUT. This can result in a timer shift clock edge if the timer output toggles as a result of the timer reset. In 8-bit Baud Counter mode this would also decrement the upper 8-bits of the counter.

In general, when the timer counter decrements to zero a timer compare event is triggered. The timer compare event causes the timer counter to load the contents of the timer compare register, the timer output to toggle, any configured transmit shift registers to load, and any configured receive shift registers to store. Depending on the timer mode, the timer status flag may also be set.

Timer Disable and Stop Bit

When the is Timer is configured to add a stop bit on each compare, the following additional events occur.

- Transmit shifters controlled by this timer output their stop bit value (if configured by SSTOP).
- Receive shifters controlled by this timer store the contents of the shift register in their shift buffer, as configured by SSTOP.
- On the first rising edge of the shifter clock after the compare, the timer counter reloads the current value of the Compare Register.

Transmit shifters must be configured to load on the first shift when the timer is configured to insert a stop bit on each compare.

When the condition configured by timer disable (TIMDIS) is detected, the following events occur.

- Timer counter reloads the current value of the Compare Register and start decrementing as configured by TIMDEC.
- Timer output clears. Shifters that are controlled by this timer do not see this as a falling edge on the timer shift clock, but can generate a shift event if the timer shift clock would otherwise generate one.
- Transmit shifters controlled by this timer output their stop bit value (if configured by SSTOP).
- Receive shifters controlled by this timer store the contents of the shift register in their shift buffer, as configured by SSTOP.

If the timer stop bit is enabled, the timer counter continues decrementing until the next rising edge of the shift clock is detected, at which point it finishes. Although the timer output is forced low during the stop bit, the timer shift clock can toggle during the stop bit, but does not generate shift events.

A timer enable condition can be detected in the same cycle as a timer disable condition (if timer stop bit is disabled), or on the first rising edge of the shift clock after the disable condition (if stop bit is enabled). When ONETIM is set, the timer status flag must be clear before the next timer enable condition is detected. Receive shift registers with stop bit enabled store the contents of the shift register into the shift buffer and verify the state of the input data on the configured shift edge while the timer is in the stop state

condition. If there is no configured edge between the timer disable and the next rising edge of the shift clock then the final store and verify do not occur.

69.3.3 Pin operation

The pin configuration for each timer and shifter can be configured to use any FlexIO pin with either polarity. Each timer and shifter can be configured as an input, output data, output enable or bidirectional output. A pin configured for output enable can be used as an open drain (with inverted polarity, since the output enable assertion would cause logic zero to be output on the pin) or to control the enable on the bidirectional output. Any timer or shifter could be configured to control the output enable for a pin where the bidirectional output data is driven by another timer or shifter.

Parallel Interface

Shifters can be configured to use multiple FlexIO pins in parallel using the SHIFTCFG[PWIDTH] field. PWIDTH is used to configure the following settings of a shifter:

1. Number of bits shifted per Shift clock.
2. Number of pins driven by the shifter per Shift clock (only on shifters supporting parallel transmit i.e. SHIFTER0, SHIFTER4).
3. Number of pins sampled by the shifter per Shift clock (only on Shifter supporting parallel receive i.e. SHIFTER3, SHIFTER7).

When configured for parallel shift, either 4, 8, 16 or 32-bits can be shifted on every Shift clock. If an adjacent shifter is selected as the input source (SHIFTCFG[INSRC]=1), the least significant 4, 8, 16 or 32-bits from the adjacent shifter is sampled on each Shift clock.

For shifters supporting parallel receive (SHIFTER3, SHIFTER7), the shifter can be configured to sample multiple pins (SHIFTCFG[INSRC]=0), with PWIDTH and PINSEL selecting the pins as follows: FXIO_D[PINSEL+PWIDTH]:FXIO_D[PINSEL]. Note that if PWIDTH is less than the number of bits being shifted on each Shift clock, then the most significant bits are masked with 0 e.g. if PINSEL=7 and PWIDTH=6, then SHIFTER[31:24] samples {0,0,FXIO_D[12:7]} on each Shift clock.

For shifters supporting parallel transmit (SHIFTER0, SHIFTER4), the shifter can be configured to drive multiple pins using SHIFTCTL[PINCFG], with PWIDTH and PINSEL selecting the pins as follows: FXIO_D[PINSEL+PWIDTH]:FXIO_D[PINSEL]. Note that if PWIDTH is less than the number of bits being shifted on each Shift clock, then the most significant pins are not driven e.g. if PINSEL=7 and PWIDTH=6, then SHIFTER[5:0] drives only FXIO_D[12:7] on each Shift clock.

Pin Synchronization

When configuring a pin as an input (this includes a timer trigger configured as a pin input), the input signal is first synchronized to the FlexIO clock before the signal is used by a timer or shifter. This introduces a small latency of between 0.5 to 1.5 FlexIO clock cycles when using an external pin input to generate an output or control a shifter. This sets the maximum setup time at 1.5 FlexIO clock cycles.

If an input is used by more than one timer or shifter then the synchronization occurs once to ensure any edge is seen on the same cycle by all timers and shifters using that input.

Note that FlexIO pins are also connected internally, configuring a FlexIO shifter or timer to output data on an unused pin makes an internal connection that allows other shifters and timer to use this pin as an input. This allows a shifter output to be used to trigger a timer or a timer output to be shifted into a shifter. This path is also synchronized to the FlexIO clock and therefore incurs a 1 cycle latency.

So when using a Pin input as a Timer Trigger, Timer Clock or Shifter Data Input, the following synchronization delays occur:

1. 0.5 to 1.5 FlexIO clock cycles for external pin
2. 1 FlexIO clock cycle for an internally driven pin

For timing considerations such as output valid time and input setup time for specific applications (SPI Master, SPI Slave, I2C Master, I2S Master, I2S Slave) please refer to the FlexIO Application Information Section.

Pin Override

The state of any FlexIO pin can be overriden at any time by software. The Pin Output Enable register configures any pin as an output and drives that pin with the value in the Pin Output Data Register.

Alias registers for the Pin Output Enable/Data Registers also exist, writing a logic one to an alias register updates the corresponding register bits in both the Pin Output Enable Register and the Pin Output Data Register as follows.

- Pin Output Disable Register clears Output Enable Register and clear Output Data Register.
- Pin Output Clear Register sets Output Enable Register and clear Output Data Register.
- Pin Output Set Register sets Output Enable Register and set Output Data Register.
- Pin Output Toggle Register sets Output Enable Register and toggle Output Data Register.

Pin Interrupt

The state of any FlexIO pin can be read by software at any time. Software can also configure any pin to set a status flag when either a rising and/or falling edge is detected on that pin. The pin status flag can also be configured to generate an interrupt.

69.3.4 Low Power Modes

The FlexIO remains functional during low power modes, provided the FlexIO functional clock remains enabled.

69.3.5 Debug Mode

The FlexIO remains functional in debug mode provided the Debug Enable bit (CTRL[DBGE]) is set.

69.3.6 Clocks

Functional clock

The FlexIO functional clock is asynchronous to the bus clock and can remain enabled in low power modes. The FlexIO functional clock must be enabled before accessing any FlexIO registers. Provided the FlexIO functional clock is at least equal to the bus clock, the CTRL[FASTACC] bit can be set to support fast register accesses.

Bus clock

The bus clock is only used for bus accesses to the control and configuration registers.

69.3.7 Reset

Chip reset

The logic and registers for the FlexIO are reset to their default state on a chip reset.

Software reset

The FlexIO implements a software reset bit in its Control Register. The CTRL[SWRST] resets all logic and registers to their default state, except for the CTRL itself.

69.3.8 Interrupts and DMA Requests

The following table illustrates the status flags that can generate the FlexIO interrupt and DMA requests.

Table 391. FlexIO Interrupts and DMA Requests

Flag	Description	Interrupt	DMA Request	Low Power Wakeup
SSF	Shifter Status Flag.	Y	Y	Y
SEF	Shifter Error Flag.	Y	N	Y
TSF	Timer Status Flag.	Y	Y	Y
PSF	Pin Status Flag.	Y	N	Y
ETSF	External Trigger Status Flag.	Y	N	Y

69.3.9 Peripheral Triggers

The connection of the FlexIO peripheral triggers with other peripherals are device specific.

Output Triggers

Each FlexIO Timer generates an output trigger equal to the timer output. The output trigger is not affected by the timer pin polarity configuration.

Input Trigger

FlexIO supports multiple external trigger inputs that can be used to trigger one or more FlexIO timers. If a rising edge is detected on an external trigger when the FlexIO is enabled, then the external trigger status flag is set. The external triggers are synchronized to the FlexIO functional clock and must assert for at least two cycles of the FlexIO functional clock to be sampled correctly.

69.4 Application Information

This section provides examples for a variety of FlexIO module applications.

69.4.1 UART Transmit

UART transmit can be supported using one Timer, one Shifter and one Pin (two Pins if supporting CTS). The start and stop bit insertion is handled automatically and multiple transfers can be supported using DMA controller. The timer status flag can be used to indicate when the stop bit of each word is transmitted.

Break and idle characters require software intervention, before transmitting a break or idle character the SSTART and SSTOP fields should be altered to transmit the required state and the data to transmit must equal 0xFF or 0x00. Supporting a second stop bit requires the stop bit to be inserted into the data stream using software (and increasing the number of bits to transmit). Note that when performing byte writes to SHIFTBUFn (or SHIFTBUFBIS for transmitting MSB first), the rest of the register remains unaltered allowing an address mark bit or additional stop bit to remain undisturbed.

FlexIO does not support automatic insertion of parity bits.

Table 392. UART Transmit Configuration

Register	Value	Comments
SHIFTCFGn	0x0000_0032	Configure start bit of 0 and stop bit of 1.
SHIFTCTLn	0x0003_0002	Configure transmit using Timer 0 on posedge of clock with output data on Pin 0. Can invert output data by setting PINPOL, or can support open drain by setting PINPOL=0x1 and PINCFG=0x1.

Table continues on the next page...

Table 392. UART Transmit Configuration (continued)

Register	Value	Comments
TIMCMPn	0x0000_0F01	Configure 8-bit transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of bits x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFGn	0x0000_2222	Configure start bit, stop bit, enable on trigger asserted and disable on compare. Can support CTS by configuring TIMEN=0x3.
TIMCTLn	0x01C0_0001	Configure dual 8-bit counter using Shifter 0 status flag as inverted internal trigger source. Can support CTS by configuring PINSEL=0x1 (for Pin 1) and PINPOL=0x1.
SHIFTBUFn	Data to transmit	Transmit data can be written to SHIFTBUF[7:0] to initiate an 8-bit transfer, use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request. Can support MSB first transfer by writing to SHIFTBUFBBS[7:0] register instead.

An alternative configuration is possible that supports slower baud rates but requires two Timers.

Table 393. UART Transmit Configuration for Slow Baud Rate

Register	Value	Comments
SHIFTCFGn	0x0000_0032	Configure start bit of 0 and stop bit of 1.
SHIFTCTLn	0x0003_0002	Configure transmit using Timer 0 on posedge of clock with output data on Pin 0. Can invert output data by setting PINPOL, or can support open drain by setting PINPOL=0x1 and PINCFG=0x1.
TIMCMPn	0x0000_000F	Configure for 8-bit transfer. Set TIMCMP[15:0] = (number of bits x 2) - 1.
TIMCFGn	0x0030_2622	Configure start bit, stop bit, enable on trigger rising edge, decrement on trigger and disable on compare.
TIMCTLn	0x0740_0003	Configure 16-bit counter using Timer 1 output as internal trigger source.
TIMCMP(n+1)	0x0000_0001	Configure baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:0] = (baud rate divider / 2) - 1.

Table continues on the next page...

Table 393. UART Transmit Configuration for Slow Baud Rate (continued)

Register	Value	Comments
TIMCFG(n+1)	0x0000_1200	Configure enable on trigger asserted and disable on Timer 0 disable. Can support CTS by configuring TIMEN=0x3.
TIMCTL(n+1)	0x01C0_0003	Configure 16-bit counter using Shifter 0 status flag as inverted internal trigger source. Can support CTS by configuring PINSEL=0x1 (for Pin 1) and PINPOL=0x1.
SHIFTBUFn	Data to transmit	Transmit data can be written to SHIFTBUF[7:0] to initiate an 8-bit transfer, use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request. Can support MSB first transfer by writing to SHIFTBUFBBS[7:0] register instead.

69.4.2 UART Receive

UART receive can be supported using one Timer, one Shifter and one Pin (two Timers and two Pins if supporting RTS). The start and stop bit verification is handled automatically and multiple transfers can be supported using the DMA controller. The timer status flag can be used to indicate when the stop bit of each word is received.

Triple voting of the received data is not supported by FlexIO, data is sampled only once in the middle of each bit. Another timer can be used to implement a glitch filter on the incoming data, another Timer can also be used to detect an idle line of programmable length. Break characters cause the error flag to set and the shifter buffer register returns 0x00.

FlexIO does not support automatic verification of parity bits.

Table 394. UART Receiver Configuration

Register	Value	Comments
SHIFTCFGn	0x0000_0032	Configure start bit of 0 and stop bit of 1.
SHIFTCTLn	0x0080_0001	Configure receive using Timer 0 on negedge of clock with input data on Pin 0. Can invert input data by setting PINPOL.
TIMCMPn	0x0000_0F01	Configure 8-bit transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of bits x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFGn	0x0204_2422	Configure start bit, stop bit, enable on pin posedge and disable on compare. Enable resynchronization to received data with TIMOUT=0x2 and TIMRST=0x4.

Table continues on the next page...

Table 394. UART Receiver Configuration (continued)

Register	Value	Comments
TIMCTLn	0x0000_0081	Configure dual 8-bit counter using inverted Pin 0 input.
SHIFTBUFn	Data to receive	Received data can be read from SHIFTBUFBYS[7:0], use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request. Can support MSB first transfer by reading from SHIFTBUFBIS[7:0] register instead.

The UART Receiver with RTS configuration uses a 2nd Timer to generate the RTS output. The RTS asserts when the start bit is detected and negate when the data is read from the shifter buffer register. No start bit is detected while the RTS is asserted, the received data is simply ignored.

Table 395. UART Receiver with RTS Configuration

Register	Value	Comments
SHIFTCFGn	0x0000_0032	Configure start bit of 0 and stop bit of 1.
SHIFTCTLn	0x0080_0001	Configure receive using Timer 0 on negedge of clock with input data on Pin 0. Can invert input data by setting PINPOL.
TIMCMPn	0x0000_0F01	Configure 8-bit transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of bits x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFGn	0x0204_2522	Configure start bit, stop bit, enable on pin posedge with trigger asserted and disable on compare. Enable resynchronization to received data with TIMOUT=0x2 and TIMRST=0x4.
TIMCTLn	0x02C0_0081	Configure dual 8-bit counter using inverted Pin 0 input. Trigger is internal using inverted Pin 1 input.
TIMCMP(n+1)	0x0000_FFFF	Never compare.
TIMCFG(n+1)	0x0030_6100	Enable on Timer N enable and disable on trigger falling edge. Decrement on trigger to ensure no compare.
TIMCTL(n+1)	0x0143_0003	Configure 16-bit counter and output on Pin 1. Trigger is internal using Shifter 0 flag.
SHIFTBUFn	Data to receive	Received data can be read from SHIFTBUFBYS[7:0], use the Shifter Status Flag to indicate when data

		can be read using interrupt or DMA request. Can support MSB first transfer by reading from SHIFTBUFBIS[7:0] register instead.

69.4.3 SPI Master

SPI master mode can be supported using two Timers, two Shifters and four Pins. Either CPHA=0 or CPHA=1 can be supported and transfers can be supported using the DMA controller. For CPHA=1, the select can remain asserted for multiple transfers and the timer status flag can be used to indicate the end of the transfer.

The stop bit is used to guarantee a minimum of 1 clock cycle between the slave select negating and before the next transfer. Writing to the transmit buffer by either core or DMA is used to initiate each transfer.

NOTE

Due to synchronization delays, the setup time for the serial input data is 1.5 FlexIO clock cycles, so the maximum baud rate is divide by 4 of the FlexIO clock frequency.

Table 396. SPI Master (CPHA=0) Configuration

Register	Value	Comments

69.4.5 I2C Master

I2C master mode can be supported using two Timers, two Shifters and two Pins. One timer is used to generate the SCL output and one timer is used to control the shifters. The two shifters are used to transmit and receive for every word, when receiving the transmitter must transmit 0xFF to tristate the output. FlexIO inserts a stop bit after every word to generate/verify the ACK/NACK. FlexIO waits for the first write to the transmit data buffer before enabling SCL generation. Data transfers can be supported using the DMA controller and the shifter error flag sets on transmit underrun or receive overflow.

The first timer generates the bit clock for the entire packet (START to Repeated START/STOP), so the compare register needs to be programmed with the total number of clock edges in the packet (minus one). The timer supports clock stretching using the reset counter when pin equal to output (although this increases both the clock high and clock low periods by at least 1 FlexIO clock cycle each). The second timer uses the SCL input pin to control the transmit/receive shift registers, this enforces an SDA data hold time by an extra 2 FlexIO clock cycles.

Both the transmit and receive shifters need to be serviced for each word in the transfer, the transmit shifter must transmit 0xFF when receiving and the receive shifter returns the data actually present on the SDA pin. The transmit shifter loads 1 additional word on the last falling edge of SCL pin, this word should be 0x00 if generating a STOP condition or 0xFF if generating a repeated START condition. During the last word of a master-receiver transfer, the transmit SSTOP bit should be set by software to generate a NACK.

The receive shift register asserts an error interrupt if a NACK is detected, but software is responsible for generating the STOP or repeated START condition. If a NACK is detected during master-transmit, the interrupt routine should immediately write the transmit shifter register with 0x00 (if generating STOP) or 0xFF (if generating repeated START). Software should then wait for the next rising edge on SCL and then disable both timers. The transmit shifter should then be disabled after waiting the setup delay for a repeated START or STOP condition.

NOTE

Due to synchronization delays, the data valid time for the transmit output is 2 FlexIO clock cycles, so the maximum baud rate is divide by 6 of the FlexIO clock frequency.

The I2C master data valid is delayed 2 cycles because the clock output is passed through a synchronizer before clocking the transmit/receive shifter (to guarantee some SDA hold time). Since the SCL output is synchronous with FlexIO clock, the synchronization delay is 1 cycle and then 1 cycle to generate the output.

Table 400. I2C Master Configuration

SHIFTCFG(n+1)	0x0000_0020	Start bit disabled and stop bit enabled (logic 0) for ACK/NACK detection.
SHIFTCTL(n+1)	0x0180_0001	Configure receive using Timer 1 on falling edge of clock with input data on Pin 0.
TIMCMPn	0x0000_2501	Configure 2 word transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of words x 18) + 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFGn	0x0102_2222	Configure start bit, stop bit, enable on trigger high, disable on compare, reset if output equals pin. Initial clock state is logic 0 and is not affected by reset.
TIMCTLn	0x01C1_0101	Configure dual 8-bit counter using Pin 1 output enable (SCL open drain), with Shifter 0 flag as the inverted trigger.
TIMCMP(n+1)	0x0000_000F	Configure 8-bit transfer. Set TIMCMP[15:0] = (number of bits x 2) - 1.
TIMCFG(n+1)	0x0020_1112	Enable when Timer 0 is enabled, disable when Timer 0 is disabled, enable start bit and stop bit at end of each word, decrement on pin input.
TIMCTL(n+1)	0x01C0_0183	Configure 16-bit counter using inverted Pin 1 input (SCL).
SHIFTBUFn	Data to transmit	Transmit data can be written to SHIFTBUFBBS[7:0], use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request.
SHIFTBUF(n+1)	Data to receive	Received data can be read from SHIFTBUFBIS[7:0], use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request.

69.4.6 I2S Master

I2S master mode can be supported using two Timers, two Shifters and four Pins. One timer is used to generate the bit clock and control the shifters and one timer is used to generate the frame sync. FlexIO waits for the first write to the transmit data buffer before enabling bit clock and frame sync generation. Data transfers can be supported using the DMA controller and the shifter error flag sets on transmit underrun or receive overflow.

The bit clock frequency is an even integer divide of the FlexIO clock frequency, and the initial frame sync assertion occurs at the same time as the first bit clock edge. The timer uses the start bit to ensure the frame sync is generated one clock cycle before the first output data.

NOTE

Due to synchronization delays, the setup time for the receiver input is 1.5 FlexIO clock cycles, so the maximum baud rate is divide by 4 of the FlexIO clock frequency.

Table 401. I2S Master Configuration

Register	Value	Comments
SHIFTCFGn	0x0000_0001	Load transmit data on first shift and stop bit disabled.
SHIFTCTLn	0x0003_0002	Configure transmit using Timer 0 on rising edge of clock with output data on Pin 0.
SHIFTCFG(n+1)	0x0000_0000	Start and stop bit disabled.
SHIFTCTL(n+1)	0x0080_0101	Configure receive using Timer 0 on falling edge of clock with input data on Pin 1.
TIMCMPn	0x0000_3F01	Configure 32-bit transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of bits x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFGn	0x0000_0202	Configure start bit, enable on trigger high and never disable. Initial clock state is logic 1.
TIMCTLn	0x01C3_0281	Configure dual 8-bit counter using inverted Pin 2 output (bit clock), with Shifter 0 flag as the inverted trigger. Clear PINPOL to invert the polarity of the output shift clock.
TIMCMP(n+1)	0x0000_007F	Configure 32-bit transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:0] = (number of bits x baud rate divider) - 1.
TIMCFG(n+1)	0x0000_0100	Enable when Timer 0 is enabled and never disable.
TIMCTL(n+1)	0x0003_0383	Configure 16-bit counter using inverted Pin 3 output (as frame sync). Clear PINPOL to invert the polarity of the output frame sync
SHIFTBUFn	Data to transmit	Transmit data can be written to SHIFTBUFBIS, use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request.

		Can support LSB first transfer by writing to SHIFTBUF register instead.
SHIFTBUF(n+1)	Data to receive	Received data can be read from SHIFTBUFBIS, use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request. Can support LSB first transfer by reading from SHIFTBUF register instead.

69.4.7 I2S Slave

I2S slave mode can be supported using three Timers, two Shifters and four Pins (for single transmit and single receive, other combinations of transmit and receive are possible).

The transmit data must be written to the transmit buffer register before the external frame sync asserts, otherwise the shifter error flag is set.

NOTE

Due to synchronization delays, the output valid time for the serial output data is 2.5 FlexIO clock cycles, so the maximum baud rate is divide by 6 of the FlexIO clock frequency.

The output valid time of I2S slave is max 2.5 cycles because there is a maximum 1.5 cycle delay on the clock synchronization plus 1 cycle to output the data

Timer 2 detects the falling edge of frame sync (start of new frame) and asserts output until rising edge of bit clock (when frame sync is normally sampled). Timer 0 detects rising edge of bit clock with Timer 2 output asserted and asserts output for length of frame. Timer 1 detects falling edge of bit clock with Timer 0 output asserted and controls shift registers for 32-bit transfers.

Table 402. I2S Slave Configuration

Register	Value	Comments
SHIFTCFGn	0x0000_0000	Start and stop bit disabled.
SHIFTCTLn	0x0103_0002	Configure transmit using Timer 1 on rising edge of shift clock with output data on Pin 0.
SHIFTCFG(n+1)	0x0000_0000	Start and stop bit disabled.
SHIFTCTL(n+1)	0x0180_0101	Configure receive using Timer 1 on falling edge of shift clock with input data on Pin 1.
TIMCMPn	0x0000_007F	Configure two 32-bit transfers per frame. Set TIMCMP[15:0] = (number of bits x 4) - 1.
TIMCFGn	0x0020_2500	Configure enable on pin rising edge (inverted bit clock) with trigger high (Timer 2) and disable on compare, initial clock state is logic 1 and decrement on pin input (bit clock).

Table continues on the next page...

Table 402. I2S Slave Configuration (continued)

TIMCFG(n+1)	0x0020_2500	Configure enable on pin (bit clock) rising edge with trigger (Timer 0) high and disable on compare, initial clock state is logic 1 and decrement on pin input (bit clock).
TIMCTL(n+1)	0x0340_0283	Configure 16-bit counter using inverted Pin 2 input (bit clock), with Timer 0 output as the trigger.
TIMCMP(n+2)	0x0000_0000	Compare on zero (first edge).
TIMCFG(n+2)	0x0020_6400	Configure enable on inverted pin (frame sync) rising edge and disable on trigger falling edge (bit clock), initial clock state is logic 1 and decrement on inverted pin input (frame sync).
TIMCTL(n+2)	0x04C0_0383	Configure 16-bit counter using inverted Pin 3 input (frame sync), with Pin 2 inverted input (bit clock) as the trigger.
SHIFTBUFn	Data to transmit	Transmit data can be written to SHIFTBUFBIS, use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request. Can support LSB first transfer by writing to SHIFTBUF register instead.
SHIFTBUF(n+1)	Data to receive	Received data can be read from SHIFTBUFBIS, use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request. Can support LSB first transfer by reading from SHIFTBUF register instead.

69.4.8 SENT Receiver

SENT receiver can be supported by using one Timer and one Pin. The Timer is configured as Input-Capture mode, and captures the conter value at falling edge of the Pin input. Once the counter value is captured, the counter is automatically restarted from counter value 0. Therefore, the captured value is always indicating the period between previous falling edge and current falling edge. CPU interrupt or DMA trigger can be configured at each capture of the counter, and the entire SENT frame decoding with the latest tick width adustment is performed by CPU software.

Table 403. SENT Receiver Configuration

Register	Value	Comments
TIMCMPn	-	Counter value at the falling edge of the Pin is stored in this register.
TIMCFGn	0x0000_6000	Timer always enabled, Timer disabled on Trigger falling edge, Decrement counter on FlexIO clock.
TIMCTLn	0xnn40_0007	Single 16-bit input capture mode, Timer pin input and output are selected by PINSEL, Timer pin output disabled, Internal trigger selected, Select Pin nn as Trigger.

69.4.9 Camera Interface

Camera Interface can be supported using one Timer, one or more Shifters and multiple Pins. Multiple transfers can be supported using DMA controller.

The example below describes FlexIO configuration for interfacing to an 8-bit CMOS sensor with PCLK, VSYNC, HREF and D[7:0] outputs. The example uses a 128-bit buffer to capture 16-pixels of image data before interrupt or DMA transfer, however a bigger or smaller buffer may be used depending on system DMA performance and FlexIO resource usage by other applications. Note that additional timers may be used to track number of pixels per row and number of rows per frame or HREF/VSYNC may be assigned as GPIO interrupts for software tracking.

Table 404. Camera Interface Configuration for 8-bit CMOS sensor

Register	Value	Comments
SHIFTCFGn...n+2[1]	0x0007_0100	Configure 8-bit parallel shift in from adjacent shifter.
SHIFTCFGn+3	0x0007_0000	Configure 8-bit parallel shift in from pins FXIO_D[7:0] (D[7:0]).

TIMCMPn	0x0000_001F	Configure 16-pixel (8 bits/pixel x 16 pixels = 128-bits) transfer. Set TIMCMP[15:0] = (number of pixels x 2) - 1.
TIMCFGn	0x0120_6600	Configure enable on trigger (HREF) rising edge and disable on trigger falling edge, initial Shift clock state is logic 0 and decrement on PCLK input.
TIMCTLn	0x12C0_0803	Configure 16-bit counter using FXIO_D[8] input (PCLK), with FXIO_D[9] input (HREF) as the inverted trigger.
SHIFTBUFn...n+3	Data to receive	Received data can be read from SHIFTBUFn...n+3, use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request.

1. n=0 or 4

69.4.10 Motorola 68K/Intel 8080 Bus Interface

The Motorola 68K and Intel 8080 bus are two parallel interfaces commonly used by Smart/Asynchronous LCD controllers. In conjunction with GPIO, FlexIO is able to drive these interfaces using one Timer and one Shifter, although additional Shifters could be used to support large transfers via the DMA controller.

The configuration below provides an example of how to drive a 16-bit 68K or 8080 bus. For a 8080 bus, two GPIO are used to drive the nCS and RS pins. For a 68K bus, an additional GPIO is required to drive the RDWR pin.

Table 405. Motorola 68K/Intel 8080 Write Configuration

Register	Value	Comments
SHIFTCFG0...7	0x000F_0100	Configure 16-bit parallel shift in from adjacent shifter.
SHIFTCTL0	0x0003_0002	Configure transmit using Timer 0 on posedge of clock with data output to FXIO_D[15:0].
SHIFTCTL1...7	0x0000_0002	Configure transmit using Timer 0 on posedge of clock.
TIMCMP0	0x0000_0101 (1-beat) 0x0000_1F01 (16-beats)	Configure 1 or 16-beat transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of beats x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFG0	0x0000_2200	Configure enable on trigger high and disable on compare. Timer output high on enable.
TIMCTL0	0x01C3_1001 (Motorola 68K, 1-beat) 0x1DC3_1001 (Motorola 68K, 16-beats) 0x01C3_1081 (Intel 8080, 1-beat) 0x1DC3_1081 (Intel 8080, 16-beats)	Configure dual 8-bit counter using FXIO_D[16] output (EN pin for 68K, nWR pin for 8080), with Shifter 0 (1-beat) or Shifter 7 (16-beats) flag as the inverted trigger.
SHIFTBUF0...7	Data to transmit	Transmit data can be written to SHIFTBUF0 (1-beat) or SHIFTBUF0...7 (16-beats) to initiate a transfer, use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request.

TIMCFG0	0x0000_2220	Configure stop_bit, enable on trigger high and disable on compare. Timer output high on enable.
TIMCTL0	0x1DC3_1001 (Motorola 68K, 1 beat) 0x01C3_1001 (Motorola 68K, 16 beats) 0x1DC3_1181 (Intel 8080, 1 beat) 0x01C3_1181 (Intel 8080, 16 beats)	Configure dual 8-bit counter using either FXIO_D[16] output (EN pin for 68K) or FXIO_D[17] output (nRD pin for 8080), with Shifter 7 flag (1-beat) or Shifter 0 flag (16-beats) as the inverted trigger.
SHIFTBUF0...7	Data received	Received data can be read from SHIFTBUF0 (1-beat) or SHIFTBUF0...7 (16-beats), use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request.

In general, any operation to a 68K/8080 bus slave begins with a register write cycle followed by one or more data read or write cycles. To accomplish this, the following program flow should be used:

1. Configure FlexIO with 1-beat write configuration
2. Configure GPIO to assert nCS, RS pins (and deassert RDWR pin for 68K)
3. Write register index data to SHIFTBUF0[15:0]
4. Configure GPIO to deassert RS pin (and assert RDWR pin for 68K data read)
5. Configure FlexIO with desired read or write configuration (e.g. 1 or 16-beats)
6. Use the Shifter Status Flag to trigger interrupt or DMA driven data transfers to/from SHIFTBUF registers
7. Configure GPIO to deassert nCS pin

69.4.11 Low Power State Machine

The configuration below details a hypothetical state machine example to illustrate the flexibility allowed when using Shifter state mode.

In this example, FlexIO waits for the FXIO_D[2] pin to assert and then drives a complementary square wave output at a frequency of FLEXIO_CLK/131072 on the FXIO_D[1:0] pins while the comparator output is asserted (This assumes comparator is connected to external trigger 15. See the chip-specific FlexIO information for actual FlexIO trigger mappings). The state diagram below shows the states and transitions implemented by this example.

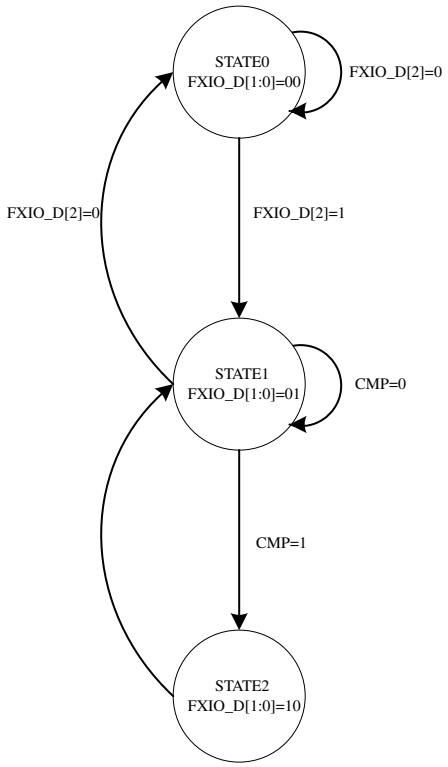

Figure 369. State Diagram

Table 407. State Machine Configuration

Register	Value	Comments
SHIFTCFG0...2	0x0000_0003	Enable FXIO_D[1:0] as outputs.
SHIFTCTL0	0x0080_0206	Configure for State mode using FXIO_D[4:2] as inputs to select next state and Timer0 output low to trigger next state.
SHIFTBUF0	0x0020_8208	State0: Drive FXIO_D[1:0]=00, transition to State0 if FXIO_D[2]=0, State1 if FXIO_D[2]=1.
SHIFTCTL1	0x0000_0206	Configure for State mode using FXIO_D[4:2] as inputs to select next state and Timer0 output high to trigger next state.
SHIFTBUF1	0x0140_8408	State1: Drive FXIO_D[1:0]=01, transition to State0 if FXIO_D[2]=0, State1 if CMP=0, State2 if CMP=1 (FXIO_D[3]=1)

Table continues on the next page...

Table 407. State Machine Configuration (continued)

Register	Value	Comments
SHIFTCTL2	0x0080_0206	Configure for State mode using FXIO_D[4:2] as inputs to select next state and Timer0 output low to trigger next state.
SHIFTBUF2	0x0224_9249	State2: Drive FXIO_D[1:0]=10, transition to State1 when Timer0 output low
TIMCMP0	0x0000_FFFF	Configure baud rate of divide by 131072 of the FlexIO clock. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFG0	0x0000_0000	Configure timer always enabled.
TIMCTL0	0x0000_0003	Configure single 16-bit counter.
TIMCFG1	0x0010_7600	Configure timer enabled on trigger rising edge, disabled on trigger falling edge, decrement on trigger edge.
TIMCTL1	0x0F03_0303	Configure timer output enabled on FXIO_D[3], external trigger 15 (comparator output) selected.

69.4.12 Keypad Interface

The Keypad Interface can support a 3x4 keypad matrix using 3 timers and 3 shifters, although a larger matrix could be supported using additional shifters. The configuration is designed for 4 columns which are configured as active low open drain pins, and 3 rows which are configured as input pins with pullup resistors enabled.

One shifter is configured in logic mode and is configured to assert its output when any of the row inputs are low, indicating a key is pressed. A timer is used to filter the shifter output to ensure the key is pressed for a minimum amount of time before performing the column scan.

Another shifter is configured for parallel transmit, this shifter is used to scan each column when a key press is detected. Whenever not scanning, the shifter output is configured to assert all active low open drain column outputs to detect any keypress. A dedicated timer is used to control the transmit shifter.

The last shifter is configured for parallel receive, this shifter is used to capture the result of the column scanning for software to decode which key or keys was pressed. This configuration captures the state of both row and colum pins for each scan, although the row state could also be deduced by the shift order. A dedicated timer is used to control the receive shifter, it shifts at half the frequency of the transmit shifter.

Once the result of the key scan is available in the receive shifter register, FlexIO continues to monitor the row inputs and can trigger multiple scans from the one key press. To support debouncing, software can decide how many consecutive scans should be considered a single key press.

Since the pins used in logic mode are fixed per shifter, and the shifters that support parallel shifts are limited, this configuration is restricted in what pins and shifters it can use. Increasing the matrix beyond 4 row inputs requires multiple shifters in logic mode and increasing beyond 4 column outputs requires concatenating transmit shifters to create a larger shift register.

Table 408. Keypad Interface Configuration

Register	Value	Comments
SHIFTCFG0	0x0003_0032	Start bit enabled (logic 0) and stop bit enabled (logic 1), configired for 4-bit shift.
SHIFTCTL0	0x0101_0402	Configure transmit using Timer 1 on rising edge of clock generating open drain output on Pins [7:4] (column outputs).
SHIFTBUF0	0x0804_0201	Static data containing the column scan pattern, each column is scanned one-hot with deadtime inbetween.
SHIFTCFG1	0x0000_0020	In logic mode, mask input 3.
SHIFTCTL1	0x0000_0007	Configure logic mode.
SHIFTBUF1	0x07ff_07ff	Static data configuring logic mode LUT. Output asserts if pins [3:1] are logic 0.
SHIFTCFG3	0x0007_0000	Configured for 8-bit shift.
SHIFTCTL3	0x0280_0001	Configure receive using Timer 2 on falling edge of clock with input data on Pins [7:0] (both rows and columns, pin 0 is don't care).
TIMCMP0	0x0000_00ff	Configures pre-scanning glitch filter to 256 FlexIO clock cycles. For different filter cycles, set TIMCMP[15:0] = (filter cycles) - 1.
TIMCFG0	0x0103_6600	Configure enable on trigger rising edge and disable on trigger falling edge. Initial clock state is logic 0 and is not affected by reset.
TIMCTL0	0x0540_0003	Configure 16-bit counter using Shifter 1 flag (logic state) as trigger.
TIMCMP1	0x0000_0f3f	Configure 8 shifts (twice for each column) at column scan rate of divide by 128. For different scan frequency, set TIMCMP[7:0] = (scan divider / 2) - 1.
TIMCFG1	0x0020_2622	Enable on trigger rising edge, disable on compare, start and stop bits are enabled.
TIMCTL1	0x0340_0001	Configure dual 8-bit counter using Timer 0 output as the trigger.
TIMCMP2	0x0000_0801	Configure 4 shifts at half the frequency of Timer 1 trigger.
TIMCFG2	0x0110_2100	Enable on Timer 1 enable, disable on compare, decrement on trigger input

Table continues on the next page...

Table 408. Keypad Interface Configuration (continued)

Register	Value	Comments
		with output initially negated and not affected by reset
TIMCTL2	0x0740_0001	Configure dual 8-bit counter using Timer 1 output as the trigger.
SHIFTBUF3	Keypad Scan Result	Keypad scan result can be read from SHIFTBUF3, each byte is the result of one scan with both row and column pin state from the scan (note that pin 0 is not used). Use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request.

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-8 —	Reserved
7-0 SSF	Shifter Status Flag The shifter status flag is updated when one of the following events occurs: For SMOD=Receive, the status flag is set when SHIFTBUF has been loaded with data from Shifter (SHIFTBUF is full), and the status flag is cleared when SHIFTBUF register is read. For SMOD=Transmit, the status flag is set when SHIFTBUF data has been transferred to the Shifter (SHIFTBUF is empty) or when initially configured for SMOD=Transmit, and the status flag is cleared when the SHIFTBUF register is written. For SMOD=Match Store, the status flag is set when a match has occured between SHIFTBUF and Shifter, and the status flag is cleared when the SHIFTBUF register is read. For SMOD=Match Continuous, returns the current match result between the SHIFTBUF and Shifter. The status flag cannot be cleared by reading SHIFTBUF. For SMOD=State, the status flag for a shifter sets when it is selected by the current state pointer. For SMOD=Logic, returns the current value of the programmable logic block output. The status flag can also be cleared by writing a logic one to the flag for all modes except Match Continuous/ State /Logic. 0b - Status flag is clear. 1b - Status flag is set.

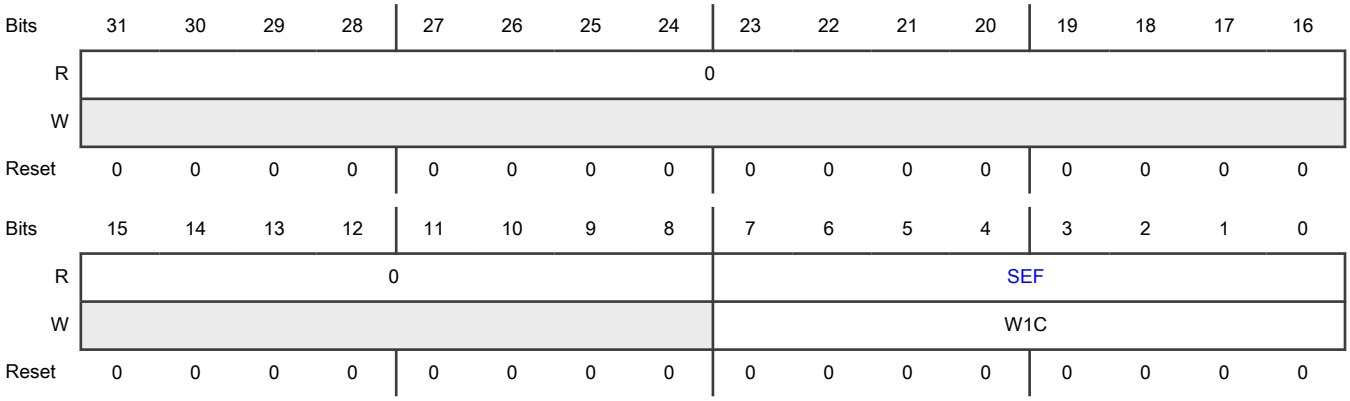
69.6.1.7 Shifter Error Register (SHIFTERR)

Offset

Register	Offset
SHIFTERR	14h

Function
This register reports shifter error flags. Write one to clear.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 SEF	Shifter Error Flags The shifter error flag is set when one of the following events occurs: For SMOD=Receive, indicates Shifter was ready to store new data into SHIFTBUF before the previous data was read from SHIFTBUF (SHIFTBUF Overrun), or indicates that the received start or stop bit does not match the expected value. For SMOD=Transmit, indicates Shifter was ready to load new data from SHIFTBUF before new data had been written into SHIFTBUF (SHIFTBUF Underrun). For SMOD=Match Store, indicates a match event occured before the previous match data was read from SHIFTBUF (SHIFTBUF Overrun). For SMOD=Match Continuous, the error flag is set when a match has occured between SHIFTBUF and Shifter. For SMOD=Logic, the error flag is set when the output of the programmable logic block has asserted. Can be cleared by writing logic one to the flag. For SMOD=Match Continuous, can also be cleared when the SHIFTBUF register is read. 0b - Shifter Error Flag is clear. 1b - Shifter Error Flag is set.

69.6.1.8 Timer Status Register (TIMSTAT)

Offset

Register	Offset
TIMSTAT	18h

Function

This register reports timer status flags. Write one to clear.

Diagram

Fields

Field	Function
31-8 —	Reserved
7-0 TSF	Timer Status Flags The timer status flag sets depending on the timer mode, and can be cleared by writing logic one to the flag. In 8-bit baud counter mode, the timer status flag is set when the upper 8-bit counter equals zero and decrements. In 8-bit high PWM mode, the timer status flag is set when the upper 8-bit counter equals zero and decrements. In 16-bit counter mode, the timer status flag is set when the 16-bit counter equals zero and decrements. In 16-bit counter disable mode, the timer status flag is set when a timer disable event is detected. In 8-bit word counter mode, the timer status flag is set when the upper 8-bit counter equals zero and decrements. In 8-bit low PWM mode, the timer status flag is set when the upper 8-bit counter equals zero and decrements. In 16-bit input capture mode, the timer status flag is set when a timer disable event is detected and the timer status flag is clear. In this mode, the timer compare register should only be read when the timer status flag is set. 0b - Timer Status Flag is clear. 1b - Timer Status Flag is set.

69.6.1.9 Shifter Status Interrupt Enable (SHIFTSIEN)

Offset

Register	Offset
SHIFTSIEN	20h

Function
Enables for Shifter Status Interrupts.

Fields

Field	Function
31-0 OUTTOG	Output Toggle Configures corresponding pins to toggle. 0b - No effect. 1b - Corresponding PINOUTD is inverted and PINOUTE is set.

69.6.1.27 Shifter Control N Register (SHIFTCTL0 - SHIFTCTL7)

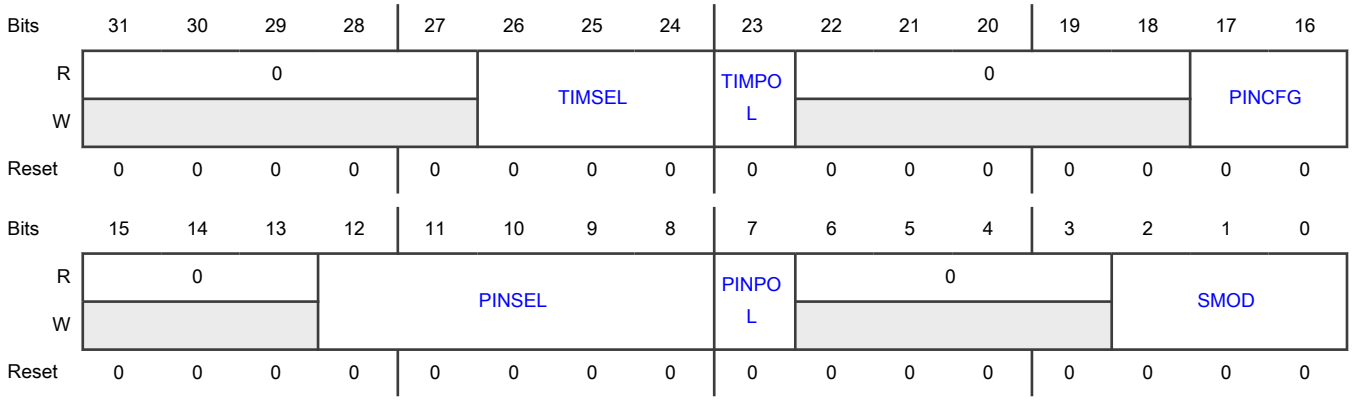
Offset

For a = 0 to 7:

Register	Offset
SHIFTCTLa	80h + (a × 4h)

Function
Control for Shift Register N

Diagram



Fields

Field	Function
31-27 —	Reserved
26-24 TIMSEL	Timer Select Selects which Timer is used for controlling the logic/shift register and generating the Shift clock. TIMSEL=i selects TIMERi.
23 TIMPOL	Timer Polarity Determines the shift occurs on the positive edge or negative edge of the shift clock. 0b - Shift on posedge of Shift clock 1b - Shift on negedge of Shift clock
22-18 —	Reserved
17-16 PINCFG	Shifter Pin Configuration For pins configured as an output (PINCFG=11), this field takes effect when the register is written. 00b - Shifter pin output disabled 01b - Shifter pin open drain or bidirectional output enable 10b - Shifter pin bidirectional output data 11b - Shifter pin output
15-13 —	Reserved
12-8 PINSEL	Shifter Pin Select Selects which pin is used by the Shifter input or output. PINSEL=i selects the FXIO_Di pin. For pins configured as an output (PINCFG=11), this field takes effect when the register is written.

Table continues on the next page...

Table continued from the previous page...

Field	Function
7 PINPOL	Shifter Pin Polarity For pins configured as an output (PINCFG=11), this field takes effect when the register is written. 0b - Pin is active high 1b - Pin is active low
6-3 —	Reserved
2-0 SMOD	Shifter Mode Configures the mode of the Shifter. 000b - Disabled. 001b - Receive mode. Captures the current Shifter content into the SHIFTBUF on expiration of the Timer. 010b - Transmit mode. Load SHIFTBUF contents into the Shifter on expiration of the Timer. 011b - Reserved. 100b - Match Store mode. Shifter data is compared to SHIFTBUF content on expiration of the Timer. 101b - Match Continuous mode. Shifter data is continuously compared to SHIFTBUF contents. 110b - State mode. SHIFTBUF contents are used for storing programmable state attributes. 111b - Logic mode. SHIFTBUF contents are used for implementing programmable logic look up table.

69.6.1.28 Shifter Configuration N Register (SHIFTCFG0 - SHIFTCFG7)

Offset

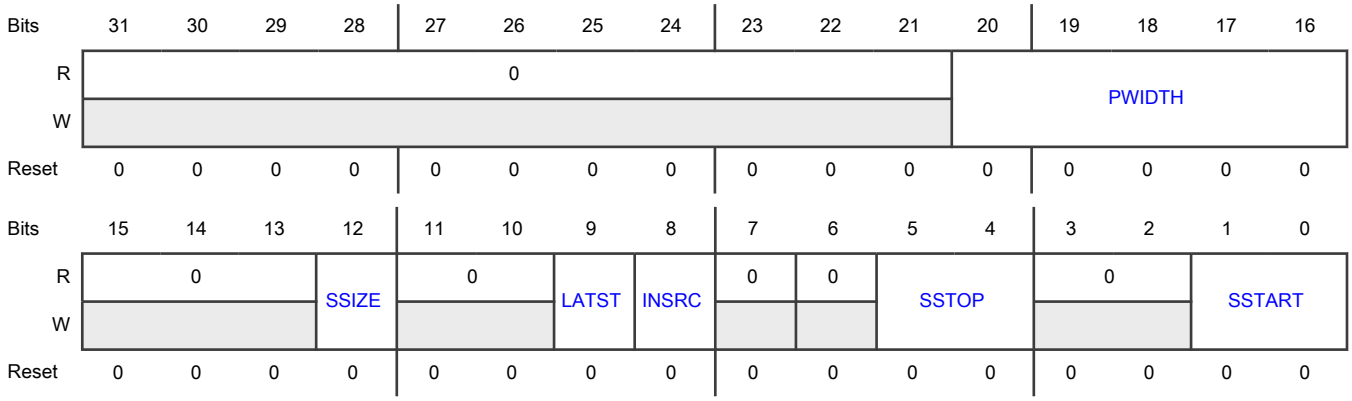
For a = 0 to 7:

Register	Offset
SHIFTCFGa	100h + (a × 4h)

Function

Contains configuration bit fields for Shifter Register N.

Diagram



Fields

Field	Function
31-21 —	Reserved
20-16 PWIDTH	Parallel Width For all Shifters, this register field configures the number of bits to be shifted on each Shift clock as follows: 1-bit shift for PWIDTH=0 2-bit shift for PWIDTH=1 4-bit shift for PWIDTH=2...3 8-bit shift for PWIDTH=4...7 16-bit shift for PWIDTH=8...15 32-bit shift for PWIDTH=16...31 For Shifters which support parallel transmit (SHIFTER0, SHIFTER4, ...) or parallel receive (SHIFTER3, SHIFTER7, ...), this register field, together with SHIFTCTL[PINSEL], also selects the pins to be driven or sampled on each Shift clock as follows: • FXIO_D[PINSEL+PWIDTH]:FXIO_D[PINSEL] Shifters which do not support parallel transmit or parallel receive only support parallel shift when INSRC=1. For SMOD=State, this field is used to disable state outputs. See State Mode section for more detail.
15-13 —	Reserved
12 SSIZE	Shifter Size Configures the size of the Shift Registers. A 24-bit shift register shifts data into bits [23:0] only and does not update bits [31:24] during shift operations. When shift register is configured for 24-bit, configuring PWIDTH=8..15 performs a 12-bit shift and PWIDTH=16..31 performs a 24-bit shift.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Shift register is 32-bit. 1b - Shift register is 24-bit.
11-10 —	Reserved
9 LATST	Late Store Configures what happens when a receive or match shift register is configured to both shift and store on the same cycle. 0b - Shift register stores the pre-shift register state. 1b - Shift register stores the post-shift register state.
8 INSRC	Input Source Selects the input source for the shifter. Configuring INSRC=1 is not supported for the last shifter. 0b - Pin 1b - Shifter N+1 Output
7 —	Reserved
6 —	Reserved
5-4 SSTOP	Shifter Stop bit For SMOD=Transmit, this field allows automatic stop bit insertion if the selected timer has also enabled a stop bit. For SMOD=Receive or Match Store, this field allows automatic stop bit checking if the selected timer has also enabled a stop bit. For SMOD=State, this field is used to disable state outputs. See 'State Mode' section for more detail. For SMOD=Logic, this field is used to mask logic pin inputs. See 'Logic Mode' section for more detail. 00b - Stop bit disabled for transmitter/receiver/match store 01b - Reserved for transmitter/receiver/match store 10b - Transmitter outputs stop bit value 0 on store, receiver/match store sets error flag if stop bit is not 0 11b - Transmitter outputs stop bit value 1 on store, receiver/match store sets error flag if stop bit is not 1
3-2 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
1-0 SSTART	Shifter Start bit For SMOD=Transmit, this field allows automatic start bit insertion if the selected timer has also enabled a start bit. For SMOD=Receive or Match Store, this field allows automatic start bit checking if the selected timer has also enabled a start bit. For SMOD=State, this field is used to disable state outputs. See 'State Mode' section for more detail. For SMOD=Logic, this field is used to mask logic pin inputs. See 'Logic Mode' section for more detail. 00b - Start bit disabled for transmitter/receiver/match store, transmitter loads data on enable 01b - Start bit disabled for transmitter/receiver/match store, transmitter loads data on first shift 10b - Transmitter outputs start bit value 0 before loading data on first shift, receiver/match store sets error flag if start bit is not 0 11b - Transmitter outputs start bit value 1 before loading data on first shift, receiver/match store sets error flag if start bit is not 1

69.6.1.29 Shifter Buffer N Register (SHIFTBUF0 - SHIFTBUF7)

Offset

For a = 0 to 7:

Register	Offset
SHIFTBUFa	200h + (a × 4h)

Function

Contains Shift buffer data.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	SHIFTBUF															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	SHIFTBUF															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 SHIFTBUF	Shift Buffer Shift buffer data is used for a variety of functions depending on the SMOD setting: For SMOD=Receive, Shifter data is transferred into SHIFTBUF at the expiration of Timer. The SHIFTBUF register should only be read when the corresponding shifter status flag is set, indicating new Shifter data is available. For SMOD=Transmit, SHIFTBUF data is transferred into the Shifter before the Timer begins. For SMOD=Match Store, SHIFTBUF[31:16] contains the data to be matched with the Shifter contents and SHIFTBUF[15:0] can be used to mask the match result (1=mask, 0=no mask). The Match is checked when the Timer expires and Shifter data [31:16] is written to SHIFTBUF[31:16] whenever a match event occurs. The SHIFTBUF register should only be read when the corresponding shifter status flag is set, indicating new Shifter data is available. For SMOD=Match Continuous, SHIFTBUF[31:16] contains the data to be matched with the Shifter contents and SHIFTBUF[15:0] can be used to mask the match result (1=mask, 0=no mask). For SMOD=Logic, SHIFTBUF[31:0] is used to implement a 5-input, 32-bit programmable logic look-up table. See Logic Mode section for more detail. For SMOD=State, SHIFTBUF[31:24] is used to drive the output value when this shifter is selected by the current state pointer and SHIFTBUF[23:0] is used to configure the value of the next state transition. See State Mode section for more detail.

69.6.1.30 Shifter Buffer N Bit Swapped Register (SHIFTBUFBIS0 - SHIFTBUFBIS7)

Offset

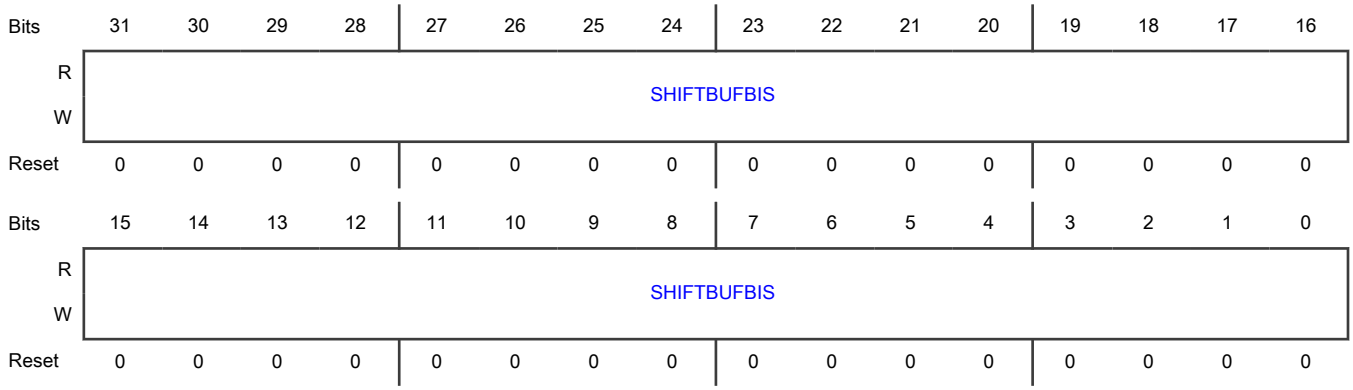
For a = 0 to 7:

Register	Offset
SHIFTBUFBISa	280h + (a × 4h)

Function

SHIFTBUF register contents, but contents of this register are bit swapped.

Diagram



Fields

Field	Function
31-0 SHIFTBUFBIS	Shift Buffer Alias to SHIFTBUF register, except reads/writes to this register are bit swapped. Reads return SHIFTBUF[0:31].

69.6.1.31 Shifter Buffer N Byte Swapped Register (SHIFTBUFBYS0 - SHIFTBUFBYS7)

Offset

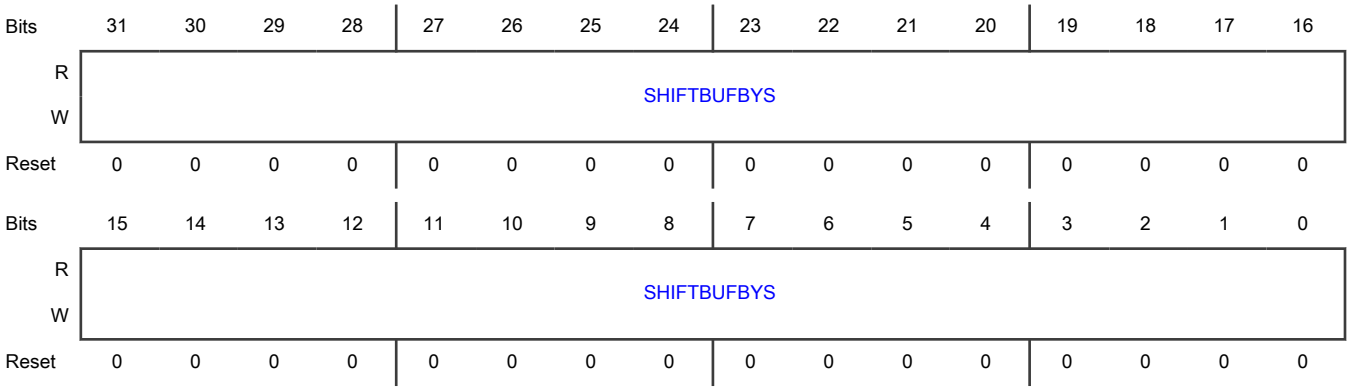
For a = 0 to 7:

Register	Offset
SHIFTBUFBYSa	300h + (a × 4h)

Function

SHIFTBUF register contents, but contents of this register are byte swapped.

Diagram



Fields

Field	Function
31-0 SHIFTBUFBYS	Shift Buffer Alias to SHIFTBUF register, except reads/writes to this register are byte swapped. Reads return { SHIFTBUF[7:0], SHIFTBUF[15:8], SHIFTBUF[23:16], SHIFTBUF[31:24] }.

69.6.1.32 Shifter Buffer N Bit Byte Swapped Register (SHIFTBUFBBS0 - SHIFTBUFBBS7)

Offset

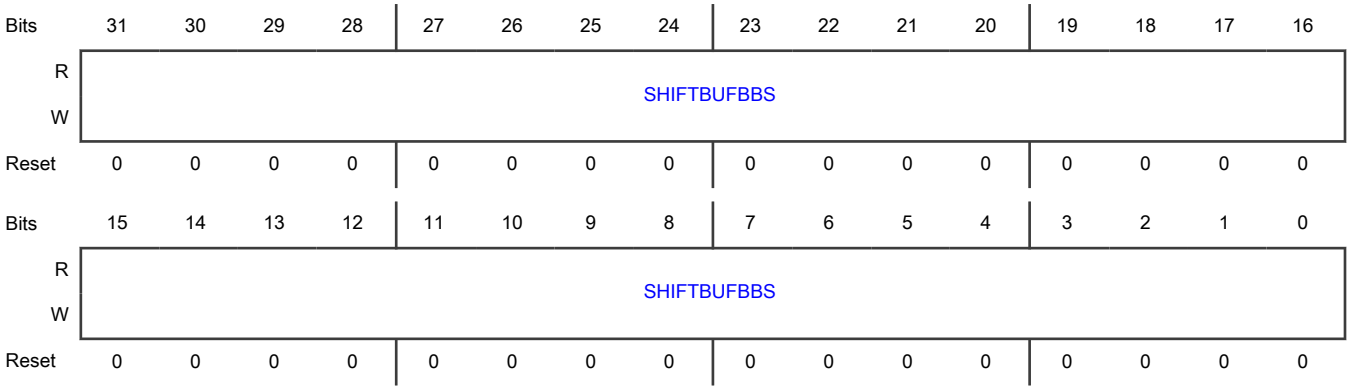
For a = 0 to 7:

Register	Offset
SHIFTBUFBBSa	380h + (a × 4h)

Function

Contains SHIFTBUF register data, but is bit swapped within each byte.

Diagram



Fields

Field	Function
31-0 SHIFTBUFBBS	Shift Buffer Alias to SHIFTBUF register, except reads/writes to this register are bit swapped within each byte. Reads return { SHIFTBUF[24:31], SHIFTBUF[16:23], SHIFTBUF[8:15], SHIFTBUF[0:7] }.

69.6.1.33 Timer Control N Register (TIMCTL0 - TIMCTL7)

Offset

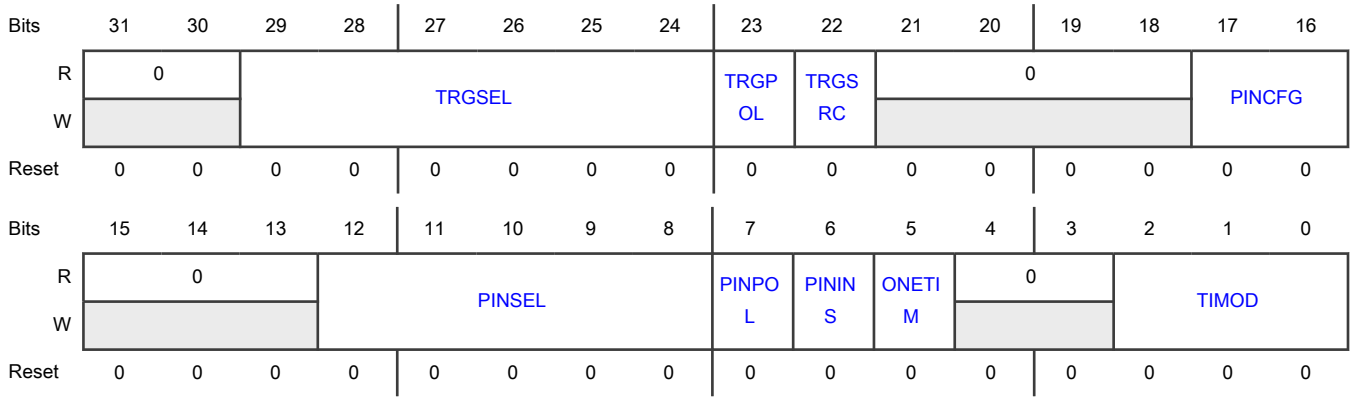
For a = 0 to 7:

Register	Offset
TIMCTLa	400h + (a × 4h)

Function

Timer Control for Timer N.

Diagram



Fields

Field	Function
31-30 —	Reserved
29-24 TRGSEL	Trigger Select The valid values for TRGSEL depends on the FLEXIO_PARAM register. • When TRGSRC = 1, the valid values for N depends on PIN, TIMER, SHIFTER fields in the FLEXIO_PARAM register. • When TRGSRC = 0, the valid values for N depends on TRIGGER field in FLEXIO_PARAM register. Refer to the chip-specific FlexIO information for external trigger selection. **NOTE** For a pin, N=0 to 31. For a Shifter, N=0 to 7. For a Timer, N=0 to 7. When TRGSRC = 0 the trigger selection is configured as follows: • N - External trigger N input When TRGSRC = 1 the internal trigger can be configured to select an input pin as follows: • 2*N - Pin N input When TRGSRC = 1 the internal trigger can be configured to select a shifter/timer signal as follows: • 4*N+1 - Shifter N status flag • 4*N+3 - Timer N trigger output In other words, the expanded internal trigger selection (TRGSRC = 1) is as follows: • 0000 = Pin 0 • 0001 = Shifter 0 Flag • 0010 = Pin 1 • 0011 = Timer 0 Trigger

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• 0100 = Pin 2 • 0101 = Shifter 1 Flag • 0110 = Pin 3 • 0111 = Timer 1 Trigger • ... • This continues up to the Pin 31, Shifter 7 and Timer 7.
23 TRGPOL	Trigger Polarity Determines if the trigger is active high or active low. 0b - Trigger active high 1b - Trigger active low
22 TRGSRC	Trigger Source Determines if the trigger source is external or internal. 0b - External trigger selected 1b - Internal trigger selected
21-18 —	Reserved
17-16 PINCFG	Timer Pin Configuration Configures the direction of the Timer pin. For pins configured as an output (PINCFG=11), this field takes effect when the register is written. 00b - Timer pin output disabled 01b - Timer pin open drain or bidirectional output enable 10b - Timer pin bidirectional output data 11b - Timer pin output
15-13 —	Reserved
12-8 PINSEL	Timer Pin Select Selects which pin is used by the Timer input or output. PINSEL=i selects the FXIO_Di pin. For pins configured as an output (PINCFG=11), this field takes effect when the register is written.
7 PINPOL	Timer Pin Polarity For pins configured as an output (PINCFG=11), this field takes effect when the register is written. 0b - Pin is active high 1b - Pin is active low

Table continues on the next page...

Table continued from the previous page...

Field	Function
6 PININS	Timer Pin Input Select When set, the timer input pin is a different pin from the timer output pin. PINSEL must select an even numbered pin when this bit is set, so the output pin is even numbered and input pin is odd numbered. 0b - Timer pin input and output are selected by PINSEL. 1b - Timer pin input is selected by PINSEL+1, timer pin output remains selected by PINSEL.
5 ONETIM	Timer One Time Operation When set, configures the timer to perform a single enable/disable iteration, after which software must clear the timer status flag for the timer to be enabled again. 0b - The timer enable event is generated as normal. 1b - The timer enable event is blocked unless timer status flag is clear.
4-3 —	Reserved
2-0 TIMOD	Timer Mode In 8-bit baud counter mode, the lower 8-bits of the counter and compare register are used to configure the baud rate of the timer shift clock, and the upper 8-bits are used to configure the shifter bit count. In 8-bit PWM high mode, the lower 8-bits of the counter and compare register are used to configure the high period of the timer shift clock, and the upper 8-bits are used to configure the low period of the timer shift clock. The shifter bit count is configured using another timer or external signal. In 16-bit counter mode, the full 16-bits of the counter and compare register are used to configure either the baud rate of the shift clock or the shifter bit count. In 16-bit counter disable mode, the full 16-bits of the counter and compare register are used to configure either the baud rate of the shift clock or the shifter bit count. In 8-bit word counter mode, the lower 8-bits of the counter and compare register are used to configure the shifter bit count, and the upper 8-bits are used to configure the shifter word count. In 8-bit PWM low mode, the lower 8-bits of the counter and compare register are used to configure the low period of the timer shift clock and the upper 8-bits are used to configure the high period of the timer shift clock. The shifter bit count is configured using another timer or external signal. In 16-bit input capture mode, the inverted value of 16-bit counter is latched into the compare register when a timer counter disable condition is detected (as configured by TIMDIS). This also sets the timer status flag. The timer counter is immediately restarted from 0xFFFF 000b - Timer Disabled. 001b - Dual 8-bit counters baud mode. 010b - Dual 8-bit counters PWM high mode. 011b - Single 16-bit counter mode. 100b - Single 16-bit counter disable mode. 101b - Dual 8-bit counters word mode.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	110b - Dual 8-bit counters PWM low mode. 111b - Single 16-bit input capture mode.

69.6.1.34 Timer Configuration N Register (TIMCFG0 - TIMCFG7)

Offset

For a = 0 to 7:

Register	Offset
TIMCFGa	480h + (a × 4h)

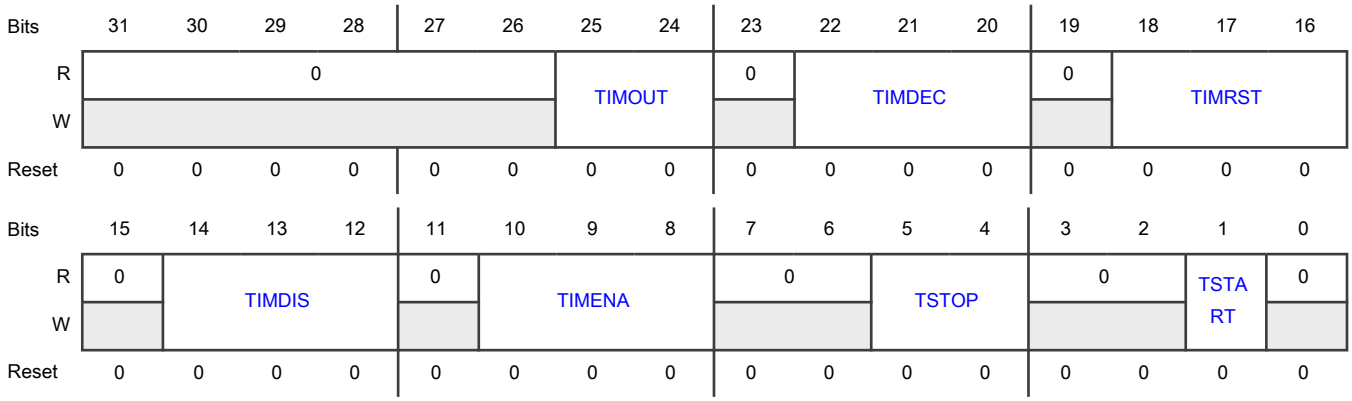
Function

The options to enable or disable the timer using the Timer N-1 enable or disable are reserved when N is evenly divisible by 4 (eg: Timer 0).

NOTE

The pin and trigger level/edges specified below refer to the signal state after being modified by the PINPOL or TRGPOL setting in the TIMCTL register. For example, "Trigger low" means a trigger is actually at logic level 1 if the TRGPOL is set to 1 (active low).

Diagram



Fields

Field	Function
31-26 —	Reserved
25-24	Timer Output

Table continues on the next page...

Table continued from the previous page...

Field	Function
TIMOUT	Configures the initial state of the Timer Output and whether it is affected by the Timer reset. 00b - Timer output is logic one when enabled and is not affected by timer reset 01b - Timer output is logic zero when enabled and is not affected by timer reset 10b - Timer output is logic one when enabled and on timer reset 11b - Timer output is logic zero when enabled and on timer reset
23 —	Reserved
22-20 TIMDEC	Timer Decrement Configures the source of the Timer decrement and the source of the Shift clock. 000b - Decrement counter on FlexIO clock, Shift clock equals Timer output. 001b - Decrement counter on Trigger input (both edges), Shift clock equals Timer output. 010b - Decrement counter on Pin input (both edges), Shift clock equals Pin input. 011b - Decrement counter on Trigger input (both edges), Shift clock equals Trigger input. 100b - Decrement counter on FlexIO clock divided by 16, Shift clock equals Timer output. 101b - Decrement counter on FlexIO clock divided by 256, Shift clock equals Timer output. 110b - Decrement counter on Pin input (rising edge), Shift clock equals Pin input. 111b - Decrement counter on Trigger input (rising edge), Shift clock equals Trigger input.
19 —	Reserved
18-16 TIMRST	Timer Reset Configures the condition that causes the timer counter (and optionally the timer output) to be reset. In 8-bit counter mode, the timer reset only resets the lower 8-bits that configure the baud rate. In all other modes, the timer reset resets the full 16-bits of the counter. 000b - Timer never reset 001b - Timer reset on Timer Output high. 010b - Timer reset on Timer Pin equal to Timer Output 011b - Timer reset on Timer Trigger equal to Timer Output 100b - Timer reset on Timer Pin rising edge 101b - Reserved 110b - Timer reset on Trigger rising edge 111b - Timer reset on Trigger rising or falling edge
15 —	Reserved

Table continues on the next page...

Field	Function
14-12 TIMDIS	Timer Disable Configures the condition that causes the Timer to be disabled and stop decrementing. 000b - Timer never disabled 001b - Timer disabled on Timer N-1 disable 010b - Timer disabled on Timer compare (upper 8-bits match and decrement) 011b - Timer disabled on Timer compare (upper 8-bits match and decrement) and Trigger Low 100b - Timer disabled on Pin rising or falling edge 101b - Timer disabled on Pin rising or falling edge provided Trigger is high 110b - Timer disabled on Trigger falling edge 111b - Reserved
11 —	Reserved
10-8 TIMENA	Timer Enable Configures the condition that causes the Timer to be enabled and start decrementing. 000b - Timer always enabled 001b - Timer enabled on Timer N-1 enable 010b - Timer enabled on Trigger high 011b - Timer enabled on Trigger high and Pin high 100b - Timer enabled on Pin rising edge 101b - Timer enabled on Pin rising edge and Trigger high 110b - Timer enabled on Trigger rising edge 111b - Timer enabled on Trigger rising or falling edge
7-6 —	Reserved
5-4 TSTOP	Timer Stop Bit The stop bit can be added on a timer compare (between each word) or on a timer disable. When stop bit is enabled, configured shifters output the contents of the stop bit when the timer is disabled. When stop bit is enabled on timer disable, the timer remains disabled until the next rising edge of the shift clock. If configured for both timer compare and timer disable, only one stop bit is inserted on timer disable. 00b - Stop bit disabled 01b - Stop bit is enabled on timer compare 10b - Stop bit is enabled on timer disable 11b - Stop bit is enabled on timer compare and timer disable

Table continues on the next page...

Field	Function
3-2 —	Reserved
1 TSTART	Timer Start Bit When start bit is enabled, configured shifters outputs the contents of the start bit when the timer is enabled and the timer counter reloads from the compare register on the first rising edge of the shift clock. 0b - Start bit disabled 1b - Start bit enabled
0 —	Reserved

69.6.1.35 Timer Compare N Register (TIMCMP0 - TIMCMP7)

Offset

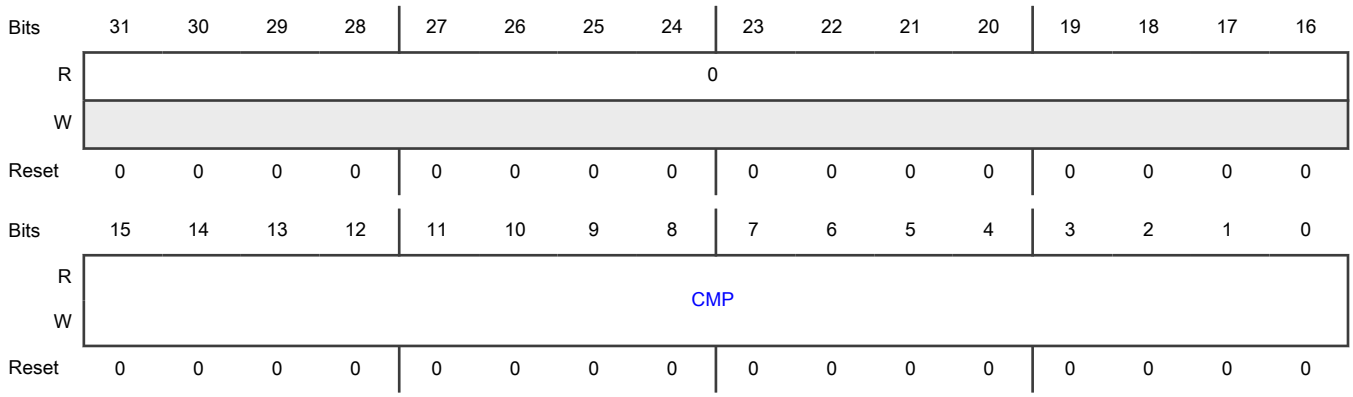
For a = 0 to 7:

Register	Offset
TIMCMPa	500h + (a × 4h)

Function

Contains the timer compare value.

Diagram



Fields

Field	Function
31-16	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
15-0 CMP	Timer Compare Value The timer compare value is loaded into the timer counter when the timer is first enabled, when the timer is reset and when the timer decrements down to zero. In 8-bit baud counter mode, the lower 8-bits configure the baud rate divider equal to (CMP[7:0] + 1) * 2. The upper 8-bits configure the number of bits in each word equal to (CMP[15:8] + 1) / 2. In 8-bit PWM high mode, the lower 8-bits configure the high period of the output to (CMP[7:0] + 1) and the upper 8-bits configure the low period of the output to (CMP[15:8] + 1). In 16-bit counter mode, the compare value can be used to generate the baud rate divider (if shift clock source is timer output) to equal (CMP[15:0] + 1) * 2. When the shift clock source is a pin or trigger input, the compare register is used to set the number of bits in each word equal to (CMP[15:0] + 1) / 2. In 16-bit counter disable mode, the compare value can be used to generate the baud rate divider (if shift clock source is timer output) to equal (CMP[15:0] + 1) * 2. When the shift clock source is a pin or trigger input, the compare register is used to set the number of bits in each word equal to (CMP[15:0] + 1) / 2. In 8-bit word counter mode, the lower 8-bits configure the number of bits in each word equal to (CMP[7:0] + 1) / 2. The upper 8-bits configure the number of words to transfer equal to (CMP[15:8] + 1) / 2. In 8-bit PWM low mode, the lower 8-bits configure the low period of the output to (CMP[7:0] + 1) and the upper 8-bits configure the high period of the output to (CMP[15:8] + 1). In 16-bit input capture mode, the compare register is updated with the inverse of the timer counter value whenever the timer status flag is set. The timer compare register should only be read when the timer status flag is set.

69.6.1.36 Shifter Buffer N Nibble Byte Swapped Register (SHIFTBUFNBS0 - SHIFTBUFNBS7)

Offset

For a = 0 to 7:

CAN (FlexCAN)

70.1 Chip-specific FlexCAN information

70.1.1 FlexCAN instances and configuration

This chip contains up to 6 instances of FlexCAN:

- FlexCAN_0
- FlexCAN_1
- FlexCAN_2
- FlexCAN_3
- FlexCAN_4
- FlexCAN_5

NOTE

The availability of 'Interrupt Masks 3 Register (IMASK3)' and 'Interrupt Flags 3 Register (IFLAG3)' registers for an instance depends upon the number of message buffers supported. See Table 410 for details.

Table 410. FlexCAN configuration and instances

Chip	Instances	Flexible Data Rate (CAN FD) protocol specification and CAN protocol.	Number of message buffers (assuming 8B payload)	Rx FIFO ID Filtering	ECC	External tick time	DMA	Enhanced RX FIFO feature (size)

FlexCAN memory initialization

All FlexCAN memory must be initialized before starting its operation in order to have the parity bits in memory properly updated. CTRL2[WRMFRZ] grants write access to all memory positions that require initialization.

These locations are as listed in this table from 080h–ADFh and from C20h–31FFh.:

Chip	Instance	Offset address ranges to be initialized
	FlexCAN3–FlexCAN7	080h–ADFh; C20h–FFFh
MWCT2D17S	FlexCAN0	080h–ADFh; C20h–31FFh
	FlexCAN1–FlexCAN5	080h–ADFh; C20h–FFFh
MWCT2D16S	FlexCAN0	080h–ADFh; C20h–31FFh
	FlexCAN1–FlexCAN3	080h–ADFh; C20h–FFFh
MWCT2016S	FlexCAN0	080h–DFh; C20h–31FFh
	FlexCAN1–FlexCAN5	080h–ADFh; C20h–FFFh
MWCT2015S	FlexCAN0	080h–ADFh; C20h–31FFh
	FlexCAN1–FlexCAN2	080h–ADFh; C20h–FFFh

NOTE

The reset value of CAN0_CTRL2 register for MWCT2016S and MWCT2D16S is 0080_0000h.

70.1.3 Reset value of MDIS bit

The CAN_MCR[MDIS] bit is set to 1 when the module is reset. Therefore, FlexCAN module is disabled following a reset. For details of CAN_MCR[MDIS] register refer to "CAN register description" section.

70.1.4 CAN Timestamp Implementation

FlexCAN uses Ethernet Media Access Controller (EMAC) and System Timer Module (STM_0) counters as time source. For details see 'FlexCAN timestamp implementation' section in Clocking chapter.

70.1.5 CAN clock setup

For clock setup, see Clocking chapter.

70.2 Overview

The FlexCAN module is a communication controller implementing the CAN protocol according to the ISO 11898-1 standard and CAN 2.0 B protocol specifications.

The CAN protocol was primarily designed to be used as a vehicle serial data bus, meeting the specific real-time processing and reliable operation requirements in the EMI environment of a vehicle. The FlexCAN module is a full implementation of the CAN protocol specification, the CAN with Flexible Data rate (CAN FD) protocol, and the CAN 2.0 version B protocol, which supports both standard and extended message frames and long payloads.

NOTE

Legacy Rx FIFO cannot be used in FD mode.

NOTE

In CAN FD mode, the Enhanced Rx FIFO feature should be used instead of Legacy Rx FIFO.

70.2.1 Block diagram

A general block diagram is shown in Figure 370, which describes the main subblocks implemented in the FlexCAN module.

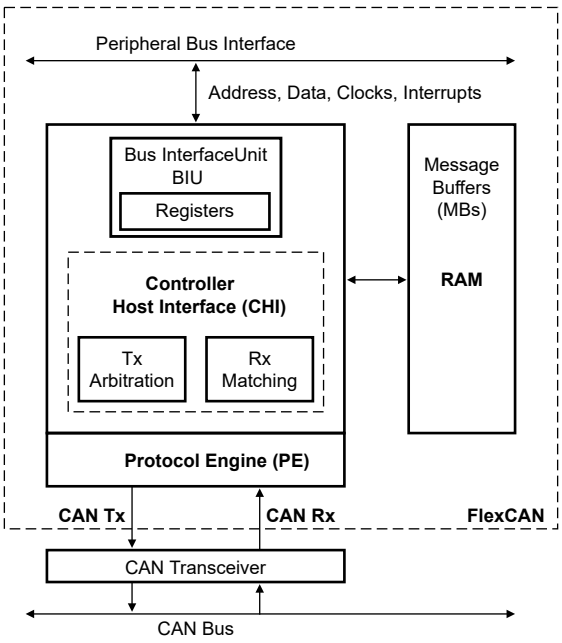

Figure 370. FlexCAN block diagram

The Protocol Engine (PE) submodule manages the serial communication on the CAN bus:

- Requesting RAM access for receiving and transmitting message frames
- Validating received messages
- Performing error handling
- Detecting CAN FD messages

The Controller Host Interface (CHI) submodule manages message buffer selection for reception and transmission, taking care of arbitration and ID matching algorithms for both CAN FD and non-CAN FD message formats.

The Bus Interface Unit (BIU) submodule controls access to and from the internal interface bus, in order to establish connection to the CPU and to other blocks. Clocks, address and data buses, interrupt outputs, DMA and test signals are accessed through the BIU.

70.2.2 Features

The FlexCAN module includes these distinctive features:

- Full implementation of the CAN with Flexible Data Rate (CAN FD) protocol specification and CAN protocol specification, Version 2.0 B
  - Standard data frames
  - Extended data frames
  - Zero to sixty four bytes data length
  - Programmable bit rate (see the chip-specific FlexCAN information for the specific maximum rate configuration)
  - Content-related addressing
- Compliant with the ISO 11898-1 standard
- Flexible mailboxes configurable to store 0 to 8, 16, 32, or 64 bytes data length
- Each mailbox configurable as receive or transmit, all supporting standard and extended messages
- Individual Rx Mask registers per mailbox
- Full-featured legacy Rx FIFO with storage capacity for up to six frames and automatic internal pointer handling with DMA support
- Full-featured enhanced Rx FIFO with storage capacity for up to 20 CAN FD frames and automatic internal pointer handling with DMA support
- Transmission abort capability
- Flexible message buffers (MBs), totaling 96 message buffers of 8 bytes data length each, configurable as Rx or Tx
- RAM not used by reception or transmission structures can be used as general purpose RAM space
- Listen-Only mode capability
- Programmable Loop-Back mode supporting self-test operation
- Programmable transmission priority scheme: lowest ID, lowest buffer number, or highest priority
- Time stamp based on 32-bit free running timer, with an optional external time tick
- Global network time, synchronized by a specific message
- Maskable interrupts
- Independence from the transmission medium (an external transceiver is assumed)
- Short latency time due to an arbitration scheme for high-priority messages
- Low power mode
- Transceiver delay compensation feature when transmitting CAN FD messages at faster data rates
- Remote request frames may be managed automatically or by software
- CAN bit time settings and configuration bits can only be written in Freeze mode
- Tx mailbox status (Lowest priority buffer or empty buffer)
- Identifier Acceptance Filter Hit Indicator (IDHIT) register for received frames
- SYNCH bit available in Error in Status 1 register to indicate that the module is synchronous with CAN bus
- CRC status for transmitted message

- Legacy Rx FIFO Global Mask register
- Selectable priority between mailboxes and Rx FIFO during matching process
- Powerful legacy Rx FIFO ID filtering, capable of matching incoming IDs against either 128 extended, 256 standard, or 512 partial (8 bit) IDs, with up to 32 individual masking capability
- Powerful Enhanced Rx FIFO ID filtering, capable of matching incoming IDs against either 64 extended or 128 standard ID filter elements with three filtering schemes: mask + filter, range, and two filters without mask.
- 100% backward compatibility with previous FlexCAN version
- Supports detection and correction of errors in memory read accesses

  Each byte of FlexCAN memory is associated to 5 parity bits, and the error correction mechanism ensures that in this 13-bit word, errors in one bit can be corrected (correctable errors) and errors in 2 bits can be detected but not corrected (non-correctable errors).

70.3 Functional description

The FlexCAN module is a CAN protocol engine with a very flexible mailbox system for transmitting and receiving CAN frames. The mailbox system is composed of a set of message buffers (MB) that store configuration and control data, time stamp, message ID, and data (see Message buffer structure). The memory corresponding to the first 38 MBs can be configured to support a Legacy FIFO reception scheme with a powerful ID filtering mechanism, capable of checking incoming frames against a table of IDs (up to 128 extended IDs or 256 standard IDs or 512 8-bit ID slices), with individual mask register for up to 32 ID filter table elements.

For Classical CAN frames, simultaneous reception through Legacy FIFO and mailbox is supported. For CAN FD frames, reception is supported through mailboxes and Enhanced Rx FIFO. For mailbox reception, a matching algorithm makes it possible to store received frames only into MBs that have the same ID programmed in the ID field. A masking scheme makes it possible to match the ID programmed on the MB with a range of IDs on received CAN frames. For transmission, an arbitration algorithm decides the prioritization of MBs to be transmitted based on the message ID (optionally augmented by 3 local priority bits) or the MB ordering.

Before proceeding with the functional description, an important concept must be explained. A message buffer is said to be active at a given time if it can participate in both the matching and arbitration processes. An Rx MB with a 0b code is inactive (see Table 443). Similarly, a Tx MB with a 1000b or 1001b code is also inactive (see Table 444).

The FlexCAN module is also able to receive and transmit messages in CAN FD format. The message buffers are sized to adequately store the quantity of data bytes selected by the FDCTRL[MBDSRn] fields. The quantity of FD MBs available for a given quantity of data bytes is described in the FDCTRL register. See also FlexCAN memory partition for CAN FD.

70.3.1 Modes of operation

The FlexCAN module has these functional modes:

- Normal mode (User or Supervisor):

  In Normal mode, the module operates receiving and/or transmitting message frames, errors are managed normally, and all CAN Protocol functions are enabled. User and Supervisor modes differ in the access to some restricted control registers.

- Freeze mode:

  Freeze mode is enabled when MCR[FRZ] is asserted. If enabled, Freeze mode is entered when MCR[HALT] is set or when is requested at chip level and MCR[FRZ_ACK] is asserted by the FlexCAN. In this mode, no transmission or reception of frames is done and synchronicity to the CAN bus is lost. See Freeze mode for more information.

- Loop-Back mode:

  The module enters this mode when CTRL1[LPB] is asserted. In this mode, FlexCAN performs an internal loop back that can be used for self-test operation. The bit stream output of the transmitter is internally fed back to the receiver input. The Rx CAN input pin is ignored and the Tx CAN output goes to the recessive state (logic '1'). FlexCAN behaves as it normally does when transmitting and treats its own transmitted message as a message received from a remote node. In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field to ensure proper reception of its own message. Both transmit and receive interrupts are generated.

- Listen-Only mode:

  The module enters this mode when CTRL1[LOM] is asserted. In this mode, transmission is disabled, all error counters are frozen, and the module operates in a CAN Error Passive mode. Only messages acknowledged by another CAN station will be received. If FlexCAN detects a message that has not been acknowledged, it will flag a BIT0 error (without changing the REC), as if it was trying to acknowledge the message.

- CAN FD Active mode:

  In this mode, FlexCAN is capable of transmitting and receiving all messages formatted according to the CAN FD Standard (2.0) and 2.0B Protocol in an interleaved fashion. The CPU can set the FlexCAN into CAN FD Active mode by configuring MCR[FDEN] in Freeze mode.

  It is important to know which features are available in CAN FD active mode. This table lists the differences between FD and classical modes.

Table 411. Differences between CAN classical and CAN FD

Feature	CAN classical	CAN FD
Legacy Rx FIFO DMA	Yes	No
Legacy Rx FIFO	Yes	No
Enhanced Rx FIFO DMA	Yes	Yes
Enhanced Rx FIFO	Yes	Yes

For low-power operation, the FlexCAN module has:

- Module Disable mode:

  This low-power mode is entered when MCR[MDIS] is asserted by the CPU and MCR[LPM_ACK] is asserted by FlexCAN. When disabled, the module issues a request to disable the clocks to the CAN Protocol Engine and Controller Host Interface submodules. Exit from this mode is done by negating MCR[MDIS]. See Module Disable mode for more information.

70.3.1.1 Modes of operation details

The FlexCAN module has functional modes and low-power modes. See Modes of operation for an introductory description of all the modes of operation. The following sub-sections contain functional details on Freeze mode and the low-power modes.

CAUTION

"Permanent Dominant" failure on CAN Bus line is not supported by FlexCAN. If a Low-Power request or Freeze mode request is done during a "Permanent Dominant", the corresponding acknowledge can never be asserted.

70.3.1.1.1 Freeze mode

This mode is requested either by the CPU through the assertion of MCR[HALT] or when the chip is put into Debug mode. In both cases it is also necessary that MCR[FRZ] be asserted and the module not be in a low-power mode. This mode is also requested by FlexCAN through the automatic assertion of both MCR[HALT] and MCR[FRZ] when MECR[NCEFAFRZ] is set and a non-correctable error is detected in a memory read access performed by FlexCAN internal processes (see Response to errors).

The acknowledgement is obtained through the assertion by the FlexCAN of MECR[FRZ_ACK]. The CPU must only consider the FlexCAN in Freeze mode when both request and acknowledgement conditions are satisfied.

When Freeze mode is requested, FlexCAN does the following:

- Waits to be in either Intermission, Passive Error, Bus Off, or Idle state.
- Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. A pending move-in does not prevent entering Freeze mode.
- Ignores the Rx input pin and drives the Tx pin as recessive.
- Stops the prescaler, thus halting all CAN protocol activities.

- Grants write access to the Error Counters register, which is read-only in other modes.
- Sets MCR[NOTRDY] and MCR[FRZACK].

After requesting Freeze mode, the user must wait for MCR[FRZ_ACK] to be asserted before executing any other action; otherwise FlexCAN may operate in an unpredictable way. In Freeze mode, all memory-mapped registers are accessible.

Exiting Freeze mode is done in one of the following ways:

- CPU negates MCR[FRZ].
- The chip is removed from Debug mode and/or the HALT bit is negated.

MCR[FRZ_ACK] is negated after the protocol engine recognizes the negation of the freeze request. When out of Freeze mode, FlexCAN tries to resynchronize to the CAN bus by waiting for 11 consecutive recessive bits.

70.3.1.1.2 Module Disable mode

This low-power mode is normally used to temporarily disable a complete FlexCAN block, with no power consumption. It is requested by the CPU through the assertion of MCR[MDIS], and the acknowledgement is obtained through the assertion by the FlexCAN of MCR[LPMACK]. The CPU must only consider the FlexCAN in Disable mode when both request and acknowledgement conditions are satisfied.

If the module is disabled during Freeze mode, it requests to disable the clocks to the PE and CHI submodules, sets MCR[LPMACK] and negates MCR[FRZACK].

If the module is disabled during transmission or reception, FlexCAN does the following:

- Waits to be in either Idle or Bus Off state, or else waits for the third bit of Intermission and then checks it to be recessive.
- Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. A pending move-in is not taken into account.
- Ignores its Rx input pin and drives its Tx pin as recessive.
- Shuts down the clocks to the PE and CHI submodules
- Sets MCR[NOTRDY] and MCR[LPMACK].

The Bus Interface Unit continues to operate, enabling the CPU to access memory-mapped registers, except the Rx Mailboxes Global Mask registers, the Rx Buffer 14 Mask register, the Rx Buffer 15 Mask register, the Legacy Rx FIFO Global Mask register. The Legacy Rx FIFO Information register, the message buffers, the Rx Individual Mask registers, and the reserved words within RAM may not be accessed when the module is in Disable mode. Exiting from this mode is done by negating the MDIS bit by the CPU, which causes the FlexCAN to request to resume the clocks and negate the LPMACK bit after the CAN protocol engine recognizes the negation of disable mode requested by the CPU.

70.3.2 Transmit process

To transmit a CAN frame, the CPU must prepare a message buffer for transmission by executing the following procedure:

1. Check whether the respective interrupt bit is set and clear it.
2. If the MB is active (transmission pending), write the ABORT code (1001b) to the CODE field of the Control and Status word to request an abort of the transmission.
3. Wait for the corresponding IFLAG bit to be asserted by polling the IFLAG register, or by the interrupt request if enabled by the respective IMASK bit.
4. Read back the CODE field to check if the transmission was aborted or transmitted (see Transmission abort mechanism).
5. Clear the corresponding interrupt flag.
6. Write the ID register (containing the local priority if enabled via MCR[LPRIO_EN]).
7. Write payload data bytes.

8. Configure the Control and Status word with the desired configuration.
    a. Set ID type via MB_CS[IDE].
    b. Set Remote Transmission Request (if needed) via MB_CS[RTR].
    c. If MCR[FDEN] is enabled, also configure the MB_CS[EDL] and MB_CS[BRS] fields. For details about the relationship between the written value and transmitted value of the MB_CS[ESI] field, see Table 422.[7]
    d. Set Data Length Code in bytes via MB_CS[DLC]. See Table 446 for detailed information.
    e. Activate the message buffer to transmit the CAN frame by setting MB_CS[CODE] to Ch.

NOTE

It is strongly recommended that all the fields in MB_CS word be configured in only one 32-bit write operation to maximize software performance. If the fields are configured in separate writes, the MB_CS[CODE] must be the last write in the C/S word.

When the MB is activated, it participates in the arbitration process and is eventually transmitted according to its priority. When the DLC value stored in the MB selected for transmission is larger than the respective MB payload size, FlexCAN adds the necessary number of bytes with constant CCh pattern to complete the expected DLC.

At the end of the successful transmission:

- The value of the free running timer is written into the Time Stamp field.
- The CODE field in the Control and Status word is updated.
- Both CRC and FDCRC registers are updated.
- A status flag is set in the Interrupt Flag register.
- An interrupt is generated if allowed by the corresponding Interrupt Mask Register bit.

The new CODE field after transmission depends on the code that was used to activate the MB (see Table 443 and Table 444 in Message buffer structure).

When the Abort feature is enabled (MCR[AEN] is asserted), after the Interrupt flag is asserted for a mailbox configured as transmit buffer, the mailbox is blocked. Therefore the CPU is not able to update it until the Interrupt Flag is negated by the CPU. This means that the CPU must clear the corresponding IFLAG bit before starting to prepare this MB for a new transmission or reception.

NOTE

If backwards compatibility is desired (MCR[AEN] is negated), write the INACTIVE code (1000b) to the CODE field to inactivate the MB. However, in this case the pending frame may be transmitted without notification (see Mailbox inactivation).

70.3.3 Arbitration process

The arbitration process scans the mailboxes, searching for the Tx mailbox that holds the message to be sent in the next opportunity. This mailbox is called the arbitration winner.

The scan starts from the lowest number mailbox and runs toward the higher ones.

The arbitration process is triggered in the following events:

- From the CRC field of the CAN frame. The start point depends on the value of CTRL2[TASD].
- During the Error Delimiter field of a CAN frame.
- During the Overload Delimiter field of a CAN frame.
- When the winner is inactivated and the CAN bus has still not reached the first bit of the Intermission field.

[7] The ESI field does not need to be written, and will automatically be transmitted dominant by error active nodes and recessive by error passive nodes. Note that there is an exception if the FlexCAN is operating as a network gateway: In that case, the CPU writes the MB_CS[ESI] bit according to the error status of the node which sent the message.

- When there is a CPU write to the C/S word of a winner MB and the CAN bus has still not reached the first bit of the Intermission field.
- When CHI is in Idle state and the CPU writes to the C/S word of any MB.
- When FlexCAN exits Bus Off state.
- Upon leaving Freeze mode or Low Power mode.

If the arbitration process does not manage to evaluate all mailboxes before the CAN bus has reached the first bit of the Intermission field, the temporary arbitration winner is invalidated and the FlexCAN will not compete for the CAN bus in the next opportunity.

The arbitration process selects the winner among the active Tx mailboxes at the end of the scan according to the settings of both CTRL1[LBUF] and MCR[LPRIOEN].

70.3.3.1 Lowest-number mailbox first

If CTRL1[LBUF] is asserted, the first (lowest number) active Tx mailbox found is the arbitration winner. MCR[LPRIOEN] has no effect when CTRL1[LBUF] is asserted.

70.3.3.2 Highest-priority mailbox first

If CTRL1[LBUF] is negated, then the arbitration process searches the active Tx mailbox with the highest priority, which means that this mailbox's frame would have a higher probability to win the arbitration on CAN bus when multiple external nodes compete for the bus at the same time.

The sequence of bits considered for this arbitration is called the *arbitration value* of the mailbox. The highest-priority Tx mailbox is the one that has the lowest arbitration value among all Tx mailboxes.

If two or more mailboxes have equivalent arbitration values, the mailbox with the lowest number is the arbitration winner.

The composition of the arbitration value depends on the MCR[LPRIOEN] setting.

70.3.3.2.1 Local priority disabled

If MCR[LPRIOEN] is negated the arbitration value is built in the exact sequence of bits as they would be transmitted in a CAN frame (see the following table) in such a way that the local priority is disabled.

Table 412. Composition of the arbitration value when local priority is disabled

Format	Mailbox arbitration value (32 bits)				
Standard (IDE = 0)	Standard ID (11 bits)	RTR (1 bit)	IDE (1 bit)	- (18 bits)	- (1 bit)
Extended (IDE = 1)	Extended ID[28:18] (11 bits)	SRR (1 bit)	IDE (1 bit)	Extended ID[17:0] (18 bits)	RTR (1 bit)

70.3.3.2.2 Local priority enabled

To enable local priority, MCR[LPRIOEN] must be asserted. In this case the mailbox PRIO field is included at the very left of the arbitration value (see the following table).

Table 413. Composition of the arbitration value when local priority is enabled

Format	Mailbox arbitration value (35 bits)					
Standard (IDE = 0)	PRIO (3 bits)	Standard ID (11 bits)	RTR (1 bit)	IDE (1 bit)	- (18 bits)	- (1 bit)
Extended (IDE = 1)	PRIO (3 bits)	Extended ID[28:18] (11 bits)	SRR (1 bit)	IDE (1 bit)	Extended ID[17:0] (18 bits)	RTR (1 bit)

Because the PRIO field is the most significant part of the arbitration value, mailboxes with low PRIO values have higher priority than mailboxes with high PRIO values regardless of the rest of their arbitration values.

Note that the PRIO field is not part of the frame on the CAN bus. Its purpose is only to affect the internal arbitration process.

70.3.3.3 Arbitration process (continued)

After the arbitration winner is found, its content is copied to a hidden auxiliary MB called Tx Serial Message Buffer (Tx SMB), which has the same structure as a normal MB but is not user accessible. This operation is called move-out and after it is done, write access to the C/S word of the corresponding MB is blocked (if MCR[AEN] is asserted). Write access is restored in the following events:

- After the MB is transmitted and the corresponding IFLAG bit is cleared by the CPU.
- FlexCAN enters Freeze mode or Bus Off.
- FlexCAN loses the bus arbitration or there is an error during the transmission.

At the first opportunity window on the CAN bus, the message on the Tx SMB is transmitted according to the CAN protocol rules.

Arbitration process can be triggered in the following situations:

- During Rx and Tx frames from CAN CRC field to end of frame. CTRL2[TASD] value may be changed to optimize the arbitration start point.
- During CAN Bus Off state from TX_ERR_CNT=124 to 128. CTRL2[TASD] value may be changed to optimize the arbitration start point.
- During C/S write by CPU in Bus Idle. First C/S write starts arbitration process, and a second C/S write during this same arbitration restarts the process. If other C/S writes are performed, Tx arbitration process is pending. If there is no arbitration winner after the arbitration process has finished, then the TX arbitration machine begins a new arbitration process. If there is a pending arbitration and Bus Idle state starts, then an arbitration process is triggered. In this case the first and second C/S write in Bus Idle will not restart the arbitration process. It is possible that there is not enough time to finish arbitration in Wait For Bus Idle state and the next state is Idle. In this case the scan is not interrupted, and it is completed during Bus Idle state. During this arbitration C/S write does not cause arbitration restart.
- Arbitration winner deactivation during a valid arbitration window.
- Upon exiting Freeze mode (first bit of the Wait For Bus Idle state). If there is a re-synchronization during Wait For Bus Idle, the arbitration process is restarted.

Arbitration process stops in the following situations:

- All mailboxes were scanned.
- A Tx active mailbox is found if lowest buffer feature is enabled.
- Arbitration winner inactivation or abort during any arbitration process.
- There was not enough time to finish Tx arbitration process (for instance, when a deactivation was performed near the end of frame). In this case arbitration process is pending.
- Error or overload flag in the bus.
- Low Power or Freeze mode request in Idle state.

Arbitration is considered pending as described below:

- It was not possible to finish arbitration process in time.
- C/S write during arbitration if write is performed in a MB whose number is lower than the Tx arbitration pointer.
- Any C/S write if there is no Tx arbitration process in progress.
- Rx Match has just updated a Rx code to Tx code.
- Entering Bus Off state.

C/S write during arbitration has the following effect:

- If C/S write is performed in the arbitration winner, a new process is restarted immediately.
- If C/S write is performed in a MB whose number is higher than the Tx arbitration pointer, the ongoing arbitration process will scan this MB as normal.

70.3.4 Receive process

To be able to receive CAN frames into a mailbox, the CPU must prepare it for reception by executing the following steps:

1. If the mailbox is active (either Tx or Rx) inactivate the mailbox (see Mailbox inactivation), preferably with a safe inactivation (see Transmission abort mechanism).
2. Write the ID word into the mailbox.
3. Write the EMPTY code (0100b) to the CODE field of the Control and Status word to activate the mailbox. No setup is required for EDL, BRS, and ESI bits—they are overwritten by the respective bit fields in the received message.

After the MB is activated, it will be able to receive frames that match the programmed filter. At the end of a successful reception, the mailbox is updated by the move-in process (see Move-in) as follows:

1. The received data field (8 bytes at most for Classical CAN message format and up to 64 bytes for CAN FD message format) is stored.
2. The received Identifier field is stored.
3. The value of the Free Running Timer at the time of the second bit of frame's Identifier field is written into the mailbox's Time Stamp field.
4. The received SRR, IDE, RTR, EDL, BRS, ESI, and DLC fields are stored.
5. The CODE field in the Control and Status word is updated (see Table 443 and Table 444 in Section Message buffer structure).
6. A status flag is set in the Interrupt Flag Register and an interrupt is generated if allowed by the corresponding Interrupt Mask Register bit.

The recommended way for the CPU to service (read) the frame received in a mailbox is by the following procedure:

1. Read the Control and Status word of that mailbox.
2. Check if the BUSY bit is deasserted, indicating that the mailbox is locked. Repeat step 1) while it is asserted. See Mailbox lock mechanism.
3. Read the contents of the mailbox. After the mailbox is locked, its contents won't be modified by FlexCAN move-in processes. See Move-in.
4. Acknowledge the proper flag at IFLAG registers.
5. Read the free running timer to unlock the mailbox.

The CPU should poll for frame reception by the status flag bit for the specific mailbox in one of the IFLAG registers and not by the CODE field of that mailbox. Polling the CODE field does not work because after a frame is received and the CPU services the mailbox (by reading the C/S word followed by unlocking the mailbox), the CODE field will not return to EMPTY. It will remain FULL, as explained in Table 443. If the CPU tries to work around this behavior by writing to the C/S word to force an EMPTY code after reading the mailbox without a prior safe inactivation, a newly received frame matching the filter of that mailbox may be lost.

CAUTION

In summary: never do polling by reading directly the C/S word of the mailboxes. Instead, read the IFLAG registers.

Note that the received frame's Identifier field is always stored in the matching mailbox, thus the contents of the ID field in a mailbox may change if the match was due to masking. When MCR[SRXDIS] is asserted, FlexCAN will not store frames transmitted by itself in any MB, even if it contains a matching Rx mailbox, and no interrupt flag or interrupt signal will be generated. Otherwise, when MCR[SRXDIS] is deasserted, FlexCAN can receive frames transmitted by itself if a matching Rx mailbox exists.

To be able to receive CAN frames through the Legacy Rx FIFO, the CPU must enable and configure the Legacy Rx FIFO during Freeze mode (see Legacy Rx FIFO). Upon receiving the Frames Available in Legacy Rx FIFO interrupt (see the description of IFLAG1[BUF5I] "Frames available in Legacy Rx FIFO"), the CPU should service the received frame using the following procedure:

1. Read the Control and Status word (optional: needed only if a mask was used for IDE and RTR bits).
2. Read the ID field (optional: needed only if a mask was used).
3. Read the data field.
4. Read the RXFIR register. (This step is optional, and is executed only if the IDHIT (Identifier Acceptance Filter Hit Indicator) is required in the application.)
5. Clear the Frames Available in Legacy Rx FIFO interrupt by writing one to IFLAG1[BUF5I] (mandatory: releases the MB and allows the CPU to read the next Rx FIFO entry).

When MCR[DMA] is asserted, upon receiving a frame in Legacy FIFO, IFLAG1[BUF5I] generates a DMA request and does not generate a CPU interrupt (see Legacy Rx FIFO under DMA operation). The IMASK1 bits in Legacy Rx FIFO region are not used.

The DMA controller must service the received frame using the following procedure:

1. Read the Control and Status word (read 80h address, optional).
2. Read the ID field (read 84h address, optional).
3. Read all data bytes (start read at 88h address, optional).
4. Read the last data bytes (read 8Ch address is mandatory).

70.3.5 Matching process

The matching process scans the MB memory looking for Rx MBs programmed with the same ID as the one received from the CAN bus. If the Legacy Rx or Enhanced Rx FIFO is enabled, the priority of scanning can be selected between mailboxes and FIFO filters. The matching starts from the lowest number message buffer toward the higher ones. If no match is found within the first structure then the other is scanned subsequently. In the event that the FIFO is full, the matching algorithm always looks for a matching MB outside the FIFO region.

For enhanced Rx FIFO see Enhanced Rx FIFO.

For legacy Rx FIFO see Legacy Rx FIFO.

As the frame is being received, it is stored in a hidden auxiliary MB called Rx Serial Message Buffer (Rx SMB).

The matching process start point depends on the following conditions:

- If the received frame is a remote frame, the start point is the CRC field of the frame.
- If the received frame is a data frame with DLC field equal to zero, the start point is the CRC field of the frame.
- If the received frame is a data frame with DLC field different than zero, the start point is the DATA field of the frame.

If a matching ID is found in the FIFO table or in one of the mailboxes, the contents of the Rx SMB are transferred to the FIFO or to the matched mailbox by the move-in process. If any CAN protocol error is detected then no match results are transferred to the FIFO or to the matched mailbox at the end of reception.

The matching process scans all matching elements of both Rx FIFO (if enabled) and the active Rx mailboxes (CODE is EMPTY, FULL, OVERRUN, or RANSWER) in search of a successful comparison with the matching elements of the Rx SMB that is receiving the frame on the CAN bus. The Rx SMB has the same structure as a mailbox. The reception structures (Rx FIFO or mailboxes) associated with the matching elements that had a successful comparison are the *matched structures*. The *matching winner* is selected at the end of the scan among those matched structures and depends on conditions described ahead. See the following table.

Table 414. Matching architecture

Structure	SMB[RTR]	CTRL2[RRS]	CTRL2[EACEN]	MB[IDE]	MB[RTR]	MB[ID[1]]	MB[CODE]
Mailbox	0	—	0	cmp[2]	no_cmp[3]	cmp_msk[4]	EMPTY or FULL or OVERRUN
Mailbox	0	—	1	cmp_msk	cmp_msk	cmp_msk	EMPTY or FULL or OVERRUN
Mailbox	1	0	—	cmp	no_cmp	cmp	RANSWER
Mailbox	1	1	0	cmp	no_cmp	cmp_msk	EMPTY or FULL or OVERRUN
Mailbox	1	1	1	cmp_msk	cmp_msk	cmp_msk	EMPTY or FULL or OVERRUN
Legacy Rx FIFO[5]	—	—	—	cmp_msk	cmp_msk	cmp_msk	—

1. For mailbox structure, If SMB[IDE] is asserted, the ID is 29 bits (ID Standard + ID Extended). If SMB[IDE] is negated, the ID is only 11 bits (ID Standard). For Legacy Rx FIFO structure, the ID depends on IDAM.
2. cmp: Compares the Rx SMB contents with the MB contents regardless the masks.
3. no_cmp: The Rx SMB contents are not compared with the MB contents.
4. cmp_msk: Compares the Rx SMB contents with MB contents taking into account the masks.
5. SMB[IDE] and SMB[RTR] are not taken into account when IDAM is type C.

NOTE

For Enhanced Rx FIFO, see Enhanced Rx FIFO matching process.

A reception structure is free-to-receive when any of the following conditions is satisfied:

- The CODE field of the mailbox is EMPTY.
- The CODE field of the mailbox is either FULL or OVERRUN and it has already been serviced (the C/S word was read by the CPU and unlocked as described in Mailbox lock mechanism).
- The CODE field of the mailbox is either FULL or OVERRUN and an inactivation (see Mailbox inactivation) is performed.
- The Legacy Rx FIFO or Enhanced Rx FIFO is not full.

The scan order for mailboxes and Legacy Rx FIFO is from the matching element with lowest number to the higher ones.

The matching winner search for mailboxes is affected by MCR[IRMQ]. If it is negated, the matching winner is the first matched mailbox regardless if it is free-to-receive or not. If it is asserted, the matching winner is selected according to the priority below:

1. the first free-to-receive matched mailbox;
2. the last non free-to-receive matched mailbox.

It is possible to select the priority of scan between mailboxes and Legacy Rx FIFO or Enhanced Rx FIFO with CTRL2[MRP].

If the selected priority is Rx FIFO first:

- If the Rx FIFO is a matched structure and is free-to-receive, then the Rx FIFO is the matching winner regardless of the scan for mailboxes.
- Otherwise (the Rx FIFO is not a matched structure or is not free-to-receive), then the matching winner is searched among mailboxes as described above.

If the selected priority is mailboxes first:

- If a free-to-receive matched mailbox is found, it is the matching winner regardless of the scan for Rx FIFO.
- If no matched mailbox is found, then the matching winner is searched in the scan for the Rx FIFO.
- If both conditions above are not satisfied and a non–free-to-receive matched mailbox is found, then the matching winner determination is conditioned by MCR[IRMQ]:
  - If MCR[IRMQ] is negated, the matching winner is the first matched mailbox.
  - If MCR[IRMQ] is asserted, the matching winner is the Rx FIFO if it is a free-to-receive matched structure; otherwise, the matching winner is the last non–free-to-receive matched mailbox.

See the following table for a summary of matching possibilities.

Table 415. Matching possibilities and resulting reception structures

RFEN or ERFEN	IRMQ	MRP	Matched in MB	Matched in FIFO	Reception structure	Description
No FIFO, only MB, match is always MB first						
0	0	X[1]	None[2]	—[3]	None	Frame lost by no match
0	0	X	Free[4]	—	First MB	
0	1	X	None	—	None	Frame lost by no match
0	1	X	Free	—	First MB	
0	1	X	Not free	—	Last MB	Overrun
FIFO enabled, no match in FIFO is as if FIFO does not exist						
1	0	X	None	None[5]	None	Frame lost by no match
1	0	X	Free	None	First MB	
1	1	X	None	None	None	Frame lost by no match
1	1	X	Free	None	First MB	
1	1	X	Not free	None	Last MB	Overrun
FIFO enabled, Queue disabled						
1	0	0	X	Not full[6]	FIFO	
1	0	0	None	Full[7]	None	Frame lost by FIFO full (FIFO overflow)
1	0	0	Free	Full	First MB	
1	0	0	Not free	Full	First MB	
1	0	1	None	Not full	FIFO	
1	0	1	None	Full	None	Frame lost by FIFO full (FIFO overflow)

Table continues on the next page...

Table 415. Matching possibilities and resulting reception structures (continued)

RFEN or ERFEN	IRMQ	MRP	Matched in MB	Matched in FIFO	Reception structure	Description
1	0	1	Free	X	First MB	
1	0	1	Not free	X	First MB	Overrun
FIFO enabled, queue enabled						
1	1	0	X	Not full	FIFO	
1	1	0	None	Full	None	Frame lost by FIFO full (FIFO overflow)
1	1	0	Free	Full	First MB	
1	1	0	Not free	Full	Last MB	Overrun
1	1	1	None	Not full	FIFO	
1	1	1	Free	X	First MB	
1	1	1	Not free	Not full	FIFO	
1	1	1	Not free	Full	Last MB	Overrun

1. This is a don't care condition.
2. Matched in MB "None" means that the frame has not matched any MB (free-to-receive or non–free-to-receive).
3. This is a forbidden condition.
4. Matched in MB "Free" means that the frame matched at least one MB free-to-receive regardless of whether it has matched MBs non-free-to-receive.
5. Matched in FIFO "None" means that the frame has not matched any filter in FIFO. It is as if the FIFO didn't exist (CTRL2[RFEN]=0 and ERFCR[ERFEN]=0).
6. Matched in FIFO "Not full" means that the frame has matched a FIFO filter and has empty slots to receive it.
7. Matched in FIFO "Full" means that the frame has matched a FIFO filter but couldn't store it because it has no empty slots to receive it.

If a non-safe mailbox inactivation (see Mailbox inactivation) occurs during matching process and the mailbox inactivated is the temporary matching winner, then the temporary matching winner is invalidated. The matching elements scan is not stopped nor restarted—it continues normally. The consequence is that the current matching process works as if the matching elements compared before the inactivation did not exist, therefore a message may be lost.

Suppose, for example, that the FIFO is disabled, IRMQ is enabled, there are two MBs with the same ID, and FlexCAN starts receiving messages with that ID. Let us say that these MBs are the second and the fifth in the array. When the first message arrives, the matching algorithm finds the first match in MB number 2. The code of this MB is EMPTY, so the message is stored there. When the second message arrives, the matching algorithm finds MB number 2 again, but it is not "free-to-receive", so it keeps looking, finds MB number 5 and stores the message there. If yet another message with the same ID arrives, the matching algorithm finds out that there are no matching MBs that are "free-to-receive", so it decides to overwrite the last matched MB, which is number 5. In doing so, it sets the CODE field of the MB to indicate OVERRUN.

The ability to match the same ID in more than one MB can be exploited to implement a reception queue (in addition to the full featured FIFO) to allow more time for the CPU to service the MBs. By programming more than one MB with the same ID, received messages are queued into the MBs. The CPU can examine the Time Stamp field of the MBs to determine the order in which the messages arrived.

Matching to a range of IDs is possible by using ID acceptance masks. FlexCAN supports individual masking per MB (see the description of Rx Individual Mask Registers (RXIMR0 - RXIMR95)). During the matching algorithm, if a mask bit is asserted, then the corresponding ID bit is compared. If the mask bit is negated, the corresponding ID bit is a "don't care". Note that the Individual Mask Registers are implemented in RAM, so they are not initialized out of reset. Also, they can only be programmed when the module is in Freeze mode; otherwise, they are blocked by hardware.

FlexCAN also supports an alternate masking scheme with only four mask registers (RXFGMASK, RXMGMASK, RX14MASK, and RX15MASK) for backwards compatibility with legacy applications. This alternate masking scheme is enabled when the IRMQ bit in the MCR register is negated.

70.3.6 Move process

There are two types of move process: move-in and move-out.

70.3.6.1 Move-in

The move-in process is the copy of a message received by an Rx SMB to an Rx mailbox or FIFO that has matched it. If the move destination is the Legacy Rx FIFO, attributes of the message are also copied to the CAN_RXFIR FIFO. Each Rx SMB has its own move-in process, but only one is performed at a given time as described ahead. The move-in starts only when the message held by the Rx SMB has a corresponding matching winner (see Matching process) and all of the following conditions are true:

- The CAN bus has either reached or already gone past:
  - The second bit of Intermission field next to the frame that carried the message that is in the Rx SMB.
  - The first bit of an overload frame next to the frame that carried the message that is in the Rx SMB.
- There is no ongoing matching process.
- The destination mailbox is not locked by the CPU.
- There is no ongoing move-in process from another Rx SMB. If more than one move-in process is to be started at the same time, both are performed and the newest substitutes for the oldest.

The term pending move-in is used throughout the documentation and stands for a move-to-be that still does not satisfy all of the aforementioned conditions.

The move-in is cancelled and the Rx SMB is able to receive another message if any of the following conditions is satisfied:

- The destination mailbox is inactivated after the CAN bus has reached the first bit of Intermission field next to the frame that carried the message and its matching process has finished.
- There is a previous pending move-in to the same destination mailbox.
- The Rx SMB is receiving a frame transmitted by the FlexCAN itself and self-reception is disabled (MCR[SRXDIS] is asserted).
- Any CAN protocol error is detected.

Note that the pending move-in is not cancelled if the module enters Freeze or Low-Power mode. It stays on hold, only waiting for Freeze and Low-Power mode to be exited and the module to be unlocked. If an MB is unlocked during Freeze mode, the move-in happens immediately.

The move-in process is the execution by the FlexCAN of the following steps:

1. Push IDHIT into the RXFIR FIFO if the message is destined for the Legacy Rx FIFO.
2. Read all data words from the Rx SMB in accordance with the selected payload size for the Rx storage element.
3. Write all data words to the Rx mailbox in accordance with the selected payload size for the Rx storage element. If the data size of the storage element is smaller than the original payload size described in the message's DLC field, the payload is truncated and the high order bytes that do not fit the destination size are lost.
4. Read the Control/Status and ID words from the Rx SMB.
5. Write Control/Status and ID words to the Rx mailbox, and update the CODE field.

The move-in process is not atomic, in such a way that it is immediately cancelled by the inactivation of the destination mailbox (see Mailbox inactivation). In this case the mailbox may remain partially updated, thus incoherent. The exception is if the move-in destination is a Legacy or Enhanced Rx FIFO message buffer; then the process cannot be cancelled.

The BUSY Bit (least significant bit of the CODE field) of the destination message buffer is asserted while the move-in is being performed to alert the CPU that the message buffer content is temporarily incoherent.

70.3.6.2 Move-out

The move-out process is the copy of the content from a Tx Mailbox to the Tx SMB when a message for transmission is available (see Arbitration process). The move-out occurs in the following conditions:

- The first bit of Intermission field
- During Bus Off state when TX Error Counter is in the 124 to 128 range
- During Bus Idle state
- During Wait For Bus Idle state

The move-out process is not atomic. Only the CPU has priority to access the memory concurrently out of Bus Idle state. In Bus Idle, the move-out has the lowest priority to the concurrent memory accesses.

70.3.7 Data coherence

In order to maintain data coherency and FlexCAN proper operation, the CPU must obey the rules described in Transmit process and Receive process.

70.3.7.1 Transmission abort mechanism

The abort mechanism provides a safe way to request the abort of a pending transmission. A feedback mechanism is provided to inform the CPU if the transmission was aborted or if the frame could not be aborted and was transmitted instead.

Two primary conditions must be fulfilled in order to abort a transmission:

- MCR[AEN] must be asserted.
- The first CPU action must be the writing of abort code (1001b) into the CODE field of the Control and Status word.

Active MBs configured for transmission must be aborted first before they can be updated. If the abort code is written to a Mailbox that is currently being transmitted or to a Mailbox that was already loaded into the Tx SMB for transmission, the write operation is blocked and the transmission is not disturbed. However, the abort request is captured and kept pending until one of the following conditions is satisfied:

- The module loses the bus arbitration.
- There is an error during the transmission.
- The module is put into Freeze mode.
- The module enters Bus Off state.
- There is an overload frame.

If none of the conditions above are reached:

- The MB is transmitted correctly.
- The interrupt flag is set in the IFLAG register.
- An interrupt to the CPU is generated (if enabled).

The abort request is automatically cleared when the interrupt flag is set. On the other hand, if only one of the above conditions is reached, the frame is not transmitted; therefore:

- The abort code is written into the CODE field.
- The interrupt flag is set in the IFLAG.
- An interrupt is (optionally) generated to the CPU.

If the CPU writes the abort code before the transmission begins internally, then the write operation is not blocked; therefore, the MB is updated and the interrupt flag is set. In this way the CPU only needs to read the abort code to make sure the active MB was safely inactivated. Although the AEN bit is asserted and the CPU wrote the abort code, in this case the MB is inactivated and not aborted, because the transmission did not start yet. One Mailbox is aborted only when the abort request is captured and kept pending until one of the previous conditions is satisfied.

70.3.7.2 Mailbox inactivation

Inactivation is a mechanism provided to protect the mailbox against updates by the FlexCAN internal processes, thus allowing the CPU to rely on mailbox data coherence after having updated it, even in Normal mode.

Inactivation of transmission mailboxes must be performed just when MCR[AEN] is deasserted.

If a mailbox is inactivated, it participates in neither the arbitration process nor the matching process until it is reactivated. See Transmit process and Receive process for more detailed instructions on how to inactivate and reactivate a mailbox.

To inactivate a mailbox, the CPU must update its CODE field to INACTIVE (either 0b or 1000b).

Because you will not be able to synchronize the CODE field update with the FlexCAN internal processes, an inactivation can have the following consequences:

- A frame in the bus that matches the filtering of the inactivated Rx mailbox may be lost without notice, even if there are other mailboxes with the same filter.
- A frame containing the message within the inactivated Tx mailbox may be transmitted without setting the respective IFLAG.

In order to perform a safe inactivation and avoid the above consequences for Tx mailboxes, the CPU must use the transmission abort mechanism (see Transmission abort mechanism).

The inactivation automatically unlocks the mailbox (see Mailbox lock mechanism).

NOTE

Message buffers that are part of the Legacy Rx FIFO or Enhanced Rx FIFO cannot be inactivated. There is no write protection on the Legacy FIFO region by FlexCAN. CPU must maintain data coherency in the Legacy FIFO region when RFEN is asserted.

70.3.7.3 Mailbox lock mechanism

Other than mailbox inactivation, FlexCAN has another data coherence mechanism for the receive process. When the CPU reads the Control and Status word of an Rx MB with codes FULL or OVERRUN, FlexCAN assumes that the CPU wants to read the whole MB in an atomic operation, and therefore it sets an internal lock flag for that MB. The lock is released when the CPU reads the free running timer (global unlock operation), or when it reads the Control and Status word of another MB regardless of its code. A CPU write into the C/S word also unlocks the MB, but this procedure is not recommended for normal unlock use because it cancels a pending move and potentially may lose a received message. The MB locking prevents a new frame from being written into the MB while the CPU is reading it.

NOTE

The locking mechanism applies only to Rx MBs that are not part of the Legacy Rx FIFO and have a code different than INACTIVE (0b) or EMPTY[1] (0100b). Also, Tx MBs cannot be locked.

Suppose, for example, that the Legacy Rx FIFO is disabled and the second and the fifth MBs of the array are programmed with the same ID, and FlexCAN has already received and stored messages into these two MBs. Suppose now that the CPU decides to read MB number 5 and at the same time another message with the same ID is arriving. When the CPU reads the Control and Status word of MB number 5, this MB is locked. The new message arrives and the matching algorithm finds out that there are no free-to-receive MBs, so it decides to override MB number 5. However, this MB is locked, so the new message cannot be written there. It will remain in the Rx SMB waiting for the MB to be unlocked, and only then will be written to the MB.

If the MB is not unlocked in time and yet another new message with the same ID arrives, then the new message overwrites the one on the Rx SMB and there will be no indication of lost messages either in the CODE field of the MB or in the Error and Status Register.

While the message is being moved in from the Rx SMB to the MB, the BUSY bit on the CODE field is asserted. If the CPU reads the Control and Status word and finds out that the BUSY bit is set, it should defer accessing the MB until the BUSY bit is negated.

[1] In previous FlexCAN versions, reading the C/S word locked the MB even if it was EMPTY. This behavior is maintained when the IRMQ bit is negated.

NOTE

If the BUSY bit is asserted or if the MB is empty, then reading the Control and Status word does not lock the MB.

Inactivation takes precedence over locking. If the CPU inactivates a locked Rx MB, then its lock status is negated and the MB is marked as invalid for the current matching round. Any pending message on the Rx SMB will not be transferred anymore to the MB. An MB is unlocked when the CPU reads the Free Running Timer Register (see Free Running Timer (TIMER)), or the C/S word of another MB.

Lock and unlock mechanisms have the same functionality in both Normal and Freeze modes.

An unlock during Normal or Freeze mode results in the move-in of the pending message. However, the move-in is postponed if an unlock occurs during a low power mode (see Modes of operation), and it takes place only when the module returns to Normal or Freeze modes.

70.3.8 Enhanced Rx FIFO

FlexCAN supports an enhanced Rx FIFO engine which can store up to 20 CAN FD messages. The region 2000h–204Fh contains the output of the FIFO which should be read by the CPU. The enhanced Rx FIFO is enabled by setting EFRCR[ERFEN]. Although FlexCAN has two FIFO options, Legacy Rx FIFO and Enhanced Rx FIFO, they cannot be enabled at the same time. Refer to Legacy Rx FIFO to find detailed information about Legacy Rx FIFO.

The enhanced Rx FIFO has a watermark which is configured by setting EFRCR[ERFWM]. If EFRCR[ERFWM] is set, the CPU is notified only if a minimum number of messages is stored in the FIFO. When the number of stored messages is greater than the value in EFRCR[ERFWM], ERFSR[ERFWMI] is set by the hardware. Optionally, an interrupt or a DMA transfer can be triggered if MCR[DMA] or ERFIER[ERFWMIIE] are set, respectively.

For the Enhanced Rx FIFO to receive, the CPU must execute the configuration procedure below. The same procedure must be done if the CPU needs to change any of the configuration of the Enhanced RX FIFO.

1. Enter Freeze mode.
2. Enable Enhanced Rx FIFO by setting ERFCR[ERFEN], if it is not already enabled.[8]
3. Write one to ERFSR[ERFCLR] to reset Enhanced Rx FIFO engine.
4. Clear EFRSR[ERFUFW], EFRSR[ERFOVF], EFRSR[ERFWMI], and EFRSR[ERFDA], if they are set.
5. Write EFRCR[NFE] to configure the total number of enhanced Rx FIFO filter elements to be used in Enhanced Rx FIFO reception.
6. Write ERFCR[NEXIF] to configure the number of extended ID and standard ID filter elements to be used in Enhanced Rx FIFO reception.[9]
7. Configure the Enhanced Rx FIFO watermark by writing ERFCR[ERFWM]. If MCR[DMA] is set, ERFCR[ERFWM] should be configures as 0x0.
8. If interrupts will be used, set the interrupt enables in the ERIER register.
9. If DMA will be used, set MCR[DMA] to enable DMA operation and write ERFCR[DMALW] to configure the number of words to transfer for each Enhanced Rx FIFO data element.
10. Configure the filter elements by writing in the ERFFEL*n* registers.[10]
11. Leave Freeze mode.

There are two types of Enhanced Rx FIFO filter elements that can be stored in ERFFEL*n* registers: extended-ID filter element and standard-ID filter element. Each extended-ID filter element is stored in two ERFFEL*n* registers while each standard-ID filter element is stored in one ERFFEL*n* register. The total number of Enhanced RX FIFO filter elements is defined by ERFCR[NFE].

In addition, the filter memory space can be split into two regions: one for extended-ID filter elements and another for standard-ID filter elements, according to ERFCR[NEXIF]. The figure below shows how the Enhanced Rx filter elements are defined. Detailed

[8] MCR[RFEN] must be cleared so that Enhanced Rx FIFO is enabled.
[9] NEXIF ≤ NFE + 1.
[10] ERFFEL*n* registers are implemented in RAM; thus they must be explicitly initialized prior to any reception.

information about the Enhanced Rx FIFO matching process and filter element formats can be found in Enhanced Rx FIFO matching process.

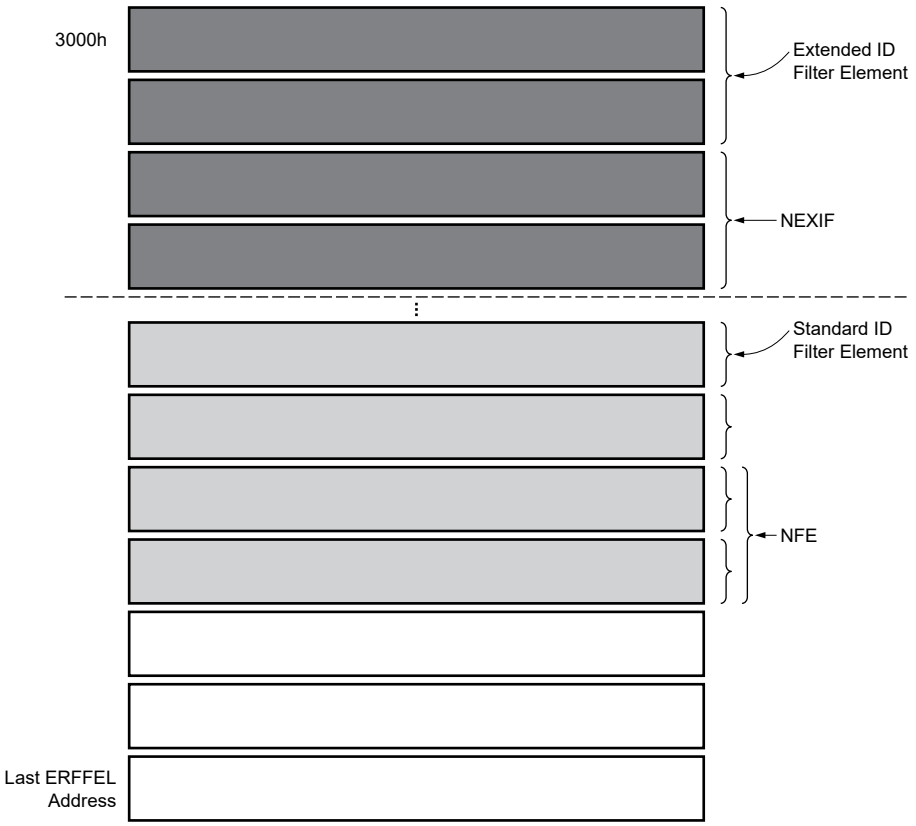

Figure 371. Number of enhanced Rx FIFO filter elemets

70.3.8.1 Enhanced Rx FIFO matching process

When ERFCR[ERFEN] is enabled, FlexCAN scans the ERFFEL*n* memory region. If at least one filter element satisfies the matching criteria, then the CAN message content is transfered to the enhanced RX FIFO memory.

NOTE

If multiple filters match the incoming message ID, then the first matching filter found by the matching process must be indicated in IDHIT.

Each ERFFEL*n* register can store one standard filter element. The matching criteria are defined by ERFFEL*n*[FSCH] in this way:

- If FSCH = b00, the filter scheme is based on mask and filter. A CAN message matches a standard ID filter element only if these criteria are reached:
  1. CAN message is base frame format (IDE = 0)
  2. (ID[*n*] = STD ID filter [*n*]) or (STD ID Mask[*n*] =0) for each bit *n* from 0 to 10
  3. (RTR = RTR Filter) or (RTR MASK = 0)

In this explanation, RTR and ID are the Remote Transmit Request field and the ID from a CAN message, respectively.

If FSCH = b00, the filters and masks are defined as shown in this table.

Table 416. Standard ID filter element with filter + mask scheme (FSCH = b00)

31	30	29	28	27	26	16	15	12	11	10	0
FSCH=b00		Reserved		RTR filter	STD ID filter		Reserved		RTR mask	STD ID mask	

- If FSCH = b01, the filter scheme is based on range. A CAN message matches a standard ID filter element only if these criteria are reached:
  1. CAN message is base frame format (IDE = 0)
  2. ID ≥ STD ID Filter1
  3. ID ≤ STD ID Filter2
  4. (RTR = RTR filter) or (RTR MASK = 0)

RTR and ID are the Remote Transmit Request bit and ID from a CAN message, respectively. If FSCH = b01, the filters and mask are defined as shown in this table.

Table 417. Standard ID filter element with range scheme (FSCH = b01)

31	30	29	28	27	26	16	15	12	11	10	0
FSCH=b01		Reserved		RTRfilter	STD ID Filter2		Reserved		RTR mask	STD ID Filter1	

- If FSCH = b10, the filter scheme is based on two filters without masks. A CAN message matches a standard ID filter element only if these criteria are reached:
  1. CAN message is base frame format (IDE = 0)
  2. (ID[*n*] = STD ID Filter1[*n*]) or (ID[*n*] = STD ID Filter2[*n*]) for each bit *n* from 0 to 10
  3. (RTR = RTR Filter1) or (RTR = RTR Filter2)

RTR and ID are the Remote Transmit Request bit and ID from a CAN message, respectively. If FSCH = b10, the filters are defined as shown in this table.

Table 418. Standard ID filter element with 2-filter scheme (FSCH = b10)

31	30	29	28	27	26	16	15	12	11	10	0
FSCH=b10		Reserved		RTR Filter 2	STD ID Filter2		Reserved		RTR Filter 1	STD ID Filter1	

Each pair of ERFFEL*n* registers can store one extended filter element. The matching criteria are defined by ERFFEL*n*[FSCH] in this way:

- If FSCH = b00, the filter scheme is based on mask and filter. A CAN message matches an extended ID filter element only if these criteria are reached:
  1. CAN message is extended frame format (IDE = 1)
  2. (ID[*n*] = EXT ID filter [*n*]) or (EXT ID Mask[*n*] =0) for each bit *n* from 0 to 28
  3. (RTR = RTR Filter) or (RTR MASK = 0)

If FSCH = b00, the filters and masks are defined as shown in this table.

Table 419. Extended ID filter element with filter + mask scheme (FSCH = b00)

31	30	29	28	0
FSCH		RTR filter	EXT ID filter	
Reserved		RTR mask	EXT ID mask	

- If FSCH = b01, the filter scheme is based on range. A CAN message matches an extended ID filter element only if the following criteria are reached:
  1. CAN message is extended frame format (IDE = 1)
  2. ID ≥ EXT ID Filter1
  3. ID ≤ EXT ID Filter2
  4. (RTR = RTR Filter) or (RTR MASK = 0)

If FSCH = b01, the filters and masks are defined as shown in this table.

Table 420. Extended ID filter element with range scheme (FSCH = b01)

31	30	29	28	0
FSCH		RTR filter	EXT ID Filter2	
Reserved		RTR mask	EXT ID filter 1	

- If FSCH = b10, the filter scheme is based on two filters without masks. A CAN message matches an extended ID filter element only if these criteria are reached:
  1. CAN message is extended frame format (IDE = 1)
  2. (ID[*n*] = EXT ID Filter1[*n*]) or (ID[*n*] = EXT ID Filter2[*n*]) for each bit *n* from 0 to 28
  3. (RTR = RTR Filter1) or (RTR = RTR Filter2)

If FSCH = b10, the filters and masks are defined as shown in this table.

Table 421. Extended ID filter element with 2-filter scheme (FSCH = b10)

31	30	29	28	0
FSCH		RTR Filter2	EXT ID Filter2	
Reserved		RTR Filter1	EXT ID filter 1	

70.3.8.2 Enhanced Rx FIFO under DMA operation

The DMA feature is enabled by asserting both ERF[ERFEN] and MCR[DMA]. The DMA controller can read the received message by reading a message buffer structure at the Enhanced FIFO output port at the address range defined in Enhanced Rx FIFO structure.

NOTE

FlexCAN supports 32-bit access only for DMA transfers.

The CPU should not access the Enhanced FIFO output port address range during DMA operation, so that the FIFO engine operates properly. Before enabling MCR[DMA], the CPU must service Enhanced Rx FIFO status bits. Otherwise, these bits may show that the FIFO has data to be serviced, and mistakenly generate a DMA request. Before disabling MCR[DMA], the CPU must first clear the ERFUFW, ERFOVF, ERMWMI, and ERFDA fields in the ERFSR register, and then clear the Enhanced RX FIFO engine by writing one to ERFSR[ERFCLR].

ERFSR[ERFDA] is set by the hardware when there is one frame available to be read from the Enhanced Rx FIFO. Upon receiving the request, the DMA controller can read the message in the Enhanced Rx FIFO output. Each message reading process must end by the address defined in ERFCR[DMALW].

The following rules must be obeyed for Enhanced Rx FIFO DMA operation:

- Because a DMA transfer cannot be dynamically changed, ERFCR[DMALW] should be programmed so that the Enhanced Rx FIFO element can store the largest CAN message present on the CAN bus.
- Data bytes are valid according to the DLC field. See Table 446.

Each time one message is read from FIFO by the DMA controller, ERFSR[ERFDA] is cleared by FlexCAN and set again if there is at least one message stored in the FIFO.

For example, suppose that the maximum number of bytes in the data field of a CAN frame for a certain application is eight, and high-resolution time stamp is enabled. In that case the last Enhanced RX FIFO address offset can be found in Table 455 and Table 456. Using this address offset, ERFCR[DMALW] can be determined like this:

- Maximum number of data bytes = 8
- HR TIME STAMP enabled
- Last address offset = TS_OFF = 2014h
- DMALW = 5

70.3.8.3 Enhanced Rx FIFO clear operation

When ERFCR[ERFEN] is set, the CPU can clear the Enhanced Rx FIFO by writing one into ERFSR[ERFCLR]. The clear operation resets the internal FIFO pointers although the FIFO content stored in RAM is not changed. This operation can only be performed in Freeze mode and is blocked by hardware in other modes. This operation does not clear the ERFUFW, ERFOVF, ERFDA, and ERFWMI fields in EFRSR. Consequently the CPU must service all these fields before executing the clear FIFO task.

70.3.9 Legacy Rx FIFO

The Legacy Rx FIFO is receive-only and is enabled by asserting MCR[RFEN]. The reset value of this bit is zero to maintain software backward compatibility with previous versions of the module that did not have the Legacy FIFO feature.

CAUTION

Legacy Rx FIFO must not be enabled when CAN FD feature is enabled.

The Legacy FIFO is 6-message deep. The memory region occupied by the Legacy FIFO structure (both message buffers and Legacy FIFO engine) is described in Legacy Rx FIFO structure. The CPU can read the received messages sequentially, in the order they were received, by repeatedly reading a message buffer structure at the output of the Legacy FIFO.

IFLAG1[BUF5I] (Frames available in Legacy Rx FIFO) is asserted when there is at least one frame available to be read from the Legacy FIFO. An interrupt is generated if it is enabled by the corresponding mask bit. Upon receiving the interrupt, the CPU can read the message (accessing the output of the Legacy FIFO as a message buffer) and the RXFIR register, and then clear the interrupt. If there are more messages in the Legacy FIFO the act of clearing the interrupt updates the output of the Legacy FIFO with the next message and updates RXFIR with the attributes of that message, reissuing the interrupt to the CPU. Otherwise, the flag remains negated. The output of the Legacy FIFO is valid only while IFLAG1[BUF5I] is asserted.

IFLAG1[BUF6I] (Legacy Rx FIFO Warning) is asserted when the number of unread messages within the Legacy Rx FIFO is increased to five from four due to the reception of a new one, meaning that the Legacy Rx FIFO is almost full. The flag remains asserted until the CPU clears it.

IFLAG1[BUF7I] (Legacy Rx FIFO Overflow) is asserted when an incoming message was lost because the Legacy Rx FIFO is full. Note that the flag will not be asserted when the Legacy Rx FIFO is full and the message was captured by a Mailbox. The flag remains asserted until the CPU clears it.

Clearing one of those three flags does not affect the state of the other two.

An interrupt is generated if an IFLAG bit is asserted and the corresponding mask bit is asserted too.

A powerful filtering scheme is provided to accept only frames intended for the target application, reducing the interrupt servicing workload. The filtering criteria is specified by programming a table of up to 128 32-bit registers, according to CTRL2[RFFN] setting, that can be configured to one of the following formats (see also Legacy Rx FIFO structure):

- Format A: 128 IDAFs (extended or standard IDs including IDE and RTR)
- Format B: 256 IDAFs (standard IDs or extended 14-bit ID slices including IDE and RTR)
- Format C: 512 IDAFs (standard or extended 8-bit ID slices)

NOTE

A chosen format is applied to all entries of the filter table. It is not possible to mix formats within the table.

Every frame available in the Legacy Rx FIFO has a corresponding IDHIT (Identifier Acceptance Filter Hit Indicator) that can be read in the IDHIT field from C/S word, as shown in the Legacy Rx FIFO Structure description. Another way the CPU can obtain this information is by accessing the RXFIR register. RXFIR[IDHIT] refers to the message at the output of the Legacy FIFO and is valid while the IFLAG1[BUF5I] flag is asserted. The RXFIR register must be read only before clearing the flag, which guarantees that the information refers to the correct frame within the Legacy FIFO.

Up to 32 elements of the filter table are individually affected by the Individual Mask Registers (RXIMRx), according to the setting of CTRL2[RFFN], allowing very powerful filtering criteria to be defined. If MCR[IRMQ] is negated, then the Legacy Rx FIFO filter table is affected by RXFGMASK.

NOTE

For more information about the difference between FD and non-FD regarding this feature, see Table 411.

70.3.9.1 Legacy Rx FIFO under DMA operation

The receive-only Legacy FIFO can support DMA. This feature is enabled by asserting both MCR[RFEN] and MCR[DMA]. The reset value of MCR[DMA] is zero to maintain backward compatibility with previous versions of the module that did not have the DMA feature.

The DMA controller can read the received message by reading a message buffer structure at the Legacy FIFO output port at the 80h–8Ch address range.

NOTE

FlexCAN supports 32-bit access only for DMA transfers.

When MCR[DMA] is asserted the CPU must not access the Legacy FIFO output port address range. Before enabling MCR[DMA], the CPU must service the IFLAGs asserted in the Legacy Rx FIFO region. Otherwise, these IFLAGs may show that the FIFO has data to be serviced, and mistakenly generate a DMA request. Before disabling MCR[DMA], the CPU must perform a clear Legacy FIFO operation.

IFLAG1[BUF5I] (Frames available in Legacy Rx FIFO) is asserted when there is at least one frame available to be read from the FIFO. Consequently a DMA request is generated simultaneously. Upon receiving the request, the DMA controller can read the message (accessing the output of the Legacy FIFO as a message buffer). The DMA reading process must end by reading address 8Ch, which clears IFLAG1[BUF5I] and updates both the FIFO output with the next message (if FIFO is not empty) and the RXFIR register with the attributes of the new message. If there are more messages stored in the FIFO, IFLAG1[BUF5I] will be re-asserted and another DMA request is issued. Otherwise, the flag remains negated.

NOTE

RXFIR register contents cannot be read after DMA completes the Legacy FIFO read. The IDHIT information is also available in the C/S word at address 080h (see Legacy Rx FIFO structure.

IFLAG1[BUF6I] and IFLAG1[BUF7I] are not used when the DMA feature is enabled.

When FlexCAN is working with DMA, the CPU does not receive any Legacy Rx FIFO interruption and must not clear the related IFLAGs. In addition, the related IMASKs are not used to mask the generation of DMA requests.

NOTE

For more information about the difference between FD and non-FD regarding this feature, see Table 411.

70.3.9.2 Clear Legacy FIFO operation

When MCR[RFEN] is asserted, the clear Legacy FIFO operation is a feature used to empty Legacy FIFO contents. With MCR[RFEN] asserted the Clear FIFO occurs when the CPU writes one in IFLAG1[BUF0I]. This operation can only be performed in Freeze mode and is blocked by hardware in other modes. This operation does not clear the FIFO IFLAGs; consequently the CPU must service all FIFO IFLAGs before executing the clear FIFO task.

When Legacy Rx FIFO is working with DMA, the clear FIFO operation clears IFLAG1[BUF5I] and the DMA request is canceled.

CAUTION

Clear Legacy FIFO operation does not clear IFLAGs, except when MCR[DMA] is asserted; in this case only IFLAG1[BUF5I] is cleared.

70.3.10 CAN protocol related features

This section describes the CAN protocol related features.

70.3.10.1 CAN FD ISO compliance

The CAN FD protocol has been improved to increase the failure detection capability that was in the original CAN FD protocol, which is also called non-ISO CAN FD, by CAN in Automation (CiA). A three-bit stuff counter and a parity bit have been introduced in the improved CAN FD protocol, now called ISO CAN FD. The CRC calculation has also been modified. All these improvements make the ISO CAN FD protocol incompatible with the non-FD CAN FD protocol. The non-ISO CAN FD is still supported by FlexCAN so that it can be used mainly during an intermediate phase, for evaluation and development purposes.

Therefore, it is strongly recommended to configure FlexCAN to the ISO CAN FD protocol by setting the ISOCANFDEN field in the CTRL2 register.

70.3.10.2 CAN FD frames

The ISO 11898-1 standard specifies the Classical Frame format compliant to ISO 11898-1 (2003) and introduces the CAN Flexible Data Rate Frame format. The Classical Frame format allows bit rates up to 1 Mbit/s and payloads up to 8 bytes per frame. The Flexible Data Rate Frame format allows bit rates higher than 1 Mbit/s and payloads longer than 8 bytes per frame. FlexCAN can receive and transmit CAN FD messages interleaved with Classical CAN messages.

There are three additional control bits in the CAN FD frame. The Extended Data Length (EDL) bit enables a longer data payload with different data length coding. The Bit Rate Switch (BRS) bit decides whether the bit rate is switched inside a CAN FD format frame. The Error State Indicator (ESI) flag is transmitted dominant by error active nodes, and recessive by error passive nodes. There are no Remote Frames (see Remote frames) in the CAN FD format. A message configured to transmit a Remote Frame is always sent out in the Classical CAN format. When an FD frame is received and matches a mailbox, the RTR bit in the receiving message buffer is negated. The RTR bit must be considered in classical frames only.

CAN FD messages may be formatted as long frames where the data field exceeds 8 bytes, and may range from 12 up to 64 bytes. They can also be configured to support bit rate switching, where the control field, the data field, and the CRC field of a CAN frame are transmitted with a higher bit rate than the beginning and the end of the frame. Messages in Classical CAN format are limited to transport a maximum payload of 8 bytes at nominal rate. The following figure illustrates the message formats for Classical and FD frames with either standard or extended ID.

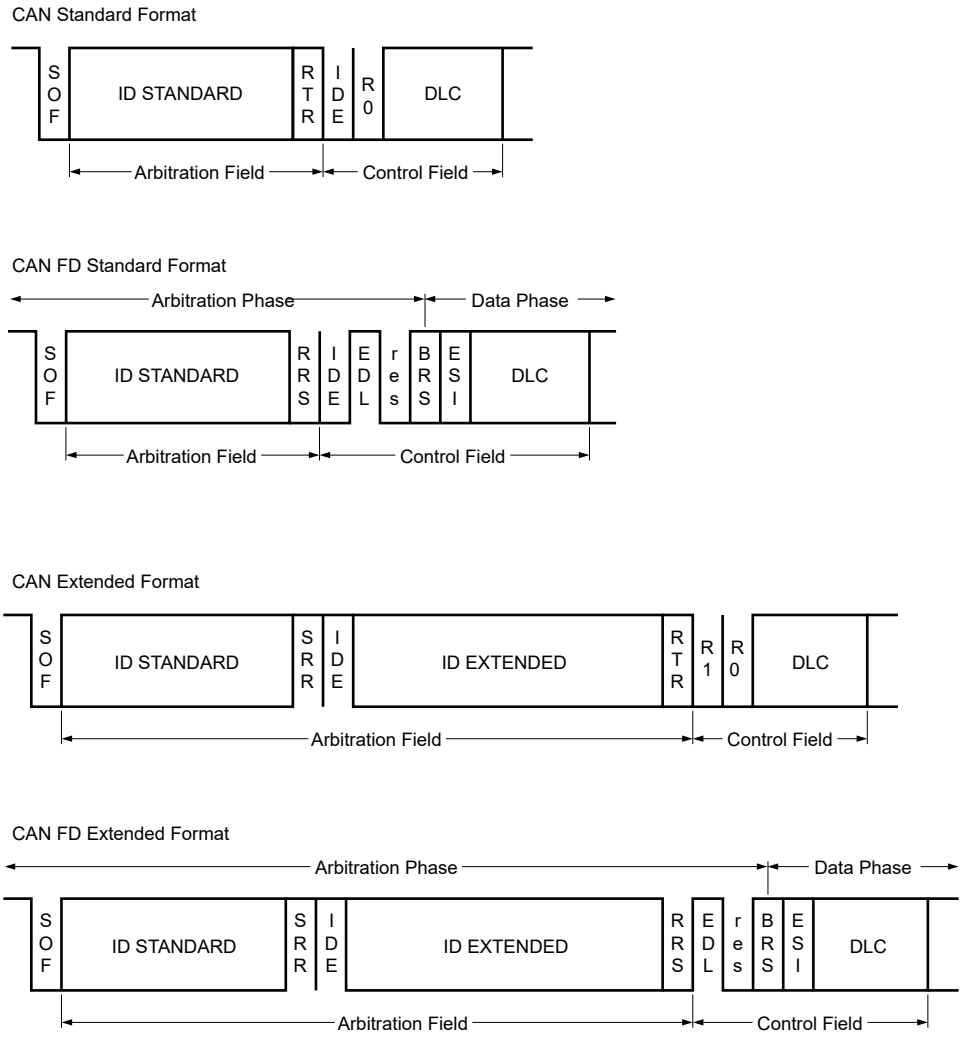

Figure 372. CAN message formats

The ability to receive and transmit CAN FD messages is enabled by MCR[FDEN]. Either a recessive R0 bit in CAN frames with 11-bit identifiers or a recessive R1 bit in CAN frames with 29-bit identifiers are decoded as an EDL bit (not a reserved one). A CAN FD frame is recognized by a recessive EDL bit, and a Classical CAN frame is recognized by a dominant EDL bit. The BRS bit specifies whether this frame switches the bit rate in its data phase. A long frame is decoded in accordance with the DLC field value (see DLC definition in Message buffer structure).

CAN FD messages can be transmitted with two different bit rates. The first part of a CAN FD frame, from the Start Of Frame (SOF) bit until the Bit Rate Switch (BRS) bit, also called the arbitration phase, is transmitted with the nominal bit rate based on a set of nominal CAN bit timing configuration values. The second part, from the BRS bit until the CRC Delimiter bit, also named the data phase, is transmitted with the data bit rate defined by a second set of CAN data bit timing configuration values. Finally, from the CRC Delimiter until the Intermission bits, the transmission returns to nominal bit rate. In CAN FD frames with bit rate switching, the bit timing is changed inside the frame at the sample point of the BRS bit if this bit is recessive. Before the BRS bit, in the CAN FD arbitration phase, the nominal CAN bit timing is used as defined by the CBT register (also by CTRL1 register for backward compatibility). Upon detecting a recessive BRS bit, the CAN data bit timing is used as defined by the FDCBT register.

NOTE

If the length of the time quantum in the nominal bit timing and the length of the time quantum in the data bit timing are not identical, a quantization error of up to one time quantum of the arbitration phase may be present as a phase error. This situation can occur after the switch from arbitration to data phase and will last until the next synchronization event. Thus, the length of the time quantum should be the same in nominal and data bit timing in order to minimize the chance of error frames on the CAN bus, and to optimize the clock tolerance in networks that use FD frames.

FDCTRL[FDRATE] enables the transmission of all frames with bit rate switching if the BRS bit in the selected Tx MB is set. If FDRATE is negated, the transmission is performed at nominal rate regardless of the BRS bit value. FDCTRL[FDRATE] can be written any time but takes effect only for the next message transmitted or received.

The nominal bit timing is resumed at either the sample point of the CRC Delimiter bit or when an error is detected, whichever occurs first. The following figure describes the mechanism for entering and leaving the data phase when BRS bit is recessive.

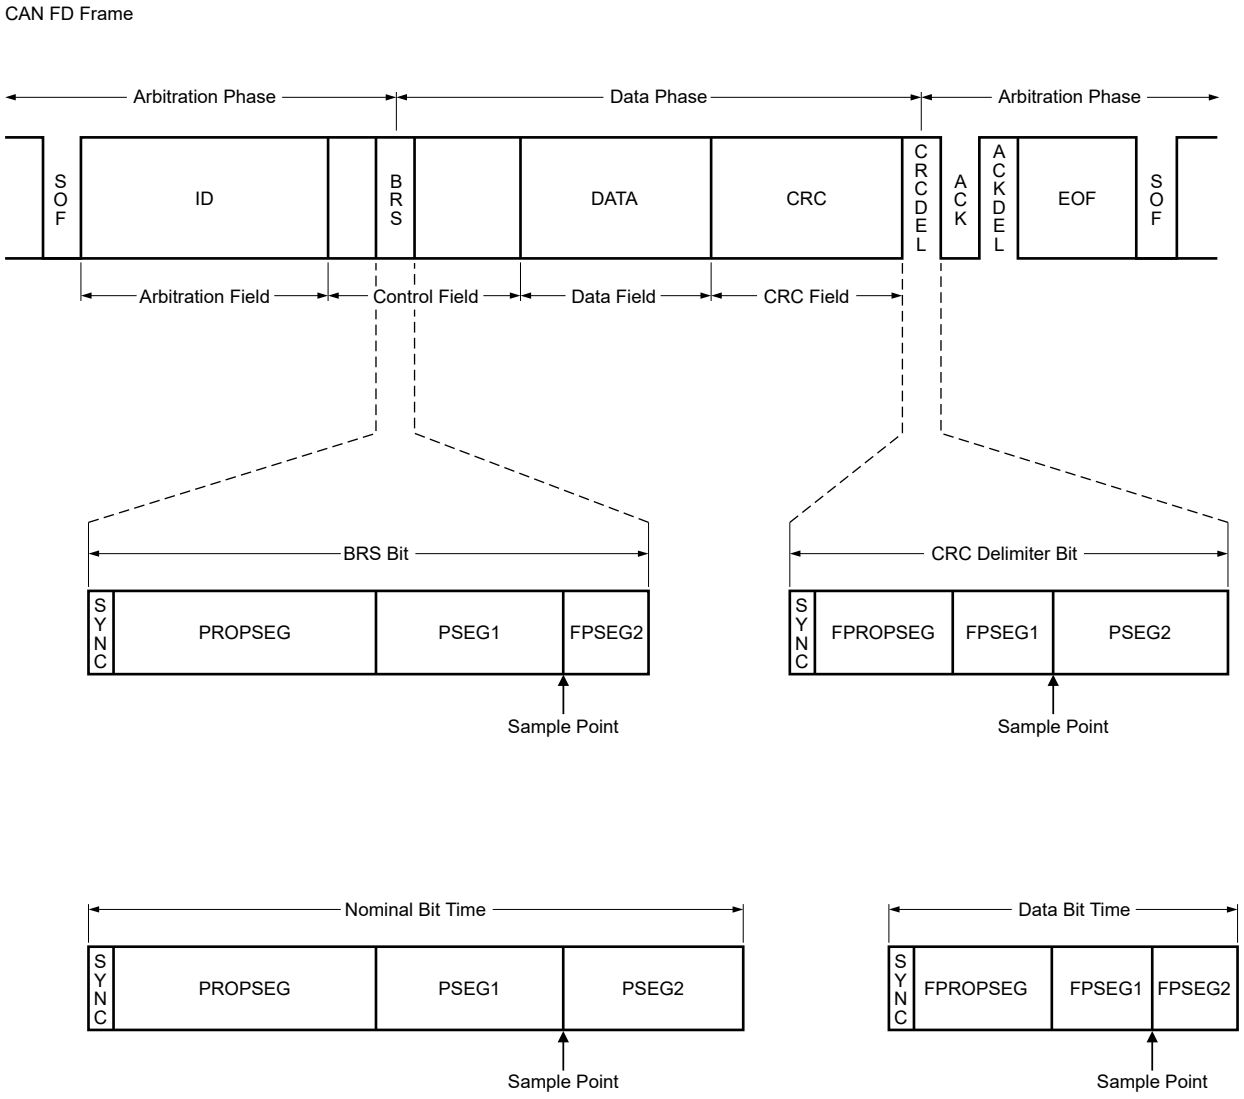

Figure 373. Bit rate switching mechanism for CAN FD messages

NOTE

In Classical CAN frames, the CRC delimiter is one single recessive bit. In CAN FD frames, the CRC delimiter may consist of one or two recessive bits. FlexCAN sends only one recessive bit as the CRC delimiter, but it accepts two recessive bits before the edge from recessive to dominant that starts the acknowledge slot. As a receiver, FlexCAN sends its acknowledge bit after the first CRC delimiter bit. In CAN FD frames, FlexCAN accepts a two-bit dominant ACK slot as a valid ACK to compensate for phase shifts between the receivers.

The maximum configurable bit rate in the CAN FD data phase depends on the clock frequency of CAN_PE subblock. For example, with a CAN_PE clock frequency of 40 MHz and the shortest configurable bit time of 5 time quanta, the bit rate in the data phase is 8 Mbit/s.[11]

The value of the ESI bit is determined either by the transmitter's error state at the start of the transmission, if the frame is originated in the FlexCAN node, or by the original transmitting node in case FlexCAN is acting as a gateway for the message. If the transmitter is error passive, ESI is transmitted recessive; otherwise, it is transmitted dominant. The permutations of the relationship between the written value and the transmitted value of the ESI are shown in this table.

Table 422. Written versus transmitted values of ESI field

FlexCAN fault confinement status at start of frame	ESI bit Of Tx MB	Transmitted ESI
Error active	0	0 (Error Active)
Error passive	0	1 (Error Passive)
Error active	1	1 (Error Passive)
Error passive	1	1 (Error Passive)

There are different CRC polynomials for different CAN frame formats. The first polynomial, CRC_15, is used for all frames in Classical CAN format. The second, CRC_17, is used for frames in CAN FD format with a data field up to sixteen bytes long. The third, CRC_21, is used for frames in CAN FD format with a data field longer than sixteen bytes. Each polynomial results in a Hamming distance of 6. At the start of the frame, all three CRC polynomials are calculated concurrently. The CRC sequence to be transmitted is selected by the values of the EDL bit and the DLC bit field. When receiving a message, FlexCAN decodes EDL and DLC to select the adequate CRC polynomial to check for a CRC error.

In CAN FD format frames, stuff bits are included in the bit stream for CRC calculation. In Classical CAN format frames, stuff bits are not included. After the transmission of the last bit relevant to the CRC calculation, the FDCRC register stores the calculated CRC for the transmitted message, with the adequate length in accordance to the type of message, for both CAN FD and non-FD messages. The CRCR register reports a valid CRC for Classical CAN messages only.

In CAN FD format frames, the CAN bit stuffing method is changed for the CRC sequence so that the stuff bits are inserted at fixed positions. When FlexCAN is transmitting a CAN FD frame, a fixed stuff bit is inserted just before the first bit of the CRC sequence, even if the last bits of the preceding field do not fulfill the CAN stuff condition. Additional stuff bits are inserted after each fourth bit of the CRC sequence. The value of any fixed stuff bit is the inverse value of its preceding bit. When FlexCAN is receiving a CAN FD frame, it discards the fixed stuff bits from the bit stream for the CRC check. A stuff error is detected if the fixed stuff bit has the same value as its preceding bit.

FlexCAN detects errors in CAN FD frames the same way as in Classical CAN frames. The error counters RXERRCNT and TXERRCNT in the ECR register accumulate the counts of Rx and Tx errors, respectively, for both FD and non-FD frames indiscriminately. There are two extra error counters (RXERRCNT_FAST and TXERRCNT_FAST) that accumulate Rx and Tx errors occurring in the data phase of CAN FD frames with the BRS bit set only. The rules for updating the error counters are the same for both CAN FD and non-FD frames (see ECR register).

Error Flags BITERR1, BITERR0, ACKERR, CRCERR, FRMERR, and STFERR in the ESR1 register report errors in both CAN FD and non-FD frames. They also generate the ERRINT interrupt if CTRL1[ERRMSK] is asserted. The ESR1 register has additional error flags (BITERR1_FAST, BITERR0_FAST, CRCERR_FAST, FRMERR_FAST, and STFERR_FAST) to individually indicate

[11] The frequency used in this example may not be supported on this chip; it is shown only to demonstrate how the maximum configurable bit rate is calculated.

the occurrence of errors in the data phase of CAN FD frames with the BRS bit set. There is no ACKERR detected in the data phase of a CAN FD frame. Fault confinement status reported in ESR1[FLTCONF] is the same for both CAN FD and Classical CAN frames, and is based on RXERRCNT and TXERRCNT error counters only. Information contained in RXERRCNT_FAST and TXERRCNT_FAST counters may be considered as status to help detect the error nature related to the bit rate value.

When FlexCAN is in the data phase, either transmitting or receiving a CAN FD message, and detects an error, it immediately switches back to the arbitration phase and to the nominal rate to start an error flag.

Resynchronization and hard synchronization occur in CAN FD frames in the same way as in Classical CAN ones. Additionally, a hard synchronization is also performed at the recessive to dominant edge from EDL to R0 in CAN FD format frames. FlexCAN does not resynchronize while transmitting in the CAN FD data phase.

70.3.10.3 Transceiver delay compensation

The CAN FD protocol allows the transmission and reception of data at a higher bit rate than the nominal rate used in the arbitration phase when the message's BRS bit is set. This feature enables the use of rates up to 8 Mbps.

During the data phase of a CAN FD frame, the transmitter detects a bit error if it cannot receive its own latest transmitted bit at the sample point of that bit. When bit rate switching is enabled (BRS bit is asserted), the length of the CAN bit time in the data phase can become shorter than the transceiver's loop delay, thus impeding the correct comparison between the transmitted bit and the received bit within the current CAN bit time interval.

Note that the TDC process defines a secondary sample point where the transmitted bit is correctly compared with the received bit in order to check for bit errors.

The TDC mechanism can be enabled by FDCTRL[TDCEN] or ETDC[ETDCEN] and is effective only during the data phase of FD frames having the BRS bit set. It has no effect either on non-FD frames, or on FD frames transmitted at normal bit rate. The TDC is active from the sample point of the BRS bit until the sample point of the CRC Delimiter bit, provided the respective message under transmission has the BRS bit set. When it is active, a comparison is done between the real received bit and the delayed transmitted bit, where the delay is calculated based on the measured transceiver loop delay.

NOTE

The actual value of the CRC Delimiter bit is disregarded by transmitters using the transceiver delay compensation mechanism. A global error at the end of the CRC field will cause the receivers to send error frames that the transmitter will detect during Acknowledge or End of Frame.

For every transmitted FD frame having the BRS bit set, the delay measurement is triggered by the transition from the recessive EDL bit to the dominant R0 bit (as shown in the next figure). The loop delay is measured in Protocol Engine (PE) clock periods (CANCLK, see Protocol timing), from the transmitted EDL-R0 edge to the received EDL-R0 edge. The position of the secondary sample point is defined by the measured loop delay time added to an offset value specified in FDCTRL[TDCOFF] or ETDC[ETDCOFF]. FDCTRL[TDCVAL] or ETDC[ETDCVAL] stores the result of this calculation. The TDCVAL and ETDCVAL value saturates at its maximum value of 63 CANCLK and 255 CANCLK when the delay measurement is too long.

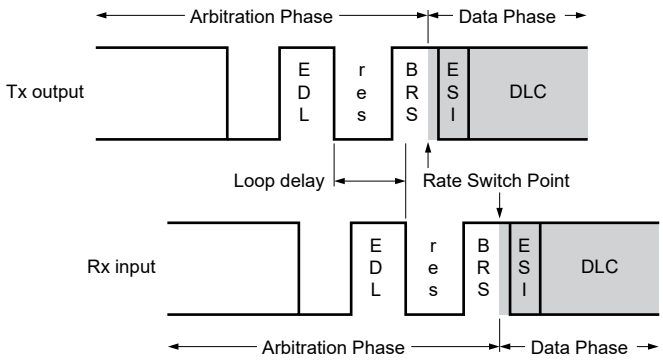

Figure 374. Transceiver loop delay measurement

The measured loop delay is not enough to be used to define the secondary sample point because it relates to the CAN bit edges. The transceiver delay compensation offset TDCOFF or ETDCOFF is used to shift the secondary sample point from the edge to an intermediate point inside the bit time, far away from its edges. Therefore, the TDCOFF or ETDCOFF value cannot be larger than the CAN bit duration in the data phase.

If the secondary sample point is set very near the CAN bit edge (SYNC field), then problems may occur during the bit sampling in the data phase. For the TDC to work reliably, the offset has to use optimal settings. To be sure the bit sampling is performed in the best region, the TDC offset should be configured as shown in this equation:

$$\text{Offset} = (\text{FPSEG1} + \text{FPROPSEG} + 2) \times (\text{FPRESDIV} + 1)$$
or
$$\text{Offset} = (\text{DTSEG1} + 2) \times (\text{EDPRESDIV} + 1), \text{ if ETDCEN}$$

The following figure shows the SSP position when these settings are used.

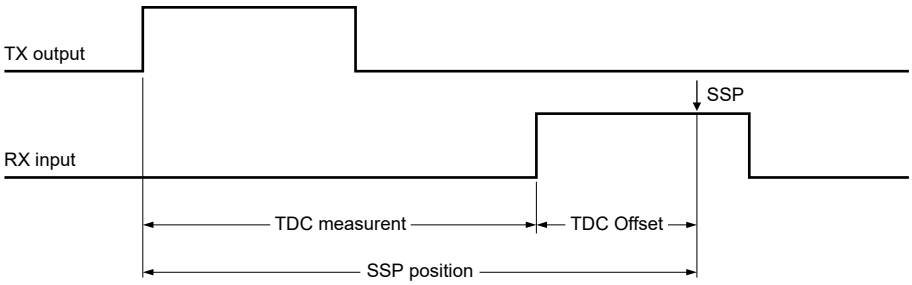

Figure 375. SSP position with optimal values

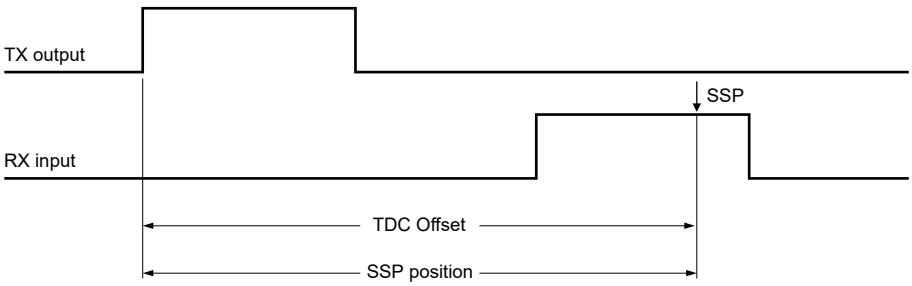

Figure 376. SSP position—TDC measurement disabled by ETDCEN and TDMDIS

Alternatively, if CTRL2[BTE] and ETDC[ETDCEN] are set, the TDMDIS bit can be set to disable the transceiver delay measurement. In this case, the SSP position is defined only by the ETDCOFF field. Figure 376 shows the secondary sample point position when the transceiver delay measurement is disabled.

During the data phase of CAN FD frames with bit rate switching enabled, at the onset of every Tx CAN bit, the transmitted Tx bit value is temporarily stored in a buffer and a time countdown based on FDCTRL[TDCVAL] or ETDC[ETDCVAL] is started which ends with the comparison of the received Rx bit (delayed by the external loop delay plus the specified offset) with the stored Tx bit. If a bit error is detected at the secondary sample point, the FlexCAN issues an error flag to the CAN bus at the next sample point.

During the arbitration phase the delay compensation is always disabled. The maximum delay which can be compensated by the FlexCAN's transceiver delay compensation during the data phase is 3 CAN bit times – 2 Tq. Beyond this limit, the FDCTRL[TDCFAIL] or ETDC[ETDCFAIL] flag is set to indicate when the transceiver delay compensation mechanism is out of range, unable to compensate the transceiver loop delay.

70.3.10.4 Remote frames

A remote frame is a special kind of frame. You can program a mailbox to be a remote request frame by configuring the mailbox as Transmit with the RTR bit set to one. After the remote request frame is transmitted successfully, the mailbox becomes a receive message buffer, with the same ID as before.

When a remote request frame is received by FlexCAN, it can be treated in four ways, depending on remote request storing (CTRL2[RRS]) and Rx FIFO Enable (MCR[RFEN]):

- If RRS is negated the frame's ID is compared to the IDs of the transmit message buffers with the CODE field 1010b. If there is a matching ID, then this mailbox frame will be transmitted. Note that if the matching mailbox has the RTR bit set, then FlexCAN will transmit a remote frame as a response. The received remote request frame is not stored in a receive buffer. It is only used to trigger a transmission of a frame in response. The mask registers are not used in remote frame matching, and all ID bits (except RTR) of the incoming received frame should match. In the case that a remote request frame is received and matches a mailbox, this message buffer immediately enters the internal arbitration process, but is considered as a normal Tx mailbox, with no higher priority. The data length of this frame is independent of the DLC field in the remote frame that initiated its transmission.
- If RRS is asserted the frame's ID is compared to the IDs of the receive mailboxes with the CODE field 0100b, 0010b, or 0110b. If there is a matching ID, then this mailbox will store the remote frame in the same fashion of a data frame. No automatic remote response frame will be generated. The mask registers are used in the matching process.
- If RFEN is asserted FlexCAN will not generate an automatic response for remote request frames that match the Legacy FIFO filtering criteria. If the remote frame matches one of the target IDs, it will be stored in the Legacy FIFO and presented to the CPU. Note that for filtering formats A and B, it is possible to select whether remote frames are accepted or not. For format C, remote frames are always accepted (if they match the ID). Remote request frames are considered as normal frames, and generate a Legacy FIFO overflow when a successful reception occurs and the Legacy FIFO is already full.
- If ERFEN is set, FlexCAN will not generate an automatic response for remote request frames that match the Enhanced Rx FIFO filtering criteria. Remote Request Frames are considered normal frames, and generate an Enhanced Rx FIFO overflow when a sucessful reception occurs and Enhanced Rx FIFO is already full.

NOTE

There is no remote frame in the CAN FD format. The RTR bit is replaced by a fixed dominant RRS bit. FlexCAN receives and transmits remote frames in the Classical CAN format.

70.3.10.5 Overload frames

FlexCAN does transmit overload frames when the following conditions are detected on the CAN bus:

- Detection of a dominant bit in the first/second bit of Intermission
- Detection of a dominant bit at the 7th bit (last) of End of Frame field (Rx frames)
- Detection of a dominant bit at the 8th bit (last) of Error Frame Delimiter or Overload Frame Delimiter

70.3.10.6 Message buffer time stamp

The value of the free running timer is sampled at the beginning of the Identifier field on the CAN bus, and is stored at the end of move-in in the TIME STAMP field of message buffer, providing network behavior with respect to time.

When CTRL2[TIMER_SRC] is asserted, the free running timer is continuously clocked by an external time tick.

When CTRL2[TIMER_SRC] is negated, the free running timer is clocked by the FlexCAN bit-clock, which defines the baud rate on the CAN bus. During a message transmission/reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate.

The free running timer is not incremented during Disable and Freeze modes. It can be reset upon a specific frame reception, enabling network time synchronization. See the TSYN description in Control 1 register (CTRL1).

Alternatively, by configuring the MTSBASE field of the Control 2 register (CTRL2), the time stamp of the message buffer can capture the lower or higher 16 bits of the high-resolution dedicated counter.

70.3.10.7 High resolution time stamp

The high-resolution time stamp, HR_TIME_STAMP, uses a dedicated timer with a 32-bit counter operating in free running mode. The high-resolution time stamp is enabled by the TSTAMPCAP field of the Control 2 register (CTRL2). When this field is not zero , the dedicated 32-bit counter value is captured during a valid CAN frame and stored in the HR_TIME_STAMP register.

Each HR_TIME_STAMP*n* corresponds to a specific message buffer. For example, HR_TIME_STAMP0 stores the 32-bit time stamp associated with message buffer 0, HR_TIME_STAMP1 stores the 32-bit time stamp associated with message buffer 1, and so on.

The counter value is captured according to the TSTAMPCAP field of the Control 2 register (CTRL2). For classical CAN frames, the capture points can be the start of frame bit or the point in time a CAN frame is considered valid, which is the seventh bit of end of frame for transmission and the sixth bit of end of frame for reception. For CAN FD frames, the capture points can be the start of frame, the point in time a CAN FD frame is considered valid, or the res bit of a CAN FD frame.

The 16-bit time stamp of the message buffer can be configured to capture the lower or higher 16 bits of the high-resolution timer. This configuration is made by CTRL2[MBTSBASE].

70.3.10.8 Protocol timing

The following figure shows the structure of the clock generation circuitry that feeds the CAN Protocol Engine (PE) submodule.

NOTE

Please see the clock distribution chapter (module clocks table) to identify the proper clock source.

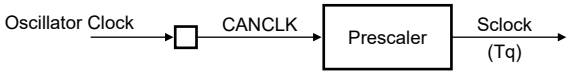

Figure 377. CAN engine clocking scheme

The FlexCAN module supports a variety of means to set up bit timing parameters that are required by the CAN protocol. The Control 1 register (CTRL1) has various fields used to control bit timing parameters: PRESDIV, PROPSEG, PSEG1, PSEG2, and RJW.

The CAN Bit Timing register (CBT) extends the range of the CAN bit timing variables in CTRL1. The CAN FD Bit Timing register (FDCBT) provides a second set of CAN bit timing variables to be applied at the data phase of CAN FD frames with the Bit Rate Switch (BRS) set.

The Enhanced Nominal CAN bit timing register (ENCBT) extends the range of CAN bit timing variables in CBT. The Enhanced Data Phase CAN bit timing register (EDCBT) extends the range of CAN bit timing variables in FDCBT. When using ENCBT and EDCBT, the bit timing nominal and data phase serial clock (Sclock) dividers must be programed in the Enhanced CAN Bit Timing Prescalers register (EPRS).

NOTE

When the CAN FD feature is enabled, always set CBT[BTF] or CTRL2[BTE] and configure the CAN bit timing variables in CBT or ENCBT. See CAN Bit Timing Register (CBT) or Enhanced Nominal CAN Bit Timing (ENCBT).

The PRESDIV field (as well as its extended range EPRESDIV (or ENPRESDIV) and FDPRESDIV (or EDPRESDIV) for the data phase bits of CAN FD messages) defines the prescaler value (see the equation below) that generates the serial clock (Sclock), whose period defines the time quantum used to compose the CAN waveform. A time quantum (Tq) is the atomic unit of time managed by the CAN engine.

$$Tq = \frac{(PRESDIV + 1)}{f_{CANCLK}}$$

Equation 10. Time quantum

The bit rate, which defines the rate the CAN message is either received or transmitted, is given by the formula:

$$\text{CAN Bit Time} = (\text{Number of Time Quanta in 1 bit time}) * \text{Tq}$$

$$\text{Bit Rate} = \frac{1}{\text{CAN Bit Time}}$$

Equation 11. CAN bit time and baud rate

A bit time is subdivided into three segments[1] (see Figure 379, Figure 380 and Table 423):

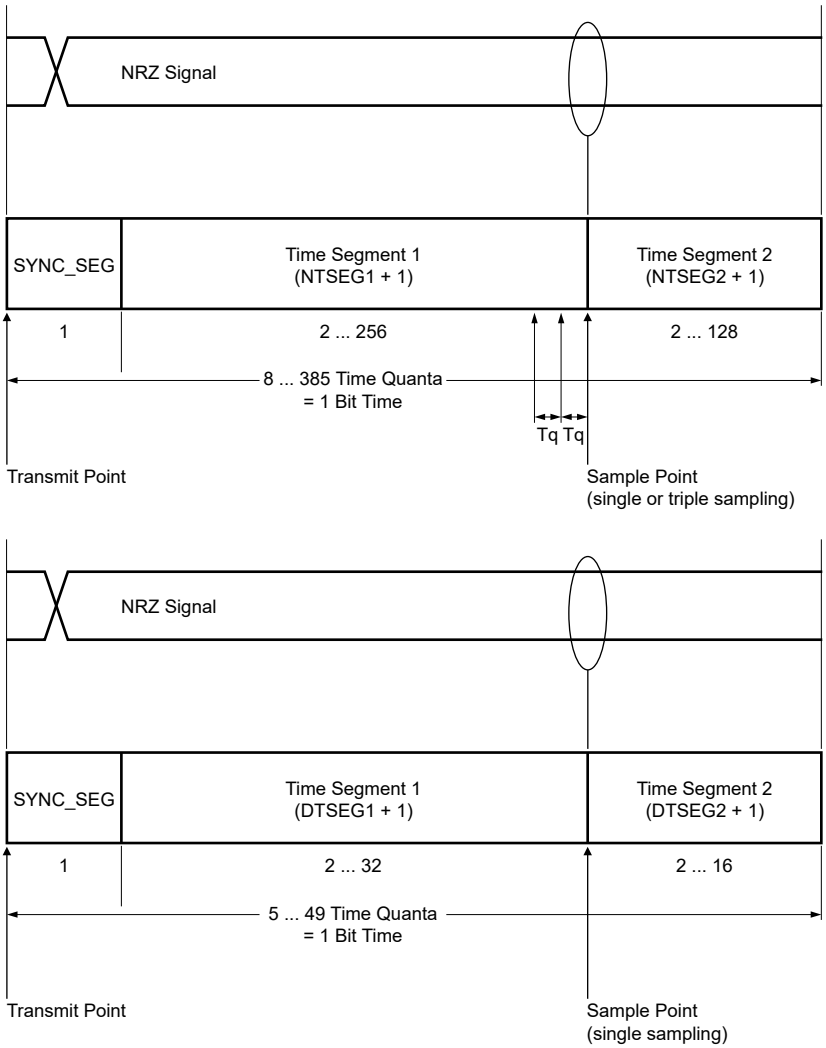

Figure 378. Segments within the bit timing (example using ENCBT and EDCBT bit timing variables)

- SYNC_SEG: This segment has a fixed length of one time quantum. Signal edges are expected to happen within this section.
- Time Segment 1: This segment includes the propagation segment and the phase segment 1 of the CAN standard. It can be programmed by setting CTRL1[PROPSEG] and CTRL1[PSEG1] so that their sum (plus 2) is in the range of 2 to 16 time quanta. When CBT[BTF] is asserted, FlexCAN uses EPROPSEG and EPSEG1 fields from CBT register so that their

[1] For further explanation of the underlying concepts, see ISO 11898-1. See also the CAN 2.0A/B protocol specification for bit timing.

sum (plus 2) is in the range of 2 to 96 time quanta. For messages in CAN FD format with the BRS bit set, FlexCAN uses FDPROPSEG and FDPSEG1 from FDCBT instead, so that their sum (plus 1) is in the range of 2 to 39 time quanta.

If CTRL2[BTE] is set, FlexCAN uses ENCBT[NTSEG1] to configure time segment 1 in the range of 2 to 256 time quanta. For the data phase in CAN FD messages with BRS set, EDCBT[DTSEG1] must be used for configuring time segment 1 in the range of 2 to 32 time quanta.

- Time Segment 2: This segment represents the phase segment 2 of the CAN standard. It can be programmed by setting CTRL1[PSEG2] (plus 1) to be 2 to 8 time quanta long. When CBT[BTF] is asserted, FlexCAN uses EPSEG2 fields of CBT register so that its value (plus 1) is in the range of 2 to 32 time quanta. For messages in CAN FD format with the BRS bit set, FlexCAN uses FDPSEG2 from FDCBT instead, so that its value (plus 1) is in the range of 2 to 8 time quanta. The time segment 2 cannot be smaller than the Information Processing Time (IPT), which value is 2 time quanta in FlexCAN.

  If CTRL2[BTE] is set, FlexCAN uses ENCBT[NTSEG2] to configure time segment 2 in the range of 2 to 128 time quanta. For the data phase in CAN FD messages with BRS set, EDCBT[DTSEG2] must be used for configuring time segment 2 in the range of 2 to 16 time quanta.

NOTE

The bit time defined by the above time segments must not be smaller than five time quanta. For bit time calculations, use an Information Processing Time (IPT) of two, which is the value implemented in the FlexCAN module.

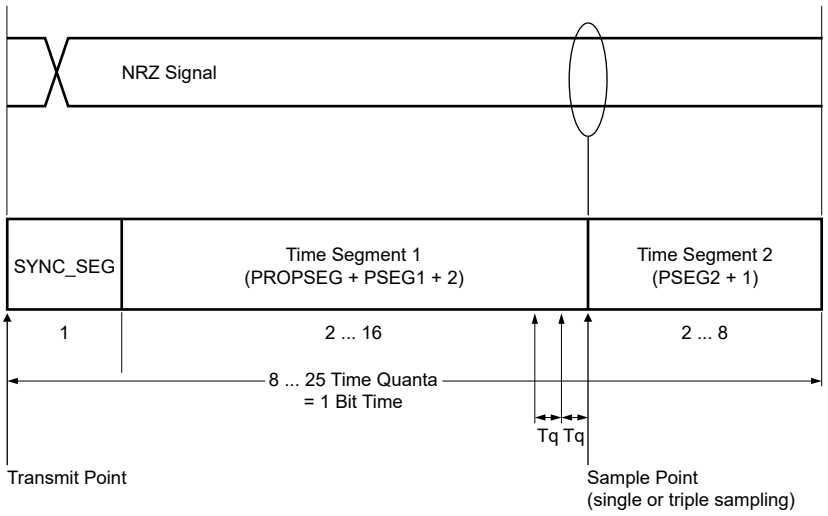

Figure 379. Segments within the bit time (example using CTRL1 bit timing variables for Classical CAN format)

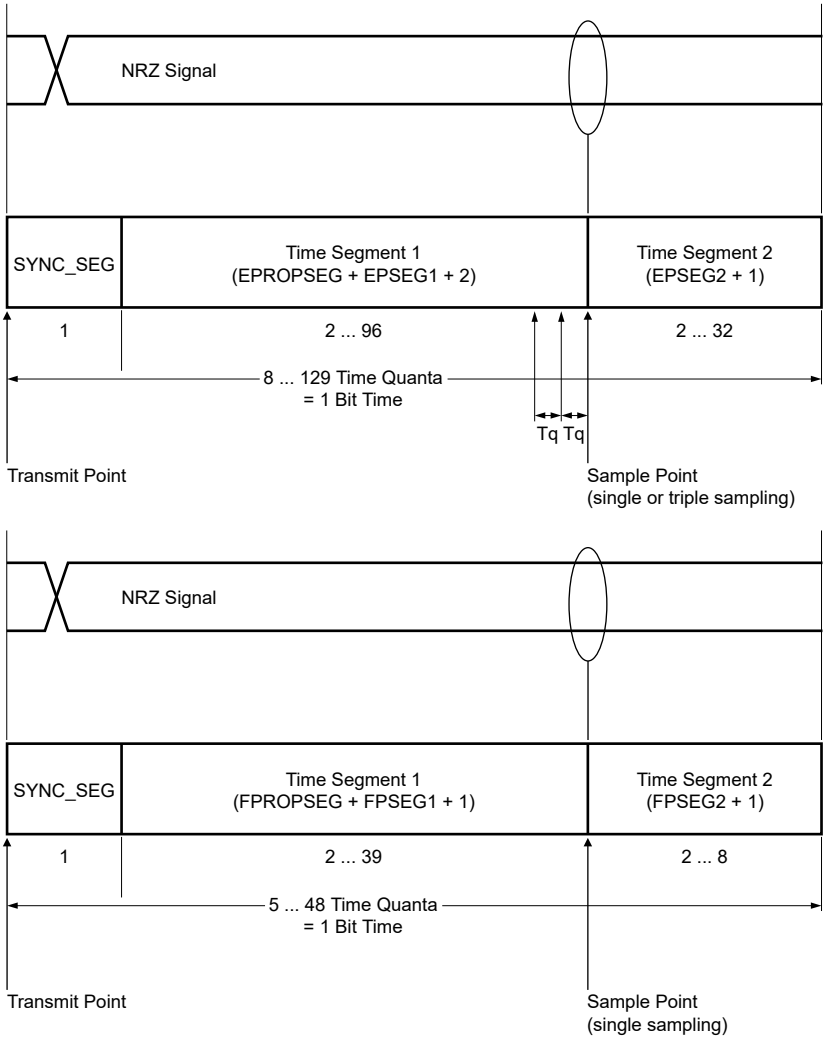

Figure 380. Segments within the bit time (example using CBT and FDCBT bit timing variables for CAN FD format)

Table 423. Time segment syntax

Syntax	Description
SYNC_SEG	System expects transitions to occur on the bus during this period.
TSEG1	Corresponds to the sum of PROPSEG and PSEG1.
TSEG2	Corresponds to the PSEG2 value.
Transmit point	A node in transmit mode transfers a new value to the CAN bus at this point.
Sample point	A node samples the bus at this point. If the three samples per bit option is selected, then this point marks the position of the third sample.

The following table gives some examples of the CAN compliant segment settings for Classical CAN format (Bosch CAN 2.0B) (non-FD) messages.

Table 424. Bosch CAN 2.0B standard compliant bit time segment settings

Time segment 1	Time segment 2	Re-synchronization jump width
5 .. 10	2	1 .. 2
4 .. 11	3	1 .. 3
5 .. 12	4	1 .. 4
6 .. 13	5	1 .. 4
7 .. 14	6	1 .. 4
8 .. 15	7	1 .. 4
9 .. 16	8	1 .. 4

NOTE

The user must ensure the bit time settings are in compliance with the CAN Protocol standard (ISO 11898-1).

Whenever CAN bit is used as a measure of time duration (for example, estimating the occurrence of a CAN bit event in a message), the number of peripheral clocks in one CAN bit (NumClkBit) can be calculated as:

$$NumClkBit = \frac{f_{SYS}}{f_{CANCLK}} \times (PRESDIV + 1) \times (PROPSEG + PSEG1 + PSEG2 + 4)$$

Equation 12. Number of peripheral clocks per CAN bit when CTRL2[BTE] = 0

or, if CTRL2[BTE] = 1:

$$NumClkBit = \frac{f_{SYS}}{f_{CANCLK}} \times (ENPRESDIV + 1) \times (NTSEG1 + NTSEG2 + 3)$$

Equation 13. Number of peripheral clocks per CAN bit when CTRL2[BTE] = 1

where:

- NumClkBit is the number of peripheral clocks in one CAN bit.
- f_{CANCLK} is the Protocol Engine (PE) Clock (see Figure 377), in Hz.
- f_{SYS} is the frequency of operation of the system (CHI) clock, in Hz.
- PSEG1 is the value in CTRL1[PSEG1] field.
- PSEG2 is the value in CTRL1[PSEG2] field.
- PROPSEG is the value in CTRL1[PROPSEG] field.
- PRESDIV is the value in CTRL1[PRESDIV] field.
- ENPRESDIV is the value in EPRS[ENPRESDIV] field.
- NTSEG1 is the value in ENCBT[NTSEG1] field.
- NTSEG2 is the value in ENCBT[NTSEG2] field.

The formula above is also applicable to the alternative CAN bit timing variables described in the CAN Bit Timing register (CBT) or the Enhanced Nominal CAN bit timing (ENCBT) register and also to the CAN FD Bit Timing register (FDCBT) or the Enhanced Nominal CAN bit timing register(ENCBT).

For example, 180 CAN bits = (180 x NumClkBit) peripheral clock periods.

70.3.10.9 Arbitration and matching timing

During normal reception and transmission, the matching, arbitration, move-in, and move-out processes are executed during certain time windows inside the CAN frame, as shown in the following figures.

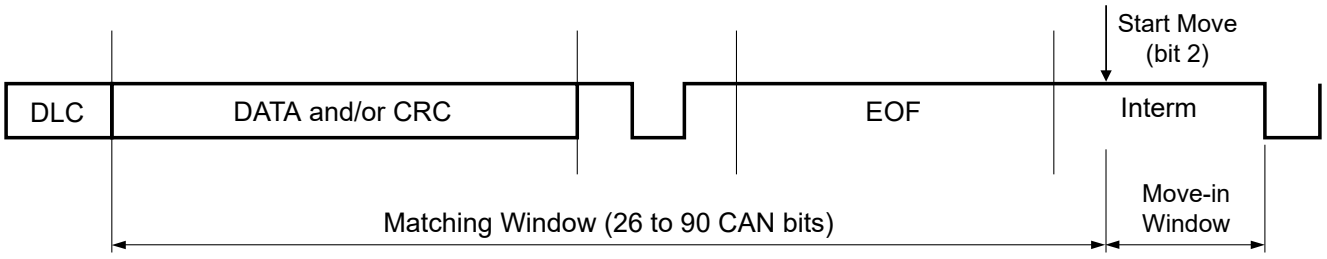

Figure 381. Matching and move-in time windows

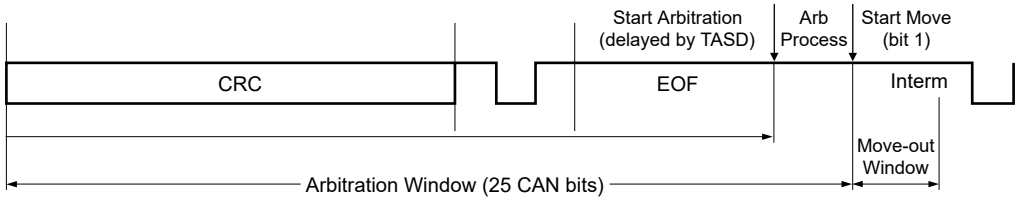

Figure 382. Arbitration and move-out time windows

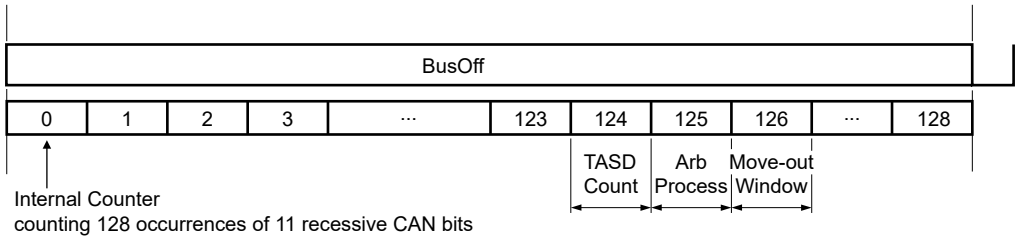

Figure 383. Arbitration at the end of bus off and move-out time windows

NOTE

In the preceding figures, the matching and arbitration timing does not take into account the delay caused by the concurrent memory access due to the CPU or other internal FlexCAN subblocks.

70.3.10.10 Tx arbitration start delay

CTRL2[TASD] (Tx Arbitration Start Delay) is a variable that indicates the number of CAN bits used by FlexCAN to delay the Tx arbitration process start point from the first bit of CRC field of the current frame. This variable can be written only in Freeze mode because it is blocked by hardware in other modes.

The transmission performance is impacted by the ability of the CPU to reconfigure message buffers (MBs) for transmission after the end of the internal arbitration process, where FlexCAN finds the winner MB for transmission (see Arbitration process). If the arbitration ends too early before the first bit of Intermission field, then there is a chance that the CPU reconfigures some Tx MBs and the winner MB is no longer the best candidate to be transmitted.

TASD is useful to optimize the transmission performance by defining the arbitration start point, as shown in the next figure, based on factors such as:

- Peripheral-to-oscillator clock ratio
- CAN bit timing variables that determine the CAN bit rate
- Number of message buffers (MBs) in use by the matching and arbitration processes

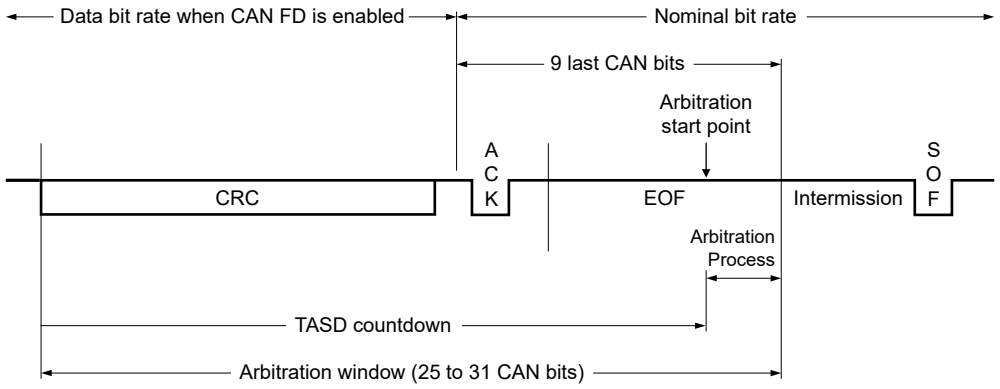

Figure 384. Optimal Tx Arbitration start point

The duration of an arbitration process, in terms of CAN bits, is directly proportional to the number of available MBs and to the CAN bit rate, and inversely proportional to the peripheral clock frequency.

The optimal arbitration timing is that in which the last MB is scanned just before the first bit of the Intermission field of a CAN frame. For instance, if there are few MBs and the peripheral/oscillator clock ratio is high and the CAN baud rate is low, then the arbitration can be placed closer to the frame's end, adding more delay to its start point, and vice-versa.

If TASD is set to 0 then the arbitration start is not delayed and more time is reserved for arbitration. On the other hand, if TASD is close to 24 then the CPU can configure a Tx MB later and less time is reserved for arbitration. If too little time is reserved for arbitration the FlexCAN may be not be able to find a winner MB in time to be transmitted with the best chance to win the bus arbitration against external nodes on the CAN bus.

The optimal TASD value can be calculated as follows:

For CAN FD frames and $(MAXMB + 1) \leq NMB_{END}$

$$TASD = 31 - \frac{2 * (MAXMB + 1) + 4}{CPCB_N}$$

For CAN FD frames and $(MAXMB + 1) > NMB_{END}$

$$TASD = 22 - \frac{2 * (MAXMB + 1) - NMB_{END}}{CPCB_F}$$

For non-FD frames

$$TASD = 25 - \frac{2 * (MAXMB + 1) + 4}{CPCB}$$

Equation 14. Optimal value for TASD

where:

$$NMB_{END} = \frac{(9 * CPCB_N) - 4}{2}$$

$$BITRATE_N = \left(\frac{f_{CANCLK}}{[1 + (EPSEG1 + 1) + (EPSEG2 + 1) + (EPROPSEG + 1)\ ] \times (EPRESDIV + 1)} \right)$$

$$BITRATE_F = \left(\frac{f_{CANCLK}}{[1 + (FPSEG1 + 1) + (FPSEG2 + 1) + FPROPSEG] \times (FPRESDIV + 1)} \right)$$

$$CPCB_N = \frac{f_{SYS}}{BITRATE_N}$$

$$CPCB_F = \frac{f_{SYS}}{BITRATE_F}$$

$$CPCB = CPCB_N$$

Equation 15. Variables used in TASD calculation

- MAXMB is the value in CTRL1[MAXMB].
- NMB_{END} is the number of message buffers that can be scanned by the arbitration process during the 9 last CAN bits at the end of a frame (see the figure above).
- $BITRATE_N$ is the CAN bit rate in bits per second calculated by the nominal CAN bit time variables.
- $BITRATE_F$ is the CAN bit rate in bits per second calculated by the data CAN bit time variables.
- $CPCB_N$ is the number of peripheral clocks per CAN bit in nominal bit rate for CAN FD frames.
- $CPCB_F$ is the number of peripheral clocks per CAN bit in data bit rate for CAN FD frames.
- CPCB is the number of peripheral clocks per CAN bit for non-FD frames.
- f_{CANCLK} is the oscillator clock, in Hz.
- f_{SYS} is the peripheral clock, in Hz.
- EPSEG1 is the value in CBT[EPSEG1] (CTRL1[PSEG1] can also be used).
- EPSEG2 is the value in CBT[EPSEG2] (CTRL1[PSEG2] can also be used).
- EPROPSEG is the value in CBT[EPROPSEG] (CTRL1[PROPSEG] can also be used).
- EPRESDIV is the value in CBT[EPRESDIV] (CTRL1[PRESDIV] can also be used).
- FPSEG1 is the value in FDCBT[FPSEG1].
- FPSEG2 is the value in FDCBT[FPSEG2].
- FPROPSEG is the value in FDCBT[FPROPSEG].
- FPRESDIV is the value in FDCBT[FPRESDIV].
- NTSEG1 is the value in ENCBT[NTSEG1].
- NTSEG2 is the value in ENCBT[NTSEG2].
- ENPRESDIV is the value in EPRS[ENPRESDIV].
- DTSEG1 is the value in EDCBT[DTSEG1].
- DTSEG2 is the value in EDCBT[DTSEG2].
- EDPRESDIV is the value in EPRS[EDPRESDIV].

If CTRL2[BTE] is set, then:

$$BITRATE_N = \frac{f_{CANCLK}}{[1 + (NTSEG1 + 1) + (NTSEG2 + 1)] \times (ENPRESDIV + 1)}$$

Equation 16. Nominal baud rate when CTRL2[BTE] = 1

$$BITRATE_F = \frac{f_{CANCLK}}{[1 + (DTSEG1 + 1) + (DTSEG2 + 1)] \times (EDPRESDIV + 1)}$$

Equation 17. Fast baud rate when CTRL2[BTE] = 1

See also Protocol timing for more details.

The following tables give the TASD value calculated for some configuration cases.

Case 1:

- Clock ratio = 2:1 (example: peripheral clock 80 MHz and oscillator clock 40 MHz)
- Bit rate in arbitration phase = 1 Mbaud

Table 425. TASD values:

Number of message buffers	TASD value	Maximum bit rate in data phase (MBd)
16	24	Invalid
32	24	8.0
64	23	8.0
96	22	8.0

Case 2:

- Clock ratio = 1:1 (example: peripheral clock 40 MHz and oscillator clock 40 MHz)
- Bit rate in arbitration phase = 1 Mbaud

Table 426. TASD values:

Number of message buffers	TASD value	Maximum bit rate in data phase (MBd)
16	24	Invalid
32	23	6.67
54	22	5.0
64	21	3.33
96	20	1.6

Case 3:

- Clock ratio = 2:1 (example: peripheral clock 40 MHz and oscillator clock 20 MHz)
- Bit rate in arbitration phase = 1 Mbaud

Table 427. TASD values:

Number of message buffers	TASD value	Maximum bit rate in data phase (MBd)
16	24	Invalid
32	23	4.0
54	22	4.0
64	21	3.33
96	20	1.54

70.3.11 Clocks

The following table describes the clock sources for FlexCAN. Please see chip clocking chapter for clock setting, configuration and gating information.

Table 428. FlexCAN clocks

Clock name	Description
ipg_clk	Peripheral clock
ipg_clk_chi	Control Host Interface (CHI) clock
ipg_clk_pe	Protocol Engine (PE) clock
ipg_clk_pe_nogate	Protocol Engine clock (no gating)
ipg_clk_s	Peripheral access clock

70.3.11.1 Clock domains and restrictions

The FlexCAN module has two clock domains asynchronous to each other:

- The bus domain feeds the Control Host Interface (CHI) submodule.
- The oscillator domain feeds the CAN Protocol Engine (PE) submodule.

When the two domains are connected to clocks with different frequencies and/or phases, there are restrictions on the frequency relationship between the two clock domains. In the case of asynchronous operation, the bus domain clock frequency must always be greater than the oscillator domain clock frequency.

NOTE

Asynchronous operation with a 1:1 ratio between peripheral and oscillator clocks is not allowed.

When doing matching and arbitration, FlexCAN needs to scan the whole message buffer memory during the time slot of one CAN frame, comprised of a number of CAN bits. In order to have sufficient time to do that, the following requirements must be observed:

- The peripheral clock frequency cannot be smaller than the oscillator clock frequency.
- There must be a minimum number of peripheral clocks per CAN bit, as specified in the table shown below.

Table 429. Minimum number of peripheral clocks per CAN bit for Classical CAN format

Number of mailboxes	Value of MCR[RFEN]	Value of ERFCR[ERFEN]	Minimum number of peripheral clocks per CAN bit
16	0	0	16
32	0	0	16
64	0	0	25
96	0	0	37
16	1	0	16
32	1	0	17
64	1	0	30
96	1	0	42
16	0	1	16
32	0	1	19
64	0	1	31
96	0	1	42

For classical frame format, the minimum number of peripheral clocks per CAN bit specified in the preceding table determines the minimum peripheral clock frequency for a given number of mailboxes and for an expected CAN bit rate. The CAN bit rate depends on the number of time quanta in a CAN bit, which can be defined by adjusting one or more of the bit timing values contained in either the Control 1 register (CTRL1) or CAN Bit Time register (CBT) or Enhanced Nominal CAN bit timing register (ENCBT). The time quantum (Tq) is defined in Protocol timing. The minimum number of time quanta per CAN bit must be 8; therefore, the oscillator clock frequency should be at least 8 times the CAN bit rate.

For CAN FD frame format, there are some constraints that need to be satisfied. The number of peripheral clocks per CAN bit in nominal bit rate (NumClkNomBit) can be calculated by the equation below.

$$\text{NumClkNomBit} = \frac{f_{SYS}}{f_{CANCLK}} \times (\text{PRESDIV} + 1) \times (\text{PROPSEG} + \text{PSEG1} + \text{PSEG2} + 4)$$

$$= \frac{f_{SYS}}{\text{NomBitRate}}$$

Equation 18. Number of peripheral clocks per nominal CAN bit

where PRESDIV, PSEG1, and PSEG2 are CAN bit time values in CTRL1 register. Alternatively, EPRESDIV, EPSEG1, and EPSEG2 values in CBT register or the values of EPRS[ENPRESDIV], ENCBT[NTSEG1], and ENCBT[NTSEG2] can be used instead. NumClkNomBit can also be calculated as a function of the expected nominal bit rate used in the arbitration phase (NomBitRate), as shown in the equation above.

The number of CAN bits in the data phase of an FD frame with the BRS bit set (fast CAN bits, in short) depends on the number of data bytes in the payload. The number of fast CAN bits (NumOfFastBits) can be determined in the table below. The fewer the number of data bytes, the fewer the number of fast CAN bits, and less time is available for FlexCAN to scan the whole message buffer memory during the internal matching and arbitration processes.

Table 430. Number of fast CAN bits in a CAN FD frame

Minimum number of data bytes	DLC field	NumOfFastBits
0	0h	21
1	1h	29
2	2h	37
3	3h	45
4	4h	53
5	5h	61
6	6h	69
7	7h	77
8	8h	85
12	9h	117
16	Ah	149
20	Bh	186
24	Ch	218
32	Dh	282
48	Eh	410
64	Fh	538

The critical part of a CAN FD frame is during the data phase, where the CAN bit rate is faster than in the arbitration phase. The minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) can be calculated to guarantee that enough time is available for FlexCAN to scan the message buffer memory during reception and transmission. The equation below calculates this constraint.

$$MinNumClkFastBit_A = \frac{(8.5 \times MaxNumOfMb) + [ERFEN \times (2 \times NFE + 4)] + 64 - (9 \times NumClkNomBit)}{NumOfFastBits}$$

Equation 19. Minimum number of peripheral clocks per fast CAN bit for FlexCAN scan process

where MaxNumOfMb is the maximum number of available mailboxes defined in MCR[MAXMB]. NFE and ERFEN are the fields defined in ERFCR register.

The clock domain crossing circuit between the CHI and PE subblocks also imposes a minimum number of peripheral clocks per fast CAN bit for the handshake mechanism to work properly without losing status information through the interface, as shown in the equation below.

$$MinNumClkFastBit_B = 3 \times \left(1 + \frac{f_{SYS}}{f_{CANCLK}}\right)$$

Equation 20. Minimum number of peripheral clocks per fast CAN bit for FlexCAN clock domain interface

Therefore, the minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) is determined by the larger of the two values calculated above.

$$MinNumClkFastBit = Maximum\ (\ MinNumClkFastBit_A,\ MinNumClkFastBit_B\ )$$

Equation 21. Minimum number of peripheral clocks per fast CAN bit

Then, the maximum CAN bit rate in the data phase of CAN FD frames (DataBitRateMAX) can be calculated as below.

$$DataBitrate_{MAX} = \frac{f_{CANCLK}}{ROUNDUP\left(\frac{MinNumClkFastBit \times f_{CANCLK}}{f_{SYS}}\right)}$$

Equation 22. Maximum achievable baud rate for data phase

The peripheral and oscillator clock frequencies, the maximum number of mailboxes, and the expected nominal bit rate affect the maximum data bit rate attainable by FlexCAN in CAN FD mode. Also, the data bit rate depends on the minimum payload size of FD frames used in a given application.

To illustrate how the CAN FD bit rate is affected by the configuration of FlexCAN variables, an application example with the peripheral and oscillator clock frequencies set to 50 MHz and 40 MHz, respectively, is considered.

1. Considering the nominal bit rate as 1 Mbps, the number of peripheral clocks per CAN bit in nominal bit rate is calculated as below.

   $$NumClkNomBit = \frac{50 \times 10^6}{1 \times 10^6} = 50$$

   Equation 23. Calculation example for number of peripheral clocks per nominal CAN bit

2. The number of fast CAN bits (NumOfFastBits) is determined in the table presented above. For example, if the minimum payload in FD frames is 8 bytes, then there are 85 CAN bits in the data phase.
3. Assuming the maximum number of mailboxes is 96, and Enhanced Rx FIFO is disabled, the minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) can be calculated.

   $$MinNumClkFastBit_A = \frac{(8.5 \times 96) + 64 - (9 \times 50)}{85} = 5.06$$

   Equation 24. Calculation example for number of peripheral clocks per fast CAN bit for FlexCAN scan process

   $$MinNumClkFastBit_B = 3 \times \left(1 + \frac{50}{40}\right) = 6.75$$

   Equation 25. Calculation example for number of peripheral clocks per fast CAN bit for FlexCAN clock domain interface

   $$MinNumClkFastBit = Maximum\ (5.06,\ 6.75) = 6.75$$

   Equation 26. Calculation example for number of peripheral clocks per fast CAN bit

4. The maximum CAN bit rate in the data phase can finally be found.

$$DataBitRate_{MAX} = \frac{40 \times 10^6}{ROUNDUP\left(\frac{6.75 \times 40 \times 10^6}{50 \times 10^6}\right)} = 6.667 \text{ Mbps}$$

Equation 27. Calculation example for maximum achievable baud rate

As demonstrated in this example, even though the oscillator clock frequency (40 MHz) is adequate to generate a data rate of 8 Mbps in CAN FD mode, the specific FlexCAN configuration limits this rate to 6.667 Mbps. This limitation is mainly due to the low peripheral clock frequency that imposes the MinNumClkFastBitB bound.

The table below shows the maximum data rate for CAN FD with Enhanced RX FIFO disabled according to clock frequencies, payload size, and number of available mailboxes. See in this table that, for some cases, if the number of available mailboxes is reduced, the FlexCAN can then achieve a data rate up to 8 Mbps.

Table 431. Maximum CAN bit rate in data phase on CAN FD frames with Enhanced Rx FIFO disabled

Peripheral clock frequency (MHz)	Payload size	Number of available mailboxes	Maximum data rate (Mbps)
40	8	94	6.667
40	8	114	5.0
40	12	117	6.667
40	12	128	5.714
50	12 to 64	128	6.667
60	8	126	8.0
60	12	128	8.0
67	6	128	8.0
80	3	128	8.0
100	0	128	8.0

70.3.12 Reset

You can reset FlexCAN in the following ways:

1. Chip level hard reset, which resets all memory-mapped registers asynchronously.
2. MCR[SOFTRST], which resets some of the memory-mapped registers synchronously. See Table 434 to see what registers are affected by soft reset.

Soft reset is synchronous and has to follow an internal request/acknowledge procedure across clock domains. Therefore, it may take some time to fully propagate its effects. MCR[SOFTRST] remains asserted while soft reset is pending, so software can poll this bit to know when the reset has completed. Also, soft reset cannot be applied while clocks are shut down in a low-power mode. The low-power mode should be exited and the clocks resumed before applying soft reset.

When the module is enabled (MCR[MDIS] negated), FlexCAN automatically enters Freeze mode. In Freeze mode, FlexCAN is un-synchronized to the CAN bus, MCR[HALT] and MCR[FRZ] are set, the internal state machines are disabled, then MCR[FRZACK] and MCR[NOTRDY] are set. The Tx pin is in recessive state and FlexCAN does not initiate any transmission or

reception of CAN frames. Note that the message buffers and the Rx Individual Mask registers are not affected by reset, so they are not automatically initialized.

70.3.13 Interrupts

The module has many interrupt sources: interrupts due to message buffers and interrupts due to the ORed interrupts from MBs, Bus Off, Bus Off Done, Error, Error Fast (errors detected in the data phase of CAN FD format messages with the BRS bit set), Tx Warning, and Rx Warning.

Each one of the message buffers can be an interrupt source, if its corresponding IMASK bit is set. There is no distinction between Tx and Rx interrupts for a particular buffer, under the assumption that the buffer is initialized for either transmission or reception. Each of the buffers has an assigned flag bit in the IFLAG registers. The bit is set when the corresponding buffer completes a successful transfer and is cleared when the CPU writes one to it (unless another interrupt is generated at the same time).

NOTE

It must be guaranteed that the CPU clears only the bit causing the current interrupt. For this reason, bit manipulation instructions (BSET) must not be used to clear interrupt flags. These instructions may cause accidental clearing of interrupt flags which are set after entering the current interrupt service routine.

If the Legacy Rx FIFO is enabled (MCR[RFEN] = 1) and DMA is disabled (MCR[DMA] = 0), the interrupts corresponding to MBs 0 to 7 have different meanings. Bit 7 of the IFLAG1 register becomes the "Legacy FIFO Overflow" flag; bit 6 becomes the "Legacy FIFO Warning" flag, bit 5 becomes the "Frames Available in Legacy FIFO" flag and bits 4-0 are unused. See the description of Interrupt Flags 1 Register (IFLAG1) for more information.

If both Legacy Rx FIFO and DMA are enabled (MCR[RFEN] and MCR[DMA] = 1) the FlexCAN does not generate any Legacy FIFO interrupt. Bit 5 of the IFLAG1 register still indicates "Frames Available in Legacy FIFO" and generates a DMA request. Bits 7, 6, 4-0 are unused.

CAUTION

Legacy FIFO cannot be enabled when CAN FD feature is enabled.

For a combined interrupt where multiple MB interrupt sources are OR'd together, the interrupt is generated when any of the associated MBs (or FIFO, if applicable) generates an interrupt. In this case, the CPU must read the IFLAG registers to determine which MB or FIFO source caused the interrupt.

The following interrupt sources generate interrupts like the MB interrupt sources, and can be read from ESR1 register

- Bus Off
- Bus Off Done
- Error
- Error Fast
- Tx Warning
- Rx Warning

The Bus Off, Error, Tx Warning, and Rx Warning interrupt mask bits are located in the CTRL1 register.

70.3.14 Bus interface

CPU access to FlexCAN registers is subject to the following rules:

- Unrestricted read and write access to supervisor registers (registers identified with S/U in Table 434 in Supervisor Mode or with S only) results in an access error.
- Read and write access to implemented reserved address space results in an access error.
- Write access to positions whose bits are all currently read-only results in an access error. If at least one of the bits is not read-only then no access error is issued. Write permission to positions or some of their bits can change depending on the mode of operation or transitory state. See register and field descriptions for details.

- Read and write access to unimplemented address space results in access error.
- Read and write access to RAM located positions during Low Power mode results in an access error.
- It is possible for the RXIMR memory region to be considered as general purpose memory and available for access. There are two ways of doing this:
  1. If MCR[IRMQ] is cleared, the individual masks (RXIMR) are disabled. In this case the RXIMR memory region is considered as general purpose memory.
  2. If MCR[MAXMB] is programmed with a value smaller than the available number of MBs, then the unused memory space can be used as general purpose RAM space. Note that reserved words within RAM cannot be used. As an example, suppose FlexCAN's RAM can support up to 16 MBs, CTRL2[RFFN] is 0h, and MCR[MAXMB] is programmed with zero. The maximum number of MBs in this case becomes one. The RAM starts at 0080h, and the space 0080h–008Fh is used by the one MB. The memory space 0090h–017Fh is available. The space 0180h–087Fh is reserved. The space 0880h–0883h is used by the one individual mask and the available memory in the mask registers space would be 0884h–08BFh. From 08C0h–09DFh there are reserved words for internal use which cannot be used as general purpose RAM. As a general rule, free memory space for general purpose depends only on MAXMB.
  3. If MCR[FDEN] is enabled, general purpose memory can be used out of Freeze mode only.

Table 432. Access permissions

Supervisor access	0				1

1. Access in low power is only possible if RAM_clk and ipg_clk are enabled.
2. If MCR[RFEN] = 1, see Legacy FIFO access rules below.

3. Write operation has no effect.
4. Enhanced Rx FIFO must not be accessed if MCR[RFEN] is set.

70.3.15 Detection and correction of memory errors

NOTE

All FlexCAN memory must be initialized before starting its operation in order to have the parity bits in memory properly updated. CTRL2[WRMFRZ] grants write access to all memory positions that require initialization, ranging from 080h–ADFh and from C20h–31FFh. The RXMGMASK, RX14MASK, RX15MASK, and RXFGMASK registers need to be initialized as well. MCR[RFEN] and ERF[ERFEN] must not be set during memory initialization.

FlexCAN supports detection and correction of errors in memory read accesses. Each byte of FlexCAN memory is associated to five parity bits that ensure a Hamming distance of four. The error correction mechanism ensures that in this 13-bit word, errors in one bit can be corrected (correctable errors) and errors in two bits can be detected but not corrected (non-correctable errors). Errors in more than two bits may not be detected. In case of non-correctable errors, the corrupted data is not changed by the error correction logic. When a read access is performed, the parity bits are used to calculate a syndrome, which indicates the error in each byte.

FlexCAN detects a noncorrectable error in the event either an all-zeros or an all-ones read occurs. See description of Error Report Syndrome Register (RERRSYNR).

Memory errors are indicated to the host through status register (Error Status Register (ERRSR)) and bus transfer errors, and reported through report registers (Error Report Address register (RERRAR), Error Report Data register (RERRDR) and Error Report Syndrome register (RERRSYNR)).

The error detection and correction mechanism can be activated or not, controlled by MECR[ECCDIS]. When disabled, updates on indications and reporting registers are stopped, but the parity bits are still calculated and written along with data in memory write operations to ensure that memory has consistent parity bits associated with the data.

To avoid accidentally changing the critical error correction configuration, this protocol must be followed to enable the update of the Memory Error Control register (MECR):

1. By default, CTRL2[ECRWRE] is zero and MECR[ECRWRDIS] is one.
2. Set CTRL2[ECRWRE].
3. Clear MECR[ECRWRDIS].
4. All writes to Memory Error Control register (MECR) must keep MECR[ECRWRDIS] cleared.
5. After configuration is done, lock the Memory Error Control register (MECR) by either setting MECR[ECRWRDIS] or clearing CTRL2[ECRWRE].

70.3.15.1 Sources of the memory access

The FlexCAN memory can be accessed by two major sources (or requestors):

- Host (CPU): the largest word accessed is 32-bit.
- FlexCAN internal processes (Rx matching, Tx arbitration, move-in on reception, move-out on transmission): the largest word accessed is 64-bit.

The way that noncorrectable errors are indicated and reported depends on the source of access.

70.3.15.2 Error indication

Memory errors are indicated by flags HANCEIF, FANCEIF, and CEIF in the Error Status Register (ERRSR). Noncorrectable errors detected in memory reads requested by the host are indicated separately than the ones detected in requests by FlexCAN internal processes. FlexCAN makes no distinction of the source of the access when correctable errors are detected. There are three independent flags for these three cases, and each flag will raise an interrupt unless it is masked by mask bits in Memory Error Control Register (MECR). If both noncorrectable and correctable errors are found in different bytes in the same read operation, both flags are set.

A noncorrectable error detected in host access is also indicated as a bus transfer error. A bus wait request may be asserted to extend the memory transaction to the moment the report registers are updated. This indication cannot be masked. If the flag bit ERRSR[HANCEIF] is not masked, the same noncorrectable error will raise a bus transfer error and an interrupt request.

Each indication flag has one overrun flag in Error Status Register (ERRSR). The overrun flags do not request interrupts. Overrun flags for noncorrectable errors indicate that other errors of the same nature were detected after current error being treated; overrun flags for correctable errors indicate that other errors of the same nature were detected before the current error being treated.

This is the recommended handling sequence for error indication:

1. Get error report information from report registers.
2. Use this information to take proper measures in the application.
3. Clear the HANCEIF, FANCEIF, and CEIF flags.
4. If the overrun flag is active:
    a. Alert application that at least one error could not be managed.
    b. Clear the overrun flag.

The FlexCAN internal processes can access memory in transactions larger than 32 bits. For the indication, this kind of access is considered a consecutive sequence of 32-bit accesses. If errors are found in two or more 32-bit words the interrupt and overrun flags are set simultaneously.

70.3.15.3 Error reporting

The report registers Error Report Address register (RERRAR), Error Report Data register (RERRDR), and Error Report Syndrome register (RERRSYNR) provide detailed information about the address read, raw data, and syndrome read with error, and are indicated by the flags described in Error indication. The address, data, and syndrome registers are updated simultaneously along with the error flags, according to these rules:

1. If either of the two non-correctable error flags is currently set, the report registers are not updated (the previous non-correctable error reporting is preserved).
2. Otherwise (either no error flag is currently set or only the correctable error flag is currently set), the report registers are updated according to the new error; or according to the most severe of new errors if non-correctable and correctable errors are simultaneously detected.

Reporting of errors detected in accesses larger than 32-bit follows the rules described in Error indication and in the description of Error Report Address Register (RERRAR).

The address reported in RERRAR and defined in ERRIAR are not the same listed in the module memory map. The relation between the reported addresses and the respective ones in the module memory map is shown in the description of Error Injection Address Register (ERRIAR).

Addresses reported when reading memory portions organized as FIFOs, such as the Legacy Rx FIFO Structure, Enhanced RX FIFO Structure and the Rx FIFO Information Register (RXFIR), refer to the address of the specific entry accessed in the FIFO, not to the FIFO base address.

To assure coherence of the error report registers it is necessary to turn off the report update by setting MECR[RERRDIS] before reading the report registers.

70.3.15.4 Response to errors

Correctable errors have no consequence on FlexCAN operation because affected data is corrected before its use by the host or FlexCAN internal processes.

For host-initiated reads, a noncorrectable error may affect the host, but does not affect FlexCAN operation.

Non-correctable errors detected on memory reads requested by the FlexCAN internal processes may result in incorrect operation depending on the state of MECR[NCEFAFRZ], as follows:

- During reception (either matching or move-in processes), when a noncorrectable error occurs, an incorrect destination may be selected to store the incoming frame, a corrupted frame may be stored in the correct destination, or both. If MECR[NCEFAFRZ] is set, FlexCAN stops operation automatically and enters in Freeze mode to prevent corrupted data from being treated as valid by FlexCAN internal processes. When MECR[NCEFAFRZ] is negated, FlexCAN continues working and a corrupted frame is received.
- During arbitration process, when a noncorrectable error occurs, either a non-highest priority Tx message buffer may be mistakenly selected for transmission or its data may be corrupted. If MECR[NCEFAFRZ] is set, FlexCAN stops operation automatically and enters Freeze mode before starting the move-out. When MECR[NCEFAFRZ] is negated, FlexCAN proceeds to move-out with a corrupted frame that will be transmitted on the CAN bus.
- During move-out process, when a noncorrectable error occurs, a corrupted frame is copied from the selected Tx MB that won the arbitration to the Tx SMB for transmission. If MECR[NCEFAFRZ] is set, FlexCAN stops operation automatically and enters Freeze mode before starting the transmission. When MECR[NCEFAFRZ] is negated, the corrupted frame is transferred from the Tx SMB to the Protocol Engine (PE) sub-block and is transmitted on the CAN bus.
- A noncorrectable error can also be detected beyond the move-out process, when Tx data is read from Tx SMB (buffer located in RAM) to be transferred to the PE subblock for transmission. In this case, a frame with corrupted ID and/or data is transmitted on the CAN bus.

  To prevent the frame from being successfully received by the external nodes, FlexCAN inverts all bits in the CRC field (CRC sequence plus CRC delimiter), and transmits an error flag just after CRC delimiter as a result of self-detecting a Bit1 error and a form error due to the CRC field inversion. When MECR[NCEFAFRZ] is set, FlexCAN stops operation automatically and enters Freeze mode just after the error frame. When MECR[NCEFAFRZ] is negated, FlexCAN may attempt to re-transmit the same frame, as long as no other higher priority Tx MB is subsequently configured for transmission.

  In the event the noncorrectable error persists, FlexCAN eventually reaches the Bus Off state because of consecutive error detections. ECR[TXERRCNT] is updated every time FlexCAN inverts the CRC field, causing errors as described above.

When MECR[NCEFAFRZ] is set and FlexCAN enters Freeze mode, only the CPU can cause FlexCAN to exit Freeze mode and resume Normal mode. The assertion of MECR[NCEFAFRZ] is the only way to prevent corrupted frames from being transmitted on the CAN bus up to the move-out internal process.

The error report registers can provide information to the application for customized management of these situations.

70.3.15.5 Error injection

The error injection registers ERRIAR, ERRIDPR, and ERRIPPR are used to inject errors in memory reads in order to force errors and consequently update the indication and reporting registers. The relation between the error injection addresses and the respective ones in the module memory map is shown in the description of Error Injection Address Register (ERRIAR).

The injection is done by flipping the data and parity bits correspondent to the bits in 1 in ERRIDPR and ERRIPPR. Injection can be selected specifically for memory accesses requested by the host or by FlexCAN internal processes.

In case of accesses larger than 32-bits, the EXTERRIE bit in Memory Error Control register (MECR) extends the injection pattern, replicating it in 32-bit words to fill the width of the access.

NOTE

It is very unlikely, but error injection may correct a bit with error. This will not raise the error flags and reports as expected.

To ensure coherence among error injection registers and avoid spurious error injections, MECR[HAERRIE] and MECR[FAERRIE] must be cleared when configuring the memory injection registers.

70.4 FlexCAN signal descriptions

The FlexCAN module has two I/O signals connected to the external chip pins. These signals are summarized in the following table and described in more detail in the next subsections.

Table 433. FlexCAN signal descriptions

Signal	Description	I/O
CAN Rx	CAN receive pin	Input
CAN Tx	CAN transmit pin	Output

70.4.1 CAN Rx

This pin is the receive pin from the CAN bus transceiver. Dominant state is represented by logic level 0. Recessive state is represented by logic level 1.

70.4.2 CAN Tx

This pin is the transmit pin to the CAN bus transceiver. Dominant state is represented by logic level 0. Recessive state is represented by logic level 1.

70.5 Initialization/application information

This section provides instructions for initializing the FlexCAN module.

70.5.1 FlexCAN initialization sequence

For any configuration change/initialization it is required that FlexCAN be put into Freeze mode (see Freeze mode). Note that the module needs to be initialized after every reset.

The following is a generic initialization sequence applicable to the FlexCAN module:

1. Initialize the Module Configuration register (MCR).
    a. Enable the individual filtering per MB and reception queue features by setting IRMQ.
    b. Enable the warning interrupts by setting WRNEN.
    c. If required, disable frame self reception by setting SRXDIS.
    d. Enable the Legacy Rx FIFO by setting RFEN or the Enhanced Rx FIFO by setting ERFEN.
    e. If Legacy Rx FIFO or Enhanced Rx FIFO is enabled and DMA is required, set DMA.
    f. Enable the abort mechanism by setting AEN.
    g. Enable the local priority feature by setting LPRIOEN.
2. Initialize the Control 1 register (CTRL1) and optionally the CAN Bit Timing register (CBT). Initialize also the CAN FD CAN Bit Timing register (FDCBT).
    a. Determine the bit timing parameters: PROPSEG, PSEG1, PSEG2, and RJW.
    b. Optionally determine the bit timing parameters: EPROPSEG, EPSEG1, EPSEG2, and ERJW.
    c. Determine the CAN FD bit timing parameters: FPROPSEG, FPSEG1, FPSEG2, and FRJW.
    d. Determine the bit rate by programming the PRESDIV field and optionally the EPRESDIV field.
    e. Determine the CAN FD bit rate by programming the FPRESDIV field.
    f. Determine the internal arbitration mode (LBUF).
3. All FlexCAN memory must be initialized if Error Code Correction (ECC) is enabled. See Detection and correction of memory errors.
4. Initialize the message buffers.
    a. The control and status word of all message buffers must be initialized.

b. If Rx FIFO was enabled, the ID filter table must be initialized.

c. Other entries in each message buffer should be initialized as required.

5. Initialize the Rx Individual Mask registers (RXIMRn).
6. Set required interrupt mask bits in
   - IMASK registers (for all MB interrupts)
   - CTRL1 / CTRL2 registers (for Bus Off and Error interrupts)
7. Negate MCR[HALT].

After the last step listed above, FlexCAN attempts to synchronize to the CAN bus.

70.6 Memory map/register definition

This section describes the registers and data structures in the FlexCAN module. The base address of the module depends on the particular memory map of the chip.

70.6.1 FlexCAN memory mapping

The address space occupied by FlexCAN has 128 bytes for registers starting at the module base address, followed by embedded RAM starting at address offset 0080h.

Each individual register is identified by its complete name and the corresponding mnemonic . The access type can be Supervisor (S) or Unrestricted (U). Most of the registers can be configured to have either Supervisor or Unrestricted access by programming MCR[SUPV]. These registers are identified as S/U in the Access column of Table 434.

NOTE

An invalid register access will result in a bus error. This includes reading a write-only register, writing a read-only register, or accessing an invalid address.

Table 434. Register access and reset information

Register	Access type	Affected by hard reset	Affected by soft reset
Module Configuration Register (MCR)	S	Yes	Yes
Control 1 Register (CTRL1)	S/U	Yes	No
Free Running Timer Register (TIMER)	S/U	Yes	Yes
Rx Mailboxes Global Mask Register (RXMGMASK)	S/U	No	No
Rx Buffer 14 Mask Register (RX14MASK)	S/U	No	No
Rx Buffer 15 Mask Register (RX15MASK)	S/U	No	No
Error Counter Register (ECR)	S/U	Yes	Yes
Error and Status 1 Register (ESR1)	S/U	Yes	Yes
Interrupt Masks 2 Register (IMASK2)	S/U	Yes	Yes
Interrupt Masks 1 Register (IMASK1)	S/U	Yes	Yes

Table continues on the next page...

Table 434. Register access and reset information (continued)

Register	Access type	Affected by hard reset	Affected by soft reset
Interrupt Flags 2 Register (IFLAG2)	S/U	Yes	Yes
Interrupt Flags 1 Register (IFLAG1)	S/U	Yes	Yes
Control 2 Register (CTRL2)	S/U	Yes	No
Error and Status 2 Register (ESR2)	S/U	Yes	Yes
CRC Register (CRCR)	S/U	Yes	Yes
Rx FIFO Global Mask Register (RXFGMASK)	S/U	No	No
Rx FIFO Information Register (RXFIR)	S/U	No	No
CAN Bit Timing Register (CBT)	S/U	Yes	No
Interrupt Masks 3 Register (IMASK3)	S/U	Yes	Yes
Interrupt Flags 3 Register (IFLAG3)	S/U	Yes	Yes
Message buffers	S/U	No	No
Rx Individual Mask Registers	S/U	No	No
Memory Error Control Register (MECR)	S/U	Yes	Yes
Error Injection Address Register (ERRIAR)	S/U	Yes	Yes
Error Injection Data Pattern Register (ERRIDPR)	S/U	Yes	Yes
Error Injection Parity Pattern Register (ERRIPPR)	S/U	Yes	Yes
Error Report Address Register (RERRAR)	S/U	Yes	Yes
Error Report Data Register (RERRDR)	S/U	Yes	Yes
Error Report Syndrome Register (RERRSYNR)	S/U	Yes	Yes
Error Status Register (ERRSR)	S/U	Yes	Yes
Enhanced CAN Bit Timing Prescalers (EPRS)	S/U	Yes	No
Enhanced Nominal CAN Bit Timing (ENCBT)	S/U	Yes	No
Enhanced Data Phase CAN bit Timing (EDCBT)	S/U	Yes	No
Enhanced Transceiver Delay Compensation (ETDC)	S/U	Yes	No
CAN FD Control Register (FDCTRL)	S/U	Yes	No
CAN FD Bit Timing Register (FDCBT)	S/U	Yes	No

Table continues on the next page...

Table 434. Register access and reset information (continued)

Register	Access type	Affected by hard reset	Affected by soft reset
CAN FD CRC Register (FDCRC)	S/U	Yes	Yes
Enhanced Rx FIFO Control Register (ERFCR)	S/U	Yes	Yes
Enhanced Rx FIFO Interrupt Enable Register (ERFIER)	S/U	Yes	Yes
Enhanced Rx FIFO Status Register (ERFSR)	S/U	Yes	Yes
High Resolution Time Stamp (HR_TIME_STAMP)	S/U	No	No
Enhanced Rx FIFO	S/U	No	No
Enhanced Rx FIFO Filter Element (ERFFEL)	S/U	No	No

The FlexCAN module can store CAN messages for transmission and reception using mailboxes and Rx FIFO structures.

70.6.2 CAN register descriptions

The table below shows the FlexCAN memory map.

The address range from offset 80h–67Fh allocates the ninety-six 128-bit message buffers (MBs).

The memory maps for the message buffers are in FlexCAN message buffer memory map.

The address range from offset 2000h–204Ch allocates the Enhanced Rx FIFO output, and the address range from offset 2050h–263Ch allocates the rest of Enhanced RX FIFO 19 elements.

The memory map for the Enhanced Rx FIFO is in Enhanced Rx FIFO structure.

70.6.2.1 CAN memory map

CAN_0 base address: 4030_4000h

CAN_1 base address: 4030_8000h

CAN_2 base address: 4030_C000h

CAN_3 base address: 4031_0000h

CAN_4 base address: 4031_4000h

CAN_5 base address: 4031_8000h

Fields

Field	Function
31 MDIS	Module Disable This bit controls whether FlexCAN is enabled or not. When disabled, FlexCAN disables the clocks to the CAN Protocol Engine and Controller Host Interface submodules. This bit is not affected by soft reset. 0b - Enable the FlexCAN module. 1b - Disable the FlexCAN module.
30 FRZ	Freeze Enable The FRZ bit specifies the FlexCAN behavior when MCR[HALT] is set or when Debug mode is requested at chip level. When FRZ is asserted, FlexCAN is enabled to enter Freeze mode. Negation of this bit field causes FlexCAN to exit from Freeze mode. This bit is set by hardware when a non-correctable error is detected (MECR[NCEFAFRZ] is asserted). 0b - Not enabled to enter Freeze mode. 1b - Enabled to enter Freeze mode.
29 RFEN	Legacy Rx FIFO Enable This bit controls whether the Legacy Rx FIFO feature is enabled or not. When RFEN is set, MBs 0 to 5 cannot be used for normal reception and transmission because the corresponding memory region (80h–DCh) is used by the FIFO engine as well as additional MBs (up to 32, depending on CTRL2[RFFN] setting) which are used as Legacy Rx FIFO ID filter table elements. RFEN also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in Table 429. This bit can be written in Freeze mode only, because it is blocked by hardware in other modes. **NOTE** This bit cannot be set when CAN FD operation is enabled (see FDEN bit). **NOTE** RFEN bit must not be set if ERFCR[ERFEN] is set. **NOTE** The descriptions of the field settings vary by module instance.

Instance	Field value and description
CAN_0	0b - Legacy Rx FIFO not enabled. 1b - Legacy Rx FIFO enabled.
CAN_1	0b - Rx FIFO not enabled. 1b - Rx FIFO enabled.
CAN_2	0b - Rx FIFO not enabled. 1b - Rx FIFO enabled.
CAN_3	0b - Rx FIFO not enabled. 1b - Rx FIFO enabled.

Field	Function
	<table><tr><th>Instance</th><th>Field value and description</th></tr><tr><td>CAN_4</td><td>0b - Rx FIFO not enabled. 1b - Rx FIFO enabled.</td></tr><tr><td>CAN_5</td><td>0b - Rx FIFO not enabled. 1b - Rx FIFO enabled.</td></tr></table>
28 HALT	Halt FlexCAN Assertion of this bit puts the FlexCAN module into Freeze mode. The CPU should clear it after initializing the message buffers and the Control registers CTRL1 and CTRL2. No reception or transmission is performed by FlexCAN before this bit is cleared. Freeze mode cannot be entered when FlexCAN is in a low power mode. The HALT bit is set by hardware when a non-correctable error is detected and MECR[NCEFAFRZ] is asserted. 0b - No Freeze mode request. 1b - Enters Freeze mode if the FRZ bit is asserted.
27 NOTRDY	FlexCAN Not Ready This read-only bit indicates that FlexCAN is either in Disable mode or Freeze mode. It is negated when FlexCAN has exited these modes. This bit is not affected by soft reset. 0b - FlexCAN module is either in Normal mode, Listen-Only mode, or Loop-Back mode. 1b - FlexCAN module is either in Disable mode or Freeze mode.
26 —	Reserved When writing to this field, always write the reset value.
25 SOFTRST	Soft Reset When SOFTRST is asserted, FlexCAN resets its internal state machines and some of the memory-mapped registers. SOFTRST can be asserted directly by the CPU when it writes to the MCR register. Because soft reset is synchronous and has to follow a request/acknowledge procedure across clock domains, it may take some time to fully propagate its effect. The SOFTRST bit remains asserted when reset is pending, and is automatically negated when reset completes. Therefore, software can poll this bit to know when the soft reset has completed. Soft reset cannot be applied when clocks are shut down in a low power mode. The module should be first removed from low power mode, and then soft reset can be applied. This bit is not affected by soft reset. 0b - No reset request. 1b - Resets the registers affected by soft reset.
24 FRZACK	Freeze Mode Acknowledge

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This read-only bit indicates that FlexCAN is in Freeze mode and its prescaler is stopped. The Freeze mode request cannot be granted until current transmission or reception processes have finished. Therefore the software can poll the FRZACK bit to know when FlexCAN has actually entered Freeze mode. If Freeze mode request is negated, then this bit is negated after the FlexCAN prescaler is running again. If Freeze mode is requested when FlexCAN is in a low power mode, then the FRZACK bit will be set only when the low-power mode is exited. See Freeze mode. This bit is not affected by soft reset. **NOTE** FRZACK will be asserted within 178 CAN bits from the Freeze mode request by the CPU, and negated within 2 CAN bits after the Freeze mode request removal (see Protocol timing). 0b - FlexCAN not in Freeze mode, prescaler running. 1b - FlexCAN in Freeze mode, prescaler stopped.
23 SUPV	Supervisor Mode This bit configures the FlexCAN to be either in Supervisor or User mode. The registers affected by this bit are marked as S/U in the "Access type" column of Table 434. Reset value of this bit is 1, so the affected registers start with Supervisor access allowance only. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0b - FlexCAN is in User mode. Affected registers allow both Supervisor and Unrestricted accesses. 1b - FlexCAN is in Supervisor mode. Affected registers allow only Supervisor access. Unrestricted access behaves as though the access was done to an unimplemented register location.
22 —	Reserved When writing to this field, always write the reset value.
21 WRNEN	Warning Interrupt Enable When asserted, this bit enables the generation of the TWRNINT and RWRNINT flags in the Error and Status Register 1 (ESR1). If WRNEN is negated, the TWRNINT and RWRNINT flags will always be zero, independent of the values of the error counters, and no warning interrupt will ever be generated. This bit can be written in Freeze mode only, because it is blocked by hardware in other modes. 0b - TWRNINT and RWRNINT bits are zero, independent of the values in the error counters. 1b - TWRNINT and RWRNINT bits are set when the respective error counter transitions from less than 96 to greater than or equal to 96.
20 LPMACK	Low-Power Mode Acknowledge This read-only bit indicates that FlexCAN is in a low-power mode (Disable mode). A low-power mode cannot be entered until all current transmission or reception processes have finished, so the CPU can poll the LPMACK bit to know when FlexCAN has actually entered low power mode. This bit is not affected by soft reset.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE LPMACK will be asserted within 180 CAN bits from the low-power mode request by the CPU, and negated within 2 CAN bits after the low-power mode request removal (see Protocol timing). 0b - FlexCAN is not in a low-power mode. 1b - FlexCAN is in a low-power mode.
19 —	Reserved When writing to this field, always write the reset value.
18 —	Reserved When writing to this field, always write the reset value.
17 SRXDIS	Self Reception Disable This bit defines whether FlexCAN is allowed to receive frames transmitted by itself. If this bit is asserted, frames transmitted by the module will not be stored in any MB, regardless if the MB is programmed with an ID that matches the transmitted frame, and no interrupt flag or interrupt signal will be generated due to the frame reception. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0b - Self-reception enabled. 1b - Self-reception disabled.
16 IRMQ	Individual Rx Masking And Queue Enable This bit indicates whether Rx matching process will be based either on individual masking and queue or on masking scheme with RXMGMASK, RX14MASK, RX15MASK, and RXFGMASK. This bit can be written in Freeze mode only because it is blocked by hardware in other modes. 0b - Individual Rx masking and queue feature are disabled. For backward compatibility with legacy applications, the reading of C/S word locks the MB even if it is EMPTY. 1b - Individual Rx masking and queue feature are enabled.
15 DMA	DMA Enable DMA controls whether the DMA feature is enabled or not. The DMA feature can only be used in Legacy Rx FIFO or Enhanced Rx FIFO, so consequently MCR[RFEN] or ERFCR[ERFEN] must be asserted. When DMA and RFEN are set, IFLAG1[BUF5I] generates the DMA request and no RX FIFO interrupt is generated. This bit can be written in Freeze mode only as it is blocked by hardware in other modes. **NOTE** The descriptions of the field settings vary by module instance.

Instance	Field value and description
CAN_0	0b - DMA feature for Legacy RX FIFO or Enhanced Rx FIFO disabled.

Table continues on the next page...

<tr><td>13
LPRIOEN</td><td>Local Priority Enable
This bit is provided for backwards compatibility with legacy applications. It controls whether the local priority feature is enabled or not. It is used to expand the ID used during the arbitration process. With this expanded ID concept, the arbitration process is done based on the full 32-bit word, but the actual transmitted ID still has 11-bit for standard frames and 29-bit for extended frames. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.
0b - Local Priority disabled.
1b - Local Priority enabled.</td></tr>
<tr><td>12
AEN</td><td>Abort Enable
When asserted, this bit enables the Tx abort mechanism. This mechanism guarantees a safe procedure for aborting a pending transmission, so that no frame is sent in the CAN bus without notification. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.
NOTE
When MCR[AEN] is asserted, only the abort mechanism (see Transmission abort mechanism) must be used for updating mailboxes configured for transmission.</td></tr>
</table>

Table continues on the next page...

Table continued from the previous page...

Field	Function
	CAUTION Writing the Abort code into Rx mailboxes can cause unpredictable results when MCR[AEN] is asserted. 0b - Abort disabled. 1b - Abort enabled.
11 FDEN	CAN FD operation enable This bit enables the CAN with Flexible Data rate (CAN FD) operation. This bit can be written in Freeze mode only. **NOTE** FlexCAN is able to transmit FD frame format according to ISO 11898-1. **NOTE** The Legacy Rx FIFO Enable (RFEN) bit cannot be set if FDEN is asserted. 0b - CAN FD is disabled. FlexCAN is able to receive and transmit messages in CAN 2.0 format. 1b - CAN FD is enabled. FlexCAN is able to receive and transmit messages in both CAN FD and CAN 2.0 formats.
10 —	Reserved
9-8 IDAM	ID Acceptance Mode This 2-bit field identifies the format of the Legacy Rx FIFO ID filter table elements. Note that all elements of the table are configured at the same time by this field (they are all the same format). See Legacy Rx FIFO structure. This field can be written only in Freeze mode because it is blocked by hardware in other modes. 00b - Format A: One full ID (standard and extended) per ID filter table element. 01b - Format B: Two full standard IDs or two partial 14-bit (standard and extended) IDs per ID filter table element. 10b - Format C: Four partial 8-bit standard IDs per ID filter table element. 11b - Format D: All frames rejected.
7 —	Reserved
6-0 MAXMB	Number Of The Last Message Buffer This 7-bit field defines the number of the last message buffers that will take part in the matching and arbitration processes. The reset value (0Fh) is equivalent to a 16 MB configuration. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Number of the last MB = MAXMB

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE MAXMB must be programmed with a value smaller than or equal to the number of available message buffers, as described in FlexCAN memory partition for CAN FD. Additionally, the definition of MAXMB value must take into account the region of MBs occupied by Legacy Rx FIFO and its ID filters table space defined by CTRL2[RFFN]. MAXMB also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in Table 429.

70.6.2.3 Control 1 Register (CTRL1)

Offset

Register	Offset
CTRL1	4h

Function

This Register is defined for specific FlexCAN control features related to the CAN bus, such as bit rate, programmable sampling point within an Rx bit, Loop Back mode, Listen-Only mode, Bus Off recovery behavior, and interrupt enabling (Bus-Off, Error, Warning). It also determines the division factor for the clock prescaler.

The CAN bit timing variables (PRESDIV, PROPSEG, PSEG1, PSEG2, and RJW) can also be configured in the CBT register, which extends the range of all these variables. If CBT[BTF] is set, PRESDIV, PROPSEG, PSEG1, PSEG2, and RJW fields of CTRL1 become read only.

If CTRL2[BTE] is set, then the PRESDIV, PROPSEG, PSEG1, PSEG2, and RJW fields in the CTRL1 register are not used by the hardware, are read as zero, and a write operation to them has no effect.

NOTE

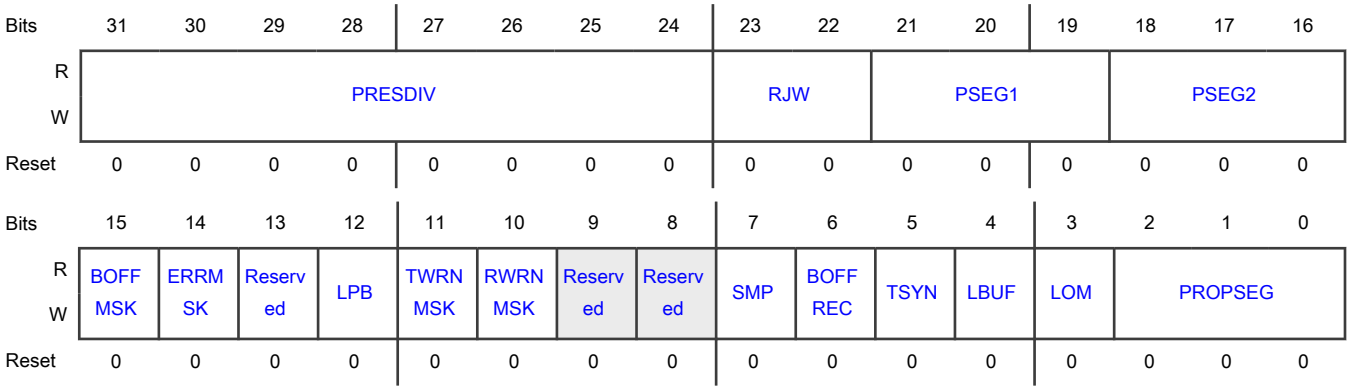
When the CAN FD feature is enabled, do not use the PRESDIV, RJW, PSEG1, PSEG2, and PROPSEG fields of the CTRL1 register for CAN bit timing. Instead use the CBT register's EPRESDIV, ERJW, EPSEG1, EPSEG2, and EPROPSEG fields.

NOTE

The CAN bit variables in CTRL1 and in CBT are stored in the same register.

The contents of this register are not affected by soft reset.

Diagram



Fields

Field	Function
31-24 PRESDIV	Prescaler Division Factor This 8-bit field defines the ratio between the PE clock frequency and the serial clock (Sclock) frequency. The Sclock period defines the time quantum of the CAN protocol. For the reset value, the Sclock frequency is equal to the PE clock frequency. The maximum value of this field is FFh, which gives a minimum Sclock frequency equal to the PE clock frequency divided by 256. See Protocol timing for more information. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Sclock frequency = PE clock frequency / (PRESDIV + 1).
23-22 RJW	Resync Jump Width This 2-bit field defines the maximum number of time quanta that a bit time can be changed by one resynchronization. One time quantum is equal to the Sclock period. The valid programmable values are 0–3. See Protocol timing for more information. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Resync Jump Width = RJW + 1.
21-19 PSEG1	Phase Segment 1 This 3-bit field defines the length of phase segment 1 in the bit time. The valid programmable values are 0–7. See Protocol timing for more information. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Phase Buffer Segment 1 = (PSEG1 + 1) × Time-Quanta.
18-16 PSEG2	Phase Segment 2 This 3-bit field defines the length of phase segment 2 in the bit time. The valid programmable values are 1–7. See Protocol timing for more information. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Phase Buffer Segment 2 = (PSEG2 + 1) × Time-Quanta.
15 BOFFMSK	Bus Off Interrupt Mask This bit provides a mask for the Bus Off interrupt ESR1[BOFFINT].

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Bus Off interrupt disabled. 1b - Bus Off interrupt enabled.
14 ERRMSK	Error Interrupt Mask This bit provides a mask for the Error interrupt ESR1[ERRINT]. 0b - Error interrupt disabled. 1b - Error interrupt enabled.
13 —	Reserved **NOTE** This field is writeable only if the module is disabled. Otherwise the access type is read-only.
12 LPB	Loop Back Mode This bit configures FlexCAN to operate in Loop-Back mode. In this mode, FlexCAN performs an internal loop back that can be used for self-test operation. The bit stream output of the transmitter is fed back internally to the receiver input. The Rx CAN input pin is ignored and the Tx CAN output goes to the recessive state (logic 1). FlexCAN behaves as it normally does when transmitting, and treats its own transmitted message as a message received from a remote node. In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field, generating an internal acknowledge bit to ensure proper reception of its own message. Both transmit and receive interrupts are generated. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. **NOTE** In this mode, MCR[SRXDIS] cannot be asserted because this will impede the self-reception of a transmitted message. **NOTE** FDCTRL[TDCEN] and ETDC[ETDCEN] must be disabled when LPB is asserted. 0b - Loop Back disabled. 1b - Loop Back enabled.
11 TWRNMSK	Tx Warning Interrupt Mask This bit provides a mask for the Tx Warning interrupt associated with the TWRNINT flag in the Error and Status Register 1 (ESR1). This bit is read as zero when MCR[WRNEN] is negated. This bit can be written only if MCR[WRNEN] is asserted. 0b - Tx Warning interrupt disabled. 1b - Tx Warning interrupt enabled.
10 RWRNMSK	Rx Warning Interrupt Mask

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This bit provides a mask for the Rx Warning interrupt associated with the RWRNINT flag in the Error and Status Register 1 (ESR1). This bit is read as zero when MCR[WRNEN] bit is negated. This bit can be written only if MCR[WRNEN] bit is asserted. 0b - Rx Warning interrupt disabled. 1b - Rx Warning interrupt enabled.
9 —	Reserved
8 —	Reserved
7 SMP	CAN Bit Sampling This bit defines the sampling mode of CAN bits at the Rx input. It can be written in Freeze mode only, because it is blocked by hardware in other modes. **NOTE** For proper operation, to assert SMP it is necessary to guarantee a minimum value of two TQs in CTRL1[PSEG1] (or CBT[EPSEG1]).This bit cannot be asserted when CAN FD is enabled (MCR[FDEN] = 1). 0b - Just one sample is used to determine the bit value. 1b - Three samples are used to determine the value of the received bit: the regular one (sample point) and two preceding samples; a majority rule is used.
6 BOFFREC	Bus Off Recovery This bit defines how FlexCAN recovers from Bus Off state. If this bit is negated, automatic recovering from Bus Off state occurs according to the CAN Specification 2.0B. If the bit is asserted, automatic recovering from Bus Off is disabled and the module remains in Bus Off state until the bit is negated by the user. If the negation occurs before 128 sequences of 11 recessive bits are detected on the CAN bus, then Bus Off recovery happens as if the BOFFREC bit had never been asserted. If the negation occurs after 128 sequences of 11 recessive bits occurred, then FlexCAN will resynchronize to the bus by waiting for 11 recessive bits before joining the bus. After negation, the BOFFREC bit can be reasserted again during Bus Off, but it will be effective only the next time the module enters Bus Off. If BOFFREC was negated when the module entered Bus Off, asserting it during Bus Off will not be effective for the current Bus Off recovery. **NOTE** See Bus off in the CAN Protocol standard (ISO 11898-1) for details. 0b - Automatic recovering from Bus Off state enabled. 1b - Automatic recovering from Bus Off state disabled.
5 TSYN	Timer Sync

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This bit enables a mechanism that resets the free running timer each time a message is received in message buffer 0. This feature provides means to synchronize multiple FlexCAN stations with a special “SYNC” message, that is, global network time. If MCR[RFEN] is set (Legacy Rx FIFO enabled), the first available mailbox, according to CTRL2[RFFN] setting, is used for timer synchronization instead of MB0. This bit can be written in Freeze mode only because it is blocked by hardware in other modes. 0b - Timer sync feature disabled 1b - Timer sync feature enabled
4 LBUF	Lowest Buffer Transmitted First This bit defines the ordering mechanism for message buffer transmission. When asserted, MCR[LPRIOEN] does not affect the priority arbitration. This bit can be written in Freeze mode only, because it is blocked by hardware in other modes. 0b - Buffer with highest priority is transmitted first. 1b - Lowest number buffer is transmitted first.
3 LOM	Listen-Only Mode This bit configures FlexCAN to operate in Listen-Only mode. In this mode, transmission is disabled, all error counters described in the ECR register are frozen, and the module operates in a CAN Error Passive mode. Only messages acknowledged by another CAN station will be received. If FlexCAN detects a message that has not been acknowledged, it will flag a BIT0 error without changing the receive error counter (ECR[RXERRCNT]), as if it was trying to acknowledge the message. Listen-Only mode is acknowledged by the state of ESR1[FLTCONF] indicating Passive Error. There can be some delay between the Listen-Only mode request and acknowledge. This bit can be written in Freeze mode only because it is blocked by hardware in other modes. 0b - Listen-Only mode is deactivated. 1b - FlexCAN module operates in Listen-Only mode.
2-0 PROPSEG	Propagation Segment This 3-bit field defines the length of the propagation segment in the bit time. The valid programmable values are 0–7. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Propagation segment time = (PROPSEG + 1) × time-quanta. Time-quantum = one Sclock period.

70.6.2.4 Free Running Timer (TIMER)

Offset

Register	Offset
TIMER	8h

Function

This register represents a 16-bit free-running counter that can be read and written by the CPU. The timer starts from 0h after Reset, counts linearly to FFFFh, and wraps around.

When CTRL2[TIMER_SRC] is asserted, the timer is continuously incremented by an external time tick. The time tick must be synchronous to the peripheral clock, with a minimum pulse width of one clock cycle.

When CTRL2[TIMER_SRC] is negated, the timer is incremented by the CAN bit clock, which defines the baud rate on the CAN bus. During a message transmission/reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate. The timer is not incremented during Disable and Freeze modes.

The timer value is captured when the second bit of the identifier field of any frame is on the CAN bus. This captured value is written into the time stamp entry in a message buffer after a successful reception or transmission of a message.

If CTRL1[TSYN] is asserted, the timer is reset whenever a message is received in the first available mailbox, according to CTRL2[RFFN] setting.

The CPU can write to this register anytime. However, if the write occurs at the same time that the timer is being reset by a reception in the first mailbox, then the write value is discarded.

Reading this register affects the mailbox unlocking procedure (see Mailbox lock mechanism).

70.6.2.5 Rx Mailboxes Global Mask Register (RXMGMASK)

Offset

Register	Offset
RXMGMASK	10h

Function

This register is located in RAM.

RXMGMASK is provided for legacy application support.

- When MCR[IRMQ] is negated, RXMGMASK is always in effect (the bits in the MG field will mask the mailbox filter bits).
- When MCR[IRMQ] is asserted, RXMGMASK has no effect (the bits in the MG field will not mask the mailbox filter bits).

RXMGMASK is used to mask the filter fields of all Rx MBs, excluding MBs 14-15, which have individual mask registers.

This register can only be written in Freeze mode as it is blocked by hardware in other modes.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	MG

R W	MG															
Reset	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u

Fields

Field	Function
31-0 MG	Rx Mailboxes Global Mask Bits These bits mask the mailbox filter bits. Note that the alignment with the ID word of the mailbox is not perfect as the two most significant MG bits affect the fields RTR and IDE, which are located in the Control and Status word of the mailbox. The following table shows in detail which MG bits mask each mailbox filter field.

SMB[RTR] [1]	CTRL2[RRS]	CTRL2[EACEN]	Mailbox filter fields			
			MB[RTR]	MB[IDE]	MB[ID]	Reserved
0	—	0	note [2]	note [3]	MG[28:0]	MG[31:29]
0	—	1	MG[31]	MG[30]	MG[28:0]	MG[29]
1	0	—	—	—	—	MG[31:0]
1	1	0	—	—	MG[28:0]	MG[31:29]
1	1	1	MG[31]	MG[30]	MG[28:0]	MG[29]

1. RTR bit of the incoming frame. It is saved into an auxiliary MB called Rx serial message buffer (Rx SMB).
2. If CTRL2[EACEN] is negated, the RTR bit of mailbox is never compared with the RTR bit of the incoming frame.
3. If CTRL2[EACEN] is negated, the IDE bit of mailbox is always compared with the IDE bit of the incoming frame.

Field	Function
	0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.

70.6.2.6 Rx 14 Mask Register (RX14MASK)

Offset

Register	Offset
RX14MASK	14h

Function

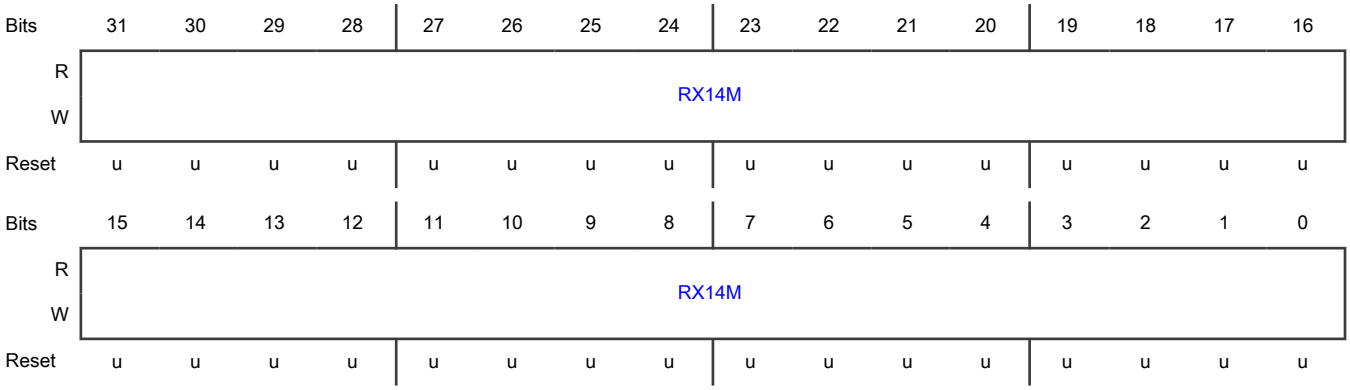
This register is located in RAM.

RX14MASK is provided for legacy application support. When MCR[IRMQ] is asserted, RX14MASK has no effect.

RX14MASK is used to mask the filter fields of message buffer 14.

This register can only be programmed when the module is in Freeze mode as it is blocked by hardware in other modes.

Diagram



Fields

Field	Function
31-0 RX14M	Rx Buffer 14 Mask Bits Each mask bit masks the corresponding mailbox 14 filter field in the same way that RXMGMASK masks other mailboxes' filters. See the description of the RXMGMASK register. 0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.

70.6.2.7 Rx 15 Mask Register (RX15MASK)

Offset

Register	Offset
RX15MASK	18h

Function

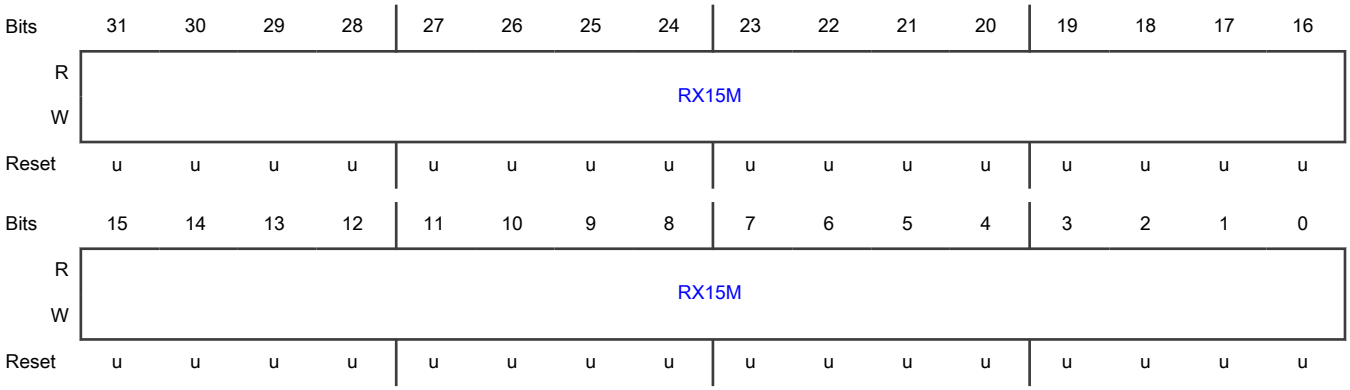
This register is located in RAM.

RX15MASK is provided for legacy application support. When MCR[IRMQ] is asserted, RX15MASK has no effect.

RX15MASK is used to mask the filter fields of message buffer 15.

This register can be programmed only when the module is in Freeze mode because it is blocked by hardware in other modes.

Diagram



Fields

Field	Function
31-0 RX15M	Rx Buffer 15 Mask Bits Each mask bit masks the corresponding mailbox 15 filter field in the same way that RXMGMASK masks other mailboxes' filters. See the description of the RXMGMASK register. 0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.

70.6.2.8 Error Counter (ECR)

Offset

Register	Offset
ECR	1Ch

Function

This register has four 8-bit fields reflecting the value of the FlexCAN error counters:

- Transmit Error Counter (TXERRCNT field)
- Receive Error Counter (RXERRCNT field)
- Transmit Error Counter for errors detected in the data phase of CAN FD messages with the BRS bit set (TXERRCNT_FAST field)
- Receive Error Counter for errors detected in the data phase of CAN FD messages with the BRS bit set (RXERRCNT_FAST field)

The TXERRCNT and RXERRCNT counters take into account all errors in both CAN FD and non-FD message formats. TXERRCNT_FAST and RXERRCNT_FAST are dedicated to count only the errors that occur in the data phase of CAN FD frames with the BRS bit set.

The Fault Confinement state (ESR1[FLTCONF]) is updated based on TXERRCNT and RXERRCNT counters only. TXERRCNT and RXERRCNT counters can be written in Freeze mode only. TXERRCNT_FAST and RXERRCNT_FAST counters are read-only except in Freeze mode when the CPU can write value zero. The rules for increasing and decreasing these counters are described in the CAN protocol and are completely implemented in the FlexCAN module.

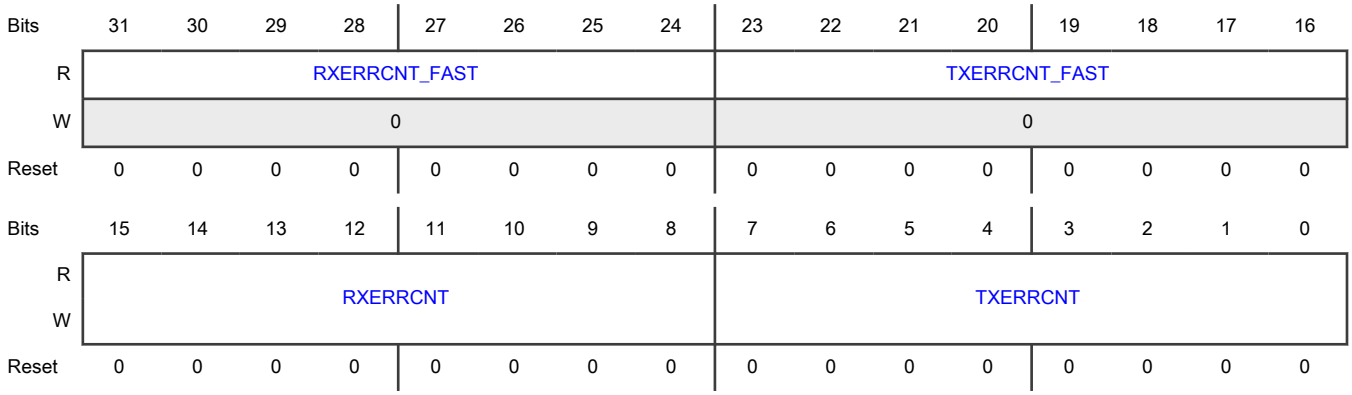
The following are the basic rules for FlexCAN bus state transitions:

- If the value of TXERRCNT or RXERRCNT becomes greater than or equal to 128, ESR1[FLTCONF] is updated to reflect Error Passive state.
- If the FlexCAN state is Error Passive, and either TXERRCNT or RXERRCNT decrements to a value less than or equal to 127 when the other already satisfies this condition, ESR1[FLTCONF] is updated to reflect Error Active state.
- If the value of TXERRCNT becomes greater than 255, ESR1[FLTCONF] is updated to reflect Bus Off state, and an interrupt may be issued. The value of TXERRCNT is then reset to zero.
- If FlexCAN is in Bus Off state, then TXERRCNT is cascaded together with another internal counter to count the 128th occurrences of 11 consecutive recessive bits on the bus. Hence, TXERRCNT is reset to zero and counts in a manner where the internal counter counts 11 such bits and then wraps around when incrementing the TXERRCNT. When TXERRCNT reaches the value of 128, ESR1[FLTCONF] is updated to be Error Active and both error counters are reset to zero. At any instance of dominant bit following a stream of less than 11 consecutive recessive bits, the internal counter resets itself to zero without affecting the TXERRCNT value. The TXERRCNT_FAST counter is frozen during Bus Off.
- If during system startup only one node is operating, then its TXERRCNT increases in each message it is trying to transmit, as a result of acknowledge errors (indicated by the ACKERR bit in the Error and Status Register). After the transition to Error Passive state, TXERRCNT does not increment anymore by acknowledge errors. Therefore the device never goes to the Bus Off state.
- If RXERRCNT increases to a value greater than 127, it is not incremented further, even if more errors are detected when being a receiver. At the next successful message reception, the counter is set to a value between 119 and 127 to return to Error Active state.
- TXERRCNT_FAST and RXERRCNT_FAST error counter values increment and decrement based on errors detected only in the data phase of CAN FD frames with the BRS bit set, following the same increment and decrement rules as TXERRCNT and RXERRCNT counters. These counters do not wrap around and get stuck at their maximum value (255). They stop counting and keep their values frozen when FlexCAN is in Bus Off state. They are reset when FlexCAN leaves Bus Off state and restart counting after FlexCAN returns to Error Active state.

NOTE

See Fault confinement in the CAN Protocol standard (ISO 11898-1) for details.

Diagram



Fields

Field	Function
31-24 RXERRCNT_FAST	Receive Error Counter for fast bits Receive error counter for errors detected in the data phase of received CAN FD messages with the BRS bit set. The RXERRCNT_FAST counter is read-only except in Freeze mode, where the CPU can write an 8-bit zero value only.
23-16 TXERRCNT_FAST	Transmit Error Counter for fast bits Transmit error counter for errors detected in the data phase of transmitted CAN FD messages with the BRS bit set. The TXERRCNT_FAST counter is read-only except in Freeze mode, where the CPU can write an 8-bit zero value only.
15-8 RXERRCNT	Receive Error Counter Receive error counter for all errors detected in received messages. The RXERRCNT counter is read-only except in Freeze mode, where it can be written by the CPU.
7-0 TXERRCNT	Transmit Error Counter Transmit error counter for all errors detected in transmitted messages. The TXERRCNT counter is read-only except in Freeze mode, where it can be written by the CPU.

70.6.2.9 Error and Status 1 Register (ESR1)

Offset

Register	Offset
ESR1	20h

Function

This register reports various error conditions detected in the reception and transmission of a CAN frame, some general status of the device, and is the source of some interrupts to the CPU. The reported error conditions are:

NOTE

Reading Host can clear these field.

- Errors detected in CAN frames of any format:
  - BIT1ERR
  - BIT0ERR
  - ACKKERR
  - CRCERR
  - FRMERR
  - STFERR
- Errors detected in the data phase of CAN FD frames with the BRS bit set only:
  - BIT1ERR_FAST
  - BIT0ERR_FAST
  - CRCERR_FAST
  - FRMERR_FAST
  - STFERR_FAST

An error detected in a single CAN frame may be reported by one or more error flags. Also, error reporting is cumulative, in case more error events happen in the next frames when the CPU does not attempt to read this register.

Status bits:

- TXWRN
- RXWRN
- IDLE
- TX
- FLTCONF
- RX
- SYNCH

Interrupt bits:

- BOFFINT
- BOFFDONEINT
- ERRINT
- ERRINT_FAST
- TWRNINT
- RWRNINT

It is recommended that the CPU use the following procedure when servicing interrupt requests generated by these bits:

1. Read this register to capture all error condition and status bits. This action clears the respective bits that were set since the last read access.
2. Write 1 to clear the interrupt bit that has triggered the interrupt request.
3. Write 1 to clear the ERR_OVR bit, if it is set.

Starting from all error flags cleared, a first error event sets either the ERRINT or the ERRINT_FAST (provided the corresponding mask bit is asserted). If other error events in subsequent frames happen before the CPU serves the interrupt request, the ERR_OVR bit is set to indicate that errors from different frames have accumulated.

Table 435. Can bus status

SYNCH	IDLE	TX	RX	FlexCAN state
0	0	0	0	Not synchronized to CAN bus
1	1	x	x	Idle
1	0	1	0	Transmitting
1	0	0	1	Receiving

NOTE

See Fault confinement in the CAN Protocol standard (ISO 11898-1) for details.

Fields

Field	Function
31 BIT1ERR_FAST	Bit1 Error in the Data Phase of CAN FD frames with the BRS bit set This bit indicates when an inconsistency occurs between the transmitted and the received bit in the data phase of CAN FD frames with the BRS bit set. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - At least one bit sent as recessive is received as dominant.
30 BIT0ERR_FAST	Bit0 Error in the Data Phase of CAN FD frames with the BRS bit set This bit indicates when an inconsistency occurs between the transmitted and the received bit in the data phase of CAN FD frames with the BRS bit set. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - At least one bit sent as dominant is received as recessive.

Table continues on the next page...

Table continued from the previous page...

Field	Function
29 —	Reserved
28 CRCERR_FAST	Cyclic Redundancy Check Error in the CRC field of CAN FD frames with the BRS bit set This bit indicates that a CRC error has been detected by the receiver node in the CRC field of CAN FD frames with the BRS bit set, that is, the calculated CRC is different from the received. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - A CRC error occurred since last read of this register.
27 FRMERR_FAST	Form Error in the Data Phase of CAN FD frames with the BRS bit set This bit indicates that a form error has been detected by the receiver node in the data phase of CAN FD frames with the BRS bit set, that is, a fixed-form bit field contains at least one illegal bit. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - A form error occurred since last read of this register.
26 STFERR_FAST	Stuffing Error in the Data Phase of CAN FD frames with the BRS bit set This bit indicates that a stuffing error has been detected in the data phase of CAN FD frames with the BRS bit set. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - A stuffing error occurred since last read of this register.
25-22 —	Reserved
21 ERROVR	Error Overrun This bit indicates that an error condition occurred when any error flag is already set. This bit is cleared by writing it to 1. 0b - Overrun has not occurred. 1b - Overrun has occurred.
20 ERRINT_FAST	Error interrupt for errors detected in Data Phase of CAN FD frames with BRS bit set This bit indicates that at least one of the error bits detected in the data phase of CAN FD frames with the BRS bit set (BIT1ERR_FAST, BIT0ERR_FAST, CRCERR_FAST, FRMERR_FAST, or STFERR_FAST) is set. If the corresponding mask bit CTRL2[ERRMSK_FAST] is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. Writing 0 has no effect. 0b - No such occurrence.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Indicates setting of any error bit detected in the data phase of CAN FD frames with the BRS bit set.
19 BOFFDONEINT	Bus Off Done Interrupt This bit is set when the Tx Error Counter (TXERRCNT) has finished counting 128 occurrences of 11 consecutive recessive bits on the CAN bus and is ready to leave Bus Off. If the corresponding mask bit in the Control 2 Register (BOFFDONEMSK) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. Writing 0 has no effect. 0b - No such occurrence. 1b - FlexCAN module has completed Bus Off process.
18 SYNCH	CAN Synchronization Status This read-only flag indicates whether the FlexCAN is synchronized to the CAN bus and able to participate in the communication process. It is set and cleared by the FlexCAN. See the table in the overall ESR1 register description. 0b - FlexCAN is not synchronized to the CAN bus. 1b - FlexCAN is synchronized to the CAN bus.
17 TWRNINT	Tx Warning Interrupt Flag If MCR[WRNEN] is asserted, TWRNINT is set when the TXWRN flag transitions from 0 to 1, meaning that the Tx error counter reached 96. If the corresponding mask bit in the Control 1 Register (CTRL1[TWRNMSK]) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. When MCR[WRNEN] is negated, this flag is masked. CPU must clear this flag before disabling MCR[WRNEN]. Otherwise it will be set when MCR[WRNEN] is set again. Writing 0 has no effect. This flag is not generated during Bus Off state. This bit is not updated during Freeze mode. 0b - No such occurrence. 1b - The Tx error counter transitioned from less than 96 to greater than or equal to 96.
16 RWRNINT	Rx Warning Interrupt Flag If MCR[WRNEN] is asserted, RWRNINT is set when the RXWRN flag transitions from 0 to 1, meaning that the Rx error counters reached 96. If the corresponding mask bit in the Control 1 Register (CTRL1[RWRNMSK]) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. When WRNEN is negated, this flag is masked. CPU must clear this flag before disabling the bit. Otherwise it will be set when WRNEN is set again. Writing 0 has no effect. This bit is not updated during Freeze mode. 0b - No such occurrence. 1b - The Rx error counter transitioned from less than 96 to greater than or equal to 96.
15 BIT1ERR	Bit1 Error This bit indicates when an inconsistency occurs between the transmitted and the received bit in a non-CAN FD message or in the arbitration or data phase of a CAN FD message.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This bit is not set by a transmitter in case of arbitration field or ACK slot, or in case of a node sending a passive error flag that detects dominant bits. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - At least one bit sent as recessive is received as dominant.
14 BIT0ERR	Bit0 Error This bit indicates when an inconsistency occurs between the transmitted and the received bit in a non-CAN FD message or in the arbitration or data phase of a CAN FD message. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - At least one bit sent as dominant is received as recessive.
13 ACKERR	Acknowledge Error This bit indicates that an Acknowledge Error has been detected by the transmitter node, that is, a dominant bit has not been detected during the ACK SLOT. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - An ACK error occurred since last read of this register.
12 CRCERR	Cyclic Redundancy Check Error This bit indicates that a Cyclic Redundancy Check (CRC) error has been detected by the receiver node either in a non-FD message or in the arbitration or data phase of a frame in CAN FD format, that is, the calculated CRC is different from the received. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - A CRC error occurred since last read of this register.
11 FRMERR	Form Error This bit indicates that a form error has been detected in a non-FD message or else in an FD message's arbitration or data phase by the receiver node, that is, a fixed-form bit field contains at least one illegal bit. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - A Form Error occurred since last read of this register.
10 STFERR	Stuffing Error This bit indicates that a stuffing error has been detected in a non-FD message or else in an FD message's arbitration or data phase by the receiver node.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - A stuffing error occurred since last read of this register.
9 TXWRN	TX Error Warning This bit indicates when repetitive errors are occurring during message transmission and is affected by the value of TXERRCNT in ECR register only. This bit is not updated during Freeze mode. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - TXERRCNT is greater than or equal to 96.
8 RXWRN	Rx Error Warning This bit indicates when repetitive errors are occurring during message reception and is affected by the value of RXERRCNT in ECR register only. This bit is not updated during Freeze mode. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - RXERRCNT is greater than or equal to 96.
7 IDLE	IDLE This bit indicates when CAN bus is in IDLE state. See the table in the overall ESR1 register description. 0b - No such occurrence. 1b - CAN bus is now IDLE.
6 TX	FlexCAN In Transmission This bit indicates if FlexCAN is transmitting a message. See the table in the overall ESR1 register description. 0b - FlexCAN is not transmitting a message. 1b - FlexCAN is transmitting a message.
5-4 FLTCONF	Fault Confinement State This 2-bit field indicates the confinement state of the FlexCAN module. If CTRL1[LOM] is asserted, after a delay that depends on the CAN bit timing, ESR1[FLTCONF] will indicate Error Passive. The very same delay affects the way that ESR1[FLTCONF] reflects an update to ECR register by the CPU. It may be necessary to wait up to one CAN bit time to get them coherent again. This bit field is affected by soft reset, but if the LOM bit is asserted, its reset value lasts just one CAN bit. After this time, ESR1[FLTCONF] reports Error Passive. 00b - Error Active 01b - Error Passive 1xb - Bus Off

Table continues on the next page...

Table continued from the previous page...

Field	Function
3 RX	FlexCAN In Reception This bit indicates if FlexCAN is receiving a message. See the table in the overall ESR1 register description. 0b - FlexCAN is not receiving a message. 1b - FlexCAN is receiving a message.
2 BOFFINT	Bus Off Interrupt This bit is set when FlexCAN enters Bus Off state. If the corresponding mask bit in the Control Register 1 (CTRL1[BOFFMSK]) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. Writing 0 has no effect. 0b - No such occurrence. 1b - FlexCAN module entered Bus Off state.
1 ERRINT	Error Interrupt This bit indicates that at least one of the error bits (BIT1ERR, BIT0ERR, ACKERR, CRCERR, FRMERR, or STFERR) is set. If the corresponding mask bit CTRL1[ERRMSK] is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. Writing 0 has no effect. 0b - No such occurrence. 1b - Indicates setting of any error bit in the Error and Status register.
0 —	Reserved

70.6.2.10 Interrupt Masks 2 Register (IMASK2)

Offset

Register	Offset
IMASK2	24h

Function

This register allows any number of a range of the 32 message buffer interrupts to be enabled or disabled for MB63 to MB32. It contains one interrupt mask bit per buffer, enabling the CPU to determine which buffer generates an interrupt after a successful transmission or reception, that is, when the corresponding IFLAG2 bit is set.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
CAN_0	IMASK2	—

Field	Function
31-0 BUF31TO0M	Buffer MBi Mask Each bit enables or disables the corresponding FlexCAN message buffer interrupt for MB31 to MB0. **NOTE** Setting or clearing a bit in the IMASK1 Register can assert or negate an interrupt request, if the corresponding IFLAG1 bit is set. 0b - The corresponding buffer interrupt is disabled. 1b - The corresponding buffer interrupt is enabled.

70.6.2.12 Interrupt Flags 2 Register (IFLAG2)

Offset

Register	Offset
IFLAG2	2Ch

Function

This register defines the flags for the 32 message buffer interrupts for MB63 to MB32. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the respective IFLAG2 bit. If the corresponding IMASK2 bit is set, an interrupt will be generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect.

Before updating MCR[MAXMB], CPU must service the IFLAG2 bits whose MB value is greater than the MAXMB to be updated; otherwise, they will remain set and be inconsistent with the number of MBs available.

NOTE

Each module instance supports a different number of registers.

Fields

Field	Function
31-0 BUF63TO32I	Buffer MBi Interrupt Each bit flags the corresponding FlexCAN message buffer interrupt for MB63 to MB32. 0b - The corresponding buffer has no occurrence of successfully completed transmission or reception. 1b - The corresponding buffer has successfully completed transmission or reception.

70.6.2.13 Interrupt Flags 1 Register (IFLAG1)

Offset

Register	Offset
IFLAG1	30h

Function

This register defines the flags for the 32 message buffer interrupts for MB31 to MB0. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding IFLAG1 bit. If the corresponding IMASK1 bit is set, an interrupt will be generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect. There is an exception when DMA for Legacy Rx FIFO is enabled, as described below.

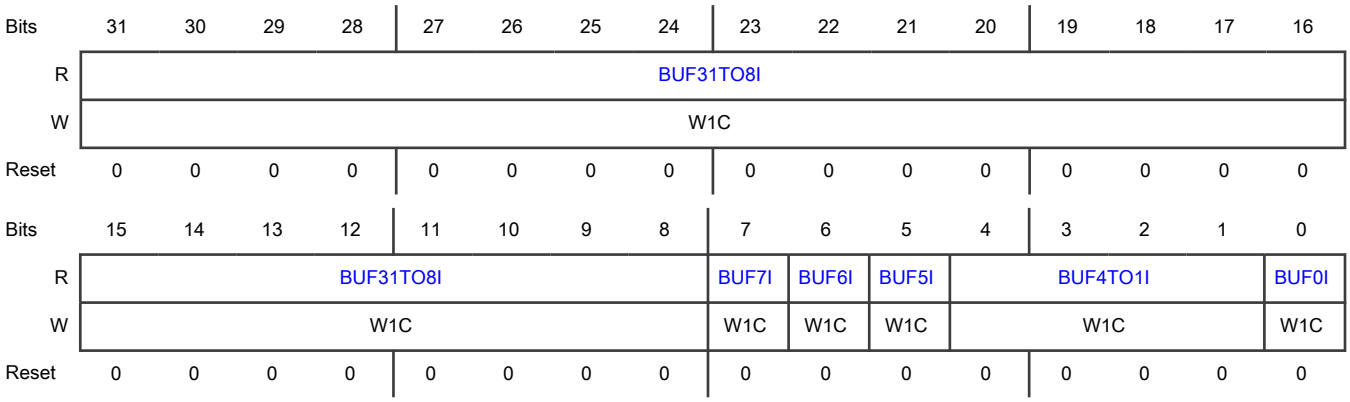
The BUF7I to BUF5I flags are also used to represent Legacy FIFO interrupts when the Legacy Rx FIFO is enabled. When MCR[RFEN] is set and MCR[DMA] is negated, the function of the eight least significant interrupt flags changes: BUF7I, BUF6I, and BUF5I indicate operating conditions of the Legacy FIFO , BUF0I is used to empty Legacy FIFO, and BUF4I to BUF1I bits are reserved.

Before enabling MCR[RFEN], the CPU must service the IFLAG bits asserted in the Legacy Rx FIFO region; see Legacy Rx FIFO. Otherwise, these IFLAG bits will mistakenly show the related MBs now belonging to Legacy FIFO as having contents to be serviced. When MCR[RFEN] is negated, the Legacy FIFO flags must be cleared. The same care must be taken when a CTRL2[RFFN] value is selected, extending Legacy Rx FIFO filters beyond MB7. For example, when RFFN is 8h, the MB0–23 range is occupied by Legacy Rx FIFO filters and related IFLAG bits must be cleared.

When both the MCR[RFEN] and MCR[DMA] bits are asserted (DMA feature for Legacy Rx FIFO enabled), the function of the eight least significant interrupt flags (BUF7I–BUF0I) are changed to support the DMA operation. BUF7I and BUF6I are not used, as well as BUF4I–BUF1I. BUF5I indicates operating condition of Legacy FIFO, and BUF0I is used to empty Legacy FIFO. Moreover, BUF5I does not generate a CPU interrupt, but generates a DMA request. IMASK1 bits in Legacy Rx FIFO region are not considered when bit MCR[DMA] is enabled. In addition the CPU must not clear the flag BUF5I when DMA is enabled. Before enabling MCR[DMA], the CPU must service the IFLAGs asserted in the Legacy Rx FIFO region. When MCR[DMA] is negated, the Legacy FIFO must be empty. Legacy FIFO must be disabled when MCR[FDEN] is enabled.

Before updating MCR[MAXMB], CPU must service the IFLAG1 bits whose MB value is greater than the MCR[MAXMB] to be updated; otherwise, they will remain set and be inconsistent with the number of MBs available.

Diagram



Fields

Field	Function
31-8 BUF31TO8I	Buffer MBi Interrupt Each bit flags the corresponding FlexCAN message buffer interrupt for MB31 to MB8. 0b - The corresponding buffer has no occurrence of successfully completed transmission or reception. 1b - The corresponding buffer has successfully completed transmission or reception.

Table continues on the next page...

Table continued from the previous page...

Field	Function
7 BUF7I	Buffer MB7 Interrupt Or Legacy Rx FIFO Overflow When MCR[RFEN] is cleared (Legacy Rx FIFO disabled), this bit flags the interrupt for MB7. **NOTE** This flag is cleared by the FlexCAN whenever MCR[RFEN] is changed by CPU writes. The BUF7I flag represents Legacy Rx FIFO overflow when MCR[RFEN] is set. In this case, the flag indicates that a message was lost because the Legacy Rx FIFO is full. Note that the flag will not be asserted when the Legacy Rx FIFO is full and the message was captured by a mailbox. **NOTE** The descriptions of the field settings vary by module instance.

Instance	Field value and description
CAN_0	0b - No occurrence of MB7 completing transmission/reception when MCR[RFEN]=0, or of Legacy Rx FIFO overflow when MCR[RFEN]=1 1b - MB7 completed transmission/reception when MCR[RFEN]=0, or Legacy Rx FIFO overflow when MCR[RFEN]=1
CAN_1	0b - No occurrence of MB7 completing transmission/reception when MCR[RFEN]=0, or of Rx FIFO overflow when MCR[RFEN]=1 1b - MB7 completed transmission/reception when MCR[RFEN]=0, or Rx FIFO overflow when MCR[RFEN]=1
CAN_2	0b - No occurrence of MB7 completing transmission/reception when MCR[RFEN]=0, or of Rx FIFO overflow when MCR[RFEN]=1 1b - MB7 completed transmission/reception when MCR[RFEN]=0, or Rx FIFO overflow when MCR[RFEN]=1
CAN_3	0b - No occurrence of MB7 completing transmission/reception when MCR[RFEN]=0, or of Rx FIFO overflow when MCR[RFEN]=1 1b - MB7 completed transmission/reception when MCR[RFEN]=0, or Rx FIFO overflow when MCR[RFEN]=1
CAN_4	0b - No occurrence of MB7 completing transmission/reception when MCR[RFEN]=0, or of Rx FIFO overflow when MCR[RFEN]=1 1b - MB7 completed transmission/reception when MCR[RFEN]=0, or Rx FIFO overflow when MCR[RFEN]=1
CAN_5	0b - No occurrence of MB7 completing transmission/reception when MCR[RFEN]=0, or of Rx FIFO overflow when MCR[RFEN]=1 1b - MB7 completed transmission/reception when MCR[RFEN]=0, or Rx FIFO overflow when MCR[RFEN]=1

Table continues on the next page...

Table continued from the previous page...

Field	Function
6 BUF6I	Buffer MB6 Interrupt Or Legacy Rx FIFO Warning When MCR[RFEN] is cleared (Legacy Rx FIFO disabled), this bit flags the interrupt for MB6. **NOTE** This flag is cleared by the FlexCAN whenever MCR[RFEN] is changed by CPU writes. The BUF6I flag represents Legacy Rx FIFO warning when MCR[RFEN] is set. In this case, the flag indicates when the number of unread messages within the Legacy Rx FIFO is increased to five from four due to the reception of a new one, meaning that the Legacy Rx FIFO is almost full. Note that if the flag is cleared when the number of unread messages is greater than four, it does not assert again until the number of unread messages within the Legacy Rx FIFO is decreased to be equal to or less than four. **NOTE** The descriptions of the field settings vary by module instance.

Instance	Field value and description
CAN_0	0b - No occurrence of MB6 completing transmission/reception when MCR[RFEN]=0, or of Legacy Rx FIFO almost full when MCR[RFEN]=1 1b - MB6 completed transmission/reception when MCR[RFEN]=0, or Legacy Rx FIFO almost full when MCR[RFEN]=1
CAN_1	0b - No occurrence of MB6 completing transmission/reception when MCR[RFEN]=0, or of Rx FIFO almost full when MCR[RFEN]=1 1b - MB6 completed transmission/reception when MCR[RFEN]=0, or Rx FIFO almost full when MCR[RFEN]=1
CAN_2	0b - No occurrence of MB6 completing transmission/reception when MCR[RFEN]=0, or of Rx FIFO almost full when MCR[RFEN]=1 1b - MB6 completed transmission/reception when MCR[RFEN]=0, or Rx FIFO almost full when MCR[RFEN]=1
CAN_3	0b - No occurrence of MB6 completing transmission/reception when MCR[RFEN]=0, or of Rx FIFO almost full when MCR[RFEN]=1 1b - MB6 completed transmission/reception when MCR[RFEN]=0, or Rx FIFO almost full when MCR[RFEN]=1
CAN_4	0b - No occurrence of MB6 completing transmission/reception when MCR[RFEN]=0, or of Rx FIFO almost full when MCR[RFEN]=1 1b - MB6 completed transmission/reception when MCR[RFEN]=0, or Rx FIFO almost full when MCR[RFEN]=1
CAN_5	0b - No occurrence of MB6 completing transmission/reception when MCR[RFEN]=0, or of Rx FIFO almost full when MCR[RFEN]=1

5 BUF5I	Buffer MB5 Interrupt Or Frames available in Legacy Rx FIFO When MCR[RFEN] is cleared (Legacy Rx FIFO disabled), this field flags the interrupt for MB5. **NOTE** This flag is cleared by the FlexCAN whenever MCR[RFEN] is changed by CPU writes. When MCR[RFEN] is set (Legacy Rx FIFO enabled), the BUF5I flag represents "Frames available in Legacy Rx FIFO" and indicates that at least one frame is available to be read from the Legacy Rx FIFO. When the MCR[DMA] bit is enabled, this flag generates a DMA request and the CPU must not clear this bit by writing 1 in BUF5I. **NOTE** The descriptions of the field settings vary by module instance. <table><tr><th>Instance</th><th>Field value and description</th></tr><tr><td>CAN_0</td><td>0b - No occurrence of MB5 completing transmission/reception when MCR[RFEN]=0, or of frame(s) available in the Legacy FIFO, when MCR[RFEN]=1 1b - MB5 completed transmission/reception when MCR[RFEN]=0, or frame(s) available in the Legacy Rx FIFO when MCR[RFEN]=1. It generates a DMA request in case of MCR[RFEN] and MCR[DMA] are enabled.</td></tr><tr><td>CAN_1</td><td>0b - No occurrence of MB5 completing transmission/reception when MCR[RFEN]=0, or of frame(s) available in the FIFO, when MCR[RFEN]=1 1b - MB5 completed transmission/reception when MCR[RFEN]=0, or frame(s) available in the Rx FIFO when MCR[RFEN]=1. BUF4TO1I</td><td>Buffer MBi Interrupt Or Reserved

When MCR[RFEN] is cleared (Legacy Rx FIFO disabled), these bits flag the interrupts for MB4 to MB1.

NOTE
These flags are cleared by the FlexCAN whenever MCR[RFEN] is changed by CPU writes.

The BUF4TO1I flags are reserved when MCR[RFEN] is set.

0b - The corresponding buffer has no occurrence of successfully completed transmission or reception when MCR[RFEN]=0.

1b - The corresponding buffer has successfully completed transmission or reception when MCR[RFEN]=0.</td></tr>
<tr><td>0

BUF0I</td><td>Buffer MB0 Interrupt Or Clear Legacy FIFO bit

When MCR[RFEN] is cleared (Legacy Rx FIFO disabled), this field flags the interrupt for MB0. If the Legacy Rx FIFO is enabled, this bit is used to trigger the clear Legacy FIFO operation. This operation empties Legacy FIFO contents. Before performing this operation the CPU must service all Legacy FIFO related IFLAGs. When MCR[DMA] is enabled this operation also clears the BUF5I flag and consequently aborts the DMA request. The clear Legacy FIFO operation occurs when the CPU writes 1 in BUF0I. It is only allowed in Freeze mode and is blocked by hardware in other conditions.</td></tr>
</table>

Fields

Field	Function
31 ERRMSK_FAST	Error Interrupt Mask for errors detected in the data phase of fast CAN FD frames This bit provides a mask for the ERRINT_FAST interrupt in ESR1 register. 0b - ERRINT_FAST error interrupt disabled. 1b - ERRINT_FAST error interrupt enabled.
30 BOFFDONEMSK	Bus Off Done Interrupt Mask This bit provides a mask for the bus off done interrupt in ESR1 register. 0b - Bus off done interrupt disabled. 1b - Bus off done interrupt enabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
29 ECRWRE	Error-correction Configuration Register Write Enable This bit enables the MECR register to be updated. This bit is automatically set to 0 if the protocol described in Detection and correction of memory errors is not followed. 0b - Disable update. 1b - Enable update.
28 WRMFRZ	Write-Access To Memory In Freeze Mode Enable unrestricted write access to FlexCAN memory in Freeze mode. This bit can only be written in Freeze mode and has no effect out of Freeze mode. MCR[RFEN] must not be set during FlexCAN memory initialization. 0b - Maintain the write access restrictions. 1b - Enable unrestricted write access to FlexCAN memory.
27-24 RFFN	Number Of Legacy Rx FIFO Filters This 4-bit field defines the number of Rx Legacy FIFO filters, as shown in Table 436. The maximum selectable number of filters is determined by the chip. This field can only be written in Freeze mode as it is blocked by hardware in other modes. This field must not be programmed with values that cause the number of message buffers occupied by Legacy Rx FIFO and Legacy Rx FIFO ID Filter to exceed the number of mailboxes present, as defined by MCR[MAXMB]. **NOTE** Each group of eight filters occupies a memory space equivalent to two message buffers, which means that the more filters are implemented the fewer mailboxes will be available. Considering that the Legacy Rx FIFO occupies the memory space originally reserved for MB0-5, RFFN should be programmed with a value corresponding to a number of filters not greater than the number of available memory words, which can be calculated as follows: (SETUP_MB - 6) × 4 where SETUP_MB is the smaller of the parameter NUMBER_OF_MB and MCR[MAXMB]. The number of remaining mailboxes available will be: (SETUP_MB - 8) - (RFFN × 2) If the number of Legacy Rx FIFO filters programmed through RFFN exceeds the SETUP_MB value (memory space available), then the exceeding ones will not be functional. **NOTE** • The number of the last remaining available mailboxes is defined by the smaller of NUMBER_OF_MB minus 1 and MCR[MAXMB]. • If Rx Individual Mask registers are not enabled then all Legacy Rx FIFO filters are affected by the Legacy Rx FIFO Global Mask.
23-19	Tx Arbitration Start Delay

<tr><td>17
RRS</td><td>Remote Request Storing
If this bit is asserted a remote request frame is submitted to a matching process and stored in the corresponding message buffer in the same fashion as a data frame. No automatic remote response frame will be generated.
If this bit is negated the remote request frame is submitted to a matching process and an automatic remote response frame is generated if a message buffer with CODE = 1010b is found with the same ID.
This bit can be written only in Freeze mode because it is blocked by hardware in other modes.
0b - Remote response frame is generated.</td></tr>
</table>

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Remote request frame is stored.
16 EACEN	Entire Frame Arbitration Field Comparison Enable For Rx Mailboxes This bit controls the comparison of IDE and RTR bits within Rx mailbox filters with their corresponding bits in the incoming frame by the matching process. This bit does not affect matching for Legacy Rx FIFO or Enhanced Rx FIFO. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0b - Rx mailbox filter's IDE bit is always compared and RTR is never compared despite mask bits. 1b - Enables the comparison of both Rx mailbox filter's IDE and RTR bit with their corresponding bits within the incoming frame. Mask bits do apply.
15 TIMER_SRC	Timer Source Selects the time tick source used for incrementing the free running timer counter. This bit can be written in Freeze mode only. 0b - The free running timer is clocked by the CAN bit clock, which defines the baud rate on the CAN bus. 1b - The free running timer is clocked by an external time tick. The period can be either adjusted to be equal to the baud rate on the CAN bus, or a different value as required. See the device-specific section for details about the external time tick.
14 PREXCEN	Protocol Exception Enable This bit enables the protocol exception feature. This field is writable only in Freeze mode. **NOTE** See Protocol exception event in the CAN Protocol standard (ISO 11898-1) for details. 0b - Protocol exception is disabled. 1b - Protocol exception is enabled.
13 BTE	Bit Timing Expansion enable This field enables the use of the EPRS, EDCBT and ENCBT registers to configure the CAN bit timing segments, instead of using the bit timing fields of CBT, FDCBT, and CTRL1 registers. If CTRL2[BTE] is set: • PRESDIV, PROPSEG, PSEG1, PSEG2, and RJW fields in CTRL1 register are read as zero, and a write operation in them has no effect. • EPRESDIV, ERJW, EPROPSEG, EPSEG1, and EPSEG2 fields in the CBT register, and the FDCBT register, are read as zero and a write operation to them has no effect. • The ETDCOFF, ETDCEN, ETDCFAIL, and ETDCVAL fields of the ETDC register are used by FlexCAN instead of TDCOFF, TDCEN, TDCFAIL, and TDCVAL fields in FDCTRL register, which are read as zero, and a write operation in them has no effect. • ETDC[TDMDIS] can be used for disabling transceiver delay measurement.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - CAN Bit timing expansion is disabled. 1b - CAN bit timing expansion is enabled.
12 ISOCANFDEN	ISO CAN FD Enable This field enables the CAN FD protocol according to ISO specification (ISO 11898-1) (see CAN FD ISO compliance). This field is writable only in Freeze mode. **NOTE** FlexCAN is able to transmit FD frame format according to CAN Protocol standard (ISO 11898-1). 0b - FlexCAN operates using the non-ISO CAN FD protocol. 1b - FlexCAN operates using the ISO CAN FD protocol (ISO 11898-1).
11 EDFLTDIS	Edge Filter Disable This bit disables the edge filter used during the bus integration state. When the Edge Filter is enabled, two consecutive nominal time quanta with dominant bus state are required to detect an edge that causes synchronization. When synchronization occurs, the counting of the sequence of eleven consecutive recessive bits is restarted. The edge filter prevents the dominant pulses that are shorter than a nominal bit time (present during the data phase of an FD frame) from being mistaken for an idle condition. This field is writable only in Freeze mode. **NOTE** See Bus Integration state in the CAN Protocol standard (ISO 11898-1) for details. 0b - Edge filter is enabled 1b - Edge filter is disabled
10 —	Reserved
9-8 MBTSBASE	Message Buffer Time Stamp Base This field selects which time base is used for capturing the 16-bit TIME_STAMP field of the message buffer register. There are three time base options: 1. TIMER 2. Lower 16 bits of high resolution time base 3. Upper 16 bits of high resolution time base This field can be written in Freeze Mode only.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	00b - Message buffer time stamp base is TIMER 01b - Message buffer time stamp base is lower 16 bits of high resolution timer 10b - Message buffer time stamp base is upper 16 bits of high resolution timer 11b - Reserved
7-6 TSTAMPCAP	Time Stamp Capture Point This field configures the point in time when a 32-bit time base is captured during a CAN frame and stored in the high resolution time stamp register (HR_TIME_STAMP). For classical CAN frames, capture points can be the start of frame bit or the point in time a CAN frame is considered valid, which is the 7th bit of end of frame for transmission and the 6th bit of the end of frame for reception. For CAN FD frames, the high resolution time stamp can be captured at the start of frame, the point in time a CAN FD frame is considered valid, or the res bit. This field can be written in Freeze mode only. 00b - The high resolution time stamp capture is disabled 01b - The high resolution time stamp is captured in the end of the CAN frame 10b - The high resolution time stamp is captured in the start of the CAN frame 11b - The high resolution time stamp is captured in the start of frame for classical CAN frames and in res bit for CAN FD frames
5-0 —	Reserved

70.6.2.15 Error and Status 2 Register (ESR2)

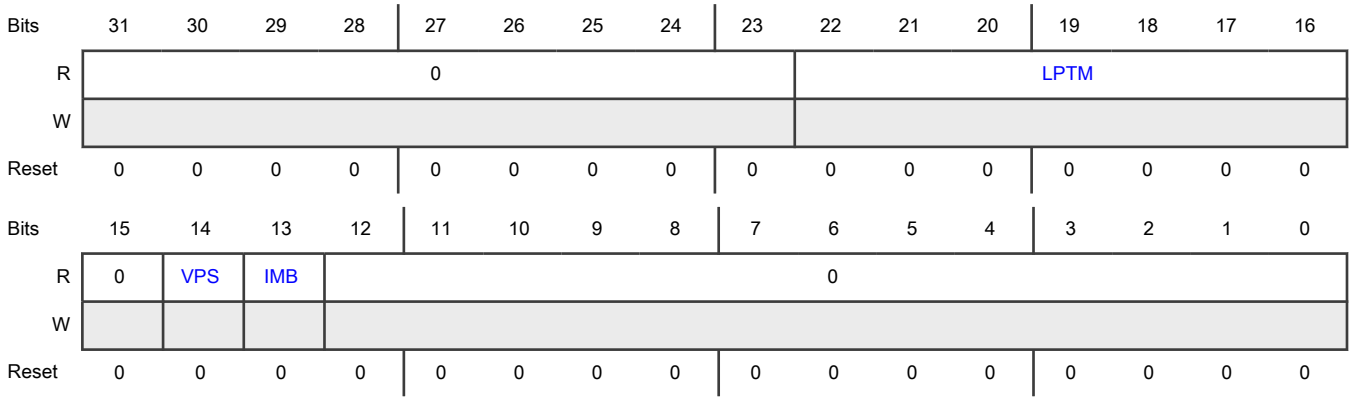
Offset

Register	Offset
ESR2	38h

Function

This register reports some general status information.

Diagram



Fields

Field	Function
31-23 —	Reserved
22-16 LPTM	Lowest Priority Tx Mailbox If ESR2[VPS] is asserted, this field indicates the lowest number inactive mailbox (see the ESR2[IMB] bit description). If there is no inactive mailbox then the mailbox indicated depends on the value of CTRL1[LBUF]. If CTRL1[LBUF] is negated, then the mailbox indicated is the one that has the greatest arbitration value (see Highest-priority mailbox first). If CTRL1[LBUF] is asserted then the mailbox indicated is the highest number active Tx mailbox. If a Tx mailbox is being transmitted it is not considered in LPTM calculation. If ESR2[IMB] is not asserted and a frame is transmitted successfully, LPTM is updated with its mailbox number.
15 —	Reserved
14 VPS	Valid Priority Status This bit indicates whether ESR2[IMB] and ESR2[LPTM] contents are currently valid or not. It is asserted upon every complete Tx arbitration process unless the CPU writes to Control and Status word of a mailbox that has already been scanned, that is, it is behind Tx Arbitration Pointer, during the Tx arbitration process. If there is no inactive mailbox and only one Tx mailbox that is being transmitted then VPS is not asserted. This bit is negated upon the start of every Tx arbitration process or upon a write to Control and Status word of any mailbox. **NOTE** ESR2[VPS] is not affected by any CPU write into Control Status (C/S) of an MB that is blocked by abort mechanism. When MCR[AEN] is asserted, the abort code write in C/S of an MB that is being transmitted (pending abort), or any write attempt into a Tx MB with IFLAG set is blocked. 0b - Contents of IMB and LPTM are invalid. 1b - Contents of IMB and LPTM are valid.

Table continues on the next page...

Table continued from the previous page...

Field	Function
13 IMB	Inactive Mailbox If ESR2[VPS] is asserted, this bit indicates whether there is any inactive mailbox (CODE field is either 1000b or 0b). This bit is asserted in the following cases: • During arbitration, if an ESR2[LPTM] is found and it is inactive. • If ESR2[IMB] is not asserted and a frame is transmitted successfully. This bit is always cleared in start of arbitration (see Arbitration process). **NOTE** ESR2[LPTM] mechanism has the following behavior: if an MB is successfully transmitted and ESR2[IMB]=0 (no inactive mailbox), then ESR2[VPS] and ESR2[IMB] are asserted and the index related to the MB just transmitted is loaded into ESR2[LPTM]. 0b - If ESR2[VPS] is asserted, the ESR2[LPTM] is not an inactive mailbox. 1b - If ESR2[VPS] is asserted, there is at least one inactive mailbox. LPTM content is the number of the first one.
12-0 —	Reserved

70.6.2.16 CRC Register (CRCR)

Offset

Register	Offset
CRCR	44h

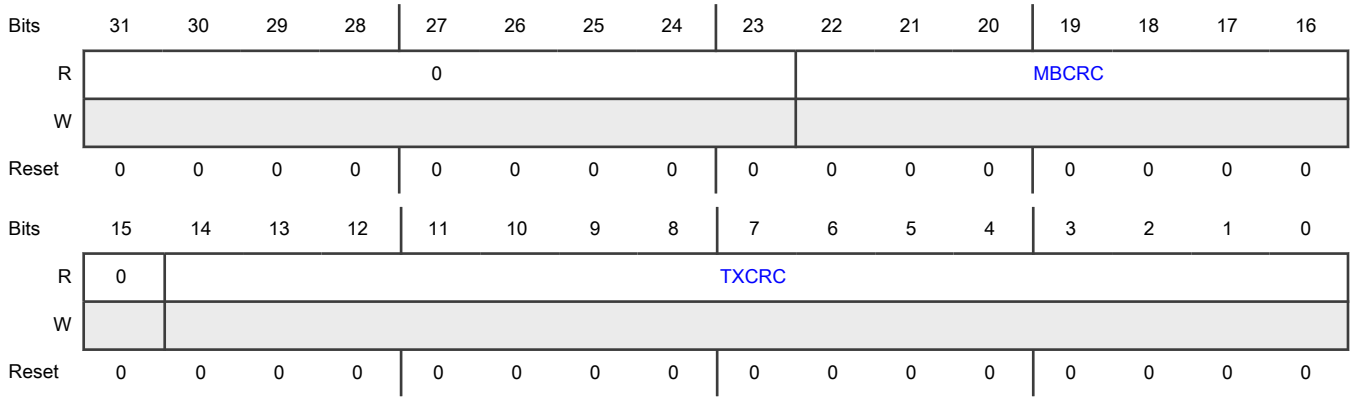
Function

This register provides information about the CRC of transmitted messages for non-FD messages. This register only reports the 15 low order bits of CRC calculations for messages in CAN FD format that require either 17 or 21 bits. For CAN FD format frames, the FDCRC register must be used. This register is updated at the same time the Tx interrupt flag is asserted.

NOTE

See CRC sequence calculation in the CAN Protocol standard (ISO 11898-1) for details.

Diagram



Fields

Field	Function
31-23 —	Reserved
22-16 MBCRC	CRC Mailbox This field indicates the number of the mailbox corresponding to the value in CRCR[TXCRC] field.
15 —	Reserved
14-0 TXCRC	Transmitted CRC value This field indicates the CRC value of the last transmitted message for non-FD frames. For FD frames, CRC value is reported in FDCRC register.

70.6.2.17 Legacy Rx FIFO Global Mask Register (RXFGMASK)

Offset

Register	Offset
RXFGMASK	48h

Function

This register is located in RAM.

If Legacy Rx FIFO is enabled, RXFGMASK is used to mask the Legacy Rx FIFO ID filter table elements that do not have a corresponding RXIMR according to CTRL2[RFFN] field setting.

This register can only be written in Freeze mode as it is blocked by hardware in other modes.

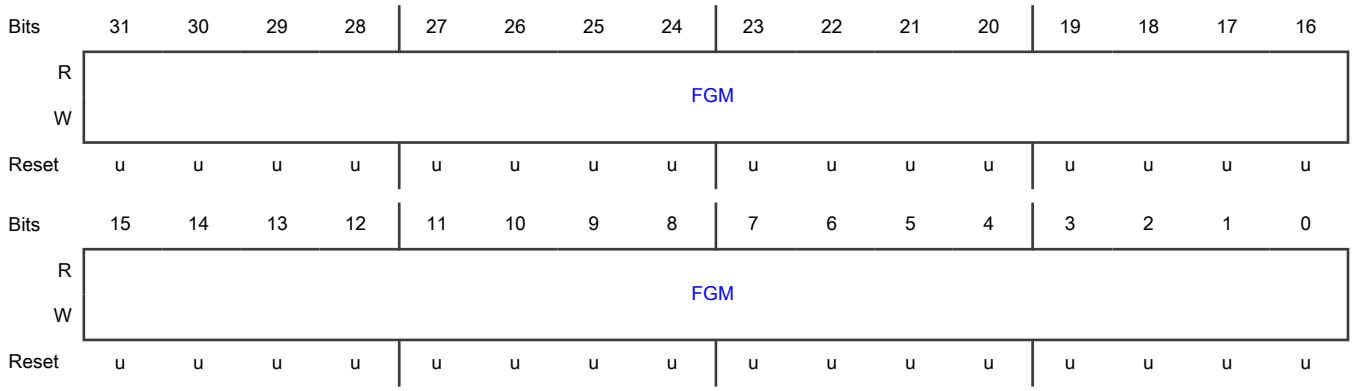
The following table shows how the FGM bits correspond to each IDAF field.

Table 437. Correspondence of Legacy Rx FIFO global mask bits to IDF fields

Legacy Rx FIFO ID filter table elements format (MCR[IDAM])	Identifier acceptance filter fields					
	RTR	IDE	RXIDA	RXIDB [1]	RXIDC [2]	Reserved
A	FGM[31]	FGM[30]	FGM[29:1]	—	—	FGM[0]
B	FGM[31], FGM[15]	FGM[30], FGM[14]	—	FGM[29:16], FGM[13:0]		—
C	—	—		—	FGM[31:24], FGM[23:16], FGM[15:8], FGM[7:0]	

1. If MCR[IDAM] is equivalent to format B, only the fourteen most significant bits of the identifier of the incoming frame are compared with the Legacy Rx FIFO filter.
2. If MCR[IDAM] is equivalent to format C, only the eight most significant bits of the identifier of the incoming frame are compared with the Legacy Rx FIFO filter.

Diagram



Fields

Field	Function
31-0 FGM	Legacy Rx FIFO Global Mask Bits These bits mask the ID filter table elements bits in a perfect alignment. 0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.

70.6.2.18 Legacy Rx FIFO Information Register (RXFIR)

Offset

Register	Offset
RXFIR	4Ch

Function

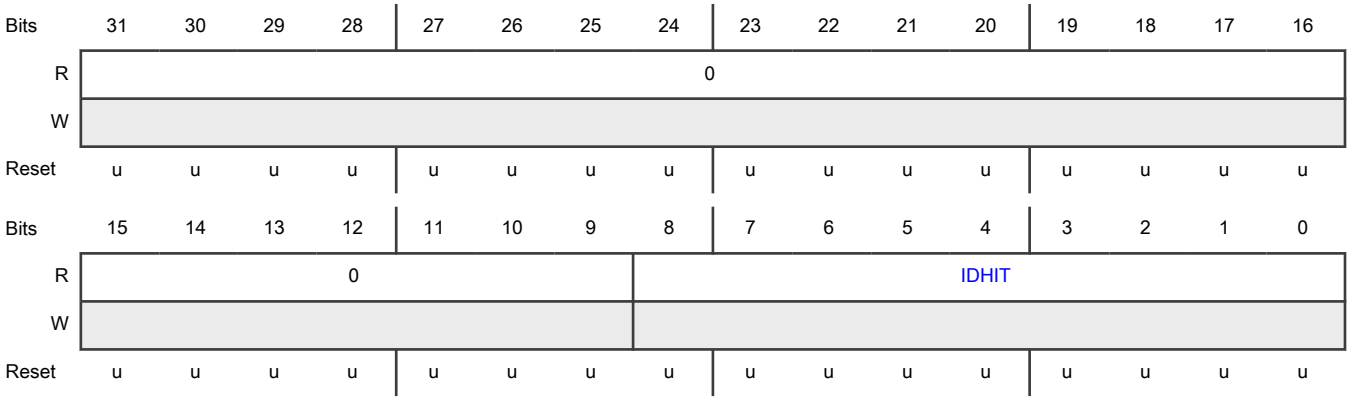
RXFIR provides information on Legacy Rx FIFO.

This register is the port through which the CPU accesses the output of the Legacy RXFIR FIFO located in RAM. The Legacy RXFIR FIFO is written by the FlexCAN whenever a new message is moved into the Legacy Rx FIFO. Also, its output is updated whenever the output of the Legacy Rx FIFO is updated with the next message. See Legacy Rx FIFO for instructions on reading this register.

NOTE

RXFIR can be written only during memory initialization, due to the error code correction (ECC) feature. In every other case the register is read-only.

Diagram



Fields

Field	Function
31-9 —	Reserved
8-0 IDHIT	Identifier Acceptance Filter Hit Indicator This field indicates which Identifier Acceptance filter was hit by the received message that is in the output of the Legacy Rx FIFO. If multiple filters match the incoming message ID then the first matching IDAF found (lowest number) by the matching process is indicated. This field is valid only when IFLAG1[BUF5I] is asserted.

70.6.2.19 CAN Bit Timing Register (CBT)

Offset

Register	Offset
CBT	50h

Function

This register is an alternative way to store the CAN bit timing variables described in CTRL1 register. EPRESDIV, EPROPSEG, EPSEG1, EPSEG2, and ERJW are extended versions of PRESDIV, PROPSEG, PSEG1, PSEG2, and RJW fields respectively.

The BTF bit selects the use of the timing variables defined in this register.

The contents of this register are not affected by soft reset.

NOTE

The CAN bit variables in CTRL1 and in CBT are stored in the same register.

NOTE

When the CAN FD feature is enabled (MCR[FDEN] is set), always set CBT[BTF].

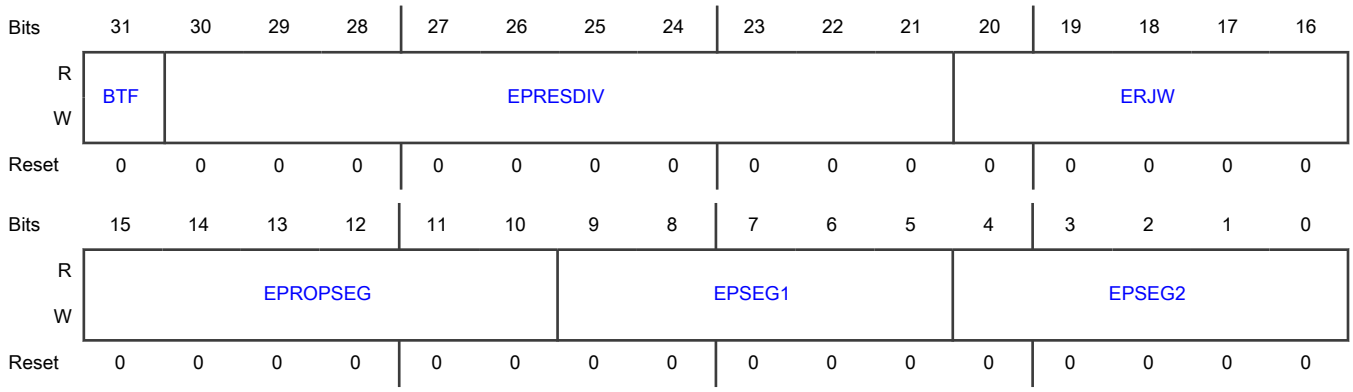
NOTE

The user must ensure bit time settings and protocol engine tolerance are in compliance with the CAN Protocol standard (ISO 11898-1).

NOTE

If CTRL2[BTE] is set, EPRESDIV, ERJW, EPROPSEG, EPSEG1, and EPSEG2 fields are read as zero, and a write operation into them has no effect.

Diagram



Fields

Field	Function
31 BTF	Bit Timing Format Enable Enables the use of extended CAN bit timing fields EPRESDIV, EPROPSEG, EPSEG1, EPSEG2. and ERJW replacing the CAN bit timing variables defined in CTRL1 register. This field can be written in Freeze mode only. 0b - Extended bit time definitions disabled. 1b - Extended bit time definitions enabled.
30-21 EPRESDIV	Extended Prescaler Division Factor This 10-bit field defines the ratio between the PE clock frequency and the serial clock (Sclock) frequency when CBT[BTF] is asserted, otherwise it has no effect. It extends the CTRL1[PRESDIV] value range. The Sclock period defines the time quantum of the CAN protocol. For the reset value, the Sclock frequency is equal to the PE clock frequency (see Protocol timing). This field can be written only in Freeze mode because it is blocked by hardware in other modes.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Sclock frequency = PE clock frequency / (EPRESDIV + 1)
20-16 ERJW	Extended Resync Jump Width This 5-bit field defines the maximum number of time quanta that a bit time can be changed by one re-synchronization when CBT[BTF] bit is asserted, otherwise it has no effect. It extends the CTRL1[RJW] value range. One time quantum is equal to the Sclock period. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Resync Jump Width = ERJW + 1.
15-10 EPROPSEG	Extended Propagation Segment This 6-bit field defines the length of the propagation segment in the bit time when CBT[BTF] bit is asserted, otherwise it has no effect. It extends the CTRL1[PROPSEG] value range. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Propagation Segment Time = (EPROPSEG + 1) × Time-Quanta. Time-Quantum = one Sclock period.
9-5 EPSEG1	Extended Phase Segment 1 This 5-bit field defines the length of phase segment 1 in the bit time when CBT[BTF] bit is asserted, otherwise it has no effect. It extends the CTRL1[PSEG1] value range. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Phase Buffer Segment 1 = (EPSEG1 + 1) × Time-Quanta. Time-Quantum = one Sclock period.
4-0 EPSEG2	Extended Phase Segment 2 This 5-bit field defines the length of phase segment 2 in the bit time when CBT[BTF] bit is asserted, otherwise it has no effect. It extends the CTRL1[PSEG2] value range. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Phase Buffer Segment 1 = (EPSEG2 + 1) × Time-Quanta. Time-Quantum = one Sclock period.

70.6.2.20 Interrupt Masks 3 Register (IMASK3)

Offset

Register	Offset
IMASK3	6Ch

Function

This register allows any number of a range of the 32 message buffer interrupts to be enabled or disabled for MB95 to MB64. It contains one interrupt mask bit per buffer, enabling the CPU to determine which buffer generates an interrupt after a successful transmission or reception, that is, when the corresponding IFLAG3 bit is set.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
CAN_0	IMASK3	—
CAN_1	—	IMASK3
CAN_2	—	IMASK3
CAN_3	—	IMASK3
CAN_4	—	IMASK3
CAN_5	—	IMASK3

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	BUF95TO64M															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 BUF95TO64M	Buffer MBi Mask Each bit enables or disables the corresponding FlexCAN message buffer interrupt for MB95 to MB64. When CAN FD is enabled, the MB range is defined in accordance with the MBDSRs bit fields of FDCTRL register. **NOTE** Setting or clearing a bit in the IMASK3 Register can assert or negate an interrupt request, if the corresponding IFLAG3 bit is set. 0b - The corresponding buffer interrupt is disabled. 1b - The corresponding buffer interrupt is enabled.

70.6.2.21 Interrupt Flags 3 Register (IFLAG3)

Offset

Register	Offset
IFLAG3	74h

Function

This register defines the flags for the 32 message buffer interrupts for MB95 to MB64. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding IFLAG3 bit. If the corresponding IMASK3 bit is set, an interrupt will be generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect.

Before updating MCR[MAXMB] field, CPU must service the IFLAG3 bits whose MB value is greater than the MAXMB to be updated; otherwise, they will remain set and be inconsistent with the number of MBs available.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
CAN_0	IFLAG3	—
CAN_1	—	IFLAG3
CAN_2	—	IFLAG3
CAN_3	—	IFLAG3
CAN_4	—	IFLAG3
CAN_5	—	IFLAG3

Fields

Field	Function
31-0 BUF95TO64	Buffer MBi Interrupt Each bit flags the corresponding FlexCAN message buffer interrupt for MB95 to MB64.When CAN FD is enabled, the MB range is defined in accordance to the MBDSRs bit fields of FDCTRL register. 0b - The corresponding buffer has no occurrence of successfully completed transmission or reception. 1b - The corresponding buffer has successfully completed transmission or reception.

70.6.2.22 Rx Individual Mask Registers (RXIMR0 - RXIMR95)

Offset

For n = 0 to 95:

Register	Offset
RXIMRn	880h + (n × 4h)

Function

The RX Individual Mask registers are used to store the acceptance masks for ID filtering in Rx MBs and the Legacy Rx FIFO.

When the Legacy Rx FIFO is disabled (MCR[RFEN] bit is negated), an individual mask is provided for each available Rx mailbox on a one-to-one correspondence. When the Legacy Rx FIFO is enabled (MCR[RFEN] bit is asserted), an individual mask is provided for each Legacy Rx FIFO ID filter table element on a one-to-one correspondence depending on the setting of CTRL2[RFFN] (see Legacy Rx FIFO).

RXIMR0 stores the individual mask associated with either MB0 or ID filter table element 0, RXIMR1 stores the individual mask associated with either MB1 or ID filter table element 1, and so on.

RXIMR registers can only be accessed by the CPU when the module is in Freeze mode; otherwise, they are blocked by hardware. These registers are not affected by reset. They are located in RAM and must be explicitly initialized prior to any reception.

It is possible for the RXIMR memory region to be accessed as general purpose memory. See Bus interface for more information.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
CAN_0	RXIMR0–RXIMR95	—
CAN_1	RXIMR0–RXIMR63	RXIMR64–RXIMR95
CAN_2	RXIMR0–RXIMR63	RXIMR64–RXIMR95

RXIMR32–RXIMR63	CAN_0–CAN_2: undefined CAN_3–CAN_5: Register not supported
RXIMR64–RXIMR95	CAN_0: undefined CAN_1–CAN_5: Register not supported

Fields

Field	Function
31-0 MI	Individual Mask Bits Each individual mask bit masks the corresponding bit in both the mailbox filter and Legacy Rx FIFO ID filter table element in distinct ways. For mailbox filters, see the RXMGMASK register description. For Legacy Rx FIFO ID filter table elements, see the RXFGMASK register description. 0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.

70.6.2.23 Memory Error Control Register (MECR)

Offset

Register	Offset
MECR	AE0h

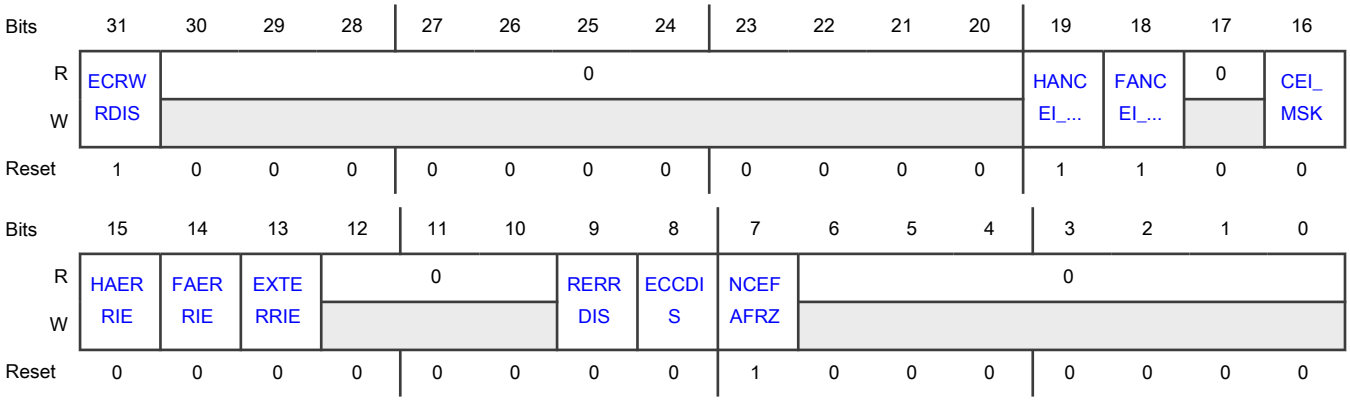
Function

This register contains control bits for memory error detection and correction (ECC).

NOTE

When bit CTRL2[ECRWRE] is 0, writes in this register are blocked, except in the ECRWRDIS bit.

Diagram



Fields

Field	Function
31 ECRWRDIS	Error Configuration Register Write Disable Disables writes on this register. This bit is automatically set to 1 (disabled) when CTRL2[ECRWRE] is enabled. The protocol described in section Detection and correction of memory errors must be followed. 0b - Write is enabled. 1b - Write is disabled.
30-20 —	Reserved
19 HANCEI_MSK	Host Access With Non-Correctable Errors Interrupt Mask Enables the interrupt in case of non-correctable errors detected in memory reads issued by the host (CPU). 0b - Interrupt is disabled. 1b - Interrupt is enabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
18 FANCEI_MSK	FlexCAN Access With Non-Correctable Errors Interrupt Mask Enables the interrupt in case of non-correctable errors detected in memory reads issued by the FlexCAN internal processes. 0b - Interrupt is disabled. 1b - Interrupt is enabled.
17 —	Reserved
16 CEI_MSK	Correctable Errors Interrupt Mask Enables the interrupt in case of correctable errors detected in memory reads issued by the host or FlexCAN internal processes. 0b - Interrupt is disabled. 1b - Interrupt is enabled.
15 HAERRIE	Host Access Error Injection Enable Enables the injection of errors only in memory reads issued by the host (CPU). 0b - Injection is disabled. 1b - Injection is enabled.
14 FAERRIE	FlexCAN Access Error Injection Enable Enables the injection of errors only in memory reads issued by the FlexCAN internal processes. 0b - Injection is disabled. 1b - Injection is enabled.
13 EXTERRIE	Extended Error Injection Enable Memory accesses performed by internal FlexCAN processes are 64-bit. This bit extends the error injection on 32-bit memory accesses to the complementary 32-bit word using the same 32-bit error injection data and parity words. See Error Injection Data Pattern Register (ERRIDPR) and Error Injection Parity Pattern Register (ERRIPPR). 0b - Error injection is applied only to the 32-bit word. 1b - Error injection is applied to the 64-bit word.
12-10 —	Reserved
9 RERRDIS	Error Report Disable Disables the update of the error report registers. The update of error-related flags and the generation of bus transfer errors are still active.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE When reading the report registers, this bit must be set to assure coherence on the consecutive register reads. 0b - Enable updates of the error report registers. 1b - Disable updates of the error report registers.
8 ECCDIS	Error Correction Disable Disables completely the memory detection and correction mechanism. Besides disabling the error report mechanism, it also stops the update of the error-related flags and generation of bus transfer errors. The parity bits continue being calculated and written into memory on write transactions. 0b - Enable memory error correction. 1b - Disable memory error correction.
7 NCEFAFRZ	Non-Correctable Errors In FlexCAN Access Put Device In Freeze Mode Determines the response when a non-correctable error is detected in a memory read performed by FlexCAN internal processes. In this case, entering Freeze mode prevents corrupted data from being treated as valid by FlexCAN internal processes. 0b - Keep normal operation. 1b - Put FlexCAN in Freeze mode (see section "Freeze mode").
6-0 —	Reserved

70.6.2.24 Error Injection Address Register (ERRIAR)

Offset

Register	Offset
ERRIAR	AE4h

Function

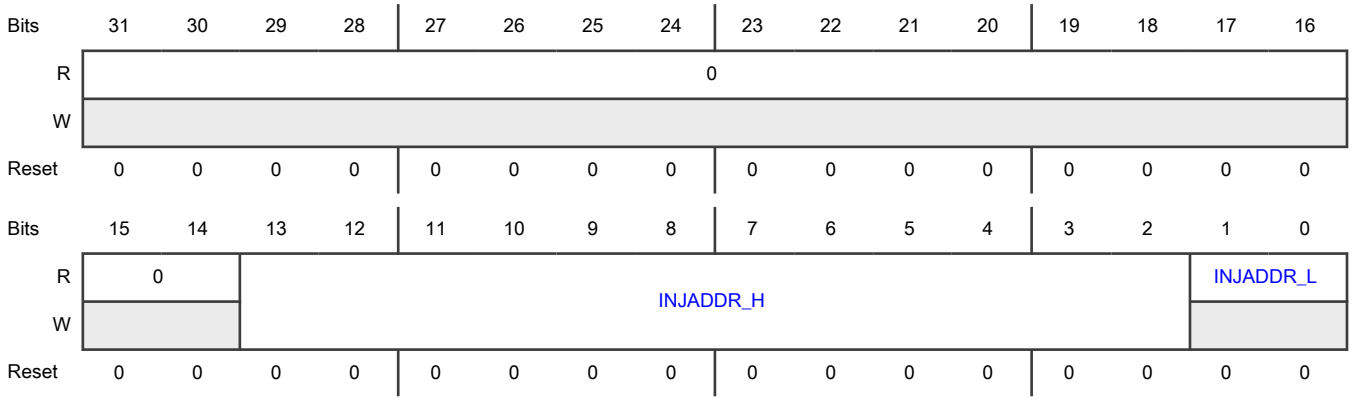
This register holds the address where error is to be injected.

See the chip-specific FlexCAN information for the FlexCAN RAM to memory map address mapping table.

NOTE

For RXFIR, Enhanced RX FIFO, and HR_TIME_STAMP addresses, you must inject ECC errors in host access only.

Diagram



Fields

Field	Function
31-14 —	Reserved
13-2 INJADDR_H	Error Injection Address High This read-write field defines the twelve most significant bits of the physical RAM address where error is to be injected (see table above).
1-0 INJADDR_L	Error Injection Address Low This read-only field defines the two least significant bits of the physical RAM address where error is to be injected. They ensure that the address is on a thirty-two-bit boundary.

70.6.2.25 Error Injection Data Pattern Register (ERRIDPR)

Offset

Register	Offset
ERRIDPR	AE8h

Function

Holds the error pattern to be injected in the data word read from memory.

4-0 PFLIP0	Parity Flip Pattern For Byte 0 (Least Significant)

70.6.2.27 Error Report Address Register (RERRAR)

Offset

Register	Offset
RERRAR	AF0h

Function

Reports the address used for an access in which an error (correctable or non-correctable) was detected, and also reports the identification of the source of that access.

This address is always reported using a 32-bit alignment. Non-aligned accesses (ERRADDR[1:0] non-0) are reported with the address aligned and data is reported in RERRDR accordingly shifted. In case of errors detected in accesses larger than 32-bit (as performed by FlexCAN internal processes), the address of the 32-bit word which the error was detected is reported. In case of errors detected in more than one 32-bit word, only the least significant address is reported.

Table 438. Source of memory access

Table continued from the previous page...

Field	Function
	• 0 = Move • 1 = Scanning SAID[0] — Operation that requested the memory read: • 0 = Transmission • 1 = Reception For more information see Table 438.
15-14 —	Reserved
13-0 ERRADDR	Address Where Error Detected See the description of the Error Injection Address Register (ERRIAR).

70.6.2.28 Error Report Data Register (RERRDR)

Offset

Register	Offset
RERRDR	AF4h

Function

Reports the raw data (unmodified by the correction performed by ECC logic) read from memory with error. The value reported does not represent the transient values of the BUSY bit (see Table 443) when reading a message buffer.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-0 RDATA	Raw data word read from memory with error

70.6.2.29 Error Report Syndrome Register (RERRSYNR)

Offset

Register	Offset
RERRSYNR	AF8h

Function

Holds the syndrome detected in a memory read with error. It also reports the bytes which were read in this 32-bit read transaction.

Each SYNDn field indicates the type of error and which bit in byte (n) is affected by the error. (SYND3 corresponds to the most significant byte in the data word read from memory; SYND0 corresponds to the least significant.)

Table 439. Syndrome definition

SYNDn (hex)	Type	Bit affected
00	—	none (no error)
01	Code	0
02	Code	1
04	Code	2
07	Data	5
08	Code	3
0E	Data	7
10	Code	4
13	Data	2
15	Data	6
16	Data	1
19	Data	3
1A	Data	4
1C	Data	0
06	—	All-zeros non-correctable error
1F	—	All-ones non-correctable error
All others	—	Non-correctable error

Each BEn field indicates which byte in the 32-bit word reported was effectively read. The syndrome bits are calculated for all bytes, even for the non-read ones. Errors detected in non-read bytes are indicated (see Error indication) and reported (see Error reporting).

0 CEIOF	Correctable Error Interrupt Overrun Flag Indicates that a correctable error was detected in a memory read when CEIF was set. No interrupt is associated to this flag. See Error indication. 0b - No overrun on correctable errors 1b - Overrun on correctable errors

70.6.2.31 Enhanced CAN Bit Timing Prescalers (EPRS)

Offset

Register	Offset
EPRS	BF0h

Function

This register defines the CAN bit timing prescalers for the nominal phase and data phase when CTRL2[BTE] is set.

This register is used by the hardware only if CTRL2[BTE] is set; otherwise a write operation has no effect and all fields are read as zero.

This register can be written only in Freeze mode because it is blocked by hardware in other modes.

The contents of this register are not affected by soft reset.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
25-16 EDPRESDIV	Extended Data Phase Prescaler Division Factor This field defines the ratio between the PE clock frequency and the serial clock (Sclock) frequency in the data phase of a CAN FD message when CTRL2[BTE] is set. The Sclock period defines the time quantum of the CAN FD protocol for the data bit rate. Sclock frequency = PE clock frequency / (EDPRESDIV + 1). **NOTE** To minimize errors when processing FD frames, use the same value for ENPRESDIV and EDPRESDIV. For more details see the first NOTE in section CAN FD frames.
15-10 —	Reserved
9-0 ENPRESDIV	Extended Nominal Prescaler Division Factor This field defines the ratio between the PE clock frequency and the serial clock (Sclock) frequency when CTRL2[BTE] is set; otherwise it reads as zero and a write operation has no effect. The Sclock period defines the time quantum of the CAN protocol in the nominal phase. For the reset value, the Sclock frequency is equal to the PE clock frequency (see Protocol timing). Sclock frequency = PE clock frequency / (ENPRESDIV + 1)

70.6.2.32 Enhanced Nominal CAN Bit Timing (ENCBT)

Offset

Register	Offset
ENCBT	BF4h

Function

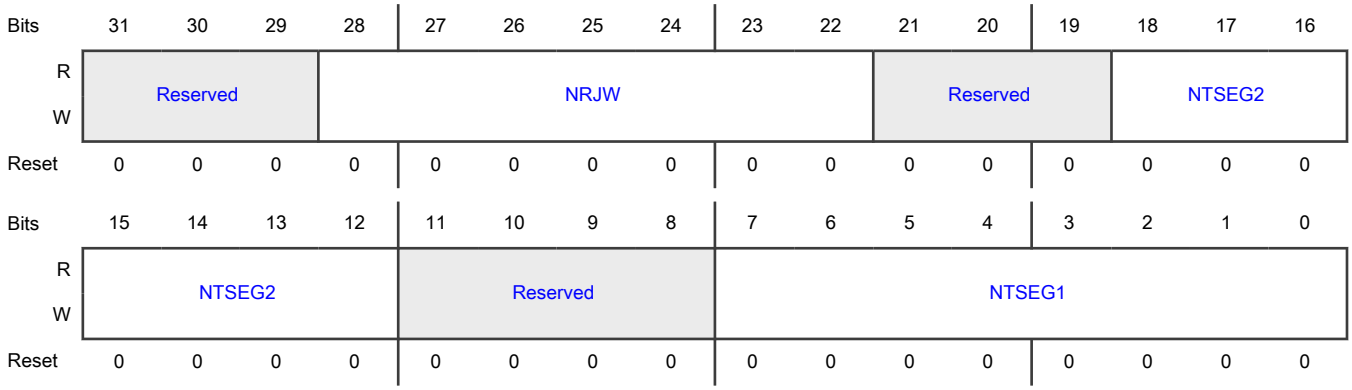
This register provides an alternative way to store the CAN bit timing variables described in the CTRL1 and CBT registers, to get higher CAN bit timing resolution.

This register is used by the hardware only if CTRL2[BTE] is set; otherwise a write operation has no effect and all fields are read as zero.

The contents of this register are not affected by soft reset.

This register can be written only in Freeze mode because it is blocked by hardware in other modes.

Diagram



Fields

Field	Function
31-29 —	Reserved
28-22 NRJW	Nominal Resynchronization Jump Width This field defines the maximum number of time quanta that a nominal bit time can be changed by one resynchronization when CTRL2[BTE] bit is asserted; otherwise it has no effect. One time quantum is equal to the Sclock period. Nominal Resync Jump Width = NRJW + 1.
21-19 —	Reserved
18-12 NTSEG2	Nominal Time Segment 2 This field defines the length of Time Segment 2 in the nominal bit time when CTRL2[BTE] is set; otherwise it has no effect. Nominal Time Segment 2 = (NTSEG2 + 1) × Time-Quanta. Time-Quantum = one Sclock period.
11-8 —	Reserved
7-0 NTSEG1	Nominal Time Segment 1 This field defines the length of Time Segment 1 in the bit time when CTRL2[BTE] is set; otherwise it has no effect. Nominal Time Segment 1 = (NTSEG1 + 1) × Time-Quanta. Time-Quantum = one Sclock period.

70.6.2.33 Enhanced Data Phase CAN bit Timing (EDCBT)

Offset

Register	Offset
EDCBT	BF8h

Function

This register provides an alternative way to store the data phase CAN bit timing variables described in the FDCBT register to achieve higher CAN bit timing resolution.

This register is used by the hardware only if CTRL2[BTE] is set; otherwise a write operation has no effect and all fields are read as zero.

The contents of this register are not affected by soft reset.

This register can be written only in Freeze mode because it is blocked by hardware in other modes.

NOTE

The user must ensure bit time settings and protocol engine tolerance are in compliance with the CAN Protocol standard (ISO 11898-1).

NOTE

DTSEG1 must be at least two time quanta.

70.6.2.34 Enhanced Transceiver Delay Compensation (ETDC)

Offset

Register	Offset
ETDC	BFCh

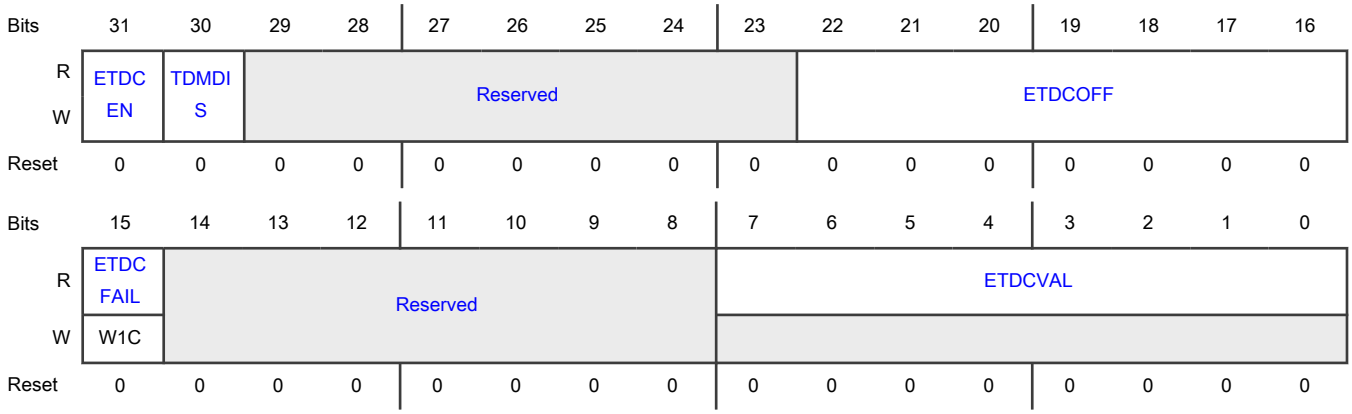
Function

This register contains extended versions of the fields FDCTRL[TDCOFF] and FDCTRL[TDCVAL]. This register is used by the hardware only if CTRL2[BTE] is set; otherwise, a write operation has no effect and all fields are read as zero.

NOTE

See Transmitter delay compensation in the CAN Protocol standard (ISO 11898-1) for details.

Diagram



Fields

Field	Function
31 ETDCEN	Transceiver Delay Compensation Enable This bit can be used for enabling and disabling the TDC feature. It can be written in Freeze mode only. **NOTE** Refer to Transmitter delay compensation in the CAN Protocol standard (ISO 11898-1) for details. **NOTE** TDC must be disabled when the Loop Back Mode is enabled (see CTRL1[LPB] register). 0b - TDC is disabled 1b - TDC is enabled
30 TDMDIS	Transceiver Delay Measurement Disable This bit can be used for disabling the transceiver delay measurement. When the TDC measurement is disabled, the secondary sample point position is determined only by the enhanced TDC offset (ETDCOFF) field. Otherwise, if the TCD measurement is enabled, then the secondary sample point position is determined by the sum of the transceiver delay measurement plus the enhanced TDC offset. This field is not affected by soft reset. **NOTE** This bit can be enabled only if CTRL2[BTE] is set. 0b - TDC measurement is enabled 1b - TDC measurement is disabled
29-23 —	Reserved
22-16 ETDCOFF	Enhanced Transceiver Delay Compensation Offset

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field contains the offset value to be added to the measured transceiver's loop delay in order to define the position of the delayed comparison point when bit rate switching is active. See Transceiver delay compensation for more details on how the loop delay measurement is performed. ETDCOFF can be written in Freeze mode only. Its value can be defined in protocol engine (PE) clock periods (CANCLK, see Protocol timing for more details), and must be selected to be smaller than the CAN bit duration in the data bit rate for proper operation. **NOTE** ETDCOFF must not be configured as zero. **NOTE** If CTRL2[BTE] is set after a chip level hard reset, ETCDOFF is read as 1h.
15 ETDCFAIL	Transceiver Delay Compensation Fail This bit indicates when the Transceiver Delay Compensation (TDC) mechanism is out of range, unable to compensate the transceiver's loop delay and successfully compare the delayed received bits to the transmitted ones (see Transceiver delay compensation). ETDCFAIL sets in the first time FlexCAN detects the out of range condition. The CPU needs to write 1 to clear it. 0b - Measured loop delay is in range. 1b - Measured loop delay is out of range.
14-8 —	Reserved
7-0 ETDCVAL	Enhanced Transceiver Delay Compensation Value This register contains the ETDCOFF field added to the measured value of the transceiver loop delay in the latest transmitted CAN FD frame, with BRS equal to recessive. This field is only updated by the hardware if ETDC[ETDCEN] is set. This field is affected by soft reset. **NOTE** If TDMDIS is set, ETDCVAL stores ETDCOFF only.

70.6.2.35 CAN FD Control Register (FDCTRL)

Offset

Register	Offset
FDCTRL	C00h

Function

This register contains control bits for the CAN FD operation. It also defines the data size of message buffers allocated in different partitions of RAM (memory blocks) as described in the table below.

When an 8-byte payload is selected:

- Block R0 allocates MB0 to MB31.
- Block R1 allocates MB32 to MB63.
- Block R2 allocates MB64 to MB95.

When a payload larger than 8 bytes is selected, the maximum number of MBs in a block is limited as described below:

Table 440. Number of message buffers

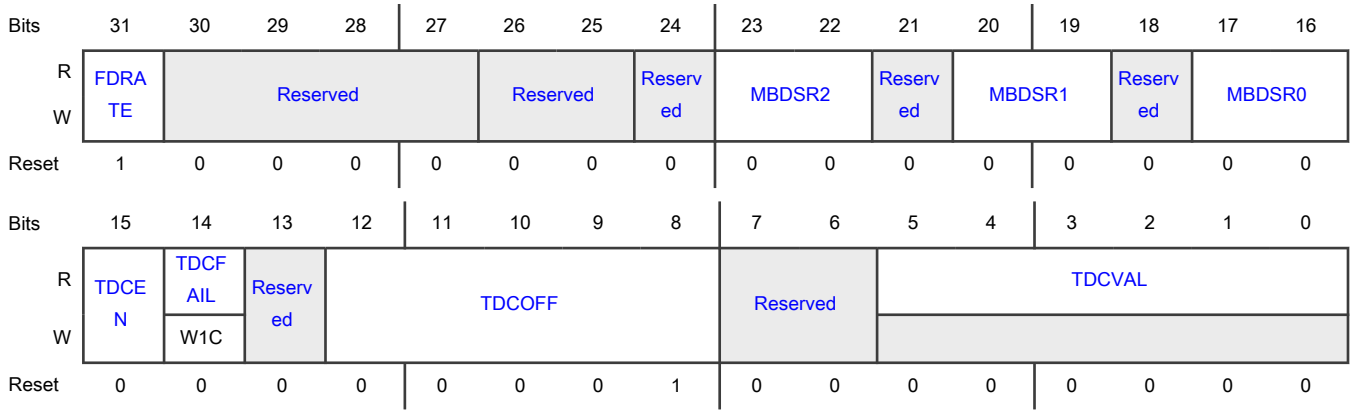
Payload size	Maximum number of message buffers per RAM block
8 bytes	32
16 bytes	21
32 bytes	12
64 bytes	7

NOTE

One memory block fits exactly 32 MBs with an 8-byte payload. For other possible payload sizes, empty memory may exist between the last MB in a block and the beginning of the next block. This empty memory corresponds to less than one MB, and must not be used.

The contents of this register are not affected by soft reset.

Diagram



Fields

Field	Function
31 FDRATE	Bit Rate Switch Enable This bit enables the effect of the Bit Rate Switch (BRS bit) during the data phase of Tx messages. The CPU can write this bit any time. However, its effect turns active only when the CAN bus is in Wait for Bus Idle, Bus Idle, or Bus Off state, or when the current frame under reception or transmission reaches the interframe space. By negating FDCTRL[FDRATE], the CPU can force all bits in CAN FD messages to be transmitted in nominal bit rate, no matter what the value is in the BRS bit of the Tx MBs.

Table continues on the next page...

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE See Transmitter delay compensation in the CAN Protocol standard (ISO 11898-1) for details. **NOTE** TDC must be disabled when Loop Back mode is enabled (see CTRL1[LPB]). **NOTE** If CTRL2[BTE] is set, TDCEN is read as zero and a write operation has no effect. 0b - TDC is disabled 1b - TDC is enabled
14 TDCFAIL	Transceiver Delay Compensation Fail This bit indicates when the Transceiver Delay Compensation (TDC) mechanism is out of range, unable to compensate the transceiver's loop delay and successfully compare the delayed received bits to the transmitted ones (see Transceiver delay compensation). TDCFAIL sets in the first time FlexCAN detects the out of range condition. The CPU needs to write one to clear it. **NOTE** If CTRL2[BTE] is set, TDCFAIL is read as zero and a write operation has no effect. 0b - Measured loop delay is in range. 1b - Measured loop delay is out of range.
13 —	Reserved
12-8 TDCOFF	Transceiver Delay Compensation Offset This bit field contains the offset value to be added to the measured transceiver's loop delay in order to define the position of the delayed comparison point when bit rate switching is active. See Transceiver delay compensation for more details on how the loop delay measurement is performed. TDCOFF can be written in Freeze mode only. Its value can be defined in Protocol Engine (PE) Clock periods (CANCLK, see Protocol timing for more details), and must be selected to be smaller than the CAN bit duration in the data bit rate for proper operation. **NOTE** If CTRL2[BTE] is set, TDCOFF is read as zero and a write operation has no effect. **NOTE** It is not recommended to have TDCOFF equal to zero.
7-6 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
5-0 TDCVAL	Transceiver Delay Compensation Value This register contains the value of the transceiver loop delay measured from the transmitted EDL to R0 transition edge to the respective received one added to the TDCOFF value specified in the FDCTRL register. This value is an integer multiple of the Protocol Engine (PE) Clock period (CANCLK). **NOTE** If CTRL2[BTE] is set, TDCVAL is read as zero. See Protocol timing for more details on how the loop delay measurement is performed.

70.6.2.36 CAN FD Bit Timing Register (FDCBT)

Offset

Register	Offset
FDCBT	C04h

Function

This register stores the CAN bit timing variables used in the data phase of CAN FD messages when the FDCTRL[FDRATE] is set, compatible with CAN FD specification. FPRESDIV, FPROPSEG, FPSEG1, FPSEG2, and FRJW are used to define the time quantum duration, the number of time quanta per CAN bit, and the sample point position for the data bit rate portion of a CAN FD message with the BRS bit set.

The contents of this register are not affected by soft reset.

NOTE

The sum of the Fast Propagation Segment (FPROPSEG) and Fast Phase Segment 1 (FPSEG1) must be at least two time quanta.

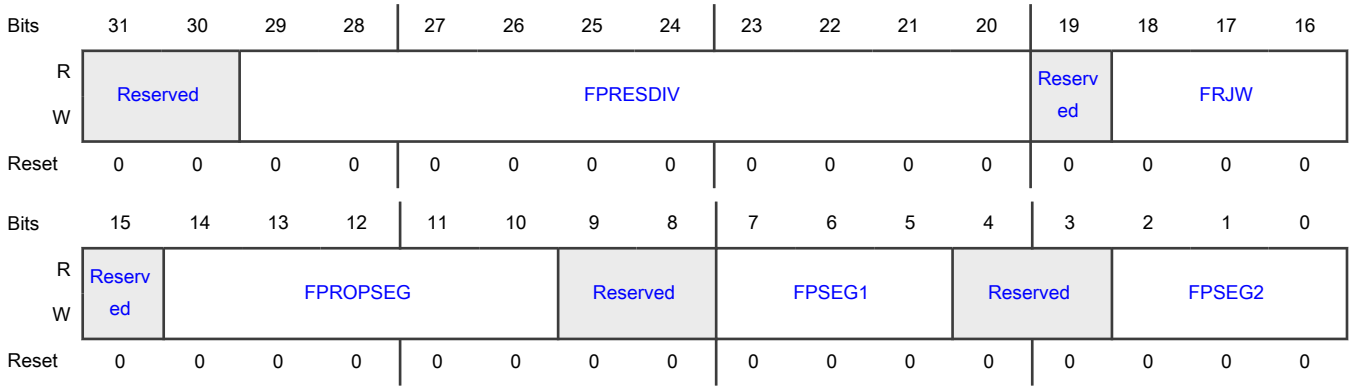
NOTE

The user must ensure bit time settings and protocol engine tolerance are in compliance with the CAN Protocol standard (ISO 11898-1).

NOTE

If CTRL2[BTE] is set, the FDCBT register is read as zero and a write operation has no effect.

Diagram



Fields

Field	Function
31-30 —	Reserved
29-20 FPRESDIV	Fast Prescaler Division Factor This 10-bit field defines the ratio between the PE clock frequency and the serial clock (Sclock) frequency in the data bit rate portion of a CAN FD message with the BRS bit set. The Sclock period defines the time quantum of the CAN FD protocol for the data bit rate. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Sclock frequency = PE clock frequency / (FPRESDIV + 1). **NOTE** To minimize errors when processing FD frames, use the same value for FPRESDIV and PRESDIV (in CBT or CTRL1). For more details see the first NOTE in section CAN FD frames.
19 —	Reserved
18-16 FRJW	Fast Resync Jump Width This 3-bit field defines the maximum number of time quanta that a bit time can be changed by one resynchronization in the data bit rate portion of a CAN FD message with the BRS bit set. One time quantum is equal to the Sclock period. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Resync Jump Width = FSJW + 1.
15 —	Reserved
14-10	Fast Propagation Segment

Table continues on the next page...

Table continued from the previous page...

Field	Function
FPROPSEG	This 5-bit field defines the length of the propagation segment in the bit time in the data bit rate portion of a CAN FD message with the BRS bit set. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Propagation Segment Time = FPROPSEG × Time-Quanta. Time-Quantum = one Sclock period.
9-8 —	Reserved
7-5 FPSEG1	Fast Phase Segment 1 This 3-bit field defines the length of phase segment 1 in the bit time in the data bit rate portion of a CAN FD message with the BRS bit set. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Phase Segment 1 = (FPSEG1 + 1) × Time-Quanta. Time-Quantum = one Sclock period.
4-3 —	Reserved
2-0 FPSEG2	Fast Phase Segment 2 This 3-bit field defines the length of phase segment 2 in the data bit rate portion of a CAN FD message with the BRS bit set. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Phase Segment 2 = (FPSEG2 + 1) × Time-Quanta. Time-Quantum = one Sclock period.

70.6.2.37 CAN FD CRC Register (FDCRC)

Offset

Register	Offset
FDCRC	C08h

Function

This register provides information about the CRC of transmitted messages.

FlexCAN uses different CRC polynomials for different frame formats, as shown below.

The CRC_15 polynomial is used for all frames in CAN format. The CRC_17 polynomial is used for frames in CAN FD format with a DATA FIELD up to sixteen bytes. The CRC_21 polynomial is used for frames in CAN FD format with a DATA FIELD longer than sixteen bytes. Each polynomial shown below results in a Hamming distance of 6. This register is updated at the same time the Tx Interrupt flag is asserted.

$$CRC\_15 = C599h: \ (x^{15} + x^{14} + x^{10} + x^8 + x^7 + x^4 + x^3 + 1)$$

$$CRC\_17 = 3685Bh: \ (x^{17} + x^{16} + x^{14} + x^{13} + x^{11} + x^6 + x^4 + x^3 + x^1 + 1)$$

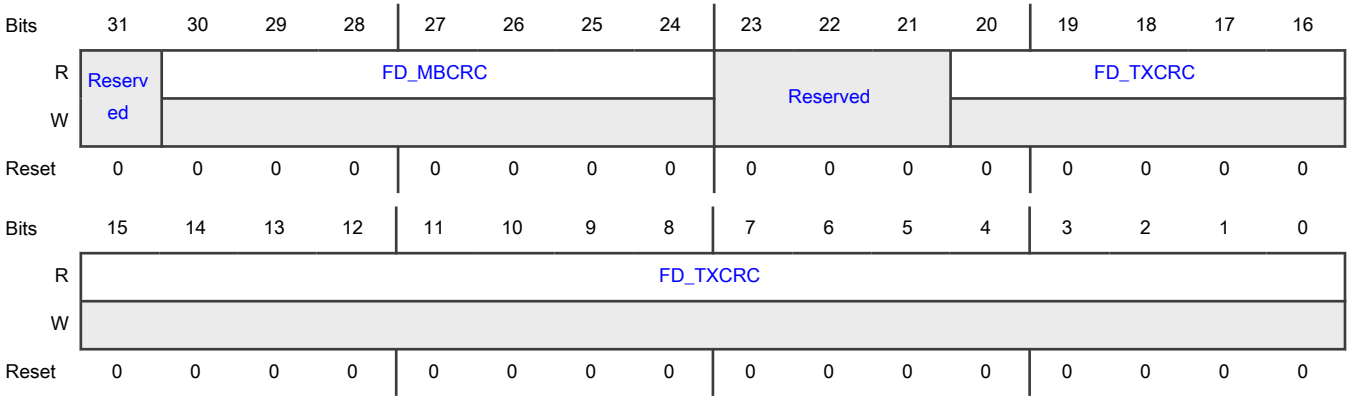
$$CRC\_21 = 302899h: \ (x^{21} + x^{20} + x^{13} + x^{11} + x^7 + x^4 + x^3 + 1)$$

Equation 28. CRC polynomial used on CAN frame

NOTE

See CRC sequence calculation in the CAN Protocol standard (ISO 11898-1) for details.

Diagram



Fields

Field	Function
31 —	Reserved
30-24 FD_MBCRC	CRC Mailbox Number for FD_TXCRC This field indicates the number of the mailbox corresponding to the value in the FD_TXCRC field, for both FD and non-FD frames. It reports the same information as in CRCR[MBCRC].
23-21 —	Reserved
20-0 FD_TXCRC	Extended Transmitted CRC value This 21-bit field contains the CRC value calculated over the most recent transmitted message. Different CRC polynomials are used for different frame formats. A 15-bit polynomial, CRC_15, is used for all frames in CAN format. The second 17-bit polynomial, CRC_17, is used for frames in CAN FD format with a data field up to sixteen bytes long. The third 21-bit polynomial, CRC_21, is used for frames in CAN FD format with a data field longer than sixteen bytes.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	For CRC_15 and CRC_17, the 6 most significant bits and the 4 most significant bits are reported as zeros, respectively. For CRC_15, this register has the same content as CRC register.

70.6.2.38 Enhanced Rx FIFO Control Register (ERFCR)

Offset

Register	Offset
ERFCR	C0Ch

Function

This register defines the Enhanced Rx FIFO configuration.

This register can be written only in Freeze mode.

All the contents of this register are affected by soft reset.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
CAN_0	ERFCR	—
CAN_1	—	ERFCR
CAN_2	—	ERFCR
CAN_3	—	ERFCR
CAN_4	—	ERFCR
CAN_5	—	ERFCR

Fields

Field	Function
31 ERFUFW	Enhanced Rx FIFO Underflow This field indicates that an underflow condition occurred in the enhanced Rx FIFO. This field generates an interrupt if ERFIER[ERFUFWIE] is set. 0b - No such occurrence 1b - Enhanced Rx FIFO underflow
30 ERFOVF	Enhanced Rx FIFO Overflow This field indicates that an overflow condition occurred in the Enhanced Rx FIFO. This field generates an interrupt if ERFIER[ERFOVFIE] is set. 0b - No such occurrence 1b - Enhanced Rx FIFO overflow
29 ERFWMI	Enhanced Rx FIFO Watermark Indication This field is set by the hardware if the number of messages available in the Enhanced Rx FIFO is greater than the watermark defined in ERFCR[ERFWM]. This field generates an interrupt if ERFIER[ERFWMIIE] is set. 0b - No such occurrence

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - The number of messages in FIFO is greater than the watermark
28 ERFDA	Enhanced Rx FIFO Data Available This field is set by the hardware when there is at least one message stored in the ERX FIFO. This field generates an interrupt if ERFIER[ERFDAIE] is set. 0b - No such occurrence 1b - There is at least one message stored in Enhanced Rx FIFO
27 ERFCLR	Enhanced Rx FIFO Clear Writing one to this field during Freeze mode clears Enhanced Rx FIFO content. Writing out of Freeze mode or writing zero to this field has no effect. 0b - No effect 1b - Clear Enhanced Rx FIFO content
26-18 —	Reserved
17 ERFE	Enhanced Rx FIFO empty This field indicates that Enhanced Rx FIFO is empty. 0b - Enhanced Rx FIFO is not empty 1b - Enhanced Rx FIFO is empty
16 ERFF	Enhanced Rx FIFO full This field indicates that Enhanced Rx FIFO is full. 0b - Enhanced Rx FIFO is not full 1b - Enhanced Rx FIFO is full
15 —	Reserved
14-6 —	Reserved
5-0 ERFEL	Enhanced Rx FIFO Elements This field indicates the number of CAN messages stored in the Enhanced Rx FIFO.

70.6.2.41 High Resolution Time Stamp (HR_TIME_STAMP0 - HR_TIME_STAMP95)

Offset

For n = 0 to 95:

Register	Offset
HR_TIME_STAMPn	C30h + (n × 4h)

Function

The High Resolution Time Stamp registers are used for storing a copy of a 32-bit timer at the start or end of a CAN frame.

HRST0 stores the 32-bit time stamp associated with MB0, HRSTS1 stores the the 32-bit time stamp associated with MB1, and so on.

These registers are not affected by reset.

NOTE

These registers must not be written out of Freeze mode.

Table 441. High Resolution Time Stamp register operation

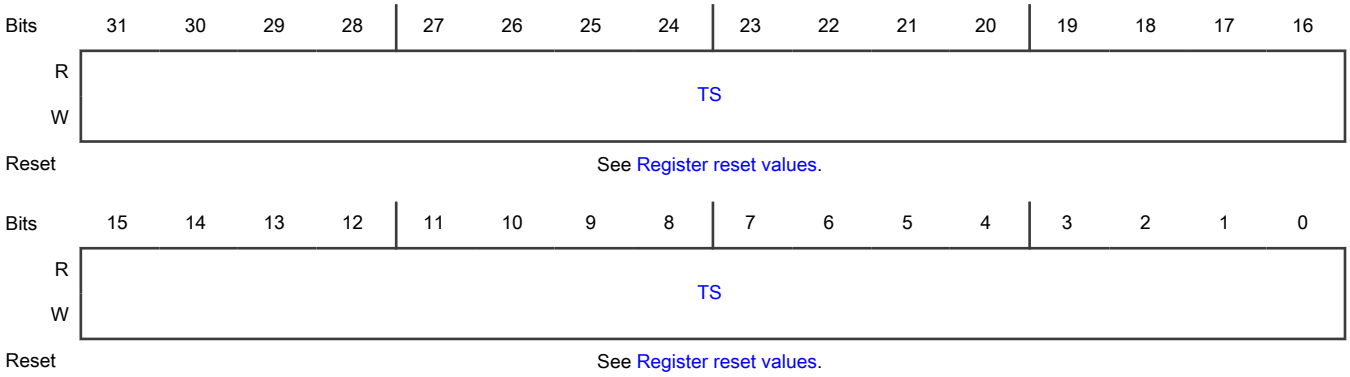
TSTAMPCAP	Captured time base	Capture point
b00	None	None
b01	32 bits of high-resolution on-chip timer	Seventh bit of the end of frame field for transmission and sixth bit of the end of frame field for reception.
b10	32 bits of high-resolution on-chip timer	Start of frame.
b11	32 bits of high-resolution on-chip timer	Start of frame for classical CAN frame format and res bit for CAN FD frame format.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
CAN_0	HR_TIME_STAMP0–HR_TIME_STAMP95	—
CAN_1	HR_TIME_STAMP0–HR_TIME_STAMP63	HR_TIME_STAMP64–HR_TIME_STAMP95
CAN_2	HR_TIME_STAMP0–HR_TIME_STAMP63	HR_TIME_STAMP64–HR_TIME_STAMP95
CAN_3	HR_TIME_STAMP0–HR_TIME_STAMP31	HR_TIME_STAMP32–HR_TIME_STAMP95
CAN_4	HR_TIME_STAMP0–HR_TIME_STAMP31	HR_TIME_STAMP32–HR_TIME_STAMP95
CAN_5	HR_TIME_STAMP0–HR_TIME_STAMP31	HR_TIME_STAMP32–HR_TIME_STAMP95

Diagram



Register reset values

Register	Reset value
HR_TIME_STAMP0–HR_TIME_STAMP31	CAN_0–CAN_5: undefined
HR_TIME_STAMP32–HR_TIME_STAMP63	CAN_0–CAN_2: undefined CAN_3–CAN_5: Register not supported
HR_TIME_STAMP64–HR_TIME_STAMP95	CAN_0: undefined CAN_1–CAN_5: Register not supported

Fields

Field	Function
31-0 TS	High Resolution Time Stamp HR_TIME_STAMP register which captures the copy of timestamp of corresponding MB always captures 32-bit timer value.

70.6.2.42 Enhanced Rx FIFO Filter Element (ERFFEL0 - ERFFEL127)

Offset

For n = 0 to 127:

Register	Offset
ERFFELn	3000h + (n × 4h)

Function

These registers are used for storing the filter elements of the Enhanced Rx FIFO.

For standard ID filtering, each ERFFEL register stores one filter element. For extended ID filtering, each pair of ERFFEL registers stores one filter element.

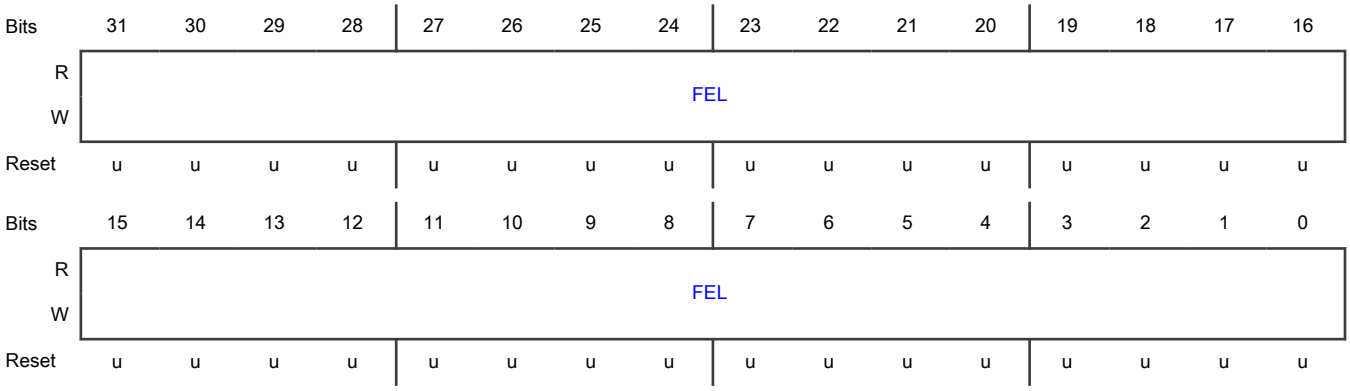
ERFFEL registers can be written only in Freeze mode; otherwise, they are blocked by hardware. These registers are not affected by reset. They are located in RAM and must be explicitly initialized prior to any reception.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
CAN_0	ERFFEL0–ERFFEL127	—
CAN_1	—	ERFFEL0–ERFFEL127
CAN_2	—	ERFFEL0–ERFFEL127
CAN_3	—	ERFFEL0–ERFFEL127
CAN_4	—	ERFFEL0–ERFFEL127
CAN_5	—	ERFFEL0–ERFFEL127

Diagram



Fields

Field	Function
31-0 FEL	Filter Element Bits Each filter element is used during the match process and, if the matching criteria are met, a message is stored in the Enhanced Rx FIFO.

70.6.3 Message buffer structure

The message buffer structure used by the FlexCAN module is represented in the following figure. Both extended (29-bit identifier) and standard (11-bit identifier) frames used in the CAN specification (Version 2.0 Part B) are represented. Each individual MB is formed by 16, 24, 40, or 72 bytes, depending on the quantity of data bytes allocated for the message payload: 8, 16, 32, or 64 data bytes, respectively.

The memory area 80h–67Fh is used by the mailboxes. When CAN FD is enabled, the exact address for each MB depends on the size of its payload. See FlexCAN memory partition for CAN FD for more detailed information.

Table 442. Message buffer structure — example with 64-byte payload

	31	30	29	28	27	24	23	22	21	20	19	18	17	16	15	8	7	0

44h	Data byte 60						Data byte 61								Data byte 62		Data byte 63	

= Unimplemented or reserved

EDL — Extended Data Length

This bit distinguishes between CAN format and CAN FD format frames. The EDL bit must not be set for message buffers configured to RANSWER with code field 1010b (see table below).

BRS — Bit Rate Switch

This bit defines whether the bit rate is switched inside a CAN FD format frame.

ESI — Error State Indicator

This bit indicates if the transmitting node is error active or error passive.

CODE — Message Buffer Code

This 4-bit field can be accessed (read or write) by the CPU and by the FlexCAN module itself, as part of the message buffer matching and arbitration process. The encoding is shown in Table 443 and Table 444. See Functional description for additional information.

Table 443. Message buffer code for Rx buffers

CODE description	Rx code BEFORE receive new frame	SRV[1]	Rx code AFTER successful reception[2]	RRS[3]	Comment
0000b: INACTIVE — MB is not active.	INACTIVE	—	—	—	MB does not participate in the matching process.
0100b: EMPTY — MB is active and empty.	EMPTY	—	FULL	—	When a frame is received successfully (after the Move-in process), the CODE field is automatically updated to FULL.
0010b: FULL — MB is full.	FULL	Yes	FULL	—	The act of reading the C/S word followed by unlocking the MB (SRV) does not make the code return to EMPTY. It remains FULL. If a new frame is moved to the MB after the MB was serviced, the code still remains FULL. See Matching process for matching details related to FULL code.
		No	OVERRUN	—	If the MB is FULL and a new frame is moved to this MB before the CPU services it, the CODE field is automatically updated to OVERRUN. See Matching process for details about overrun behavior.

Table continues on the next page...

Table 443. Message buffer code for Rx buffers (continued)

CODE description	Rx code BEFORE receive new frame	SRV[1]	Rx code AFTER successful reception[2]	RRS[3]	Comment
0110b: OVERRUN — MB is being overwritten into a full buffer.	OVERRUN	Yes	FULL	—	If the CODE field indicates OVERRUN and CPU has serviced the MB, when a new frame is moved to the MB then the code returns to FULL.
		No	OVERRUN	—	If the CODE field already indicates OVERRUN, and another new frame must be moved, the MB will be overwritten again, and the code will remain OVERRUN. See Matching process for details about overrun behavior.
1010b: RANSWER[4] — A frame was configured to recognize a Remote Request frame and transmit a Response frame in return.[5]	RANSWER	—	TANSWER(1110b)	0	A Remote Answer was configured to recognize a remote request frame received. After that an MB is set to transmit a response frame. The code is automatically changed to TANSWER (1110b). See Matching process for details. If CTRL2[RRS] is negated, transmit a response frame whenever a remote request frame with the same ID is received.
		—	—	1	This code is ignored during

Table continues on the next page...

Table 443. Message buffer code for Rx buffers (continued)

CODE description	Rx code BEFORE receive new frame	SRV[1]	Rx code AFTER successful reception[2]	RRS[3]	Comment
					matching and arbitration process. See Matching process for details.
CODE[0]=1: BUSY — FlexCAN is updating the contents of the MB. The CPU must not access the MB.	BUSY[6]	—	FULL	—	Indicates that the MB is being updated. It will be negated automatically and does not interfere with the next CODE.
		—	OVERRUN	—	

1. SRV: Serviced MB. MB was read and unlocked by reading TIMER or other MB.
2. A frame is considered a successful reception after the frame to be moved to MB (move-in process). See Move-in for details.
3. Remote Request Stored bit, see "Control 2 register (CTRL2)" for details.
4. Code 1010b is not considered Tx and an MB with this code should not be aborted.
5. Code 1010b must be used in message buffers configured in CAN FD format, having the EDL bit set.
6. Note that for Tx MBs, the BUSY bit should be ignored upon read, except when AEN bit is set in the MCR register. If this bit is asserted, the corresponding MB does not participate in the matching process.

Table 444. Message buffer code for Tx buffers

CODE Description	Tx Code BEFORE tx frame	MB RTR	Tx Code AFTER successful transmission	Comment
1000b: INACTIVE — MB is not active	INACTIVE	—	—	MB does not participate in arbitration process.
1001b: ABORT — MB is aborted	ABORT	—	—	MB does not participate in arbitration process.
1100b: DATA — MB is a Tx data frame (MB RTR must be 0)	DATA	0	INACTIVE	Transmit data frame unconditionally once. After transmission, the MB automatically returns to the INACTIVE state.
1100b: REMOTE — MB is a Tx Remote Request frame (MB RTR must be 1)	REMOTE	1	EMPTY	Transmit remote request frame unconditionally once. After transmission, the MB automatically becomes an Rx Empty MB with the same ID.

Table continues on the next page...

Table 444. Message buffer code for Tx buffers (continued)

CODE Description	Tx Code BEFORE tx frame	MB RTR	Tx Code AFTER successful transmission	Comment
1110b: TANSWER — MB is a Tx Response frame from an incoming Remote Request frame	TANSWER	—	RANSWER	This is an intermediate code that is automatically written to the MB by the CHI as a result of a match to a remote request frame. The remote response frame will be transmitted unconditionally once, and then the code will automatically return to RANSWER (1010b). The CPU can also write this code with the same effect. The remote response frame can be either a data frame or another remote request frame depending on the RTR bit value. See Matching process and Arbitration process for details.

SRR — Substitute Remote Request

Fixed recessive bit, used only in extended format. It must be set to one by the user for transmission (Tx Buffers) and will be stored with the value received on the CAN bus for Rx receiving buffers. It can be received as either recessive or dominant. If FlexCAN receives this bit as dominant, then it is interpreted as an arbitration loss.

1 = Recessive value is compulsory for transmission in extended format frames

0 = Dominant is not a valid value for transmission in extended format frames

IDE — ID Extended Bit

This field identifies whether the frame format is standard or extended.

1 = Frame format is extended

0 = Frame format is standard

RTR — Remote Transmission Request

This bit affects the behavior of remote frames and is part of the reception filter. See Table 443, Table 444, and the description of the RRS field in Control 2 register (CTRL2) for additional details.

If FlexCAN transmits this bit as '1' (recessive) and receives it as '0' (dominant), it is interpreted as an arbitration loss. If this bit is transmitted as '0' (dominant), then if it is received as '1' (recessive), the FlexCAN module treats it as a bit error. If the value received matches the value transmitted, it is considered a successful bit transmission.

1 = Indicates the current MB may have a remote request frame to be transmitted if MB is Tx. If the MB is Rx then incoming remote request frames may be stored.

0 = Indicates the current MB has a data frame to be transmitted. In Rx MB it may be considered in matching processes.

NOTE

When configuring CAN FD frames, the RTR bit must be negated.

DLC — Length of Data in Bytes

This 4-bit field is the length (in bytes) of the Rx or Tx data, which is located in offset 8h–Fh of the MB space (see Table 442). In reception, this field is written by the FlexCAN module, copied from the DLC (Data Length Code) field of the received frame. In transmission, this field is written by the CPU and corresponds to the DLC field value of the frame to be transmitted. When RTR = 1, the frame to be transmitted is a remote frame and does not include the data field, regardless of the DLC field (see Table 446).

TIME STAMP — Free-Running Counter Time Stamp

This 16-bit field is a copy of the Free-Running Timer, captured for Tx and Rx frames at the time when the beginning of the Identifier field appears on the CAN bus.

Table 445. Time stamp operation

TSTAMPCAP	MBTSBASE	TIMER_SOURCE	Captured time base	Capture point
b00	bxx	0	CAN_TIMER incremented by CAN bit clock	Second bit of identifier field
b00	bxx	1	CAN_TIMER incremented by on-chip timer clock	Second bit of identifier field
bxx	b00	0	CAN_TIMER incremented by CAN bit clock	Second bit of identifier field
bxx	b00	1	CAN_TIMER incremented by on-chip timer clock	Second bit of identifier field
b01	b01	x	Lower 16 bits of high-resolution on-chip timer	Seventh bit of the end of frame field for transmission and sixth bit of the end of frame field for reception
b01	b10	x	Upper 16 bits of high-resolution on-chip timer	Seventh bit of the end of frame field for transmission and sixth bit of the end of frame field for reception
b10	b01	x	Lower 16 bits of high-resolution on-chip timer	Start of frame
b10	b10	x	Upper 16 bits of high-resolution on-chip timer	Start of frame
b11	b01	x	Lower 16 bits of high-resolution on-chip timer	Start of frame for classical CAN frame format and res bit for CAN FD frame format
b11	b10	x	Upper 16 bits of high-resolution on-chip timer	Start of frame for classical CAN frame

Table continues on the next page...

Table 445. Time stamp operation (continued)

TSTAMPCAP	MBTSBASE	TIMER_SOURCE	Captured time base	Capture point
				format and res bit for CAN FD frame format

PRIO — Local priority

This 3-bit field is used only when MCR[LPRIO_EN] is set, and it only makes sense for Tx mailboxes. These bits are not transmitted. They are appended to the regular ID to define the transmission priority. See Arbitration process.

ID — Frame Identifier

In standard frame format, only the 11 most significant bits (28 to 18) are used for frame identification in both receive and transmit cases. The 18 least significant bits are ignored. In extended frame format, all bits are used for frame identification in both receive and transmit cases.

DATA BYTE 0 to 63 — Data Field

Up to sixty four bytes can be used for a data frame, depending on the size of payload selected for the message buffers.

For Rx frames, the data is stored as it is received from the CAN bus. DATA BYTE (*n*) is valid only if *n* is less than DLC as shown in the table below.

Table 446. DATA BYTEs validity

DLC	Valid DATA BYTEs
0	none
1	DATA BYTE 0
2	DATA BYTE 0 to 1
3	DATA BYTE 0 to 2
4	DATA BYTE 0 to 3
5	DATA BYTE 0 to 4
6	DATA BYTE 0 to 5
7	DATA BYTE 0 to 6
8	DATA BYTE 0 to 7
9	DATA BYTE 0 to 11
10	DATA BYTE 0 to 15
11	DATA BYTE 0 to 19
12	DATA BYTE 0 to 23
13	DATA BYTE 0 to 31
14	DATA BYTE 0 to 47
15	DATA BYTE 0 to 63

70.6.4 FlexCAN memory partition for CAN FD

When CAN FD is enabled, the FlexCAN RAM can be partitioned in blocks of 512 bytes. Each block can accommodate a number of message buffers which depends on the configuration provided by FDCTRL[MBDSRn] bit fields as shown in table below.

Table 447. RAM partition

RAM block	Number of MBs with 8 bytes (default range)	Size control bit field in FDCTRL register	Number of MBs of different sizes, per block
0	0 to 31	MBDSR0	MBDSR0=00, 32 MBs with 8 bytes payload MBDSR0=01, 21 MBs with 16 bytes payload MBDSR0=10, 12 MBs with 32 bytes payload MBDSR0=11, 7 MBs with 64 bytes payload
1	32 to 63	MBDSR1	MBDSR1=00, 32 MBs with 8 bytes payload MBDSR1=01, 21 MBs with 16 bytes payload MBDSR1=10, 12 MBs with 32 bytes payload MBDSR1=11, 7 MBs with 64 bytes payload
2	64 to 95	MBDSR2	MBDSR2=00, 32 MBs with 8 bytes payload MBDSR2=01, 21 MBs with 16 bytes payload MBDSR2=10, 12 MBs with 32 bytes payload MBDSR2=11, 7 MBs with 64 bytes payload

When payload sizes of 16, 32, or 64 bytes are configured in some or all RAM blocks, the total number of MBs and its respective number order may differ from the default configuration of 8 bytes. For example, suppose Block0 is configured to 8 bytes payload, Block1 to 16 bytes, Block2 to 32 bytes, Then the following table indicates how the message buffers will be arranged in RAM.

Table 448. RAM partition example

RAM block	Payload size	Number of MBs in the RAM block	Message buffer range
0	FDCTRL[MBDSR0]=00, 8 bytes payload	32	0 to 31
1	FDCTRL[MBDSR1]=01, 16 bytes payload	21	32 to 52
2	FDCTRL[MBDSR2]=10, 32 bytes payload	12	53 to 64

70.6.5 FlexCAN message buffer memory map

The FlexCAN memory buffers are allocated in memory according to the tables below.

70.6.6 Legacy Rx FIFO structure

When MCR[RFEN] is set, the memory area 80h–DCh (which is normally occupied by MBs 0–5) is used by the reception Legacy FIFO engine.

The region 80h–8Ch contains the output of the Legacy Rx FIFO which must be read by the CPU as a message buffer. This output contains the oldest message that has been received but not yet read. The region 90h–DCh is reserved for internal use of the Legacy Rx FIFO engine.

An additional memory area, which starts at E0h and may extend up to 2DCh (normally occupied by MBs 6–37) depending on the CTRL2[RFFN] field setting, contains the ID filter table (configurable from 8 to 128 table elements) that specifies filtering criteria for accepting frames into the Legacy Rx FIFO.

Out of reset, the ID filter table flexible memory area defaults to E0h and extends only to FCh, which corresponds to MBs 6 to 7 for RFFN = 0, for backward compatibility with previous versions of FlexCAN.

The following shows the Legacy Rx FIFO data structure.

Table 453. Legacy Rx FIFO structure

	31 28 24	23 22 21 20	19 18 17 16	15 8	7 0
80h	IDHIT	SRR IDE RTR	DLC	TIME STAMP	
84h		ID standard		ID extended	
88h	Data byte 0	Data byte 1		Data byte 2	Data byte 3
8Ch	Data byte 4	Data byte 5		Data byte 6	Data byte 7

Table continues on the next page...

Table 453. Legacy Rx FIFO structure (continued)

90h–DCh	Reserved
E0h	ID filter table element 0
E4h	ID filter table element 1
E8h–2D4h	ID filter table elements 2 to 125
2D8h	ID filter table element 126
2DCh	ID filter table element 127
	= Unimplemented or reserved

Each ID filter table element occupies an entire 32-bit word and can be compounded by one, two, or four Identifier Acceptance Filters (IDAF) depending on the MCR[IDAM] field setting. The following figures show the IDAF indexation.

The following table shows the three different formats of the ID table elements. Note that all elements of the table must have the same format. See Legacy Rx FIFO for more information.

Table 454. ID table structure

Format	31	30	29 24	23 16	15	14	13 8	7 1	0
A	RTR	IDE	RXIDA (standard = 29–19, extended = 29–1)						
B	RTR	IDE	RXIDB_0 (standard = 29–19, extended = 29–16)		RTR	IDE	RXIDB_1 (standard = 13–3, extended = 13–0)		
C	RXIDC_0 (std/ext = 31–24)		RXIDC_1 (std/ext = 23–16)		RXIDC_2 (std/ext = 15–8)		RXIDC_3 (std/ext = 7–0)		
	= Unimplemented or Reserved								

RTR — Remote frame

This bit specifies if remote frames are accepted into the Legacy FIFO if they match the target ID.

1 = Remote frames can be accepted and data frames are rejected

0 = Remote frames are rejected and data frames can be accepted

IDE — Extended frame

Specifies whether extended or standard frames are accepted into the Legacy FIFO if they match the target ID.

1 = Extended frames can be accepted and standard frames are rejected

0 = Extended frames are rejected and standard frames can be accepted

RXIDA — Rx frame identifier (Format A)

Specifies an ID to be used as acceptance criteria for the Legacy FIFO. In the standard frame format, only the 11 most significant bits (29 to 19) are used for frame identification. In the extended frame format, all bits are used.

RXIDB_0, RXIDB_1 — Rx frame identifier (Format B)

Specifies an ID to be used as acceptance criteria for the Legacy FIFO. In the standard frame format, the 11 most significant bits (a full standard ID) (29 to 19 and 13 to 3) are used for frame identification. In the extended frame format, all 14 bits of the field are compared to the 14 most significant bits of the received ID.

RXIDC_0, RXIDC_1, RXIDC_2, RXIDC_3 — Rx frame identifier (Format C)

Specifies an ID to be used as acceptance criteria for the Legacy FIFO. In both standard and extended frame formats, all 8 bits of the field are compared to the 8 most significant bits of the received ID.

IDHIT — Identifier acceptance filter hit indicator

This 9-bit field indicates which identifier acceptance filter was hit by the received message that is in the output of the Legacy Rx FIFO. See Legacy Rx FIFO for more information.

70.6.7 Enhanced Rx FIFO structure

When ERFCR[ERFEN] is set, the Enhanced Rx FIFO is enabled. The region 2000h–204Ch contains the output of the Enhanced Rx FIFO which must be read by the CPU as a message buffer. This output contains the oldest message that has been received but not yet read. The following table shows the Enhanced Rx FIFO data structure.

Table 455. Enhanced RX FIFO Structure

	31	30	29	28 … 24	23	22	21	20	19	18	17	16	15 … 8	7	6 … 0

14	2038h	203Ch
15	2048h	204Ch

EDL — Extended Data Length

This bit distinguishes between classical CAN format and CAN FD format frames.

0 – Classical CAN frame format

1 – CAN FD frame format

BRS — Bit Rate Switch

This bit defines whether the bit rate is switched inside a CAN FD format frame.

0 – Bit rate is not switched in a CAN FD frame

1 – Bit rate is switched in a CAN FD frame

ESI — Error State Indicator

This bit indicates if the transmitting node is error active or error passive. This bit is meaningful only if EDL = 1.

0 – Transmitting node is error active

1 – Transmitting node is error passive

SRR — Substitute Remote Request

Fixed recessive bit, used only in extended format. Transmitting nodes always send it as recessive and receiving nodes can receive it as either recessive or dominant. If FlexCAN receives this bit as dominant, then it is interpreted as an arbitration loss.

IDE — ID Extended Bit

This field identifies whether the frame format is standard or extended.

0 – Frame format is standard

1 – Frame format is extended

RTR — Remote Frame

0 = Indicates the current frame is a data frame

1 = Indicates the current frame is remote request

DLC — Data Length Code

This 4-bit field defines the number of bytes in the data field of a CAN frame (Data byte 0 to Data byte 63). When RTR = 1, the frame is a remote request and does not include the data field, regardless of the DLC field. Refer to Table 446 for more details.

LEGACY TIME STAMP — 16-bit Time Stamp

This 16-bit field is a copy of the Free-Running Timer, captured during the CAN frame. See Table 445 to find more details about legacy time stamp operation.

ID — Frame Identifier

In base frame format, only the 11 most significant bits are used for frame identification. The 18 least significant bits are ignored. In extended frame format, all bits are used for frame identification.

DATA BYTE 0 to 63 — Data Field

Up to sixty four bytes can be stored in the data field.

IDHIT — Identifier Acceptance Filter Hit Indicator

This field indicates which Enhanced Rx FIFO Filter Element (ERFFELn) was hit by the received message that is in the output of the Enhanced Rx FIFO. For each filter region, standard-ID filter space and extended-ID filter space, there is an independent index starting from zero. Table 457 shows how IDHIT is written by FlexCAN according to each filter element.

Table 457. IDHIT for Enhanced Rx FIFO

Enhanced Rx FIFO filter element — ERFFEL	ID HIT value	Filter element type
ERFFEL0	0	Extended-ID
ERFFEL1	1	Extended-ID
. . .	. . .	Extended-ID
ERFFEL(m–1)	m–1	Extended-ID
ERFFEL(m)	0	Standard-ID
ERFFEL(m+1)	1	Standard-ID
. . .	. . .	Standard-ID
ERFFEL(2n–m+1)	2x(n–m)+1	Standard-ID

NOTE

Where m = NEXIF and n = NFE. If NEXIF = 0, only standard-ID filter elements exist, and if NEXIF > NFE, then only extended-ID filter elements exist.

HR TIME STAMP — High-resolution Time Stamp

32-bit time base captured during the CAN frame. When CTRL2[TSTAMPCAP] is different from zero, a 32-bit time base is captured from a dedicated on-chip timer which operates in free running mode. See TSTAMPCAP field description in Control 2 Register (CTRL2) to find more details about capture point configuration of the high-resolution time stamp.

70.7 Glossary

Active message buffer	A message buffer is *active* if it can participate in the current matching or arbitration process.
Bus interface unit	FlexCAN submodule responsible for the interface to the CPU.
Bus off	See CAN Specification.[212]
CAN	Controller Area Network, a serial communication protocol defined in CAN Specification[212] and ISO International Standard.[213]
CHI	Controller-host interface, a FlexCAN submodule responsible for message buffer matching and arbitration algorithms.
CRC	Cyclic redundancy check
Dominant bit	A dominant bit wins the arbitration on the CAN bus. It is transmitted as 0.
Doze mode	A system low-power mode where the CPU bus remains active and a global Doze mode request is sent to all peripherals asking them to enter low power mode.
Error active	See CAN Specification.[212]
Error frame	See CAN Specification.[212]
Error passive	See CAN Specification.[212]
Form error	See CAN Specification.[212]
Hard reset	A reset coming from an external pin and/or following power-on. It resets everything.
Idle	See CAN Specification.[212]
Information processing time	See CAN Specification.[212]
Intermission	See CAN Specification.[212]
Matching elements	Data used in the matching process, such as ID, filter, mask, etc.
MB	See Message buffer.
Message buffer	Internal FlexCAN data structure containing bytes received from, or to be transmitted to, the CAN line, as well as information about this data.
Overload frame	See CAN Specification.[212]
Phase buffer segment	See CAN Specification.[212]
Recessive bit	A recessive bit loses the arbitration on the CAN bus. It is transmitted as 1.
Sclock	Serial clock. Obtained by dividing the clock feeding the CAN engine (oscillator or bus clock) by a prescaler factor. The Sclock period defines the time quantum for CAN protocol timing.

[12] Controller Area Network – CAN Specification Version 2.0 Part A, Part B, Robert Bosch GmbH, 1991.
[13] ISO International Standard – ISO 11898 First Edition 1993 Road Vehicles – Interchange of Digital Information – Controller Area Network (CAN) for high-speed Communication.

Soft reset	Global reset typically used by peripherals to reinitialize some of its registers, but not all of them.
Stop mode	A system low-power mode in which all chip clocks are stopped for maximum power savings.
Stuffing error	See CAN Specification.[212]
Time quantum	This is equal to the Sclock period. It is the minimum time period used to compose the CAN protocol bit timing.

Chapter 71
Synchronous Audio Interface (SAI)

71.1 Chip-specific SAI information

71.1.1 SAI instances and configuration

Table 458. SAI instances

Instance	MWCT2D16S/MWCT2D17S	MWCT2015S/ MWCT2016S
SAI_0	Yes	No
SAI_1	Yes	No

Table 459. SAI configuration

Chip	Instances	Synchronous operation between instances	DMA support	Data Rate/ channel	No. of Channels	Frame Synchronization	Master Clock Frequency	FIFO size(TX/RX)/ Channel	No. of words/ frame
MWCT2D16S, MWCT2D17S	SAI_0 SAI_1	No	Yes	12.288 Mbps	4 1	I2S, AC97, and CODEC/DSP interfaces	24.576 external audio	8X32 bit	8-16 words

NOTE

The SAI_BCLK (SAI_TX_BCLK, SAI_RX_BCLK), SAI_SYNC (SAI_TX_SYNC, SAI_RX_SYNC), and SAI_DATA (SAI_TX_DATA, SAI_RX_DATA) pins are shared between each module instance's (SAI_0, SAI_1) receiver and transmitter. See the IOMUX file attached to this document for details. At any specific time, either the SAI receiver or the SAI transmitter should be active or they should operate synchronously (only one active at a time). The SAI transmitter and SAI receiver should not be configured to operate simultaneously with inconsistent configurations.

NOTE

Timing specification of SAI master and SAI slave may limit maximum frequency.

71.2 Overview

The Synchronous Audio Interface (SAI) provides an interface that supports full-duplex serial interfaces with frame synchronization formats such as I^2S, AC97, TDM, and codec/DSP interfaces.

71.2.1 Block diagram

The following block diagram also shows the module clocks.

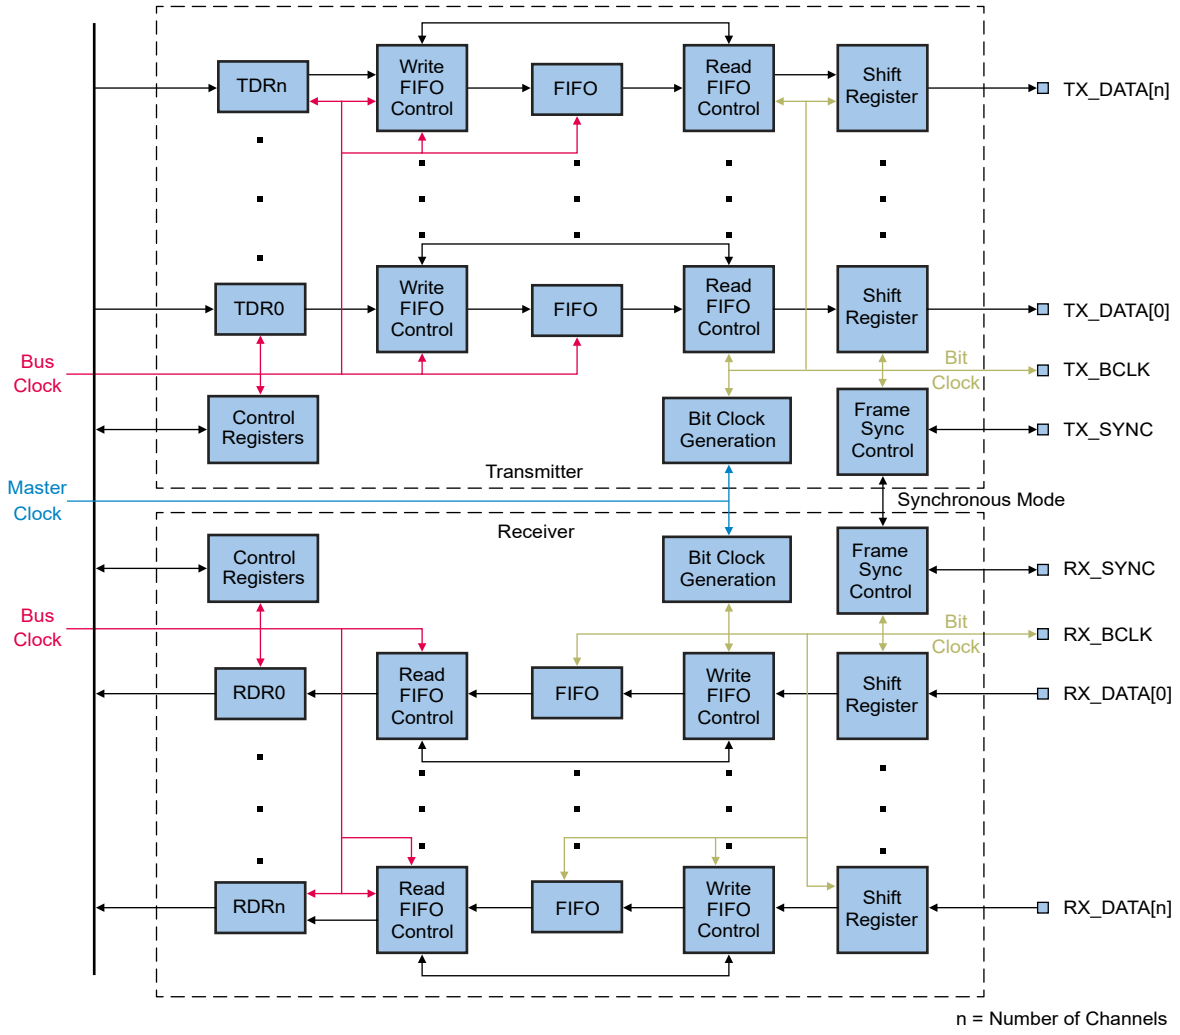

Figure 385. SAI block diagram

71.2.2 Features

Some of the features are not supported across all SAI instances; see the chip-specific SAI information in the first section of this chapter.

- Transmitter with independent bit clock and frame sync supporting 4 data lines
- Receiver with independent bit clock and frame sync supporting 4 data lines
- Each data line can support a maximum frame size of 16 words
- 8- to 32-bit word size
- Word size configured separately for the first word and remaining words in a frame
- Asynchronous 8 x 32-bit FIFO for each transmit and receive data line supporting:
  - Graceful restart after FIFO error
  - Automatic restart after FIFO error without software intervention
  - 8-bit and 16-bit data packing into each 32-bit FIFO word
  - Multiple data line FIFOs combining into single data line FIFO

71.3 Functional description

This section provides a complete functional description of the block.

71.3.1 Modes of operation

Module power modes include Run mode, and Debug mode.

Run mode

In Run mode, the SAI transmitter and receiver operate normally.

Debug mode

In Debug mode, the SAI transmitter and/or receiver continues operating if the Debug Enable bit is set. When TCSR[DBGE] or RCSR[DBGE] bit is clear and Debug mode is entered, the SAI is disabled after completing the current transmit or receive frame. Debug mode does not affect the transmitter and receiver bit clocks.

71.3.2 Synchronous modes

The SAI transmitter and receiver can operate synchronously to each other.

Synchronous mode

The SAI transmitter and receiver can be configured to operate with synchronous bit clock and frame sync.

If both the transmitter and receiver use the transmitter bit clock and frame sync:

- Configure the transmitter for asynchronous operation and the receiver for synchronous operation.
- Enable the receiver in synchronous mode only after both the transmitter and receiver are enabled.
- Enable the transmitter last and disable the tranmitter first.

If both the transmitter and receiver use the receiver bit clock and frame sync:

- Configure the receiver for asynchronous operation and the transmitter for synchronous operation.
- Enable the transmitter in synchronous mode only after both the receiver and transmitter are enabled.
- Enable the receiver last and disable the receiver first.

When operating in synchronous mode, the transmitter and receiver share only the bit clock, frame sync, and transmitter/receiver enable. Otherwise, the transmitter and receiver operate independently, although the configuration registers must be configured consistently across both the transmitter and receiver.

71.3.3 Frame sync configuration

When enabled, the SAI continuously transmits and/or receives frames of data. Each frame consists of a fixed number of words and each word consists of a fixed number of bits. Within each frame, any given word can be masked causing the receiver to ignore that word and the transmitter to tri-state for the duration of that word.

The frame sync signal indicates the start of each frame. A valid frame sync requires a rising edge (if active high) or falling edge (if active low) to be detected and the transmitter or receiver cannot be busy with a previous frame. A valid frame sync is also ignored (slave mode) or not generated (master mode) for the first four bit clock cycles after enabling the transmitter or receiver.

The transmitter and receiver frame sync can be configured independently with any of the following options:

- Generate externally or internally
- Require active high or active low
- Assert with the first bit in frame or assert one bit early
- Assert for a duration of between 1 bit clock and the first word length

- Set frame length from 1 to 16 words per frame
- Support word length of 8 to 32 bits per word
  - — First word length and remaining word lengths can be configured separately
- Transmit/Receive words MSB first or LSB first

These configuration options cannot be changed after enabling the SAI transmitter or receiver.

71.3.4 Data FIFO

Each transmit and receive channel includes a 8 x 32-bit size FIFO. To access the FIFO data use the SAI Transmit/Receive Data Registers.

71.3.4.1 Data alignment

Data in the FIFO can be aligned anywhere within the 32-bit wide register through the use of the First Bit Shifted configuration field, which selects the bit index (between 31 and 0) of the first bit shifted.

Examples of supported data alignment and the required First Bit Shifted configuration are illustrated in Figure 386 for LSB First configurations and Figure 387 for MSB First configurations.

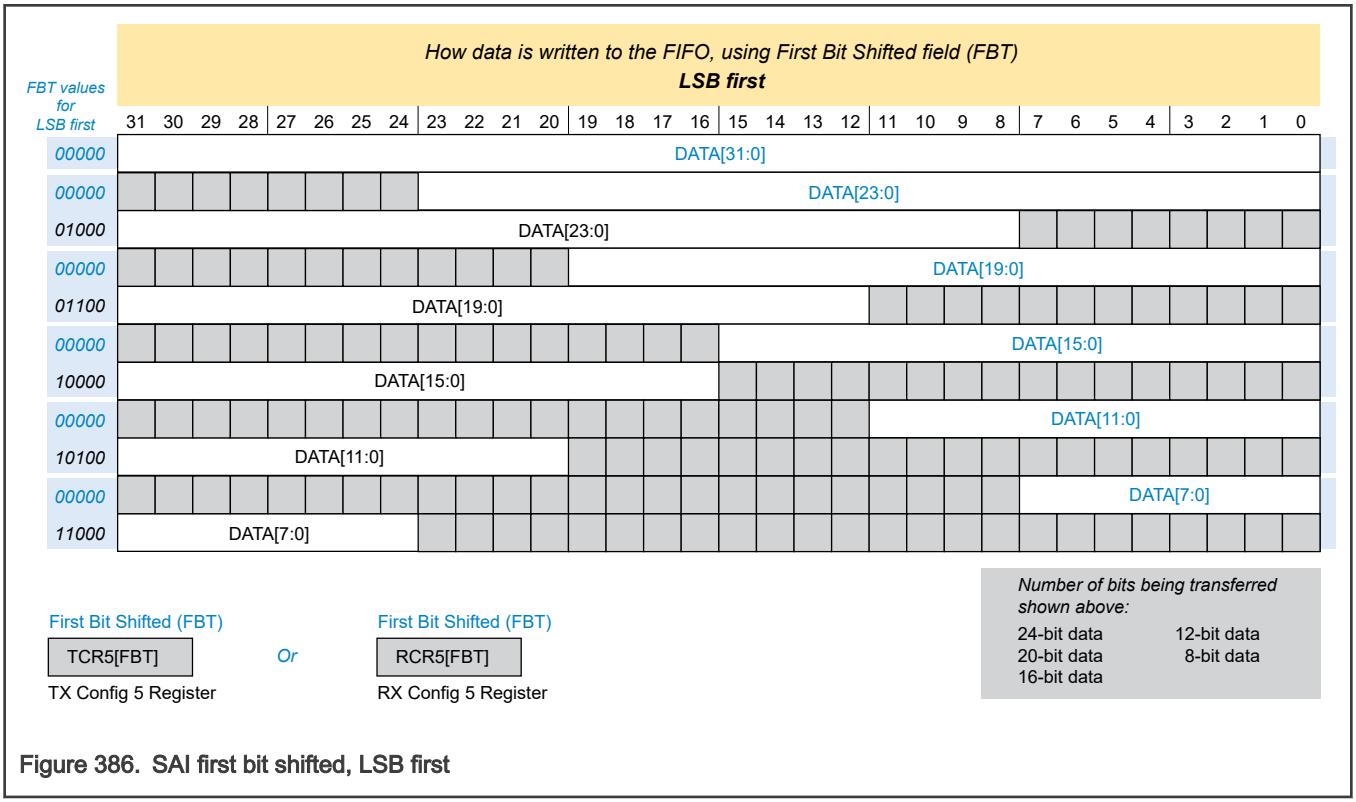

Figure 386. SAI first bit shifted, LSB first

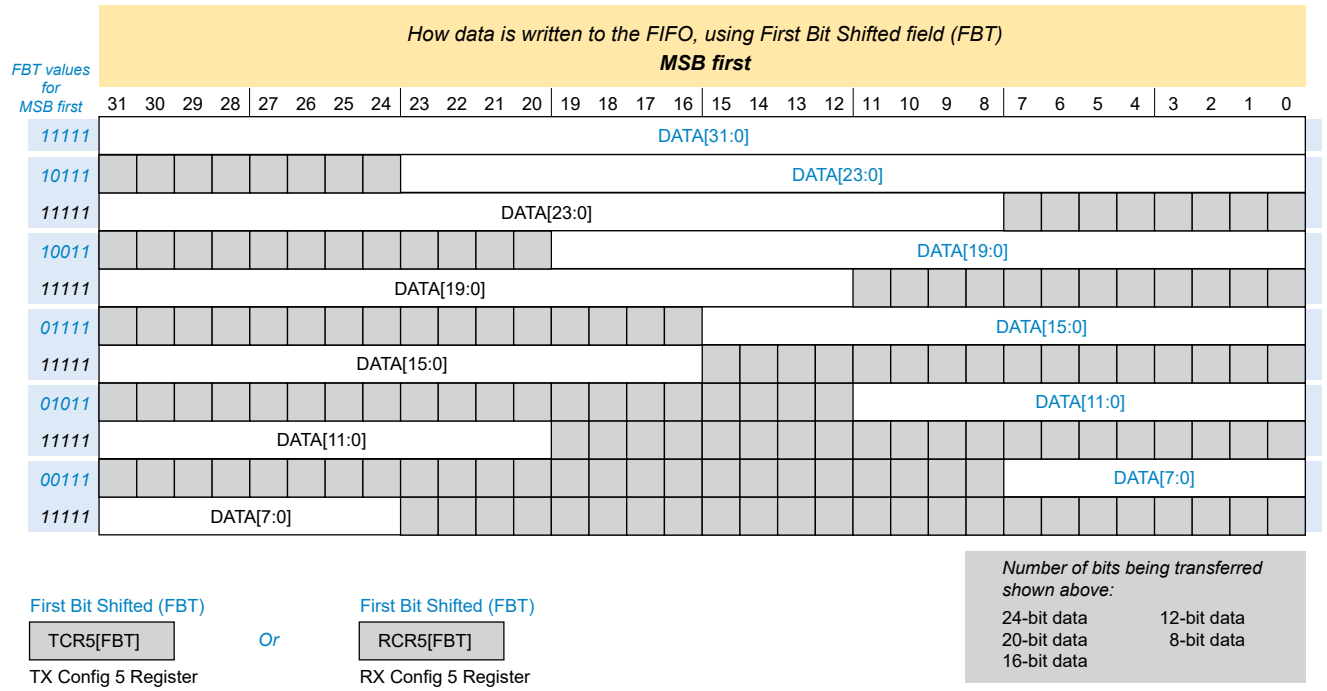

Figure 387. SAI first bit shifted, MSB first

71.3.4.2 FIFO pointers

When writing to a Transmit Data Register (TDR*n*), the Write FIFO Pointer (WFP) of the corresponding Transmit FIFO Register (TFR*n*) increments after each valid write. The SAI supports 8-bit, 16-bit, and 32-bit writes to the Transmit Data Register and the FIFO pointer increments after each individual write. Note that 8-bit writes should only be used when transmitting up to 8-bit data; 16-bit writes should only be used when transmitting up to 16-bit data.

- If the Transmit FIFO is full, writes to a Transmit Data Register are ignored.
- If the Transmit FIFO is empty, to avoid a FIFO underrun, write to the Transmit Data Register at least 3 bit clocks before the start of the next unmasked word. Before enabling the transmitter, initialize the Transmit FIFO with data (because after enabling the transmitter, the transmitter starts a new frame, and if no data is in the FIFO, then the transmitter immediately give an error).

When reading a Receive Data Register (RDR*n*), the Read FIFO Pointer (RFP) of the corresponding Receive FIFO Register (RFR*n*) increments after each valid read. The SAI supports 8-bit, 16-bit and 32-bit reads from the RDR and the FIFO pointer will increment after each individual read. Note that 8-bit reads should only be used when receiving up to 8-bit data; 16-bit reads should only be used when receiving up to 16-bit data.

- If the Receive FIFO is empty, reads from a Receive Data Register are ignored.
- If the Receive FIFO is full, to avoid a FIFO overrun, read the Receive Data Register at least 3 bit clocks before the end of an unmasked word.

71.3.4.3 FIFO packing

FIFO packing supports storing multiple 8-bit or 16-bit data words in one 32-bit FIFO word for the transmitter and/or receiver. While this can be emulated by adjusting the number of bits per word and number of words per frame (for example, one 32-bit word per frame versus two 16-bit words per frame), FIFO packing does not require even multiples of words per frame and fully supports word masking. When FIFO packing is enabled, the FIFO pointers only increment when the full 32-bit FIFO word has been written (transmit) or read (receive) by software, supporting scenarios where different words within each frame are loaded/stored in different areas of memory.

Using 16-bit FIFO packing for transmit, the transmit shift register loads at the start of each frame and after every second unmasked transmit word. The first word transmitted is taken from 16-bit word at byte offset 0x0 (the first bit is selected by TCR5[FBT] and must be configured within this 16-bit word) and the second word transmitted is taken from the 16-bit word at byte offset 0x2 (the first bit is selected by TCR5[FBT][3:0]). The transmitter transmits logic zero until the start of the next word once the 16-bit word has been transmitted.

Using 16-bit FIFO packing for receive, the receive shift register is stored after every second unmasked received word, and at the end of each frame if there is an odd number of unmasked received words in each frame. The first word received is stored in the 16-bit word at byte offset 0x0 (the first bit is selected by RCR5[FBT] and must be configured within this 16-bit word) and the second word received is stored in the 16-bit word at byte offset 0x2 (the first bit is selected by RCR5[FBT][3:0]). The receiver ignores received data until the start of the next word once the 16-bit word has been received.

The 8-bit FIFO packing is similar to 16-bit packing except four words are loaded or stored into each 32-bit FIFO word. The first word is loaded/stored in byte offset 0x0, second word in byte offset 0x1, third word in byte offset 0x2 and fourth word in byte offset 0x3. The TCR5[FBT] and/or RCR5[FBT] must be configured within byte offset 0x0.

71.3.4.4 FIFO Combine

FIFO Combining mode allows the separate FIFOs for multiple data channels to be used as a single FIFO for either software accesses or a single data channel or both. Note that the enabled data channels must be contiguous and data channel 0 must be enabled when using FIFO Combine mode.

Combining FIFOs for software access (writing transmit FIFO registers, reading receive FIFO registers) allows a DMA controller or software to read or write multiple FIFOs without incrementing the address that is accessed. Once enabled, the first software access to a FIFO register accesses the first enabled channel FIFO, while the second access to a FIFO register accesses the second enabled channel FIFO. This continues until software accesses the last enabled channel FIFO and the pointer resets back to the first enabled channel FIFO. To reset the pointer manually, software can reset the FIFOs or disable FIFO combining on software accesses.

Combining FIFOs for transmit data channels allows one data channel to use the FIFOs of all enabled channel FIFOs, with identical data output on each enabled data channel. The transmit shift registers for all enabled data channels load at the start of each frame and every N unmasked words (where N is the number of enabled data channels). The first word transmitted loads from the first enabled channel FIFO, while the second word transmitted loads from the second enabled channel FIFO, and so on until the end of the frame. Because the first word in each frame always loads from the first enabled data channel, it is recommended that the number of unmasked words in each frame is evenly divisible by the number of enabled data channels.

Combining FIFOs for receive data channels allows one data channel to use the FIFOs of all enabled channel FIFOs, with received data from channel 0 stored into each enabled data channel. The receive shift register for all enabled data channels are stored after every N unmasked words (where N is the number of enabled data channels). The first word received stores to the first enabled channel FIFO, while the second word received stores to the second enabled channel FIFO, and so on until the end of the frame. Because the first word in each frame always stores to the first enabled data channel, it is recommended that the number of unmasked words in each frame is evenly divisible by the number of enabled data channels.

Note that combining FIFOs for data channels loads or stores each channel FIFO at the same time. This means that FIFO error conditions are only checked every N words (where N is the number of enabled data channels) and that the FIFO warning and request flags assert if any of the enabled data channel meets the warning flag or request flag conditions.

71.3.5 Word mask register

The SAI transmitter and receiver each contain a word mask register (TMR and RMR) that can be used to mask any word in the frame. Because the word mask register is double buffered, software can update it before the end of each frame to mask a particular word in the next frame.

The TMR causes the Transmit Data pin to be tri-stated for the length of each selected word and the transmit FIFO is not read for masked words.

The RMR causes the received data for each selected word to be discarded and not written to the receive FIFO.

71.3.6 Interrupts and DMA requests

The SAI transmitter and receiver generate separate interrupts and separate DMA requests, but support the same status flags. Asynchronous interrupts are only generated when the system clock is gated provided the corresponding BCLK continues.

71.3.6.1 FIFO request flag

The FIFO request flag sets based on the number of entries in the FIFO and the FIFO watermark configuration.

The transmit FIFO request flag sets when the number of entries in any of the enabled transmit FIFOs is less than or equal to the transmit FIFO watermark configuration and clears when the number of entries in each enabled transmit FIFO is greater than the transmit FIFO watermark configuration.

The receive FIFO request flag sets when the number of entries in any of the enabled receive FIFOs is greater than the receive FIFO watermark configuration and clears when the number of entries in each enabled receive FIFO is less than or equal to the receive FIFO watermark configuration.

The FIFO request flag can generate an interrupt or a DMA request.

71.3.6.2 FIFO warning flag

The FIFO warning flag sets based on the number of entries in the FIFO.

The transmit warning flag sets when the number of entries in any of the enabled transmit FIFOs is empty and clears when the number of entries in each enabled transmit FIFO is not empty.

The receive warning flag sets when the number of entries in any of the enabled receive FIFOs is full and clears when the number of entries in each enabled receive FIFO is not full.

The FIFO warning flag can generate an Interrupt or a DMA request.

71.3.6.3 FIFO error flag

The Transmit FIFO Error Flag (TCSR[FEF] = 1]) sets when any of the enabled transmit FIFOs underrun. After the error flag sets, all enabled transmit channels transmit zero data before TCSR[FEF] clears.

When FIFO Continue on Error is enabled (TCR4[FCONT] = 1), the FIFO continues transmitting data following an underrun without software intervention. To ensure that data transmits in the correct order, the transmitter continues from the same word number in the frame that caused the FIFO to underrun, but only after new data writes to the transmit FIFO. Software should still clear the TCSR[FEF] flag, but without reinitializing the transmit FIFOs.

The Receive FIFO Error Flag sets (RCSR[FEF] = 1) when any of the enabled receive FIFOs overflow. After the flag is set, all enabled receive channels discard received data until RCSR[FEF] clears and the next receive frame starts. Empty all enabled receive FIFOs before RCSR[FEF] clears.

When Receive FIFO Continue on Error is enabled (RCR4[FCONT] = 1) the FIFO continues receiving data following an overflow without software intervention. To ensure that data is received in the correct order, the receiver continues from the same word number in the frame that caused the FIFO to overflow, but only after data has been read from the receive FIFO. Software should still clear the RCSR[FEF] flag, but without emptying the receive FIFOs.

The FIFO Error Flag can generate only an interrupt.

71.3.6.4 Sync error flag

The Sync Error Flag, TCSR[SEF] or RCSR[SEF], sets when configured for an externally generated frame sync and the external frame sync asserts when the transmitter or receiver is busy with the previous frame. The external frame sync assertion is ignored and the sync error flag sets. When the Sync Error Flag sets, the transmitter or receiver continues checking for frame sync assertion when idle or at the end of each frame.

The Sync Error Flag can only generate an interrupt.

71.3.6.5 Word start flag

The Word Start Flag sets (TCSR[WSF] = 1) at the start of the second bit clock for the selected word, as configured by the Word Flag Configuration field (TCR3[WDFL]).

The Word Start Flag can generate an interrupt only.

71.3.7 SAI clocking

The SAI clocks include:

- Audio master clock
- Bit clock
- Bus clock

Audio master clock

The audio master clock generates the bit clock when the receiver or transmitter is configured for an internally generated bit clock. The transmitter and receiver can independently select between the bus clock and up to three audio master clocks to generate the bit clock.

The audio master clock generation and selection is chip-specific. Refer to chip-specific clocking information about how the audio master clocks are generated.

Bit clock

The SAI transmitter and receiver support asynchronous free-running bit clocks that can be generated internally from an audio master clock or supplied externally. There is also the option for synchronous bit clock and frame sync operation between the receiver and transmitter or between multiple SAI peripherals.

- If both transmitter and receiver are configured for asynchronous operation, then the transmitter and receiver will each use *their own* bit clock and frame sync.
- If the *transmitter* is configured for asynchronous mode and the receiver is configured for synchronous mode, then both transmitter and receiver will use the *transmitter* bit clock and frame sync.
- If the *receiver* is configured for asynchronous mode and the transmitter is configured for synchronous mode, then both transmitter and receiver will use the *receiver* bit clock and frame sync.

Note that the software configures synchronous or asynchronous mode, and that choice selects the bit clock/frame sync used.

Externally generated bit clocks must be:

- Enabled before the SAI transmitter or receiver is enabled
- Disabled after the SAI transmitter or receiver is disabled and completes its current frames

If the SAI transmitter or receiver uses an externally generated bit clock in asynchronous mode and that bit clock is generated by an SAI that is disabled in stop mode, then the transmitter or receiver should be disabled by software before entering stop mode. This issue does not apply when the transmitter or receiver is in a synchronous mode because all synchronous SAIs are enabled and disabled simultaneously.

Bus clock

The bus clock is used by the control and configuration registers and to generate synchronous interrupts and DMA requests.

NOTE

Although there is no minimum bus clock frequency specified, the bus clock frequency must be fast enough (relative to the bit clock frequency) to ensure that the FIFOs can be serviced, without generating either a transmitter FIFO underrun or receiver FIFO overflow condition.

71.3.8 SAI resets

The SAI is asynchronously reset on system reset. The SAI has a software reset and a FIFO reset.

Software reset

The SAI transmitter includes a software reset that resets all transmitter internal logic, including the bit clock generation, status flags, and FIFO pointers. This software reset does not reset the configuration registers. The software reset remains asserted until cleared by software.

The SAI receiver includes a software reset that resets all receiver internal logic, including the bit clock generation, status flags and FIFO pointers. This software reset does not reset the configuration registers. The software reset remains asserted until cleared by software.

FIFO reset

The SAI transmitter includes a FIFO reset that synchronizes the FIFO write pointer to the same value as the FIFO read pointer. This FIFO reset empties the FIFO contents and is used after TCSR[FEF] is set, and before the FIFO is re-initialized and TCSR[FEF] is cleared. The FIFO reset is asserted for one cycle only.

The SAI transmitter can also reset the FIFO of individual data channels by setting the appropriate TCR3[CFR] bit. This should only be done when the corresponding TCR3[TCE] bit is clear.

The SAI receiver includes a FIFO reset that synchronizes the FIFO read pointer to the same value as the FIFO write pointer. This empties the FIFO contents and is to be used after the RCSR[FEF] is set and any remaining data has been read from the FIFO, and before the RCSR[FEF] is cleared. The FIFO reset is asserted for one cycle only.

The SAI receiver can also reset the FIFO of individual data channels by setting the appropriate RCR3[CFR] bit. This should only be done when the corresponding RCR3[RCE] bit is clear.

71.4 External signals

Name	Function	I/O
TX_BCLK	Transmit Bit Clock. The bit clock is an input when externally generated and an output when internally generated.	I/O
TX_SYNC	Transmit Frame Sync. The frame sync is an input sampled synchronously by the bit clock when externally generated and an output generated synchronously by the bit clock when internally generated.	I/O
TX_DATA[3:0]	Transmit Data. The transmit data is generated synchronously by the bit clock and is tristated whenever not transmitting a word.	O
RX_BCLK	Receive Bit Clock. The bit clock is an input when externally generated and an output when internally generated.	I/O
RX_SYNC	Receive Frame Sync. The frame sync is an input sampled synchronously by the bit clock when externally generated and an output generated synchronously by the bit clock when internally generated.	I/O

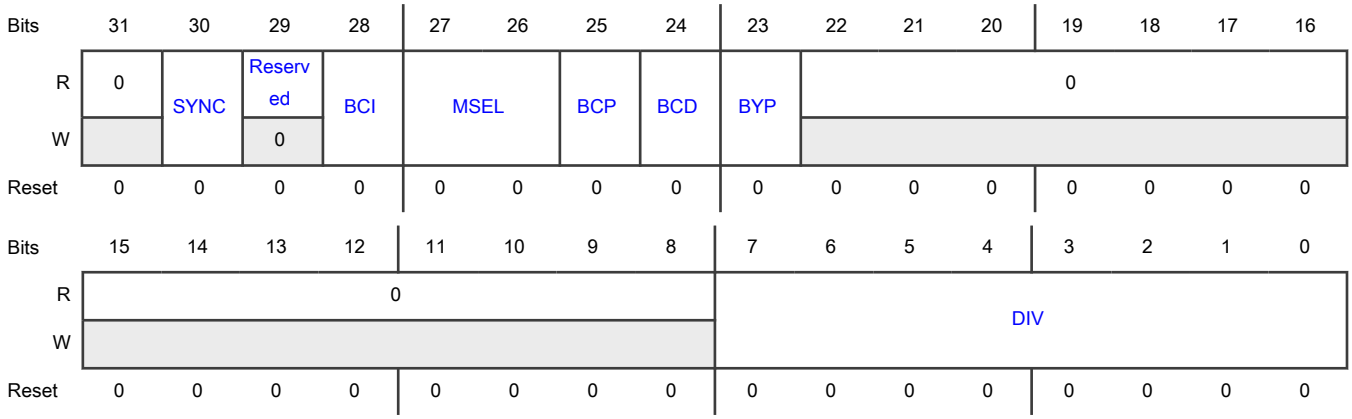
NOTE

This register must not be altered when TCSR[TE] is set.

Diagram



Fields

Field	Function
31 —	Reserved
30 SYNC	Synchronous Mode Configures between asynchronous and synchronous modes of operation. When configured for a synchronous mode of operation, the receiver must be configured for asynchronous operation. 0b - Asynchronous mode. 1b - Synchronous with receiver.
29 —	Reserved
28 BCI	Bit Clock Input When this field is set and using an internally generated bit clock in either synchronous or asynchronous mode, the bit clock actually used by the transmitter is delayed by the pad output delay (the transmitter is clocked by the pad input as if the clock was externally generated). This has the effect of decreasing the data input setup time, but increasing the data output valid time. The slave mode timing from the datasheet should be used for the transmitter when this bit is set. In synchronous mode, this bit allows the transmitter to use the slave mode timing from the datasheet, while the receiver uses the master mode timing. This field has no effect when configured for an externally generated bit clock . 0b - No effect. 1b - Internal logic is clocked as if bit clock was externally generated.
27-26 MSEL	MCLK Select Selects the audio Master Clock option used to generate an internally generated bit clock. This field has no effect when configured for an externally generated bit clock.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE Depending on the device, some Master Clock options might not be available. See the chip-specific information for the meaning of each option. 00b - Bus Clock selected. 01b - Master Clock (MCLK) 1 option selected. 10b - Master Clock (MCLK) 2 option selected. 11b - Master Clock (MCLK) 3 option selected.
25 BCP	Bit Clock Polarity Configures the polarity of the bit clock. 0b - Bit clock is active high with drive outputs on rising edge and sample inputs on falling edge. 1b - Bit clock is active low with drive outputs on falling edge and sample inputs on rising edge.
24 BCD	Bit Clock Direction Configures the direction of the bit clock. 0b - Bit clock is generated externally in Slave mode. 1b - Bit clock is generated internally in Master mode.
23 BYP	Bit Clock Bypass Bypasses the bit clock divider, internal bit clock is divide by 1 of the audio master clock. 0b - Internal bit clock is generated from bit clock divider. 1b - Internal bit clock is divide by one of the audio master clock.
22-8 —	Reserved
7-0 DIV	Bit Clock Divide Divides down the audio master clock to generate the bit clock when configured for an internal bit clock. The division value is (DIV + 1) * 2.

71.5.1.7 Transmit Configuration 3 (TCR3)

Offset

Register	Offset
TCR3	14h

Function

Contains the transmit channel settings.

Diagram

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-28 —	Reserved
27-24 CFR	Channel FIFO Reset Resets the FIFO pointers for a specific channel. Reading this field always returns zero. FIFO pointers should only be reset when a channel is disabled or the FIFO error flag is set. The width of CFR field = the number of transmit channels (call it N). For example, if CFR is 2 bits wide, then bit position 24 refers to transmit channel 1 FIFO pointer and bit position 25 refers to transmit channel 2 FIFO pointer. Setting bit 24 resets transmit channel 1 FIFO pointer, and setting bit 25 enables transmit channel 2 FIFO pointer. Setting bit N will reset transmit channel N FIFO pointer. **NOTE** When there is only a single channel, there is no need for individual channel FIFO reset (TCR3[CFR]). In the case of a single channel, use the global FIFO reset (TCSR[FR]). 0b - No effect. 1b - Transmit data channel N FIFO is reset. **NOTE** This field is not supported in every instance. The following table includes only supported registers.
23-20 —	Reserved

<tr><td>15-4
—</td><td>Reserved</td></tr>
<tr><td>3-0
WDFL</td><td>Word Flag Configuration
Configures which word sets the start of word flag. The value written must be one less than the word number. For example, writing 0 configures the first word in the frame. When configured to a value greater than TCR4[FRSZ], then the start of word flag is never set.</td></tr>
</table>

71.5.1.8 Transmit Configuration 4 (TCR4)

Offset

Register	Offset
TCR4	18h

Function

Contains the transmit fields for FIFO Combine Mode, FIFO Packing Mode, and frame sync settings.

NOTE

This register must not be altered when TCSR[TE] is set.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0			FCONT	FCOMB		FPACK		0				FRSZ			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0			SYWD					0		CHMOD	MF	FSE	ONDEM	FSP	FSD
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-29 —	Reserved
28 FCONT	FIFO Continue on Error Configures when the SAI will continue transmitting after a FIFO error has been detected. 0b - On FIFO error, the SAI will continue from the start of the next frame after the FIFO error flag has been cleared. 1b - On FIFO error, the SAI will continue from the same word that caused the FIFO error to set after the FIFO warning flag has been cleared.
27-26 FCOMB	FIFO Combine Mode When FIFO combine mode is enabled for FIFO writes, software writing to any FIFO data register will alternate the write among the enabled data channel FIFOs. For example, if two data channels are enabled then the first write will be performed to the first enabled data channel FIFO and the second write will be performed to the second enabled data channel FIFO. Reseting the FIFO or disabling FIFO combine mode for FIFO writes will reset the pointer back to the first enabled data channel. When FIFO combine mode is enabled for FIFO reads from the transmit shift registers, the transmit data channel output will alternate between the enabled data channel FIFOs. For example, if two data channels are enabled then the first unmasked word will be transmitted from the first enabled data channel FIFO and the second unmasked word will be transmitted from the second enabled data channel FIFO. Since the first word of the frame is always transmitted from the first enabled data channel FIFO, it is recommended that the number of unmasked words per frame is evenly divisible by the number of enabled data channels. **NOTE** This field is not supported in every instance. The following table includes only supported registers.

Instance	Field supported in	Field not supported in
SAI_0	TCR4	—

Field	Function
	<table><tr><th>Instance</th><th>Field supported in</th><th>Field not supported in</th></tr><tr><td>SAI_1</td><td>—</td><td>TCR4</td></tr></table> 00b - FIFO combine mode disabled. 01b - FIFO combine mode enabled on FIFO reads (from transmit shift registers). 10b - FIFO combine mode enabled on FIFO writes (by software). 11b - FIFO combine mode enabled on FIFO reads (from transmit shift registers) and writes (by software).
25-24 FPACK	FIFO Packing Mode Enables packing of 8-bit data or 16-bit data into each 32-bit FIFO word. If the word size is greater than 8-bit or 16-bit then only the first 8-bit or 16-bits are loaded from the FIFO. The first word in each frame always starts with a new 32-bit FIFO word and the first bit shifted must be configured within the first packed word. When FIFO packing is enabled, the FIFO write pointer will only increment when the full 32-bit FIFO word has been written by software. 00b - FIFO packing is disabled. 01b - Reserved 10b - 8-bit FIFO packing is enabled. 11b - 16-bit FIFO packing is enabled.
23-20 —	Reserved
19-16 FRSZ	Frame size Configures the number of words in each frame. The value written must be one less than the number of words in the frame. For example, write 0 for one word per frame. The maximum supported frame size is 16 words.
15-13 —	Reserved
12-8 SYWD	Sync Width Configures the length of the frame sync in number of bit clocks. The value written must be one less than the number of bit clocks. For example, write 0 for the frame sync to assert for one bit clock only. The sync width cannot be configured longer than the first word of the frame.
7-6 —	Reserved
5 CHMOD	Channel Mode Configures if transmit data pins are configured for TDM mode or Output mode.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - TDM mode, transmit data pins are tri-stated when slots are masked or channels are disabled. 1b - Output mode, transmit data pins are never tri-stated and will output zero when slots are masked or channels are disabled.
4 MF	MSB First Configures whether the LSB or the MSB is transmitted first. 0b - LSB is transmitted first. 1b - MSB is transmitted first.
3 FSE	Frame Sync Early 0b - Frame sync asserts with the first bit of the frame. 1b - Frame sync asserts one bit before the first bit of the frame.
2 ONDEM	On Demand Mode When set, and the frame sync is generated internally, a frame sync is only generated when the FIFO warning flag is clear. 0b - Internal frame sync is generated continuously. 1b - Internal frame sync is generated when the FIFO warning flag is clear.
1 FSP	Frame Sync Polarity Configures the polarity of the frame sync. 0b - Frame sync is active high. 1b - Frame sync is active low.
0 FSD	Frame Sync Direction Configures the direction of the frame sync. 0b - Frame sync is generated externally in Slave mode. 1b - Frame sync is generated internally in Master mode.

71.5.1.9 Transmit Configuration 5 (TCR5)

Offset

Register	Offset
TCR5	1Ch

Function

Contains transmit word width and bit index settings.

NOTE

This register must not be altered when TCSR[TE] is set.

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-28 —	Reserved
27-24 CFR	Channel FIFO Reset Resets the FIFO pointers for a specific channel. Reading this field will always return zero. FIFO pointers should only be reset when a channel is disabled or the FIFO error flag is set. The width of CFR field = the number of receive channels (call it N). For example, if CFR is 2 bits wide, then bit position 24 refers to receive channel 1 FIFO pointer and bit position 25 refers to receive channel 2 FIFO pointer. Setting bit 24 resets receive channel 1 FIFO pointer, and setting bit 25 enables receive channel 2 FIFO pointer. Setting bit N will reset receive channel N FIFO pointer.

Table continued from the previous page...

<table>
<tr><th>Field</th><th>Function</th></tr>
<tr><td></td><td>0b - No effect.
1b - Receive data channel N FIFO is reset.

<tr><td>SAI_1</td><td>—</td><td>RCR3</td></tr>
</table></td></tr>
<tr><td>23-20
—</td><td>Reserved</td></tr>
<tr><td>19-16
RCE</td><td>Receive Channel Enable
Enables the corresponding data channel for receive operation. Changing this field will take effect immediately for generating the FIFO request and warning flags, but at the end of each frame for receive operation.
The width of RCE field = the number of receive channels (call it N). For example, if RCE field is 2 bits wide, then bit position 16 refers to receive channel 1 and bit position 17 refers to receive channel 2. Setting bit 16 enables receive channel 1, and setting bit 17 enables receive channel 2. Setting bit N will enable receive channel N.
NOTE
When there is only a single channel, there is no need for individual channel FIFO reset (RCR3[CFR]). In the case of a single channel, use the global FIFO reset (RCSR[FR]).
0b - Receive data channel N is disabled.
1b - Receive data channel N is enabled.
NOTE
This field is not supported in every instance. The following table includes only supported registers.
<table>

28	FIFO Continue on Error

Table continues on the next page...

Table continued from the previous page...

<table>
<tr><th>Field</th><th>Function</th></tr>
<tr><td>FCONT</td><td>Configures when the SAI will continue receiving after a FIFO error has been detected.
0b - On FIFO error, the SAI will continue from the start of the next frame after the FIFO error flag has been cleared.
1b - On FIFO error, the SAI will continue from the same word that caused the FIFO error to set after the FIFO warning flag has been cleared.</td></tr>
<tr><td>27-26
FCOMB</td><td>FIFO Combine Mode
When FIFO combine mode is enabled for FIFO reads, software reading any FIFO data register will alternate the read among the enabled data channel FIFOs. For example, if two data channels are enabled then the first read will be performed to the first enabled data channel FIFO and the second read will be performed to the second enabled data channel FIFO. Reseting the FIFO or disabling FIFO combine mode for FIFO reads will reset the pointer back to the first enabled data channel.
When FIFO combine mode is enabled for FIFO writes from the receive shift registers, the first enabled data channel input will alternate between the enabled data channel FIFOs. For example, if two data channels are enabled then the first unmasked received word will be stored in the first enabled data channel FIFO and the second unmasked received word will be stored in the second enabled data channel FIFO. Since the first word of the frame is always stored in the first enabled data channel FIFO, it is recommended that the number of unmasked words per frame is evenly divisible by the number of enabled data channels.
NOTE
This field is not supported in every instance. The following table includes only supported registers.
<table><tr><th>Instance</th><th>Field supported in</th><th>Field not supported in</th></tr><tr><td>SAI_0</td><td>RCR4</td><td>—</td></tr><tr><td>SAI_1</td><td>—</td><td>RCR4</td></tr></table>00b - FIFO combine mode disabled.

71.5.1.21 Receive Mask (RMR)

Offset

Register	Offset
RMR	E0h

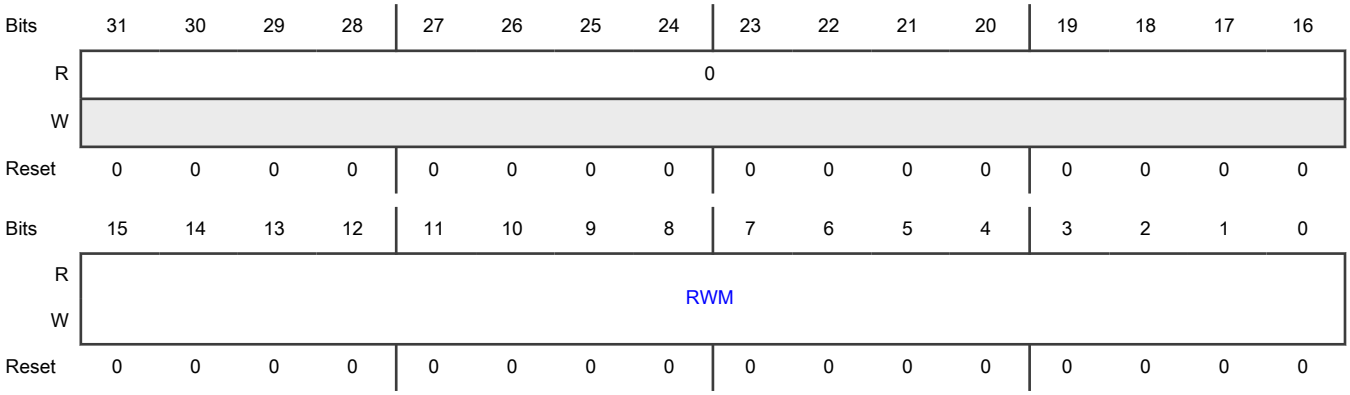
Function

This register is double-buffered and updates:

1. When RCSR[RE] is first set
2. At the end of each frame

This allows the masked words in each frame to change from frame to frame.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 RWM	Receive Word Mask Configures whether the receive word is masked (received data ignored and not written to receive FIFO) for the corresponding word in the frame. 0000_0000_0000_0000b - Word N is enabled. 0000_0000_0000_0001b - Word N is masked.

71.6 Glossary

FIFO	First-in first-out
LSB	Least significant bit
MSB	Most significant bit

Chapter 72
Ethernet Media Access Controller (EMAC)

72.1 Chip-specific EMAC information

72.1.1 EMAC instance and configuration

This chip supports up to 1 instance of EMAC IP.

Table 460. EMAC instance

Instance	MWCT2D16S/MWCT2D17S	MWCT2015S/MWCT2016S
EMAC	Yes	No

NOTE

DWC_EQOS refer to the Synopsys Ethernet MAC IP.

NOTE

The description for some EMAC registers include references to configurations of the Synopsis Ethernet MAC IP. Refer to MAC_HW_Feature registers for the specific features available in this chip.

NOTE

EMAC operates only in Clock options A and B, since the module clock becomes lower than the protocol clock (RMII/MII clocks) in other modes.

Following key features are supported:

- This chip supports only MII/RMII interfaces
- 4 bit MII interface operating at 2.5/25/50Mhz, MII can run at 10/100/200 Mbps.
- 2 bit RMII interface operating at 50Mhz, RMII can run at 10/100Mbps
- 4 bit MII-Lite interface operating at 2.5/25Mhz
- 4 PPS are supported using DMA trigger
- 200Mbps data rate is supported on Ethernet MII interface
- MTL Receive FIFO size 8192bytes
- MTL Transmit FIFO size 8192bytes

NOTE

The DMA referred within EMAC chapter refers to the internal EMAC DMA engine and not the device AXBS master DMA.

NOTE

Register access beyond 8k address space is not supported and will generate a transfer error.

NOTE

Always use store and forward mode if possible. In cut through mode, if multiple masters are active then there is chance (even in round robin arbitration mode) that EMAC DMA may starve for data resulting in insufficient data in TX FIFO leading to Tx underflow. To avoid this, increase MTL_TxQ0_Operation_Mode[TTC] value as needed.

The table below provides the information on the specific configuration utilized for the MWCT2D17S and MWCT2D16S devices.

Table 461. Specific configuration information

Application Interface		
	Application interface configuration	EQOS-AHB
	Data width	32
	Endian mode	Little Endian
	Address width	32
	CSR interfcae	APB3 interface
General feature		
	Mode of operation	10/100
	Enable double VLAN processing	Yes
	Enable Que/channel based VLAN tag inertion on Tx	Yes
	Enable SA and VLAN insertion on Tx	Enabled by default
Buffer management		
	MTL Receive FIFO size in bytes	8192
	MTL Receive FIFO size in bytes	8192
	Enable debug memory access	Yes
	Use single port memory	Yes
PHY interface		
	Enable RGMII, RMII only	Enable RMII, GMII/MII default
	Enabled signel phy interface	No
	Enable MDIO interface	Yes
Filtering		
	Enable Additional 1-31 MAC address registers	2
	Enable Address Filter Hash Table	Yes
	Hash Table Size	64
	Enable VLAN Hash table based filtering	Yes
	Extended Rx VLAN Filter Enable	Yes
	Number of VLAN tag Filters	4
	Enable Layer3 and Layer4 Packet Filter	Yes
	Number of layer3 and Layer 4 packet filters	4
	Enable Flexible Programmable Receive Parser	Yes

	Enable the MAC Management Counters for Reciever TCP/IP Checksum offload	No
Automotive safety feature		
	Enable all automotive safety feature	Yes

72.1.2 Impact of MAC flush commands on MAC_PPSx_Target_Time_Seconds register

If the software discards the media clock generation request by configuring the PPSCTRL_PPSCMD (or PPSCMD#i) field of MAC_PPS_Control register to 0, the MAC does not flush the captured presentation time, i.e., the MAC_PPSx_Target_Time_Seconds register contents don't get changed.

72.3 Introduction

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

EMAC:

- Supports the 10/100 Mbps application in compliance with IEEE802.3-2015 specifications
- Can support advanced applications such as time-sensitive networking and AVB
- Supports a MAC core that has prominent features such as a flexible receive parser, media clock recovery and generation, and safety

72.3.1 Features

EMAC supports these features in addition to the default feature defined in the IEEE802.3 specification:

- MII (10/100 Mbps), RMII (10/100 Mbps)
- Time-aware shaper (IEEE802.1bv), time synchronization (IEEE802.1AS-rev), and frame preemption (IEEE802.1Qbu) for time-sensitive networking
- Media clock recovery and generation for AVB
- AMBA 2.0 for AHB master and APB3 interface
- RMII specification version 1.2 from RMII consortium
- Separate interface for transmit, receive, and control paths
- Two-buffer ring

- Broadcast and multicast packet duplication
- Full-duplex flow control operations (IEEE 802.3x pause packet and priority flow control)
- Network statistics with MAC management (RMON) counters
- Flexibility to control the pulse per second (PPS) output signal
- MDIO clause 22 and clause 45 interface for configuration and management of the PHY device
- Preamble and SFD insertion and deletion
- Automatic CRC and pad generation/stripping option
- Option to disable CRC checking
- Programmable insert packet gap
- Source address insertion or replacement
- VLAN insertion, replacement, and deletion in transmitted packets with per-packet or static-global control, insertion, replacement, and deletion of up to two VLAN tags, insertion, replacement, and deletion of queue or channel-based VLAN tags
- IEEE802.1Q VLAN tag detection and an option to delete the tags in the receive packets
- Programmable safety watchdog timeout limits
- Flexible address filtering modes that allow:
  - Up to two additional 48-bit perfect DA filters with masks for each byte
  - Up to two 48-bit SA comparison checks with masks for each byte
  - 64-bit hash filter for multicast and unicast DA addresses
  - Option to pass all multi-cast addressed packets
  - Promiscuous mode to pass all packets without any filtering for network monitoring
  - Passing of all incoming packets (according to filter) with a status report
- Additional packet filtering that is based on:
  - Virtual local area network (VLAN) tag—perfect match and hash-based filtering, which is based on either outer or inner VLAN tag, is possible
  - Layer 3 and layer 4—TCP or UDP over IPv4 or IPv6
  - Extended VLAN tag—filtering based on four filter selections

NOTE

The DCB feature discussed in the following section(s) is not supported.

72.3.2 Functional block diagram

This figure shows the EMAC block diagram. EMAC has four main blocks to perform all the functions.

- The AHB interface is connected to all DMA channels.
- The DMA arbiter helps in the arbitration of all paths (transmit and receive) in DMA channels.
- Each channel has a separate set of control and status registers (CSRs) for managing the transmit and receive functions, descriptor handling, and interrupt handling.

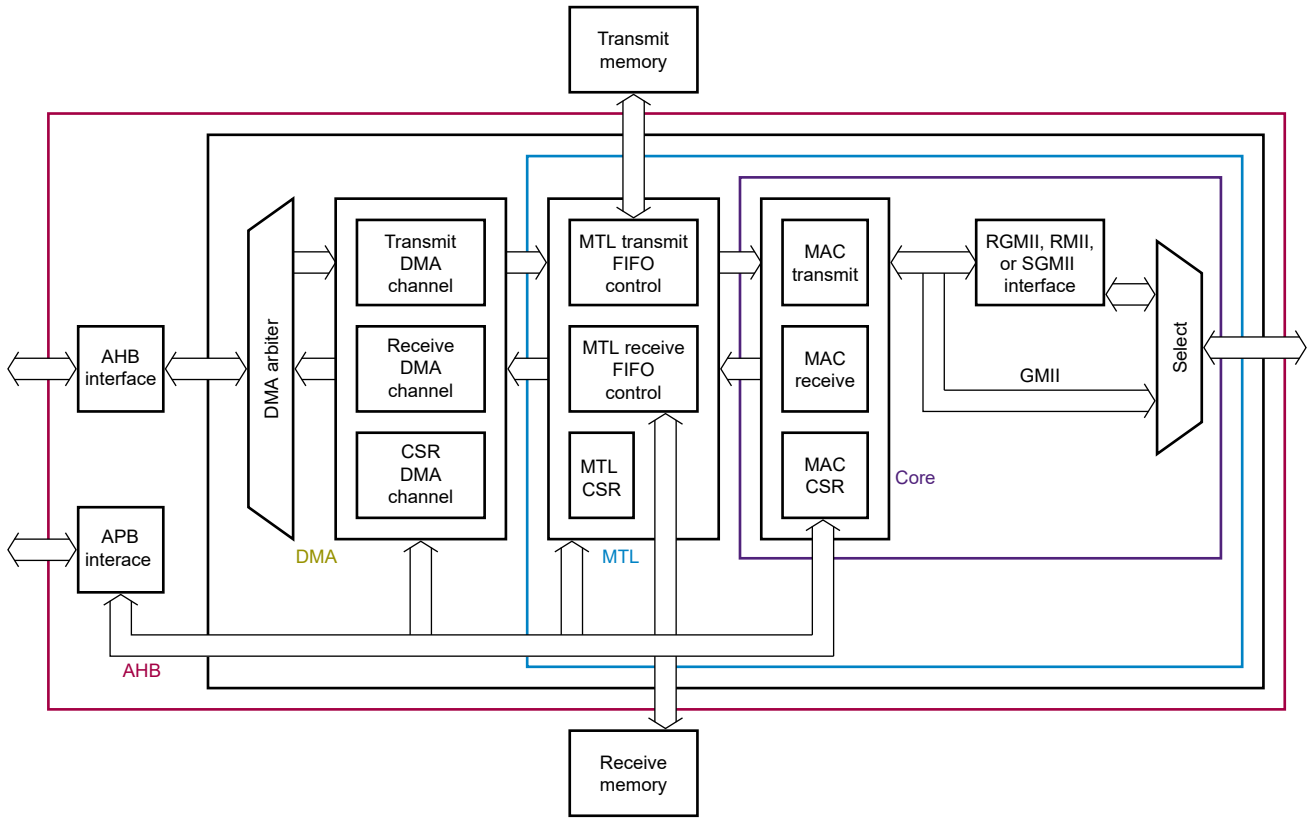

Figure 388. System-level block diagram

72.4 Architecture

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

The section describes EMAC interfaces, protocols, and functionality. These are its main blocks:

- AHB master and APB3 slave interface
- DMA controller
- MTL
- MAC
- Interrupts

72.4.1 AHB master and CSR slave (APB3) interface

The 32-bit APB3 slave interface:

- Provides access to DMA, MTL, and MAC control and status registers (CSRs)
- Supports the 32-bit write and read transfers to these CSRs
- Supports single- and all-burst transfers, and an OKAY response

The DMA block uses the AHB master interface to interact with the external world. The AHB master interface:

- Controls data transfer
- Is AMBA 2.0-compliant with no restrictions
- Supports 32-bit data transfer

- Supports single and INCR transfers
- Supports burst-length modes such as Fixed, Unspecified, and Mixed

72.4.2 DMA inclusions

DMA controller:

- Includes independent transmit (Tx) and receive (Rx) engines, and a CSR space. The transmit engine transfers data from the system memory to the MTL interface, whereas the receive engine transfers data from the MTL interface to the system memory.
- Is designed for packet-oriented data transfers such as packets in Ethernet.
- Communicates with the host through CSR, descriptor lists, and data buffers.

DMA descriptors

DMA supports up to two transmit and two receive descriptor lists (or DMA channels). The base address of each list is written to the respective transmit and receive descriptor list address registers. A descriptor list is forward linked and the next descriptor is always considered at a fixed offset to the current one, and DMA_CH0_Control[DSL] contols the offset. The number of descriptors in the list is programmed using the respective DMA Channel 0 Tx Descriptor Ring Length (DMA_CH0_TxDesc_Ring_Length) and DMA Channel 0 Rx Descriptor Ring Length (DMA_CH0_RxDesc_Ring_Length) registers. After the DMA processes the last descriptor in the list, it automatically jumps to the descriptor in the list address register to create a descriptor ring.

EMAC supports the ring structure for DMA descriptors. For more information, see Descriptors .

The DMA engine uses descriptors to efficiently move data from source to destination with minimal host intervention, and the DMA controller can be programmed to interrupt the host in certain situations. These situations may include packet transmit and receive transfer completion and other normal or error conditions.

The descriptor lists reside in the physical memory address space of the application. Each descriptor can point to a maximum of two buffers in the system memory, enabling two buffers to be used and physically addressed rather than contiguous buffers in the memory.

Data buffers

A data buffer resides in the application physical memory space and consists of an entire packet or part of a packet but cannot exceed a single packet. Buffers contain only data. The buffer status is maintained in the descriptor. Data chaining refers to packets that span multiple data buffers. However, a single descriptor cannot span multiple packets. The DMA skips to the data buffer of the next packet when an EOP is detected.

The next few sections discuss DMA controller.

72.4.2.1 DMA controller bus burst access

DMA engines attempt to transfer data in a burst of the maximum size programmed using DMA_CH0_Tx_Control[TxPBL] and DMA_CH0_Rx_Control[RxPBL] of the respective DMAs, which always access the receive and transmit descriptors in the maximum possible (limited by PBL or 16 * 8/bus width) burst length for 16 bytes to be read. The burst transfers that the DMA initates can be split into multiple burst transfers according to the AHB requirements and settings specified in DMA System Bus Mode (DMA_SysBus_Mode).

The transmit DMA initiates a data transfer only when sufficient space is available in the MTL transmit queue to accommodate either of these:

- Bytes corresponding to the configured burst (PBL * bus_width/8)
- Remaining bytes in the transmit buffer without EOP
- Number of bytes till EOP

The receive DMA initiates a data transfer in these conditions:

- Sufficient data is available in the MTL receive queue to accommodate the configured burst
- EOP (when it is less than the configured burst length) is detected in the receive queue

DMA indicates the start address and the number of transfers required to the AHB master interface. When the interface is configured for fixed-length burst, it transfers data by using the best combination of the INCR4, INCR8, or INCR16 and SINGLE transactions. If EOP is reached before the fixed burst ends on the AHB interface, DMA performs dummy transfers to complete the fixed burst. Otherwise, DMA_SysBus_Mode[FB] becomes 0. The DMA transfers the data using undefined length (INCR) and SINGLE transactions.

When the AHB interface is configured for address-aligned beats, both DMA engines ensure that the first-burst transfer that AHB initates is less than or equal to the size of the configured PBL value, and the subsequent beats start at an address aligned to this value. The DMA can only align the address for beats up to size 16 (for PBL > 16) for the AHB interface because it does not support more than INCR16.

72.4.2.2 DMA application data buffer alignment

The transmit and receive data buffers do not have any restrictions on start address alignment. For example, in systems with 32-bit memory, the start address for buffers can be aligned to any of the four bytes. However, the DMA always initiates write transfers with an address aligned to the bus width and dummy data (old data) in the invalid byte lanes. The process of write transfer typically happens during the beginning or end of an Ethernet packet transfer. The software driver must discard the dummy bytes based on the start address of the buffer and size of the packet.

Table 462. Data buffer alignment examples

Examples	
Buffer read	If the transmit buffer address is FF2h (for a 32-bit data bus) and 15 bytes need to be transferred, the DMA reads five full words from address FF0h. However, when DMA transfers data to the MTL transmit queue, the extra bytes (the first two bytes) are dropped or ignored. Similarly, the last 3 bytes of the last transfer are also ignored. The DMA always ensures that it transfers a full 32-bit data to the MTL transmit queue, unless it is the end of the packet.
Buffer write	If the receive buffer address is FF2h (for a 64-bit data bus) and 16 bytes of a received packet need to be transferred, the DMA writes 3 full words from address FF0h. However, the first 2 bytes of the first transfer and the last 6 bytes of the third transfer have dummy data. The DMA considers the offset address only if it is the first receive buffer of the packet. It ignores the offset address and performs full-word writes for the middle and last receive buffers of the packet.

72.4.2.3 DMA buffer size calculations

DMA does not update the size fields in the transmit and receive descriptors. It updates only the status fields (RDES and TDES) of the descriptors. The driver performs the size calculations.

The transmit DMA transfers the exact number of bytes (as the buffer size field of TDES2 indicates) to MAC. If a descriptor is marked as first (TDES3[FD] = 1), the DMA marks the first transfer from the buffer as SOP, and if the descriptor is marked as last (TDES3[LD]), the DMA marks the last transfer from that data buffer as EOP to the MTL.

The receive DMA transfers data to a buffer until the buffer is full or MTL sends the end of packet. When TDES3[FD] = 1, the amount of valid data in a buffer is accurately indicated by the buffer size fields in DMA Channel Rx Control (DMA_CH0_Rx_Control) minus the data buffer pointer offset. The offset is 0 when the data buffer pointer is aligned to the data bus width. If a descriptor is marked as last, the buffer may not be full (as indicated by DMA_CH0_Rx_Control[RBSZ_13_y] and DMA_CH0_Rx_Control[RBSZ_x_0]). To compute the amount of valid data in this final buffer, the driver must read the packet length (PL fields of RDES3[14:0]) and subtract the sum of the buffer sizes of the preceding buffers in this packet. The receive DMA always transfers the start of the next packet with a new descriptor.

72.4.2.4 DMA arbiter

The arbiter inside the DMA module performs the arbitration between the transmit and receive channel accesses to the AHB master interface. These two types of arbitrations are supported:

- Round-robin: If DMA_Mode[DA] = 0 and both transmit and receive DMAs simultaneously request access, the arbiter allocates the data bus in ratio sets defined in DMA_Mode[PR].
- Fixed-priority: If DMA_Mode[DA] = 1, receive DMA is always prioritized over transmit DMA for data access by default. If DMA_Mode[TXPR] = 1, transmit DMA is prioritized over receive DMA as explained in Table 479.

72.4.3 MTL

MTL provides the FIFO memory interface to buffer and regulate the packets between system memory and MAC. It also enables data to be transferred between the system clock and MAC clock domains. The MTL layer has two data paths: transmit path and receive path. MTL communicates with the host through ATI on the transmit path and through ARI on the receive path.

72.4.3.1 Transmit path

The internal DMA:

- Handles all transactions for the transmit path through ATI.
- Pushes the Ethernet packet reads from system memory to the corresponding queue.

The Ethernet packet, then, pops out and is transfered to MAC when the queue reaches its threshold (Threshold mode) or if the complete packet is in the queue (Store-and-Forward mode). When EOP is transferred, the status of the transmission is taken from MAC and transferred back to the internal DMA.

72.4.3.1.1 Transmit control word

This control information related to packet transmission is provided as part of the control word through the ATI interface:

- Packet length (if DCB is enabled with WFQ scheduling algorithm)
- CRC pad control
- Source address insertion control
- VLAN insertion and replacement control and VLAN tag for outer and inner VLAN tags
- TCP/IP checksum insertion control
- One-step timestamping control correction
- Transmit timestamp enable

72.4.3.1.2 Transmit operation

These two modes of operation trigger data read towards MAC:

- Threshold (or cut-through) mode: This is the default mode. In this mode, as soon as the number of bytes in the queue crosses the configured threshold level (or when the end of packet is written before the threshold is crossed), the data is ready to be popped out and forwarded to MAC. The threshold level is configured by using MTL_TxQ0_Operation_Mode[TTC].
- Store-and-Forward mode: In this mode, MTL pops the packet out to MAC only when one or more of the following conditions are true:
  - A complete packet is stored in the queue.
  - The transmit FIFO becomes almost full.
  - The ATI watermark becomes low.

  The watermark becomes low when the requested queue is not spacious enough to accommodate the requested burst length on ATI. Therefore, MTL, when operating in Store-and-Forward mode, allows packet transmission even if the packet length is bigger than the transmit queue size.

You can flush the complete content of the transmit queue by writing 1 to MTL_TxQ0_Operation_Mode[FTQ] or MTL_TxQ1_Operation_Mode[FTQ], depending on the queue. Doing so initializes the queue pointers to the default state. The FTQ

field returns to 0 by itself. If you write 1 to the FTQ field during a packet transfer from MTL to MAC, MTL stops further transfers because MTL considers the queue to be empty. Therefore, an underflow event occurs at the MAC transmitter.

72.4.3.1.3 Initialization flow

After reset, MTL is ready to manage the data flow between DMA and MAC.

- With single-transmit queue configurations, there are no initialization requirements for enabling MTL.
- With multiple-transmit queue configurations, initialize the queue size for each of the queues by programming MTL_TxQ0_Operation_Mode[TQS] corresponding to a transmit queue. Also, initialize the MAC block. Internal DMA controllers must be individually enabled through their respective CSRs.

72.4.3.2 Receive path

MAC sends packets to the MTL receive module and pushes them into the receive queue. MTL indicates the status (fill level) of the queue to the application or DMA when it crosses the configured receive threshold (MTL_RxQ0_Operation_Mode[RTC]), or when the MTL receive module receives the complete packet in Store-and-Forward mode. MTL also indicates the fill level of the queue so that DMA can initiate preconfigured burst transfers to the AHB interface.

72.4.3.2.1 Receive operation

During a receive operation, MTL is MAC's slave. This is the general sequence of events:

1. When MAC receives a packet, it indicates the availability of receive data.
2. MAC indicates the SOP and EOP delimiters.
3. MTL accepts the data and pushes it into the corresponding receive queue.
4. When MAC transfers EOP to the MTL receive module, MAC also drives the status word that MTL pushes into the corresponding receive queue.
5. MTL takes the data out of the queue and sends it to DMA depending on these modes:
   - Threshold mode
   - Store-and-Forward mode

   The sections that follow discuss these modes.

72.4.3.2.1.1 Threshold mode

In Threshold (default) mode, MTL reads the data and indicates its availability to the application or DMA when one of these occurs:

- Data bytes equal to the threshold amount are written to the receive queue (to MTL_RxQ0_Operation_Mode[RTC] and MTL_RxQ1_Operation_Mode[RTC]).
- A full packet of data is received into the queue.

72.4.3.2.1.2 Store-and-Forward mode

In this mode (when MTL_RxQ0_Operation_Mode[RSF] = 1), the initial receive queue locations are reserved for the status words before writing the SOP. A packet is read out only after it is completely written into the receive queue. In this mode, all error packets are dropped (if configured through MTL_RxQ0_Operation_Mode[FEP]) in such a way that only valid packets are read and forwarded to the application.

72.4.3.2.2 Multi-packet receive operation

In Threshold mode, the packet status is available immediately after the packet data. In Store-and-Forward mode, the packet data is available after the packet status. MTL is capable of storing any number of packets in the queue as long as it is not full.

If MAC receives a packet when the corresponding receive queue is full, MTL ignores that packet and overflow pulse generates on the corresponding receive queue. In addition, MTL increments the overflow counter in MTL Rx Queue Missed Packet Overflow Count (MTL_RxQ0_Missed_Packet_Overflow_Cnt) for the corresponding queue.

72.4.3.2.3 Error handling in receive operation

MTL performs these actions if the MTL receive queue is full before it receives the EOP data from MAC:

1. Declares an overflow
2. Drops the whole packet (including the status word)
3. Increments the overflow counter in DMA (MTL Rx Queue Missed Packet Overflow Count (MTL_RxQ0_Missed_Packet_Overflow_Cnt))

This is true even if MTL_RxQ0_Operation_Mode[FEP] is 1.

If the start address of such a packet is already transferred to the read controller, the rest of the packet is dropped and a dummy EOP is written to the queue along with the status word with overflow status. The status indicates a partial packet because of overflow. In such packets, the Packet Length field is invalid. If the MTL receive queue is configured to operate in the Store-and-Forward mode and the length of the received packet is more than the queue size, overflow occurs and all such packets are dropped.

The MTL receive control logic can filter errors and undersized packets, if enabled by using MTL_RxQ0_Operation_Mode[FEP] and MTL_RxQ0_Operation_Mode[FUP]. If the start address of one such packet is already transferred to the receive queue read controller, the packet is not filtered. The start address of the packet is transferred to the read controller after the packet crosses the receive threshold defined using MTL_RxQ0_Operation_Mode[RTC].

If the MTL receive queue is configured to operate in Store-and-Forward mode, all error packets can be filtered and dropped. For the application or DMA to flush the error packet being read from the queue, it must assert the flush signal. MTL then stops transferring data to the application (DMA). It internally reads the rest of the packet and drops it. MTL then starts transferring the next packet, if it's available.

72.4.4 MAC

MAC can support the MII and RMII PHY interface and it consists of:

- MTI
- MRI
- MCI

72.4.4.1 MAC transmission

The MAC transmission process is as follows:

1. The transmission initiates when MTL pushes in data with the SOP signal asserted.
2. After the SOP signal is detected, MAC accepts the data and begins transmitting to RMII or MII.
3. After the EOP signal is transferred to MAC, it performs one of these steps:
   - Completes normal packet transmission and sends the transmission status to MTL
   - Sends retry requests if a normal collision (in Half-Duplex mode) occurs during transmission, and until one of the following is true:
     - Packet is successfully transmitted.
     - Maximum retry requests have expired. When this happens, MAC aborts the packet transmission with "excessive collision transmit" status. MAC accepts and drops all further data until it receives the next SOP. The MTL block must retransmit the same packet from SOP on observing a retry request (in the status) from MAC.
   - If any one of the following happens, MAC aborts the packet transmission:

- No carrier (Half-Duplex mode)
- Loss of carrier (Half-Duplex mode)
- Excessive deferral (Half-Duplex mode)
- Late collisions (Half-Duplex mode)
- Jabber
- MAC accepts and drops all further data until it receives the next SOP

4. MAC issues an underflow status if MTL is not able to provide data continuously during transmission. Until the next SOP is received, MAC accepts and drops all further data.
5. During the normal transfer of a packet from MTL, if MAC receives an SOP without getting an EOP for the previous packet, it ignores the SOP and considers the new packet as a continuation of the previous packet.

72.4.4.2 MAC reception

The receive operation initiates as follows:

1. MAC detects a state-of-frame data on RMII or MII.
2. MAC strips the preamble and SFD before processing an Ethernet packet.
3. The MAC AFM:
   - Checks the header fields (SA and DA) of an incoming packet for filtering
   - Verifies the CRC contained in the packet's FCS field
4. MAC's AFM checks the header fields (SA and DA) of an incoming packet for filtering.
5. FCS verifies the CRC of the received packet.
6. MAC stores the received packet in a shallow buffer until address filtering is performed.
7. AFM drops the packet if it fails the address filter.

72.4.5 Interrupts

EMAC supports interrupt coalescing, which reduces the number of interrupts generated by the module and reduces the CPU load. MAC Interrupt Status (MAC_Interrupt_Status) captures various interrupt events. If the interrupt enable field of an interrupt is 1, the corresponding interrupt generates based on the event status in the Status registers. The Interrupt mode (INTM) field decides whether the interrupt signal is a level signal or pulse signal. See the following table and interrupt map file attached to this document for details.

Table 463. Interrupt request

Interrupt request	Interrupt Enable / Mask Register	Interrupt Flag Register
Common interrupt	MAC Interrupt Enable (MAC_Interrupt_Enable)	MAC Interrupt Status (MAC_Interrupt_Status)
	MMC Receive Interrupt Mask (MMC_Rx_Interrupt_Mask)	MMC Receive Interrupt (MMC_Rx_Interrupt)
	MMC Transmit Interrupt Mask (MMC_Tx_Interrupt_Mask)	MMC Transmit Interrupt (MMC_Tx_Interrupt)
	MMC FPE Transmit Interrupt Mask (MMC_FPE_Tx_Interrupt_Mask)	MMC Transmit FPE Fragment Counter Interrupt Status (MMC_FPE_Tx_Interrupt)

Table continues on the next page...

Table 463. Interrupt request (continued)

Interrupt request	Interrupt Enable / Mask Register	Interrupt Flag Register
	MMC FPE Receive Interrupt Mask (MMC_FPE_Rx_Interrupt_Mask)	MMC Receive Packet Assembly Error Counter Interrupt Status (MMC_FPE_Rx_Interrupt)
	MTL Debug Control (MTL_DBG_CTL)	MTL Debug Status (MTL_DBG_STS)
	MTL EST Interrupt Enable (MTL_EST_Intr_Enable)	MTL EST Status (MTL_EST_Status)
	MTL Rx Parser Interrupt Control Status (MTL_RXP_Interrupt_Control_Status)	MTL Rx Parser Interrupt Control Status (MTL_RXP_Interrupt_Control_Status)
	MTL Queue 0 Interrupt Control Status (MTL_Q0_Interrupt_Control_Status)	MTL Queue 0 Interrupt Control Status (MTL_Q0_Interrupt_Control_Status)
	MTL Queue 1 Interrupt Control Status (MTL_Q1_Interrupt_Control_Status)	MTL Queue 1 Interrupt Control Status (MTL_Q1_Interrupt_Control_Status)
	DMA Channel 0 Interrupt Enable (DMA_CH0_Interrupt_Enable)(transfer complete interrupts only)	DMA_CH0_Interrupt_Status
	DMA Channel 1 Interrupt Enable (DMA_CH1_Interrupt_Enable)(transfer complete interrupts only)	DMA_CH1_Interrupt_Status
		DMA Interrupt Status (DMA_Interrupt_Status) (First level status. Indicates major block event source: DMA channel, MTL or MAC)
		MTL Interrupt Status (MTL_Interrupt_Status) (Status summary for MTL block interrupts: Rx Parser, EST, FIFO Debug, Queue 1/Queue 0)
Tx interrupt 0/1	DMA Channel Tx Control (DMA_CH0_Tx_Control)	DMA Channel 0 Status (DMA_CH0_Status)
	DMA Channel 0 Interrupt Enable (DMA_CH0_Interrupt_Enable)	
	DMA Channel 1 Tx Control (DMA_CH1_Tx_Control)	DMA Channel 1 Status (DMA_CH1_Status)
	DMA Channel 1 Interrupt Enable (DMA_CH1_Interrupt_Enable)	
Rx interrupt 0/1	DMA Channel Rx Control (DMA_CH0_Rx_Control)	DMA Channel 0 Status (DMA_CH0_Status)
	DMA Channel 0 Interrupt Enable (DMA_CH0_Interrupt_Enable)	
	DMA Channel 1 Rx Control (DMA_CH1_Rx_Control)	DMA Channel 1 Status (DMA_CH1_Status)
	DMA Channel 1 Interrupt Enable (DMA_CH1_Interrupt_Enable)	

Table continues on the next page...

Table 463. Interrupt request (continued)

Interrupt request	Interrupt Enable / Mask Register	Interrupt Flag Register
Safety interrupt	MTL ECC Interrupt Enable (MTL_ECC_Interrupt_Enable)	MTL ECC Interrupt Status (MTL_ECC_Interrupt_Status)
		MTL Safety Interript Status (MTL_Safety_Interrupt_Status)
	MTL DPP Control (MTL_DPP_Control)	MAC DPP FSM Interrupt Status (MAC_DPP_FSM_Interrupt_Status)
	MAC FSM Control (MAC_FSM_Control)	

These are the interrupt output signals that are synchronous to the CSR clock.

- Sbd_intr_o – common interrupt
- Sbd_perch_tx_intr_o[max_dma_ch] – interrupt per transmit channel
- Sbd_perch_rx_intr_o [max_dma_ch] – interrupt per receive channel

NOTE

max_dma_ch = number of transmit/receive queues, which is 2

The sbd_intr_o common interrupt is a level signal. When it is asserted, a corresponding interrupt event source can be found in DMA Interrupt Status (DMA_Interrupt_Status), which is a read-only register that contains the event source fields corresponding to each DMA channel (transmit and receive queue pair), MAC transaction layer, and MAC blocks. You must then read the following registers and look for the fields that are 1:

- MAC Interrupt Status (MAC_Interrupt_Status)
- MTL Interrupt Status (MTL_Interrupt_Status)
- DMA Channel 0 Status (DMA_CH0_Status)

The sbd_intr_o interrupt deasserts only when all the enabled interrupt events are clear in their respective status registers, and correspondingly, all the fields in DMA Interrupt Status (DMA_Interrupt_Status) are 0. DMA Channel 0 Status (DMA_CH0_Status) captures all the interrupt events of that transmit DMA and receive DMA channel pair.

DMA Channel 0 Interrupt Enable (DMA_CH0_Interrupt_Enable) contains the corresponding enable fields for each of the interrupt events. These are the two groups of interrupts in the DMA channel:

- Normal—DMA_CH0_Status[NIS] indicates this interrupt, which is used for events that occur during the normal transfer of packets (TI, RI, TBU).
- Abnormal—DMA_CH0_Status[AIS] indicates this interrupt, which is used for error events.

Interrupts are not queued. If the same interrupt event occurs again before the driver responds to the previous one, no additional interrupts generate.

The common sbd_intr_o output signal asserts for the transfer complete interrupts only when the corresponding interrupts are enabled in DMA Channel 0 Interrupt Enable (DMA_CH0_Interrupt_Enable).

EMAC also supports these per-channel transfer-complete interrupt signals:

- sbd_perch_tx_intr_o[max_dma_ch] (transmit per channel interrupts)
- sbd_perch_rx_intr_o[max_dma_ch] (receive per channel interrupts)

The behavior of the RI/TI/sbd_perch_tx_intr_o[]/sbd_perch_rx_intr_o[] changes depends on the configuration specified in DMA_Mode[INTM]. This table explains the transfer complete interrupt behavior.

Table 464. Transfer complete interrupt behavior

Interrupt mode	Behavior of sbd_perch_tx_intr_o[] and sbd_perch_rx_intr_o[]	Behavior of the TI/RI interrupts and sbd_intr_o
INTM = 1	In this mode, these signals indicate the values of the corresponding DMA_CH0_Status[RI] and DMA_CH0_Status[TI] fields when DMA_CH0_Status[RI] and DMA_CH0_Status[TI] are 1, respectively. Therefore, they are level signals that you clear by writing 1 to these fields. The signals do not assert when DMA_CH0_Status[RI] or DMA_CH0_Status[TI] is 0.	DMA_CH0_Status[RI] and DMA_CH0_Status[TI] are configured as explained. For any RI/TI events: • The sbd_intr_o signal does not assert. • DMA_CH0_Status[NIS] remains 0.
INTM = 2	In this mode, RI/TI are queued and indicate the values of the corresponding DMA_CH0_Status[RI] and DMA_CH0_Status[TI] fields when any of these fields is 1. RI and TI are level signals that you clear by writing 1 to these fields. However, the fields become 1 again if another TI/RI event is detected before DMA_CH0_Status[RI] and DMA_CH0_Status[TI] become 1 for the previous event.	DMA_CH0_Status[RI] and DMA_CH0_Status[TI] become 1 whenever the transfer complete event is detected and are reset whenever the software driver changes them to 0 by writing 1. However, if another transfer complete event is detected before the software changes it to 0 (services it), EMAC automatically writes 1 to these fields again. The generation of the sbd_intr_o signal; however, is not based on DMA_CH0_Status[RI] or DMA_CH0_Status[TI].

72.5 Signal descriptions

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

72.5.1 Module signals

This table provides port/signal names and their descriptions. See the IOMUX file attached to this document for details.

Table 465. Module signals

Port name (clock/signal)	I/O	Description
MII_RMII_TXCLK (Clock)	I	MII: The external PHY provides this transmission clock, which operates at a frequency of 25 MHz in 100 Mbps mode and at 2.5 MHz in 10 Mbps mode. All transmission signals that MAC generates are synchronous to this clock, which is required for all PHY interfaces.

Table continues on the next page...

Table 465. Module signals (continued)

Port name (clock/signal)	I/O	Description
		RMII: The RMII interface uses this 50 MHz clock. If you select RMII mode, MII_RX_CLK (25 MHz or 2.5 MHz) must be derived from the RMII reference clock.
MII_RX_CLK (Clock)	I	The external PHY provides this receive clock for the MII and RMII interfaces. The clock operates at a frequency of 25 MHz in 100 Mbps mode and at 2.5 MHz in 10 Mbps mode. All MII receive signals that MAC receives are synchronous to MII_RX_CLK. The clock's input is required for all PHY interfaces.
EMAC_PPS[3:0] (Signals)	I/O	This group of signals is used as pulse per second in Output mode and as media clock generation trigger in Input mode. The signals trigger input to DUT to capture presentation time. Based on the presentation control value of MAC PPS Control (MAC_PPS_Control), the signals can be defined as pulse or level signals.
MII_RMII_TX_EN (Signal)	O	MAC drives this signal, which performs multiple functions depending on the selected PHY interface as described in this list: • MII: When high, indicates that valid data is being transmitted to the phy_txd_o bus. MII_RMII_TX_EN is synchronous to MII_RMII_TX_CLK. • RMII: When high, indicates that valid data is being transmitted to the phy_txd_o bus. MII_RMII_TX_EN is synchronous to MII_RMII_RX_CLK.
MII_RMII_TXD[3:0] (Signals)	O	This is a group of transmit data signals driven by MAC. These signals perform multiple functions depending on the selected PHY interface as described in this list: • MII: Bits[3:0] provide the MII transmit data nibble. The data is valid only when the MII_RMII_TX_EN signal is high. MII_RMII_TXD[3:0] is synchronous to MII_MII_TX_CLK. • RMII: Bits[1:0] provide the RMII transmit data. The data is valid

Table continues on the next page...

Table 465. Module signals (continued)

Port name (clock/signal)	I/O	Description
		only when the MII_RMII_TX_EN signal is high. MII_RMII_TXD[3:0] is synchronous to MII_RMII_TX_CLK.
MII_CRS (Signal)	I	This signal is valid only in MII mode. The PHY drives this signal high when the transmit or receive medium is not idle, and drives the signal low when both these mediums are idle. The signal is not synchronous to any clock.
MII_COL (Signal)	I	This signal is valid only in MII mode. The PHY drives this signal high when a collision is detected on the medium. The signal is not synchronous to any clock.
MII_RMII_RX_DV (Signal)	I	The PHY drives this signal. It performs multiple functions depending on the selected PHY interface as described in this list: • MII: Indicates that the data on the MII_RXD bus is valid. It remains high continuously from the first recovered byte or nibble of the packet through the final recovered byte or nibble of the packet. MII_RMII_RX_DV is synchronous to MII_RX_CLK. • RMII: Contains the CRS and data valid information of the receive interface. MII_RMII_RX_DV is synchronous to MII_RMII_TX_CLK.
MII_RMII_RX_ER (Signal)	I	The PHY drives this signal. It performs multiple functions depending on the selected PHY interface as described in this list: • MII: Indicates an error or carrier extension in the received packet of the MII_RXD[3:0] bus. MII_RMII_RX_ER is synchronous to MII_RX_CLK. • RMII: Is not used.
MII_RMII_RXD[3:0] (Signals)	I	This is a group of data signals received from the PHY. These signals perform multiple functions depending on the selected PHY interface as described in this list:

Table continues on the next page...

Table 465. Module signals (continued)

Port name (clock/signal)	I/O	Description
		• MII: Bits [3:0] provide the MII receive data nibble. The data is valid only when the MII_RMII_RX_DV signals are high. MII_RMII_RXD[3:0] is synchronous to MII_RX_CLK. • RMII: Bits [1:0] provide the RMII receive data. The data is valid only when the MII_RMII_RX_DV signal is high. MII_RMII_RXD[3:0] is synchronous to MII_RMII_TX_CLK.
MII_RMII_MDC	O	MAC provides timing reference for MII_RMII_MDIO or MII through this periodic clock. The application clock generates this clock through a clock divider that MAC_MDIO_Address[CR] controls.
MII_RMII_MDIO (Signal)	I/O	MDIO uses this signal to transfer control and data information to PHY.

72.6 Using PHY interfaces

This section is Synopsys Proprietary. Used with permission.

This module support the following modes:

- RMII 10/100 Mbps interface
- MII 10/100 Mbps interface

Phy_intf_sel input signal decides which mode is selected. Samples the Phy_intf_sel signal at reset. See Signal descriptions for more information. MAC_Configuration[PS] and MAC_Configuration[FES] selects the mode's speed.

The module supports the IEEE802.3-2015 specification for MII and RMII specification version 1.2 from RMII consortium.

NOTE

RMII reference clock (50 MHz) can be fed to IP from an external source or internally from PLL on SoC.

The module supports the access of the phy registers through SMA. It is a two wire Station management interface (MIM):

1. MDC
2. MDIO

According to IEEE 802.3 specification, maximum operating frequency of MDC is 2.5 Mhz which system clock derives using a divider. MAC_MDIO_Address[CR] programs to generate different MDC clock frequency.

SMA supports MDIO clause 45 and clause 22 frame structure per the IEEE802.3 specification. Writing 1 to MAC_MDIO_Address[C45E] enables the clause 45 frame structure.

The MII interface reduces the accuracy of the 1588 timestamp if it is overclocked to run at 200 Mbps. This happens because the MAC logic uses the MII interface speed,to adjust or compensate for the timestamps taken at MII, as compared to the time generated in the PTP clock domain as specified in MAC_Configuration[FES].

72.7 VLAN and double VLAN insertion, deletion, replacement and tagging

This section and all its sub-sections are Synopsys proprietary. These are used with permission.

The following sections describe the VLAN and double VLAN features.

72.7.1 Double VLAN processing

In the double VLAN tagging processing, the module supports the processing of two VLAN tags. The two VLAN tags are:

1. Inner VLAN tag (C-VLAN)
2. Outer VLAN tag (S-VLAN)

If there is only one tag in a packet then it is considered as an outer tag.

The module uses MAC_VLAN_Incl and MAC_Inner_VLAN_Incl and MAC_VLAN_Tag registers to support the following functions in a double VLAN processing feature.

- Insertion, replacement, or deletion of up to two VLAN tags in the transmit path.
- Packet filtering and stripping on the basis of any one of the two VLAN tags in the receive path. Stripping and providing up to two VLAN tags in the receive path as a part of the receive status.

72.7.1.1 Transmit path

Table 466. Double VLAN processing features in transmit path

Feature	Description
Support for C-VLAN and S-VLAN tag types	The inner or outer VLAN tag can be of C-VLAN and S-VLAN type. MAC_VLAN_Incl[CSVL] and MAC_Inner_VLAN_Incl[CSVL] specifies the VLAN type. The module supports the processing of any sequence of outer and inner VLAN tags. NOTE The module does not support the C-VLAN and S-VLAN sequence. MAC does not examine whether the packet, which the application provides has a valid sequence of the VLAN tag types or the insertion or replacement operation results in an invalid sequence of VLAN tag type. Therefore, the application must provide a correct sequence of VLAN tag types and program the MAC in such a way that it results in correct sequence of VLAN tag types in the transmitted packet. The application must ensure the following: • The inner tag should not be S-VLAN when outer C-VLAN Tag insertion is enabled. • The outer tag should not be C-VLAN when inner S-VLAN Tag insertion is enabled. • The inner tag should not be S-VLAN when C-VLAN replaces the outer tag. • The outer tag should not be C-VLAN when S-VLAN replaces the inner tag.
VLAN tag deletion	MAC_VLAN_Incl[VLC] or MAC_Inner_VLAN_Incl[VLC] respectively enables the VLAN tag deletion for an outer or inner tag. When you enable the VLAN deletion, MAC deletes the tag present at the corresponding position. When a packet has only one tag, it is considered as the outer tag. If you enable the inner tag deletion and if there is only one tag in the packet, then the MAC does not delete the tag.
VLAN tag insertion or replacement	MAC_VLAN_Incl[VLC] or MAC_Inner_VLAN_Incl[VLC] respectively enables the VLAN tag insertion or replacement for an outer or inner tag. When you enable the VLAN tag insertion or replacement, the MAC_VLAN_Incl[VLTI] or

Table continues on the next page...

Table 466. Double VLAN processing features in transmit path (continued)

	MAC_Inner_VLAN_Incl[VLTI] determines whether the VLAN tag must be fetched from the register or from the control word.

72.7.1.2 Receive path

Table 467. Double VLAN processing in receive path

Feature	Description
Outer or inner VLAN tag-based filtering	Mac can filter packets through the ERIVLT bit on the basis of the outer or inner VLAN tag.
C-VLAN or S-VLAN tag-based filtering	Mac can filter packets through the ERSVLM bit on the basis of the C-VLAN or S-VLAN type.
Outer and inner VLAN tag stripping	Mac can strip the outer and inner VLAN tags from received frame on the basis of the EVLS and EIVLS bits.
16-bit outer and inner VLAN tag and type in Rx status	Mac can provide the 16-bit outer and inner VLAN tag and type in the Rx status on the basis of the EVLRXS and EIVLRXS bits, respectively.
Disabling or skipping checking of outer VLAN tag type	Mac can disable or skip checking of an outer VLAN tag type to match C-VLAN or S-VLAN on the basis of the DOVLTC bit.

72.7.1.3 Source address and VLAN insertion, replacement, or deletion

This module supports the SA, and VLAN insertion, replacement and deletion feature. The SA and VLAN fields are Tx packet-related control information that interfaces provide as part of the control word. IP supports the feature to insert or replace the source address on the basis of the information in the MAC address registers, and it also supports the feature to insert, replace, or delete the VLAN fields (VLAN type and VLAN tag) on the basis of the setting of the MAC_VLAN_Incl[VLTI]. SA insertion or replacement feature is enabled for all the transmit packets or selective packets. Similarly, VLAN insertion, replacement, or deletion feature is enabled for all the Tx packets or selective packets.

72.7.1.4 Programming source address insertion or replacement

You can use the SA insertion or replacement feature to instruct MAC to perform the following actions for Tx packets:

- Insert the content of the MAC address registers in the SA field
- Replace the content of the SA field with the content of the MAC address registers

When SA insertion is enabled, the application must ensure that the packets sent to MAC do not have the SA field. The MAC does not check whether the SA field is present in the transmit packet and it inserts the content of MAC address registers in the SA field. Similarly, when the SA replacement is enabled, the application must ensure that the SA field is present in the packets sent to the MAC.

MAC replaces the six bytes following the DA field in the transmit packet with the content of the MAC address registers.

- Configure MAC_Configuration[SARC] to enable the SA insertion or replacement for all Tx packets.
- Enable the SA insertion for selective packet by configuring the SA insertion control field (bits [25:23] of TDES3) in the first transmit descriptor of the packet. When you write 1 to bit 25 of TDES3, the SA insertion control field indicates insertion or replacement by MAC Address1 registers. When bit 25 of TDES3 resets, it indicates insertion or replacement by MAC Address 0 registers.

If you do not enable the MAC Address1 registers, then the MAC Address0 registers are used for insertion or replacement irrespective of the value of the most-significant bit of the SA insertion control field.

72.7.1.5 Programming VLAN insertion, replacement, or deletion

You can use the VLAN insertion, replacement, or deletion feature to instruct MAC to perform the following actions for the Tx packets:

- Delete the VLAN type and VLAN tag fields.
- Insert or replace the VLAN type and VLAN tag fields.

Insertion or replacement is done on the basis of the setting of the MAC_VLAN_Incl[VLTI] as described in theTable 468:

Table 468. VLAN insertion or replacement based on VLTI bit

Condition	Description
VLTI bit=1	MAC inserts or replaces the following: • VLAN type field (C-VLAN or S-VLAN as indicated by the MAC_VLAN_Incl[CSVL]) • VLAN tag field depending on the content of the VT field of transmit context descriptor of the packet
VLTI bit resets	MAC inserts or replaces the following: • VLAN type field (C-VLAN or S-VLAN as indicated by the MAC_VLAN_Incl[CSVL]) • VLAN tag field with the MAC_VLAN_Incl[VLT]

When the VLAN replacement or deletion is enabled, MAC checks whether the VLAN type field (0x8100 or 0x88a8) is present after the DA and SA fields in the transmit packet. The replace or delete operation does not occur if the VLAN type field is not detected in two bytes following the DA and SA fields. However, when the VLAN insertion is enabled, MAC does not check the presence of VLAN type field in the transmit packet and just inserts the VLAN type and VLAN tag fields.

Configuring MAC_VLAN_Incl[VLC] and MAC_VLAN_Incl[VLP] enables the VLAN insertion, replacement, or deletion feature for all Tx packets.

Configuring the VTIR field of TDES2 normal descriptor enables the VLAN insertion, replacement, or deletion for selective packets.

In addition, the VLP (VLAN Priority control) field must reset in MAC_VLAN_Incl (for outer VLAN) and MAC_Inner_VLAN_Incl register (in inner VLAN) for MAC to take the control inputs from the host, depending on the configuration.

72.8 Packet Filtering

This section and all its sub-sections are Synopsys proprietary. Used with permission.

MAC receiver contains various packet filtering scheme. Figure 2 shows the filtering sequence in their precedence order of received packet.

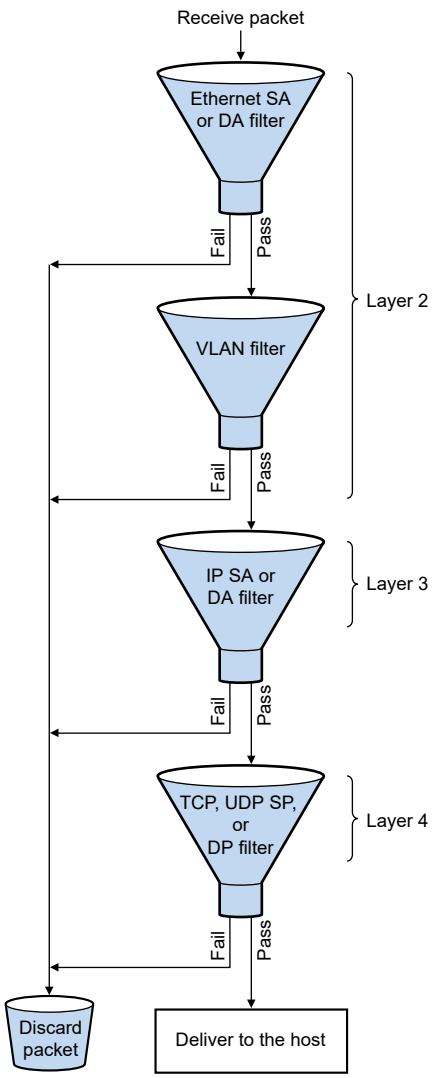

Figure 389. Packet filtering sequence

If you do not enable any of the layer filters, then that filter is bypassed and the subsequent filter is applied. Discard the packet that fails any of the filters. However, you can forward the discarded packet to the host on the basis of the register control.

72.8.1 Source address or destination address filtering

The address filtering module of MAC checks the SA and DA fields of each incoming packet. Programming of different types of address filtering is described in the sections that follows.

72.8.1.1 Unicast destination address filtering

MAC supports up to three MAC addresses for unicast perfect filtering. If perfect filtering is selected (MAC_Packet_Filter[HUC] resets), MAC compares all 48 bits of received unicast address with the programmed MAC address for any match. Default MacAddr0 is always enabled. MAC selects the MacAddr1 to MacAddr2 addresses with an individual enable field. Each byte of MacAddr1 to MacAddr2 can be masked when you compare them with corresponding received DA byte by writing 1 to the corresponding Mask byte control field in the register. This enables group address filtering for the DA.

In hash filtering mode (when you write 1 to HUC bit), MAC performs imperfect filtering by using a 64-bit hash table for unicast addresses . For hash filtering, MAC uses the upper 6 bits CRC of the received destination address to index the content of the hash table. A value of 00000 selects bit 0 of selected register, and a value of 11111 selects bit 63 of hash table register. If the value of

the corresponding bit (indicated by the 6-bit CRC) is 1, the unicast packet is considered to have passed the hash filter, otherwise, the packet is considered to have failed the hash filter.

72.8.1.2 Multicast destination address filtering

Enable MAC_Packet_Filter[PM] to pass all the multicast packets or disable to do multicast addresses filtering on the basis of MAC_Packet_Filter[HMC]. Compare the multicast address with the configured MAC destination address registers (1–2), also supports the group address filtering.

In Hash filtering mode, MAC performs imperfect filtering using a 64-bit hash table. MAC uses the upper 6-bits CRC of received multicast address to index the content of the hash table. A value of 000000 selects bit 0 of selected register and a value of 111111 selects bit 63 of the hash table register. The multicast packet is considered to have passed the hash filter if the value of the corresponding bit is equal to 1. Otherwise, the packet is considered to have failed the hash filter.

72.8.1.3 Hash or perfect address filtering

Configure MAC_Packet_Filter[HPF] to enable or disable the destination address filtering either by hash filter or perfect filter. Also configure MAC_Packet_Filter[HUC] and MAC_Packet_Filter[HMC] to select the hash filtering or perfect filtering for unicast or multicast packet.

72.8.1.4 Broadcast address filtering

MAC does not filter any broadcast packets by default. You must write 1 to MAC_Packet_Filter[DBF] to reject the broadcast packets.

72.8.1.5 Unicast source address filtering

MAC by default compares the source address field with the value configured in the source address registers. Configure bit 30 of MAC address register [1-2] to use it for source address instead of destination address comparison. MAC also supports group filtering with SA. You can filter a group of addresses by masking one or more bytes of the address. MAC drop the packets that fail the SA filter if you write 1 to MAC_Packet_Filter[SAF] field. Otherwise, the result of the SA filter is given as a status bit in the receive status word. When you write 1 to the SAF field, the SA filter and DA filter results ends to decide whether you can forward the packets. This means that the packet is dropped if either filter fails. The packet is forwarded to the application only if the packet passes both filters in-order.

72.8.1.6 Inverse filtering

For DA and SA filtering, you can invert the filter-match result at the final output by writing 1 to the DAIF and SAIF fields of MAC_Packet_Filter register. The DAIF field is applicable for both the unicast and multicast DA packets. The unicast or multicast destination address filter result is inverted in this mode. Similarly, writing 1 to the SAIF field reverses the result of unicast SA filter.

Table 469 and Table 470 summarize the DA and SA filtering on the basis of the type of packets received.

Table 469. Destination address filtering

Packet type	PR	HPF	HUC	DAIF	HMC	PM	DBF	DA filter operation
Broadcast	1	X	X	X	X	X	X	Pass
	0	X	X	X	X	X	0	Pass
	0	X	X	X	X	X	1	Fail
Unicast	1	X	X	X	X	X	X	All packets pass
	0	X	0	0	X	X	X	Pass on perfect or group filter match

Table continues on the next page...

Table 469. Destination address filtering (continued)

	0	X	0	1	X	X	X	Fail on perfect or group filter match
	0	0	1	0	X	X	X	Pass on hash filter match
	0	0	1	1	X	X	X	Fail on hash filter match
	0	1	1	0	X	X	X	Pass on hash or perfect or group filter match
	0	1	1	1	X	X	X	Fail on hash or perfect or group filter match
Multicast	1	X	X	X	X	X	X	Pass all packets
	X	X	X	X	X	1	X	Pass all packets
	0	X	X	0	0	0	X	Pass on perfect or group filter match and drop pause packets if PCF = 0x
	0	0	X	0	1	0	X	Pass on hash filter match and drop pause packets if PCF = 0x
	0	1	X	0	1	0	X	Pass on hash or perfect or group filter match and drop pause packets if PCF = 0x
	0	X	X	1	0	0	X	Fail on perfect or group filter match and drop pause packets if PCF = 0x
	0	0	X	1	1	0	X	Fail on hash filter match and drop pause packets if PCF = 0x
	0	1	X	1	1	0	X	Fail on hash or perfect/group filter match and drop pause packets if PCF = 0x

Table 470. Source address filtering

Packet type	PR	SAIF	SAF	SA filter operation
Unicast	1	X	X	Pass all packets.
	0	0	0	Pass status on perfect or group filter match but do not drop packets that fail
	0	1	0	Fail status on perfect or group filter match but do not drop packet
	0	0	1	Pass status on perfect or group filter match and drop packets that fail
	0	1	1	Fail status on perfect or group filter match and drop packets that fail

NOTE

When you write 1 to the MAC_Packet_Filter[RA] field, all packets are forwarded to the system along with the correct result of the address filtering in the Rx Status.

72.8.2 VLAN filtering

VLAN tag filter can be done either by perfect match or hash table. Depending upon the configuration, MAC can compare either lower 12 bits or all 16 bits of received VLAN tag for perfect match. MAC forward the VLAN tagged packet with match status when it drop all the packets which do not match.

MAC uses 16-bit VLAN hash table for group address filtering on the basis of the VLAN tag. If MAC enables the hash filtering then the most significant 4-bit of CRC-32 of VLAN tag are used to index the content of the MAC_VLAN_Hash_Table. A value of 1 in the VLAN hash table register, corresponding to the index indicates that the VLAN tag of the packet has matched and the packet should be forwarded. A value of 0 indicates that VLAN-tagged packet should be dropped.

MAC supports the inverse matching for VLAN packets. In the Inverse matching mode, the packet must be dropped when the VLAN tag of a packet matches the perfect or hash filter. If MAC enables the VLAN perfect and VLAN hash match, then a packet is considered as matched if either the VLAN hash or the VLAN perfect filter matches. When inverse match is set, MAC forwards a packet only when both the perfect and hash filters indicate mismatch.

Table 471 specifies the different possibilities for VLAN matching and the final VLAN match status. When you write 1 to MAC_Packet_Filter[RA] all packets are received and it indicates the VLAN match status in the VF field of RDES2 normal descriptor (write-back format). When the RA field is not set and when you write 1 to MAC_Packet_Filter[VTFE] the packet drops if the final VLAN match status fails

When VLAN VID programs to 0 in the VL field of MAC_VLAN_Tag register, consider that all the VLAN-tagged packets are perfectly matched but the status of the VLAN hash match depends on the VTHM and VTIM fields in MAC_VLAN_Tag register.

Table 471. VLAN match status

VID	VLAN perfect filter match result	VTHM bit	VLAN hash filter match result	VTIM bit	Final VLAN match status
VID = 0	Pass	0	X	X	Pass
	Pass	1	X	0	Pass
	Pass	1	Fail	1	Pass
	Pass	1	Pass	1	Fail
VID1= 0	Pass	X	X	0	Pass
	Fail	0	X	0	Fail
	Fail	1	Fail	0	Fail
	Fail	1	Pass	0	Pass
	Fail	0	X	1	Pass
	Pass	X	X	1	Fail
	Fail	1	Pass	1	Fail
	Fail	1	Fail	1	Pass

In Table 471, X represents any value.

72.8.3 VLAN filter fail packets queue

When you enable VLAN filtering, route the VLAN filter fail packets to a programmable queue (VFFQ) when the value of MAC_Packet_Filter[RA] = 1 or MAC_Packet_Filter[VTFE] = 0 and write 1 to MAC_RxQ_Ctrl4[VFFQE] for the queue.

Route the packets that passes the VLAN filtering to Rx queues on the basis of the VLAN tag priority field by configuring the PSRQ field in the corresponding MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers. Discard the packets that fail the VLAN filter if RA=0 or VTFE=1. However, when RA=1 or VTFE=0, forward the VLAN filter fail packets to the application. In such case, when you write 1 to the VLAN filter fail queue enable (VFFQE) field, the VLAN filter fail packets forward to the Rx queue number programmed in the VFFQ field. If the value of VFFQE=0, the VLAN priority mapping determines the Rx queue number per the PSRQ fields.

Table 472 shows the Rx queue routing table for unicast tagged packets, with DA or SA filter enabled.

Table 472. Rx queue routing table for unicast tagged packets

RA	VFTE	SA or DA filter result	VLAN filter result	VFFQE	Queue routing
X	X	Pass	Pass	X	PSRQ
0	0	Pass	Fail	0	PSRQ
0	0	Pass	Fail	1	VFFQ
0	X	Fail	X	X	Dropped
0	1	Pass	Fail	X	Dropped
1	X	Fail	X	0	UFFQ*/PSRQ
1	X	Fail	X	1	UFFQ*/VFFQ
1	X	Pass	Fail	0	PSRQ
1	X	Pass	Fail	1	VFFQ

X : Don't care condition * : When UFFQE is enabled else PSRQ.

72.8.4 Extended receive VLAN filtering and routing

When the extended Rx VLAN filtering and routing is enabled then both the perfect filtering and hash filtering can be enabled. The overall VLAN filter result is based on the perfect filter result and hash filter result (if enabled). Filter result is passed to application as part of the status bit. Extended routing will take place only if VLAN filter has passed. Routing is only based on perfect filter result. Each perfect filter has a DMA channel enable and DMA channel number filed which must be programmed for routing.

See the extended VLAN based DMA selection in Dynamic (per packet) mapping for more information about routing.

72.8.4.1 Comparison mode

Application has these comparison option for each VLAN tag filter:

- Programs MAC to compare the inner or outer VLAN tag either with 12 bits or 16 bits programmed VID.
- Selects whether the VID comparison is for SVLAN or CVLAN type frames, if type check is enabled for a filter.

72.8.4.2 Filtering

Perfect filtering is done on the basis of the MAC_VLAN_Tag_Filter registers. MAC compares the relevant VLAN tag ID and gives a result for each VLAN tag filter.

The results for each VLAN tag filter are:

- Pass- If any one of the VLAN tag filters gives a match.
- Fail- If the frame mismatches all the filters.

This behavior is applicable only when the inverse filtering is not enabled in MAC_VLAN_Tag_Ctrl.

If inverse filtering is enabled and the frame mis-matches all the relevant filters then it is considered to have passed the VLAN filter. If the frame matches any one of the relevant filters then it is considered to have failed. The frame is bypassed to the application if none of the enabled filters can perform a comparison or if none of the filters are enabled.

The overall filter result and the programming on MAC_Packet_Filter[VTFE] and MAC_Packet_Filter[RA] determines if the frame will drop or it is forwarded to the application. If the value of RA = 1 or VTFE = 0, then the frame is always forwarded whether the filter result is a pass or fail, . If the value of RA = 0 and VTFE = 1, only then, if the VLAN tag filter result is a pass the MAC forwards the frame. If the frame is forwarded to the application, then the relevant filter result is indicated through the status bits.

72.8.4.3 Filter status

The extended receive VLAN filtering and routing feature provides two status fields to show the comparison result of the VLAN tags.

By default, MAC indicates the VLAN filter status through one bit in the status VF field in RDES2. When you enable the extended RX VLAN filtering and routing, two status fields will show the comparison result of the VLAN tags. The outer VLAN tag filter pass and inner VLAN tag filter pass bits are defined in the following positions. The status indicated through these fields depends on the programming as described below.

In RDES2:

- Bit 15 – Outer VLAN tag filter status
- Bit 14 – Inner VLAN tag filter status

In ARI status: MAC filter status:

- Bit 15 – Outer VLAN tag filter status
- Bit 14 – Inner VLAN tag filter status

In MRI status:

- Bit 47 – Outer VLAN tag filter status
- Bit 46 – Inner VLAN tag filter status

Outer VLAN tag filter status (OTS)

- In perfect filtering, without enabling inverse filtering, if you write 1 to this field, it indicates that the frame's outer VLAN tag has matched one of the VLAN tag filters.
- If this field resets, it indicates that the frame's outer VLAN tag has either failed the relevant outer VLAN tag filters or bypassed them.
- This field resets if none of the filters are enabled for outer VLAN tag comparison.
- If inverse filtering is enabled and if you write 1 to this field, then the frame's VLAN tag has passed all the relevant VLAN tag filters. If it is resets, then it has failed at least one filter or bypassed all the filters programmed for outer VLAN tag comparison.
- This bit is valid for both single and double VLAN tagged frames.

Inner VLAN tag filter status (ITS)

- In perfect Filtering, without enabling inverse filtering, if you write 1 to this field, it indicates that the frame's inner VLAN tag has matched one of the VLAN tag filters.
- If this field resets, it indicates that the frame's inner VLAN tag has either failed the relevant inner VLAN tag filters or bypassed them.
- This field resets if none of the filters are enabled for inner VLAN tag comparison.
- If Inverse Filtering is enabled and if you write 1 to this field, then the frame's VLAN tag has passed all the relevant VLAN tag filters. If it resets, then it has failed at least one filter or bypassed all the filters programmed for inner VLAN tag comparison.

- This bit is valid for only double VLAN tagged frames, when double VLAN processing is enabled.

The application must observe the status fields and the program to determine if the frame has passed or failed the VLAN filter.

Table 473 and Table 474 describes the possible filter combinations and the corresponding filter results and they also explain the scenarios when the double VLAN processing and the hash VLAN filter are enabled in the design.

Legend for the table OTS and ITS Bit Values with at least 1 perfect filter enabled

- VTIM: VLAN tag inverse match enable – bit 17 in VLAN_Tag_Ctrl register.
- HFO: Hash filter enabled for outer VLAN tag comparison - bit 25 and bit 27 in VLAN_Tag_Ctrl register.
- HFI: Hash filter enabled for inner VLAN tag comparison – bit 25 and bit 27 in VLAN_Tag_Ctrl register.
- PFO – Perfect filter comparison enabled for outer VLAN tag - Any of the MAC_VLAN_Tag_Filter registers is enabled (write 1 to bit 16) and programmed for outer VLAN tag comparison (write 0 to bit 20).
- PFI – Perfect filter comparison enabled for Inner VLAN Tag - Any of the MAC_VLAN_Tag_Filter registers is enabled (write 1 to bit 16) and programmed for inner VLAN tag comparison (write 1 to bit 20).
- OTS – Outer VLAN tag filter status
- ITS – Inner VLAN tag filter status

Table 473 shows the possible values of status bits (OTS and ITS) when at least one perfect filter is enabled.

Table 473. OTS and ITS bit values with at least 1 perfect filter enabled

VTIM	HFO	HFI	PFO	PFI	OTS	ITS
0	0	0	0	1	0	1/0
0	0	0	1	0	1/0	0
0	0	0	1	1	1/0	1/0
0	1	0	1	1	1/0	1/0
0	1	0	1	0	1/0	0
0	1	0	0	1	1/0	1/0
0	0	1	1	1	1/0	1/0
0	0	1	1	0	1/0	1/0
0	0	1	0	1	0	1/0
1	0	0	0	1	0	1/0
1	0	0	1	0	1/0	0
1	0	0	1	1	1/0	1/0
1	1	0	1	1	1/0	1/0
1	1	0	1	0	1/0	0
1	1	0	0	1	1/0	1/0

Table continues on the next page...

Table 473. OTS and ITS bit values with at least 1 perfect filter enabled (continued)

VTIM	HFO	HFI	PFO	PFI	OTS	ITS
1	0	1	1	1	1/0	1/0
1	0	1	1	0	1/0	1/0
1	0	1	0	1	0	1/0

Table 474 shows the possible values of status bits (OTS and ITS) when no perfect filters are enabled except the VLAN hash filter is enabled.

Table 474. OTS and ITS bit values with only VLAN hash filter enabled

VTIM	HFO	HFI	OTS	ITS
0	0	0	0	0
0	1	0	1/0	0
0	0	1	1/0	1/0
1	0	0	1/0	0
1	1	0	1/0	0
1	0	1	1/0	1/0

With no perfect filters enabled, any VLAN packet is considered to have bypassed the perfect filter. If Hash Filter is enabled for one of the Tags, then the respective Status bit depends on the Filter's result. The Status bits are set to 0 if VLAN Hash Filter is also not enabled.

If the value of ITS/OTS is shown as 1/0; then it indicates that the final result is dependent on the enabled relevant filter's result.

Example 1: The second row of OTS and ITS bit values with only VLAN hash filter enabled indicates that at least one Perfect Filter is enabled for Outer VLAN tag comparison and none of the filters are enabled for Inner VLAN tag comparison. Inverse VLAN Filtering is not enabled. The bit OTS is given as 1/0. If the received frame passes atleast one of the enabled Outer VLAN Tag filters then the bit is set to 1. If the frame doesn't pass any of the enabled Outer VLAN Tag filters, then the bit is set to 0.

Example 2: The last row of table "OTS and ITS bit values with only VLAN hash filter enabled" indicates that the inverse filtering is enabled, hash filter and at least one perfect filter is enabled for Inner VLAN Tag comparison, then if the received frame's Inner VLAN tag mismatches with both the Hash Filter and all the enabled Perfect filters, then the frame will have the ITS bit set to 1 else it is set to 0. OTS will be set to 0 as no comparison is performed.

72.8.4.4 Stripping

Each VLAN tags has individual control over stripping. The programming options of always strip, never strip, strip on pass and strip on fail are available. Inner or outer VLAN tag stripping is based on the pass or fail results of the individual tag. If all the relevant filters bypasses a tag, stripping is not applicable for the tag.

- If strip on pass is enabled for the outer VLAN tag, then the stripping occurs only if the outer VLAN tag has passed the relevant filters. The outer VLAN tag filter result field will be 1.
- If strip on fail is enabled for the outer VLAN tag, then the stripping occurs only if the outer VLAN tag has failed relevant filters. The outer VLAN tag filter result field will reset.
- If the outer VLAN tag of the received frame is bypassed by the entire filter (no comparison has been made), then the tag is not stripped, though the status bit is 0.

- As multiple filters are enabled, it is possible that the received VLAN frame could have matched any one or more of thefilters. The VLAN Tag's value is not always deterministic from the filter status bits.

If an application strips the VLAN tag on the basis of the filter result, it might lose the VID. You can use it, if stripping is enabled for any of the tags, place the tag in the status. For this the software or application will enable the respective VLAN tag in status bit - 24 or 31 in the MAC VLAN tag control register.

See section Programming guidelines for extended VLAN filtering and routing on receive for more information.

72.8.5 Layer 3 and layer 4 filtering

IP supports the layer 3 based packet filtering which is an IP source or destination address filtering in the IPv4 or IPv6 packets, and layer 4 based packet filtering which is a source or destination port number filtering in TCP or UDP. When you enable layer 3 and layer 4 packet filtering then packets are filtered in the following manner.

- Matched packets: MAC forward the packets that match all enabled fields to the application along with the status. It gives the matched field status only if MAC_Configuration[IPC] = 1 and if one of the following conditions is true:
  - All enabled layer 3 and layer 4 fields match
  - At least one enabled field matches and other fields are bypassed or disabled

When you enable multiple layer 3 and layer 4 filters, any filter match is considered as a match. If more than one filter matches, MAC provides the status of the lowest filter where filter 0 is the lowest filter and filter 3 is the highest filter.

- Unmatched packets: MAC drop the packets that do not match any enabled fields. You can use the inverse match feature to block or drop a packet with specific TCP or UDP over IP fields and forward all other packets.
- Non-TCP or UDP IP packets: By default, all the non-TCP or UDP IP packets bypasses the layer 3 and layer 4 filters. You can optionally program MAC to drop all the non-TCP or UDP packets over IP packets.
- IP has a control register MAC_L3_L4_Control to control the layer L3 and L4 packet filtering along with address registers to program the layer L3 and L4 fields to be matched.

72.8.6 Flexible receive parser

When you enable this function, all incoming packets are parsed per the programmable instruction stored in memory. It perform these functions:

- Packet filter (Accept or reject)
- DMA channel selection

Flexible receive parser block operates over the first 128 bytes data of receive packet on the basis of 64 bytes of instruction on each packet. Figure 390 shows the functional block diagram of flexible receive parser.

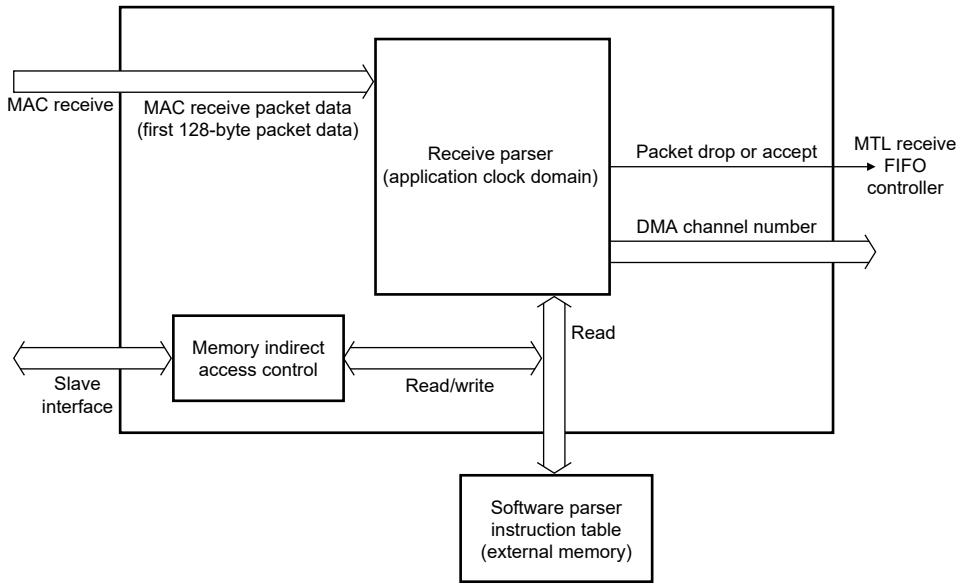

Figure 390. Functional block diagram of flexible recieve parser

72.8.6.1 Instruction table format of the flexible receive parser

You must build the 96-bit wide instruction before enabling the receive parser feature and program each instruction as an entry in the instruction memory.

Table 475 shows the format of each entry in the instruction table .

Table 475. Rx parser instruction entry format

Field	Field Name	Description
31:0	MATCH_DATA	This is a 4-byte data. You can use it to compare with incoming packet data which starts at the frame offset as defined in [79:72] of the entry. The comparison is done only on those bits whose corresponding mask bits are 1 (MATCH_EN bits of [63:32]). See the notes (below this table) on the byte order relative to Ethernet arrival data and endianness which the QoS IP supports on the slave interface. The programming of this instruction table must adhere to the same.
62:32	MATCH_EN	When the MATCH_EN = 1, you can use the corresponding packet data bit for comparing. Otherwise, corresponding data bit is don’t care.
64	AF	Accept frame
65	RF	Reject frame
66	IM	Inverse match
67	NC	Next instruction control
71:68	Reserved	-

Table continues on the next page...

Table 475. Rx parser instruction entry format (continued)

Field	Field Name	Description
79:72	Frame offset	[77:72] indicates the frame offset in terms of 4 bytes. (Here [79:78] always 0) Conpare the frame offset in the packet data for Match.This is in terms of 4 bytes. The value of actual frame offset in bytes are 0 01 42 8… ..63 252 The max value programmed in this instruction table is 128 B. The 'Actual frame offset' must not cross this limit.
87:80	OK index	If (NIC==0) the memory index you can use next when ENTRY_MATCH==1 and neither AF or RF = 1. If (NIC==1) the memory index you can use next when ENTRY_MATCH==0
95:88	DMA Ch No	Indicates the DMA channel number (1-bit for each). You can use this when ENTRY_MATCH ==1 and AF = 1 (Accept frame). The following bits give the encoding: bit[0]- DMA channel number o, bit[1]- DMA channel number , 1bit[2]- DMA channel number 2… bit[7]- DMA channel number 7. **NOTE** You can encode the DMA channel number using bit wise as QoS IP support multicasting or broadcast across DMA channels. See section 3.3.12 for more information and proper usage.
128:96	Reserved	0 (This field is only for software view and reserved for future enhancements. The memory width remains as 96-bits).

The parser begins parsing from the 0th entry, for each received packet. The subsequent parsing entry location (next entry or OK_INDEX[]) depends on the current entry parser result. Flexible receive parser flow chart shows the detailed flow.

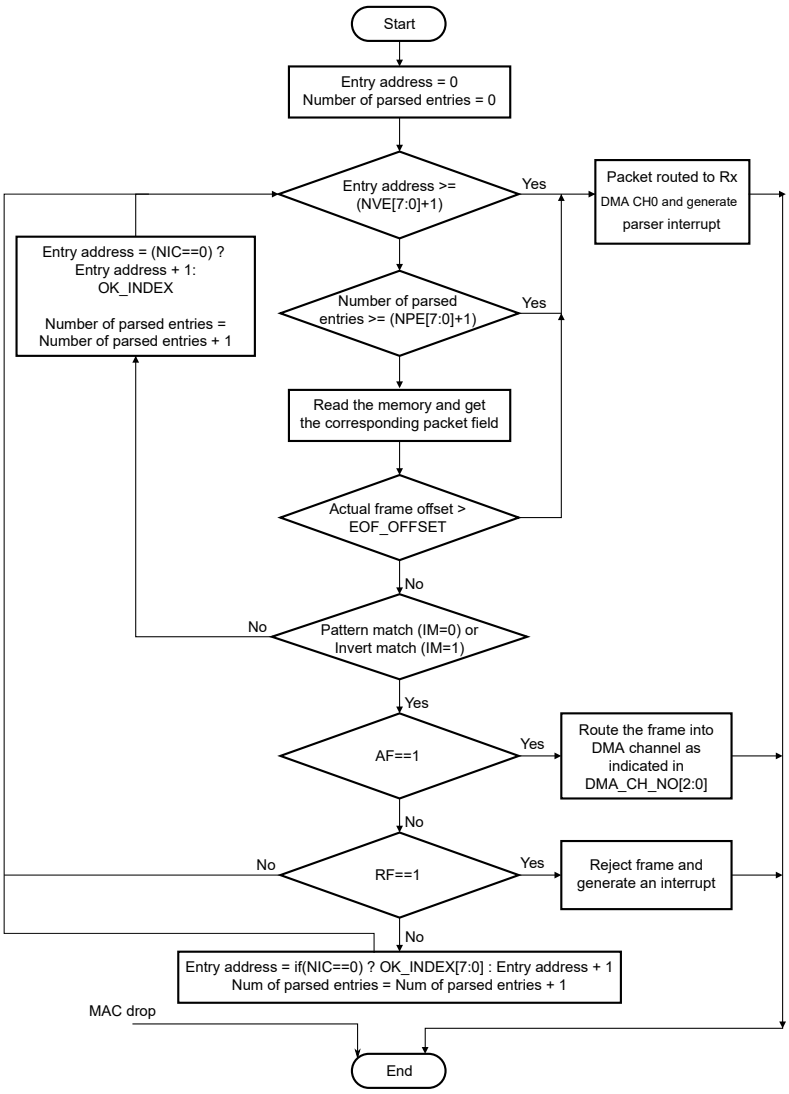

Figure 391. Flexible recieve parser flow chart

The EOF_OFFSET shown in the figure is the least among the following:

- Actual packet size
- 128 Byte when frame pre-emption feature is not enabled or configured
- 128 Byte when frame pre-emption feature is enabled and packet is pre-emptible
- 64 Byte when frame pre-emption feature is enabled and packet is express packet

72.8.6.2 Number of valid entries (NVE)

NVE indicates the number of valid entries in the instruction table. The default value is 64. You can change this value by writing into MTL_RXP_Control_Status[NVE].

When parsing, an error is flagged in MTL_RXP_Interrupt_Control_Status[NVEOVIS], if the entry address is greater than MTL_RXP_Control_Status[NVE] + 1. IP generates an interrupt status (MTL_Interrupt_Status[MTLPIS]).

72.8.6.3 Number of parsable entries (NPE)

NPE indicates the number of entries that you can parse on an incoming packet. The default value is 64. Write into MTL_RXP_Control_Status[NPE] to change this value.

When parsing, an error is flagged in MTL_RXP_Interrupt_Control_Status[NPEOVIS], if the number of parsed of parsed entries is more than MTL_RXP_Control_Status[NPE] + 1. IP generates an interrupt status (MTL_Interrupt_Status[MTLPIS]).

NVE[] indicates the number of valid entries in the receive parser memory which you have built and NPE[] indicates the worstcase parsable entries considering the various possible paths that the parser can take. (NVE[] >= NPE[]).

72.8.6.4 Frame offset

It indicates the frame offset, in terms of 4 bytes which you use when comparing against the current table entry.

In an entry, an error is flagged in MTL_RXP_Interrupt_Control_Status[FOOVIS] in any of the following cases:

When frame offset is more than:

- Packet size
- 128B if pre-emption is disabled
- 128B if pre-emption is enabled and packet is pre-empitble
- 64B if pre-emption is enabled and packet is an express packet

IP generates an interrupt status (<xref href="DWC_ether_qos.dita#MTL_Interrupt_Status/MTL_Interrupt_Status.MTLPIS" >MTL_Interrupt_Status[MTLPIS]</xref>).

NOTE

If the frame ends after the (frame_offset *4) bytes but before ((frame_offset *4)+4) bytes, the receive parser declares a frame offset error if you enable comparison (via MASK bits) for the non-received bytes; from (frame_offset *4) to ((frame_offset *4)+4).

72.8.6.5 Frame reject

You can drop the frame in cases, where an entry matches (considering the inverse match, IM bit in the instruction table) and frame accept bit is not 1, and frame reject bit (RF) = 1.

When a frame drops because RF = 1, IP generates an interrupt status (MTL_Interrupt_Status[MTLPIS]).

72.8.6.6 Out of order processing

The Rx parser flow can be out of order. The decision tree is not based on the order in which packet arrives. This implies that the next entry and next frame offset (OK_INDEX[] and FRAME_OFFSET[]) can be less than the current entry address and current frame offset.

72.8.6.7 DMA channel selection

When you enables the receive parser (MTL_Operation_Mode[FRPE] = 1) it overrides the MAC DMA selection criteria.

When you disables the receive parser (MTL_Operation_Mode[FRPE] = 0) the MAC/MTL determines the DMA channel number.

72.8.6.8 Receive queue selection

The existing MAC functionality determines the receive queue, irrespective of whether the receive parser is enabled or disabled. This is because the receive parser is mainly designed to select the DMA channel and the MAC decides the receive queuing to enable the proper functioning of the pause or PFC feature.

NOTE

When there are multiple queues and multiple DMA Channels are enabled, a particular DMA channel might receive out of order packets because queue selection is based on MAC criteria (VLAN Priority and other criteria) and Rx DMA channel selection is based on receive parser.

72.8.6.9 MAC packet filtering/drop/error handling

Packet filtering is done on the basis of the received packet fields. You must disable the packet filtering features inside the MAC when the receive parser is enabled. Follow these steps to disable the packet filtering features inside the MAC :

1. Write 1 to the Promiscuous mode (MAC_Packet_Filter[PR]).
2. Write 1 to all other fields in MAC_Packet_Filter to its default values.

When MAC decides to drop the packet due to the receive MAC dependent error such as:

- GMII error
- Receive watchdog error
- CRC error
- Giant frame error

the packet drops irrespective of the receive parser decision.

72.8.6.10 Pad strip or CRC strip handling

Software controls the pad strip and CRC strip and it is applicable to all the received packets. Also,software must build the receive parser instructions accordingly, when you enable these features.

NOTE

Enable pad and CRC stripping in real use case.

72.8.6.11 VLAN strip handling

MAC supports stripping the outer VLAN as well as inner VLAN. When you program MAC to strip the VLAN, the receive parser considers those VLAN tags to be part of the incoming packet.

72.8.6.12 Multicast and broadcast support

IP supports multicast and broadcast packet and the packet route to the highest queue number.

When you enables the receive parser, the DMA channel numbers (DMA CH NO, Bits [95:88]) in the instruction table, decide the packet routing.

When you disables the receive parser, DCS (DMA Channel Select) field of the MAC_AddressX_High register determines the packet routing. See the Broadcast/multicast packet duplication.

NOTE

You can select multiple DMA channels for the packet routing because the DCS/DMA CH NO field is per the DMA channel control.

72.8.6.13 Pre-emption support

IP supports the frame pre-emption feature when the flexible receive parser feature is enabled. It has the following limitations:

- Number of bytes would be 64, so that the receive parser can operate on an express traffic
- Number of bytes would be 128, so that receive parser can operate on a pre-emptible traffic.

72.8.6.14 Software access to the flexible receive parser memory

Software can read and write into the receive parser memory. It uses the following registers via indirect addressing.

- MTL_RXP_Indirect_Acc_Control_Status
- MTL_RXP_Indirect_Acc_Data

For more details, see EMAC register descriptions.

72.8.6.15 Statistical counters

IP supports these statistics counters for flexible receive parser.

1. MTL_RXP_Drop_Cnt
2. DMA_RXP_Error_Cnt

DMA_CH(#i)_Rxp_Accept_cnt (i=0; i<2)

For more details, see EMAC register descriptions.

72.8.6.16 Changing the instruction table by software

Software can update the instruction table in the memory in the following ways:

- Disables the MAC receiver and receive parser by writing 0 to MAC_Configuration[RE] and MTL_Operation_Mode[FRPE]. It waits for receive parser to become inactive (RXPIA, MTL_RXP_Control_Status register bit[31]).
- (Optional) Programs in the entry address 0 to unconditionally (all MATCH_EN bit 0) skip to OK_INDEX[] (to certain location in the memory), where you can program it to reject or accept all the packets.

72.8.6.17 Receive cut-through functionality

In the Cut-Through mode, the receive controller transfer the received packets to DMA just after it receives the cut-through threshold amount of packet data (RTC field in the MTL_RxQx_Operation_Mode register).

However due to Rx parser's result worst case arrival time can be more than the programmed cut-through threshold. So, the receive controller delays the packet transfer to DMA accordingly, and the cut-through functionality is re-defined as follows:

The receive controller transfers packet to DMA after at least RTC number of bytes have been received and receive parser results are available.

72.8.6.18 Receive packet drop indication

In most cases, the packet drops internally in the receive queue. However, back-to-back packets can arrive for the same queue and the first packet's receive parser result is not available when the second packet arrives. In such cases, the packet cannot be flushed internally and forwarded to DMA or the application interface and indicates the status accordingly. See RDES2, bit 16(RXPD) in Receive normal descriptor (write-back format) for more information.

72.8.6.19 Runt packet handling

The receive parser can performs the operation with 64B minimum size packet. If the runt packet is received (MAC must indicate it), the receive parser assumes that it is dropped in the MAC, this is because, the back-to-back runt packets (< 64B) cannot be handled in the receive parser.

72.8.6.20 Uncorrectable ECC error handling

The packet does not drops when the parser detects an uncorrectable ECC error while parsing the parser memory. The packet is sent to the application with an error indication. The RXPI (RX parser incomplete) sets in the packet status along with error summary (ES) bit.

See the Receive normal descriptor (write-back format) for more information.

72.9 IEEE 1588 timestamp support

This section and all its sub-sections are Synopsys proprietary. Used with permission.

IP supports the IEEE 1588 precision time protocol (PTP). It is also able to do precise time stamping and captures incoming and outgoing frame because of the PTP protocol implementation in the IP. It supports all the clock types defined in IEEE 1588-2008. The typical frequency of PTP timestamp clock is 125 MHz.

IP supports these features:

- Provides an option to take snapshot of all packets or only PTP type packets
- Provides an option to take snapshot of only event messages
- Identifies the PTP message type, version, and PTP payload in packets sent directly over Ethernet and sends the status
- Provides an option to measure sub-second time in digital or binary format

72.9.1 Delay request-response mechanism

The system or network is classified into the master and slave nodes for distributing the timing and clock information. Figure 392 shows the process that PTP uses for synchronizing a slave node to a master node by exchanging PTP messages.

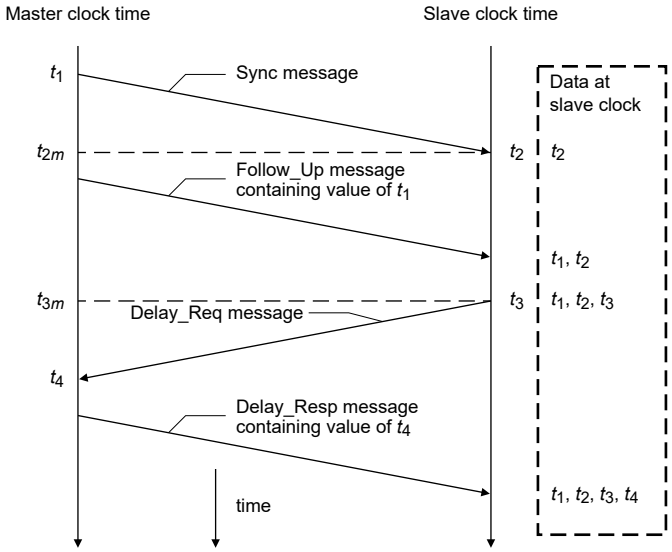

Figure 392. Networked time synchronization

As shown in the figure, PTP uses this process:

1. The master broadcast the PTP sync messages to all its nodes. The sync message contains the reference time information of the master. This message leaves the system of the master at t1. You must capture this time for Ethernet ports at GMII or MII.
2. The slave receives the sync message and it also captures the exact time, t2, using its timing reference.
3. The master sends a Follow_Up message to the slave, which contains t1 information for later use.
4. The slave sends a Delay_Req message to the master and note the exact time, t3, at which this packet leaves the GMII or MII interface.
5. The master receives the message, capturing the exact time t4, at which the message enters its system.
6. The master sends the t4 information to the slave in the Delay_Resp message.
7. The slave use the four values of t1, t2, t3, and t4 to synchronize its local timing reference to the master's timing reference.

Most of the PTP implementation is done in the software above the Ethernet layer. However, the hardware captures the exact time when specific PTP packets enter into or leave the Ethernet port at the MII interface. This timing information must be captured and returned to the software for proper implementation of PTP with high accuracy.

72.9.2 Peer-to-peer PTP transparent clock (P2P TC) message support

The IEEE 1588-2008 supports the peer-to-peer PTP (Pdelay) message in addition to the sync, delay request, follow-up, and delay response messages. Figure 393 shows the method to calculate the propagation delay in clocks supporting the peer-to-peer path correction.

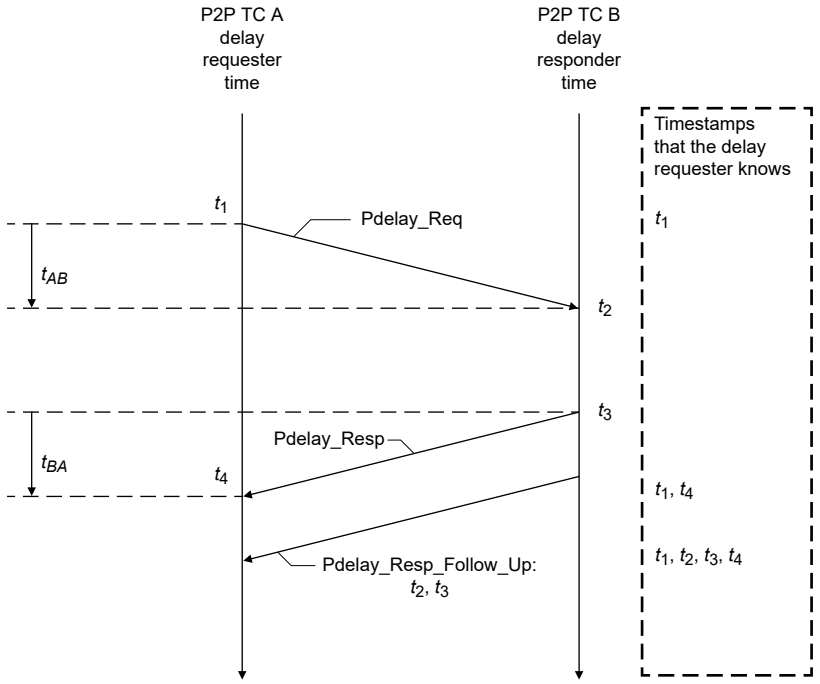

Figure 393. Propagation delay calculation in clocks supporting peer-to-peer path correction

As shown in the above figure, the propagation delay is calculated in the following way:

1. Port 1 issues a Pdelay_Req message and generates a timestamp (t1) for the Pdelay_Req message.
2. Port 2 receives a Pdelay_Req message and generates a timestamp (t2) for this message.
3. Port 2 returns a Pdelay_Resp message and generates a timestamp (t3) for this message. Port 2 returns the Pdelay_Resp message as quickly as possible after the receipt of the Pdelay_Req message, to minimize the errors because of any frequency offset between the two ports. Port 2 returns any one of the following:
   - Difference between the timestamps t2 and t3 in the Pdelay_Resp message
   - Difference between the timestamps t2 and t3 in the Pdelay_Resp_Follow_Up message
   - Timestamps t2 and t3 in the Pdelay_Resp and Pdelay_Resp_Follow_Up messages, respectively
4. Port 1 generates a timestamp (t4) after receiving the Pdelay_Resp message.
5. Port 1 uses all the four timestamps t1, t2, t3, and t4 to compute the mean link delay.

72.9.3 Timestamp correction

According to the IEEE 1588 specification, you must capture a timestamp when the PTP message timestamp point (leading edge of the first bit of the octet immediately following the start frame delimiter octet) crosses the boundary between the node and the network. As MAC takes the timestamp at an internal point far from the actual boundary of the node and network, you must correct or update the captured timestamp for the ingress or egress path latency (including the delay in the PHY layers). Further

correction is done for the inaccuracies or errors introduced because the clock (MII Tx, Rx clock) is different at the capture point as compared to the PTP clock (clk_ptp_ref_i) that generates the time. The resultant CDC (Clock domain crossing) circuits add an error depending on the clock period of the MII and PTP clocks.

72.9.3.1 Ingress correction

The timestamp captured at the internal snapshot point In the receive side is delayed (later in time) as compared to the time at which the packet's SFD bit is received at the port's boundary. Therefore, the ingress latency and the errors in CDC sampling reduces the captured timestamp. You must determine or calculate the correction value and write into the MAC_Timestamp_Ingress_Corr_* registers.

The correction value consists of these three components:

1. External latency in the PHY layer between boundary point and the input of the core.

   If the PHY is compliant with the IEEE 802.3 Clause 45 MMD registers, it has a register which indicates the maximum and minimum ingress latency. You can read these registers and determines the average ingress latency in the PHY. Alternatively (if the PHY does not support these registers), you must determine the ingress latency from its datasheet or timing characteristics.

2. Internal latency from the core's input to the internal capture point.

   You can read the internal ingress latency from MAC_Timestamp_Ingress_Latency. This is a read-only register and provides the latency in scaled nanoseconds format as defined in IEEE 1588 Clause 5.3.2. The latency differs on the basis of the active PHY interface (MII, RMII, so on) and the operating speed. Therefore, you must read this register after any speed change in MAC, to determine the current internal latency.

3. CDC synchronization

   The CDC synchronization error is almost equal to twice the clock-period of the PTP clock (clk_pt-p_ref_i).

You must add the values that these three components determine and must write into the TSIC and TSICSNS fields of the MAC_Timestamp_Ingress_Corr_* registers.

NOTE

The value written into the register must be negative (two's complement as explained below), because it is subtracted from the captured timestamp. The MAC receiver adds the value in this register to the captured timestamp and then gives the resultant value as the timestamp of the received packet.

When MAC_Timestamp_Control[TSCTRLSSR] is 1, it indicates that the nanoseconds field of the captured timestamp is in decimal format with a granularity of 1ns. So the Bit31 of TSIC must be 1 (for negative value) and bits[30:0] must write with "10^9 - total ingress_correction_value[nanosecond part]" represented in binary. For example, if the required correction value is -5 ns, then the value is 0xBB9A_C9FB.

When MAC_Timestamp_Control[TSCTRLSSR] becomes 0, it indicates that the nanoseconds field of the captured timestamp is in binary format with a granularity of ~0.466ns. Therefore, bits[30:0] must write with "2^31 - total ingress_correction_value" represented in binary with bit[31] = 1.

72.9.3.2 Egress correction

The timestamp captured at the internal snapshot point in the transmit side is earlier (advanced in time) as compared to the time at which the packet's SFD bit is output at the port's boundary. Therefore, the egress latency and the errors in CDC sampling must compensate the captured timestamp. You must determine or calculate this correction value and write into the MAC_Timestamp_Egress_Corr_* registers.

The correction value consists of these three components:

1. External latency in the PHY layer between the core output and the port and the network boundary

   If the PHY is compliant with the IEEE 802.3 Clause 45 MMD registers, it has a register which indicates the maximum and minimum egress latency. You can read these registers and determine the average egress latency in the PHY. Alternatively (if the PHY does not support these registers), you must dertermine the egress latency from its datasheet or timing characteristics.

2. Internal latency from the internal capture point and the core output of the c

   You can read this internal egress latency from MAC_Timestamp_Egress_Latency. This is a read-only register and gives the latency in scaled nanoseconds format as defined in IEEE 1588 Clause 5.3.2. The latency differs on the basis of the active PHY interface (MII, RMII, so on) and the operating speed. Therefore, you must read this register after any speed change in MAC to determine the current internal latency.

3. CDC synchronization error

   The CDC synchronization error value for one-step timestamping = (1 * period of clk_ptp_ref_i + 4 * period of clk_tx_i). Otherwise (Two-step timestamping mode), the value = -(2 * period of clk_ptp_ref_i).

72.9.3.3 Frequency range of reference timing clock

The timestamp information is transferred across asynchronous clock domains that is from the MAC clock domain to the application/system clock domain. Therefore, a minimum delay is required between the two consecutive timestamp captures. This delay is 4 clock cycles of MII and 3 clock cycles of PTP clocks. If the delay between the two captured timestamp is less than this delay, MAC does not take a timestamp snapshot for the second packet.

72.9.3.4 PTP processing and control

Table 476 shows the common message header for the PTP messages. This format is defined in the IEEE 1588-2008.

Table 476. Message format defined in IEEE 1588-2008

Bits								Octet	Offset
7	6	5	4	3	2	1	0		
transportSpecific				messageType				1	0
Reserved				versionPTP				1	1
messageLength								2	2
domainNumber								1	4
Reserved								1	5
flagField								2	6
correctionField								8	8
Reserved								4	16
sourcePortIdentity								10	20
sequenceId								2	30
controlField (*)								1	32
logMessageInterval								1	33

(*) – control Field is used in version 1. In version 2 message type field is used for detecting different message types.

There are some fields in the Ethernet payload that detects the PTP packet type and controls the snapshot to be taken. These fields are specified in Table 477 for PTP packets over Ethernet.

Following table provides the information about the fields that match to control the snapshots for the PTP packets sent over Ethernet for IEEE 1588 version 1 and version 2. The octet positions are offset by 4 for the tagged packets. This is based on the IEEE 1588-2008, Annex D, and the message format.

Table 477. Ethernet PTP packet fields required for control And status

Field matched	Octet position	Matched value	Description
MAC destination multicast address[1]	0–5	01-1B-19-00-00-00 01-80-C2-00-00-0E	All PTP messages can use any of the following multicast addresses[2]: • 01-1B-19-00-00-00 • 01-80-C2-00-00-0E[3]
MAC packet type	12, 13	0x88F7	PTP Ethernet packet
PTP control field (IEEE 1588 version 1)	46	0x00, 0x01, 0x02, 0x03, or 0x04	• 0x00: SYNC • 0x01: Delay_Req • 0x02: Follow_Up • 0x03: Delay_Resp • 0x04: Management
PTP message type field (IEEE 1588 version 2)	14 (nibble)	0x0, 0x1, 0x2, 0x3, 0x8, 0x9, 0xB, 0xC, or 0xD	• 0x0: SYNC • 0x1: Delay_Req • 0x2: Pdelay_Req • 0x3: Pdelay_Resp • 0x8: Follow_Up • 0x9: Delay_Resp • 0xA: Pdelay_Resp_Follow_Up • 0xB: Announce • 0xC: Signaling • 0xD: Management
PTP version	15 (nibble)	0x1 or 0x2	• 0x1: Supports PTP version 1 • 0x2: Supports PTP version 2

1. The unicast address match of destination addresses (DA), which is programmed in MAC address 0 to 31, is used if MAC_Timestamp_Control[TSENMACADDR] = 1.
2. IEEE 1588-2008, Annex F
3. MAC does not consider the PTP version 1 messages with peer delay multicast address (01-80-C2-00-00-0E) as valid PTP messages.

72.9.4 Transmit path functions

MAC captures a timestamp when the start packet delimiter (SFD) of a packet is sent on the MII interface. You can control the packets, for which the timestamps are captured on a per-packet basis and mark each transmit packet to indicate whether to capture a timestamp for it. MAC does not process the transmitted packets to identify the PTP packets. You can use the control bits in the transmit descriptor to specify the packets. MAC returns the timestamp to the software inside the corresponding transmit descriptor and therefore connects the timestamp automatically to the specific PTP packet. You must write the 64-bit timestamp information to TDES0 and TDES1 fields. The TDES0 field holds the 32 least significant bits of the timestamp.

72.9.5 Receive path functions

You can program MAC to capture the timestamp of all packets received on the MII interface or to process the packets to identify the valid PTP messages.

You can use these options of MAC_Timestamp_Control to control the snapshot of the time sent to the application:

- Enable snapshot for all packets
- Enable snapshot for IEEE 1588 version 1 or version 2 timestamp
- Enable snapshot for PTP packets transmitted directly over Ethernet
- Enable timestamp snapshot for the received packet for IPv4 or IPv6
- Enable timestamp snapshot only for EVENT messages (SYNC, DELAY_REQ, PDELAY_REQ, or PDELAY_RESP)
- Enable the node to be a master or slave and select the snapshot type

Table 478. Timestamp snapshot dependency on register bits

SNAPTYPSEL	TSMSTRENA	TSEVNTENA	PTP messages
00	x	0	SYNC, Follow_Up, Delay_Req, Delay_Resp
00	0	1	SYNC
00	1	1	Delay_Req
01	x	0	SYNC, Follow_Up, Delay_Req, Delay_Resp, Pdelay_Req, Pdelay_Resp, Pdelay_Resp_Follow_Up
01	0	1	SYNC, Pdelay_Req, Pdelay_Resp
01	1	1	Delay_Req, Pdelay_Req, Pdelay_Resp
10	x	x	SYNC, Delay_Req
11	x	x	Pdelay_Req, Pdelay_Resp

DMA returns the timestamp to the software inside the corresponding receive descriptor. The extended status, contains the timestamp message status and the IPC status. You must write the extended status in the normal descriptor RDES1 and the snapshot of the timestamp in RDES0 and RDES1 fields of context descriptor. The RDES0 field holds the 32 least significant bits of the timestamp.

See the System time correction for programming guidelines for IEEE 1588 timestamping (System time correction).

72.9.6 IEEE 1588 system time source

IP supports both the external and internal time source for reference timestamping.

- External time source uses the 64-bit external time reference and clock as an input in IP. The clock input synchronizes the external timing reference into the MAC clock domain. Upper 32-bit indicates the time in seconds and the lower 32-bit indicates the time in nanoseconds.
- Internal time source uses the only clock input to generate timing reference internally for snapshot and capture timestamps. Internal time reference has two fields.
  - UInteger48 seconds field: The seconds field is the integer portion of the timestamp in seconds units. It is 48-bit wide.

    For example, 2.000000001 seconds are represented as seconds field = 0x0000_0000_0002.

— UInteger32 nanoseconds field The nanoseconds field is the fractional portion of the timestamp in nanoseconds units.

For example, 2.000000001 seconds are represented as nanoseconds field = 0x0000_0001. The nanoseconds field supports the following two modes:

- Digital rollover mode: In this mode, the maximum value in the nanoseconds field is 0x3B9A_C9FF, that is, (10e9-1) nanoseconds.
- Binary rollover mode: In this mode, the nanoseconds field rolls over and increments the seconds field after 0x7FFF_FFFF value . Accuracy is ~0.466 ns per bit.

There is a system time register module, it is used when you use an internal time reference. The 80-bit time is maintained in this module and updated using the input reference clock (clk_ptp_ref_i). This time is the source for taking snapshots (timestamps) of Ethernet packets which is transmitted or received at the MII interface.

Initialize or correct the system time counter using the coarse correction method. In this method, write the initial value or the offset value to the timestamp update register. For initialization, write the system time counter with the value in the timestamp update register. For system time correction, the offset value is added to or subtracted from the system time.

In the fine correction method, correct the frequency offset and/or frequency drift of a slave clock (clk_ptp_ref_i) with respect to the master clock (as defined in IEEE 1588-2002) over a period of time instead of in one clock, as in coarse correction. This maintains linear time and does not introduce drastic changes (or a large jitter) in the reference time between the PTP sync message intervals.

See Initialization guidelines for system time generation for programming guidelines for IEEE 1588 timestamping (For internal timestamp source configuration).

72.9.7 IEEE 1588 higher word register

You can invoke the higher word register if system time source is internal. MAC timestamp is 64-bit wide. The values of the upper 16-bits of the seconds field are read from the CSR register.

72.9.8 Flexible pulse-per-second output

IP supports the flexibility of programming the start or stop time, generates pulse width and interval on pulse-per-second output. It also support four such output signals. By default, IP is in fixed pulse-per-second output mode with interval of 1 second.

Initially you must program the start time in target time registers "MAC_PPSx_Target_Time_Seconds and MAC_PPSx_Target_Time_Nanoseconds" for all desired or enabled pps output. If you re-programs start or stop time then you must do it after the synchronization of earlier programmed value. Bit 31 of MAC_PPS#_Target_Time_Nanoseconds register indicates that the synchronization is complete. If the application programs a start or stop time that has already elapsed, MAC sets an error status bit which indicates the programming error. If enabled, MAC also sets the target time reached interrupt event. The application can cancel the start or stop request only if the corresponding start or stop time has not elapsed. If the time has elapsed, the cancel command has no effect.

Program the PPS width and interval in terms of granularity of system time, that is, the number of units of sub-second increment value.

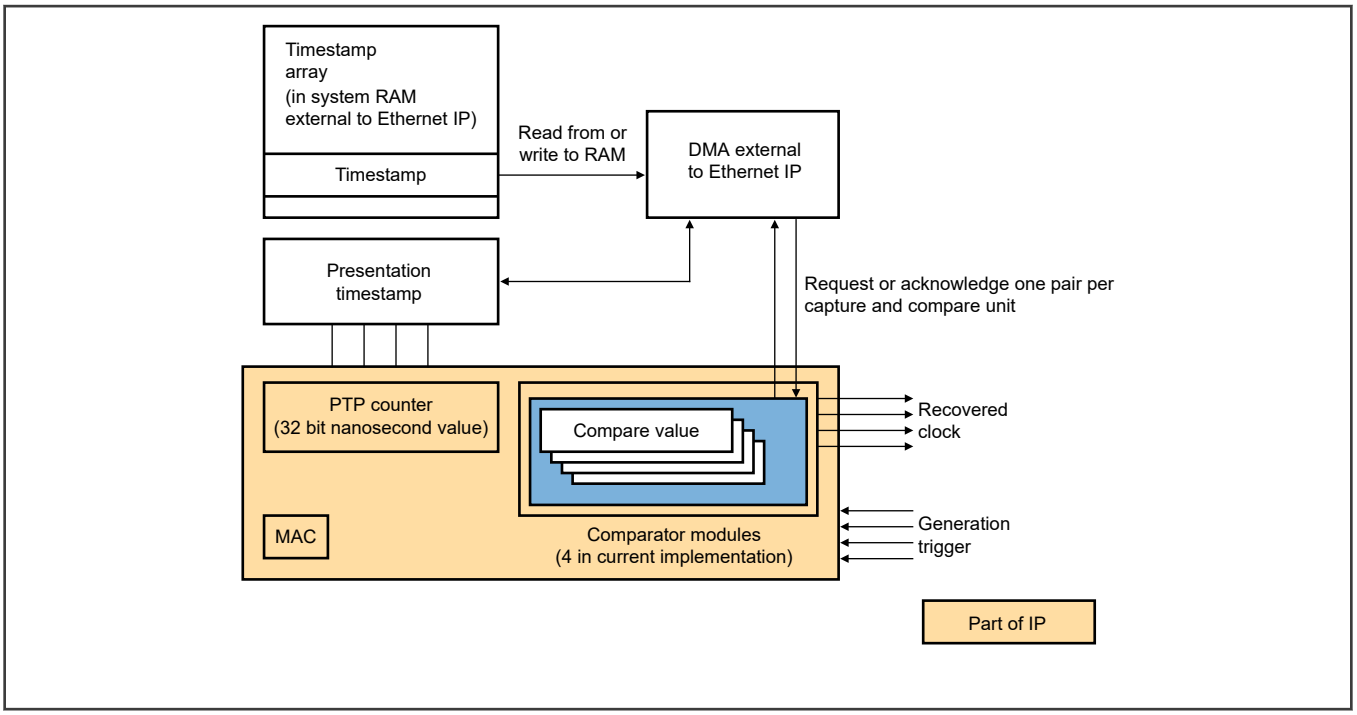
See Programming guidelines for flexible pulse-per-second output for more information.

72.9.9 Media clock generation and recovery

Media clock recovery and generation requires a dedicated hardware and software to complete the operation. IP generates a reference clock with the help of a dedicated hardware which multiplies to get the desired media clock. Software extracts the presentation time from the incoming PTP 1722 frames and program these values into CSR registers so that IP can read them for media clock recovery.

Figure 394 shows that the timestamp array and the DMA module are external to IP. IP supports a 32-bit presentation time counter in nanoseconds that completes at the full 32-bit value to match with 1722 presentation time format and an handshake mechanism with an external application (such as DMA) to program the presentation time into CSR register.

Figure 394. Media clock generation and recovery block diagram



72.9.9.1 Presentation time counter

Presentation time counter provides an another perspective of the PTP system time (1588 timer). For a given PTP system time (PTP[63:32] represents time in seconds Comparator modules and PTP[31:0] represents time in nanoseconds), there exists a corresponding presentation time (32-bit value in nanosecond). The presentation time computed is referred to as current presentation time (CPT).

CPT derives from 64-bit PTP system time. PTPNS[63:0] = (PTP[63:32] * 32'd1,000,000,000) + PTP[31:0] where, PTPNS is the PTP system time converted into a 64-bit nanosecond value.

Current presentation time[31:0] = PTPNS[31:0]

Media clock recovery is possible when the system time is internally generated in IP and compute the CPT in the same way as the internal PTP system time generation. The increment cycle of CPT and system time are same because the values of both the timers are in nanoseconds and they are synchronous. The timer updates at the same instance, but the updated value could be different. You must compute a separate 32-bit update value in nanoseconds for the CPT update. CPT sampled at different edges of a triggering input generates media clock timestamps that are inserted in 1722 based AVBTP packets, to recover the clock at the destination.

72.9.9.2 Comparator modules

Figure 394 shows that the module supports four comparator modules to handle multiple media clocks that it may require. When MAC_Timestamp_Control[PTGE] is 1, it indicates that the comparator modules handshake with the application to program the timestamps into the MAC_PPS(#i)_Target_Time_Seconds register.

Write 1 to presentation time control fields of the particular instance for recovery mode.

The timestamps received from the application are referred as target presentation time (TPT).

When MCGREN#i field of MAC_PPS_Control is 1, it indicates that the IP operates in MCGR mode. The comparator module sends upto two requests to the application for TPT write, when MAC_Timestamp_Control[PTGE] and the presentation time control bits of the particular instance are 1 for MCGR mode. Subsequent requests are generated each time a presentation time match occurs. CPT transitions from a value less than TPT, to a value greater than or equal to CPT. The first request asserts when a specific comparator instance sets to MCGR mode with a non-zero presentation time control and an additional request is made when the comparator receives the first data. This allows the application to write the next TPT value when IP processes the previous TPT value for a match.

TPT read from the MAC_PPS(#i)_Target_Time_Second is considered as a future time. A toggle or pulse is generated in the next cycle when a match is detected. Also,the mcgr_dma_req_o#i request for that comparator asserts (to obtain next TPT) until the corresponding application acknowledgment is set, when a match is detected.

The presentation control fields (PPSCMD#i field of MAC_PPS_Control) determine the shape of the generated waveform. You can program these fields to either toggle or generate a high/low pulse for one PTP clock cycle, when matched.

Media clock recovery: A match occurs, when the free-running CPT value matches the received TPT value. An output signal, EMAC_TMR signal as shown in the IO mux sheet asserts (toggle, low pulse, or high pulse) on the basis of the programmed presentation control value.

Media clock generation: On the basis of the presentation control value programmed in MAC_PPS_Control, the particular comparator captures the presentation time and programs it into MAC_PPS(#i)_Target_Time_Second register. The captured timestamp is read when a request is raised to the application. No new timestamps are captured, until the read operation is complete acknowledgment is received from the application.

72.9.9.3 Media clock generation and recovery flow

Figure 395 shows the media clock generation and recovery flow. Write 1 to MAC_Timestamp_Control[PTGE] for CPT generation and write 1 to MAC_PPS_Control MCGREN#i field to enable the corresponding instance in the MCGR mode, for both media clock generation and recovery.

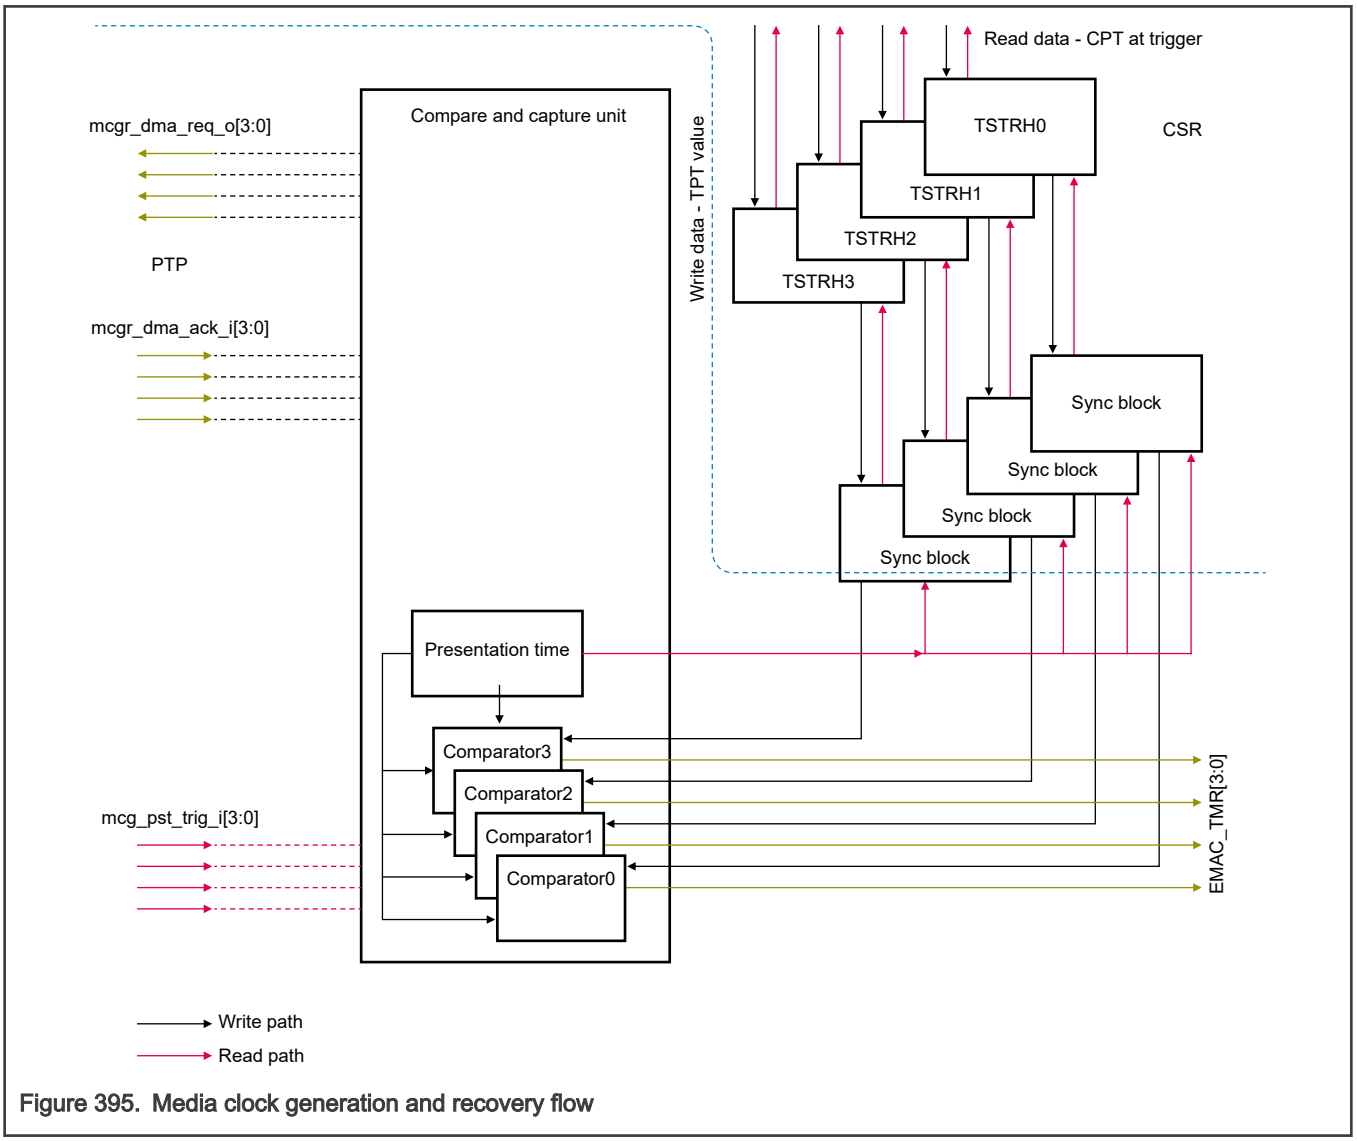


Figure 395. Media clock generation and recovery flow

NOTE

1. The consecutive triggers to sample the presentation time must assert after a few PTP clock cycles so as to allow synchronization delays. (There is no such issue when the input trigger maximum frequency is 8 KHz and the PTP clock runs at least at 1MHz)
2. In the Media Clock Recovery mode, the DMA acknowledgment is both posted as well as non-posted.

See Programming guidelines for media clock generation and recovery for more information.

72.9.10 One step timestamp

IP supports the one step timestamp feature. Writing 1 to bit 20 (OSTC) in the control word, enables the one step timestamp feature for a packet.

See the Programming guidelines for IEEE 1588 timestamping for more information.

72.9.11 IEEE 1588 sub nanoseconds timestamp

IP supports the ingress and egress correction accuracy in sub nanoseconds. It is programmed in MAC_Timestamp_Ingress_Corr_Subnanosec[TSICSNS] and MAC_Timestamp_Egress_Corr_Subnanosec[TSECSNS], respectively. In this case, the correction has an unit of nanosecond, multiplied by 2^8. You must program the least significant 8 bits of the value in the sub-nanoseconds register.

For example, if the required egress correction is 3.6 nS and MAC_Timestamp_Control[TSCTRLSSR] is 1, then MAC_Timestamp_Egress_Corr_Nanosecond[TSEC] must be 0x3 and MAC_Timestamp_Egress_Corr_Subnanosec[TSECSNS] must be 0x99 (0.6 * 256). Similarly, if the required ingress correction is -3.6 nS and MAC_Timestamp_Control[TSCTRLSSR] is 1, then MAC_Timestamp_Ingress_Corr_Nanosecond[TSIC] must be 0xBB9A_C9FC and MAC_Timestamp_Ingress_Corr_Subnanosec[TSICSNS] must be 0x66 (fractional part of (10^9 - 3.6) * 256).

72.10 Multiple channels and queues support

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

IP support two queues and channel on Tx and Rx paths. Figure 396 shows the architecture of IP with two queues and channel.

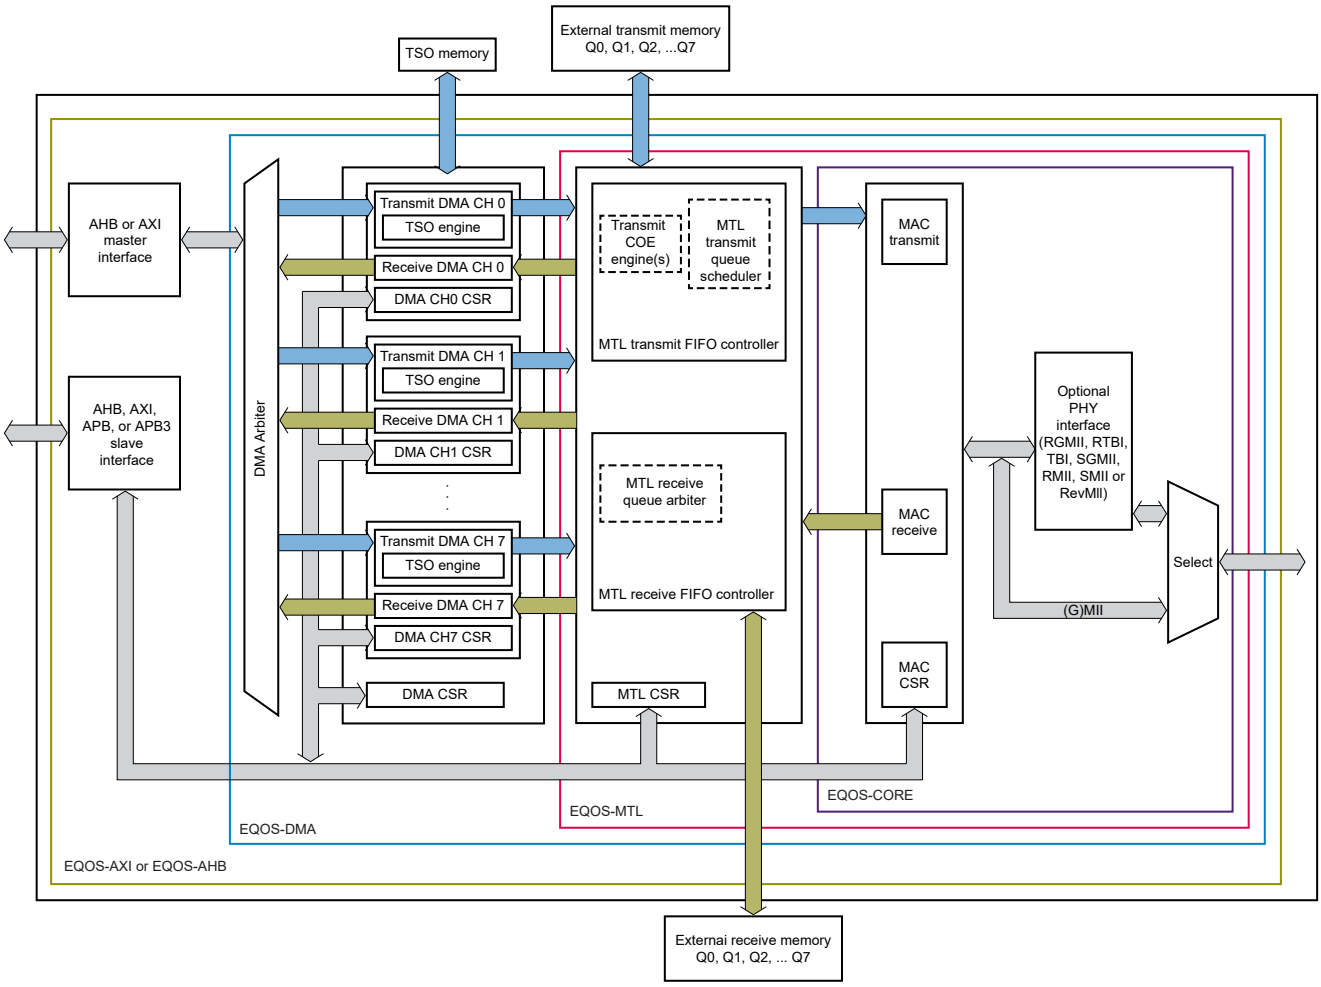

Figure 396. Module with multiple channels and queues block diagram

The above block diagram, support only two queues.

IP DMA arbiter support two types of arbitration scheme, fixed priority and weighted round-robin. The DMA arbiter performs the arbitration between the Tx and Rx paths of DMA channels to access descriptors and data buffers. DMA_Mode[DA] specifies the arbitration scheme (fixed or weighted round-robin) between the channel Tx and Rx DMA.

DMA_Mode[TXPR] sets the priority between the corresponding Tx DMA and Rx DMA. Writing 1 to DMA_Mode[PR] specifies the weighted priority between the Tx DMA and Rx DMA in round robin arbitration scheme.

Table 479 provides an information about the priority scheme between Tx DMA and Rx DMA.

Table 479. Priority scheme for Tx DMA and Rx DMA

Bit 14	Bit 13	Bit 12	Bit 11	Bit 10	Priority schemes
x	x	x	0	1	Rx always has priority over Tx
0	0	0	0	0	Tx and Rx have equal priority. Rx gets the access first on simultaneous requests
0	0	1	0	0	Rx has priority over Tx in ratio 2:1

Table continues on the next page...

Table 479. Priority scheme for Tx DMA and Rx DMA (continued)

Bit 14	Bit 13	Bit 12	Bit 11	Bit 10	Priority schemes
0	1	0	0	0	Rx has priority over Tx in ratio 3:1
0	1	1	0	0	Rx has priority over Tx in ratio 4:1
1	0	0	0	0	Rx has priority over Tx in ratio 5:1
1	0	1	0	0	Rx has priority over Tx in ratio 6:1
1	1	0	0	0	Rx has priority over Tx in ratio 7:1
1	1	1	0	0	Rx has priority over Tx in ratio 8:1
x	x	x	1	1	Tx always has priority over Rx
0	0	0	1	0	Tx and Rx have equal priority. Tx gets the access first on simultaneous requests
0	0	1	1	0	Tx has priority over Rx in ratio 2:1
0	1	0	1	0	Tx has priority over Rx in ratio 3:1
0	1	1	1	0	Tx has priority over Rx in ratio 4:1
1	0	0	1	0	Tx has priority over Rx in ratio 5:1
1	0	1	1	0	Tx has priority over Rx in ratio 6:1
1	1	0	1	0	Tx has priority over Rx in ratio 7:1
1	1	1	1	0	Tx has priority over Rx in ratio 8:1

72.10.1 Multiple queues and channels support in the transmit path

IP support two transmit queues and two channels.

Fixed priority scheme is the default priority scheme for the DMA channels and channel with highest priority always wins the arbitration when it requests for the bus. Channel 0 is always of lowest priority and channel 1 is always of highest priority.

In weighted strict priority (WSP), the weight corresponds to the number of burst transfers given to a channel in one arbitration cycle. Reallocate the unused burst transfers of one or more channels on the basis of the priority. The channel with highest priority receives the unused burst transfer time before it is allocated to a channel with the next highest priority. You can process the next lower priority, when a channel uses the allocated burst transfers. After processing the allocated bandwidth of all the channels that have packets to transmit, allocate any unused burst transfer time to the channel of the highest priority (if required), and then next highest priority (if required), and so on.

In weighted round robin (WRR) priority scheme, program the weight through TCW field of DMA_CH#_Tx_Control register. IN WRR scheme, service all channels in round-robin order according to the weights settings. Table 480 shows that the TCW field of DMA_CH#_Tx_Control register provides the weight for each transmit channel.

Table 480. Weight for DMA channels

TCW Field	Transmit Channel Weight
000	1
001	2
010	3
011	4
100	5
101	6
110	7
111	8

The configured weights correspond to the number of burst transfers given to a channel in one arbitration cycle. The unused or excess burst transfers are distributed equally to all channels.

See Programming guidelines for multi-channel multi-queuing for more information.

72.10.2 Multiple queues and channels support in the receive path

IP support two receive channels and two queues.

In the receive direction, the MTL Rx controller selects the Rx DMA for which it transfers or reads the data from the receive FIFO memory. This scheduling is based on the programming done in the respective MTL_RxQ[x]_Control register.

Each Rx DMA indicates when it is ready to transfer data and the size of the burst-length (number of beats) that it will transfer. The scheduler checks whether sufficient data (of requested burst length) is available to transfer to these DMAs and then selects the receive DMA that is serviced using the programmed priorities.

See Programming guidelines for multi-channel multi-queuing for more information.

72.10.3 Rx queue to DMA mapping

You can program MTL_RxQ_DMA_Map0 (for queues 0 and 1) to route the packets in the MTL receive queues to any one of the multiple DMA channels.

The following types of receive queue to DMA mapping is possible through programming.

72.10.3.1 Static mapping

In this mode, you can connect all the packets of the receive queue to a specific DMA channel. For example, all the packets from the receive queue 0 program MTL_RxQ_DMA_Map0[Q0MDMACH] (bit[3:0]) and MTL_RxQ_DMA_Map0[Q0DDMACH] (bit[7] = 0) to route to a DMA channel.

Similarly, packets from other receive queues program register fields corresponding to each queue to route to any DMA channel.

72.10.3.2 Dynamic (per packet) mapping

In this mode, the destination DMA channel of a packet read from a Rx queue is not constant but it is decided independently for each packet. For example, if you write 1 to MTL_RxQ_DMA_Map0[Q1DDMACH], it indicates that the static mapping disables for receive queue 1 and ignores the value in MTL_RxQ_DMA_Map0[Q1MDMACH]. The MAC receiver decides the destination DMA channel for each packet, depending on the following in decreasing order of priority:

1. **L3-L4 filter based DMA selection**: The TCP/UDP and IP header fields of the received packet are matched against the corresponding values programmed and enabled for comparison in the MAC_L3_L4_Address_Control register. If the match is successful, the DMA channel number programmed in the DMCHN field of the MAC_L3_L4_Address_Control register is selected as the destination DMA channel number, if DMCHEN field of the same register is 1. If none of the L3-L4 registers give a comparison match, then the module proceeds to the next step below.
2. **Extended VLAN based DMA selection**: Extended routing is applicable only if the VLAN filter has passed. Routing is done only on the basis of the perfect filter result. Each perfect filter has a DMA channel enable and a DMA channel number field which you can program. Routing is applicable for a filter, only if the DMA channel enable field is 1. The frame routes to the smallest matching filter's DMA channel, if it is enabled. If the filter's DMA channel number is not enabled, the frame route to channel 0. For example, if a frame's VLAN tag matches filters 7, 3, and 1, then the MAC checks if DMA channel number of filter 1 is enabled through programming. If yes, the frame route to the programmed value; otherwise it route to DMA. When the inverse filter is enabled; is routed to the least mismatched filter's DMA channel number provided it is enabled. If the DMA Channel enable bit is not set, then the frame routes on the basis of the DA based addressing or to channel 0.

   If hash filter is also enabled, it is determines the filter result only. Routing will still depends on the enabled perfect filters. Routing based on the VLAN filter will not occur if none of the perfect filters are enabled or if all of them are bypassed. The frame will route via DA based addressing or to channel 0. If all the perfect filters fails and the hash filter has passed, then the VLAN filter result is a pass but routing will be based on DA based addressing or to channel 0. Similar behavior is seen when you enables inverse filtering as well.
3. **Ethernet DA-based DMA selection**: The DA address of the received packet is compared against the programmed DA values in MAC address registers. If the address matches any of the programmed values, the corresponding DCS field (when enabled) determines the destination DMA channel number.

If none of the above operations make a successful match or decision, then the packet routes to the DMA channel 0 by default.

72.10.3.2.1 Broadcast/multicast packet duplication

This feature provides a mechanism to send the received broadcast or multicast packets to multiple DMA channels.

MAC_Address0_High[DCS] and other optional MAC_Address(#i)_High (i=1 to 2) registers determines the DMA channel number to which the received packet (that matches the MAC address present in that register) must route.

DMA channel routing mechanisms such as extended VLAN, or L3-L4 based routing does not support the packet duplication.

The packet duplication feature is supported only on the highest MTL queue configured. Therefore, you must program MAC_RxQ_Ctrl1[MCBCQ] to the highest RxQ present in the configuration for the packet duplication for broadcast or multicast packets.

72.10.4 Selection of tag priorities assigned to receive queues

Program the PSRQ field in the corresponding MAC_RxQ_Ctrl2 to assign the VLAN tag priorities to receive queues. The bit corresponding to the VLAN tag priority can be set in the PSRQ field for assigning that priority to the receive queue. For example, if you want to assign VLAN tag priority of 3 to receive queue 0, write 1 to bit [3] in PSRQ field of MAC_RxQ_Ctrl2. The VLAN tag priority assigned to particular receive queue must be unique, that is, you cannot assign more than one receive queue to the same VLAN tag priority. However, more than one VLAN tag priorities can be assigned to same receive queue.

The settings in the PSRQ field is used for VLAN tagged receive packet routing to receive queues as well as for PFC based transit flow control. The received VLAN tagged receive packet route to receive queue that has the VLAN tag priority match. In PFC based transit flow control, PSRQ field corresponding to a particular receive queue enables VLAN tag priorities in the PFC packet transmitted when corresponding receive queue reach the threshold level.

72.10.5 Receive side routing from MAC to queues

IP supports receive side routing from MAC to queues. MAC route the receive packets to the receive queues on the basis of the these packet types in that order

- Unicast/Multicast destination address packets that fail the destination address filter

- Multicast/Broadcast destination address packets that pass the destination address filter
- VLAN tag priority field in VLAN tagged AV data packets
- AV control packets
- VLAN tagged IEEE 1588 PTP over Ethernet packets
- Untagged IEEE1588 PTP over Ethernet packets
- VLAN tag priority field in VLAN tagged packets
- Untagged packets

You can route the outer C-VLAN tagged AV data receive packets on the basis of the priorities assigned to receive queues through PSRQ field in the corresponding MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 and the corresponding receive queue is enabled for AV through RXQ#EN field in MAC_RxQ_Ctrl0. These packets may be single VLAN tagged with C-VLAN type or double VLAN tagged with outer VLAN tag of C-VLAN type when double VLAN feature enables (MAC_VLAN_Tag_Ctrl[EDVLP] = 1) with an inner C-VLAN tagged or inner S-VLAN tagged when SVLAN processing is enabled (MAC_VLAN_Tag_Ctrl[ESVL] = 1). This type of Rx packet routing is available when you select the AV feature and multiple receive queues in the configuration.

You can route the AV control receive packets on the basis of the receive queue number specified in MAC_RxQ_Ctrl1[AVCPQ] and the corresponding receive queue is enabled for AV through RXQ#EN field in MAC_RxQ_Ctrl0. These packets may be single VLAN tagged with C-VLAN type or double VLAN tagged with outer VLAN tag of C-VLAN type when double VLAN feature is enabled (MAC_VLAN_Tag_Ctrl[EDVLP] = 1) with inner C-VLAN tagged or inner S-VLAN tagged when SVLAN processing is enabled (MAC_VLAN_Tag_Ctrl[ESVL] = 1). This type of receive packet routing is available when you select the AV feature and multiple receive queues in the configuration.

You can route the VLAN tagged receive packets on the basis of the priorities assigned to receive queues through PSRQ field in corresponding MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 and RXQ#EN field in MAC_RxQ_Ctrl0 enables the corresponding receive queue for DCB/generic. This type of receive packet routing is available when you select the multiple receive queues in the configuration.

You can route the untagged IEEE 1588 PTP over Ethernet receive packets on the basis of the receive queue number specified in MAC_RxQ_Ctrl1[PTPQ] and the corresponding receive queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0. Also, you can route the VLAN tagged IEEE 1588 PTP over Ethernet receive packets on the basis of the priorities assigned to receive queues through PSRQ field in corresponding MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 or the receive queue number specified in the MAC_RxQ_Ctrl1[PTPQ] and RXQ#EN field in MAC_RxQ_Ctrl0 register enables the corresponding Rx queue. Programming MAC_RxQ_Ctrl1[TPQC] determines this. This type of receive packet routing is available when IEEE 1588 timestamp feature supports and the multiple receive queues are selected in the configuration. The VLAN tagged IEEE 1588 PTP over Ethernet receive packets are detected only when you disables 802.1AS mode (MAC_Timestamp_Control[AV8021ASMEN] = 0), otherwise this type of receive packets are routed as generic VLAN tagged Rx packets.

You can route the multicast or broadcast destination address receive packets that passes the destination address filter on the basis of the receive queue number specified in MAC_RxQ_Ctrl1[MCBCQ]the MCBCQ field of MAC_RxQ_Ctrl1 register when enabled through MAC_RxQ_Ctrl1[MCBCQEN] and the corresponding receive queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0. This type of Rx packet routing is available when you select the multiple receive queues in the configuration.

You can route the untagged receive packets on the basis of the receive queue number specified in MAC_RxQ_Ctrl1[UPQ] and RXQ#EN field in MAC_RxQ_Ctrl0 enables the corresponding receive queue. This type of receive packet routing is available when you select the multiple receive queues in the configuration.

The unicast destination address receive packets that fail the destination address filter can be routed based on the receive queue number specified in MAC_RxQ_Ctrl4[UFFQ] when enabled through MAC_RxQ_Ctrl4[UFFQE]UFFQE, MAC_Packet_Filter[RA] = 1 and the corresponding receive queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0. This type of receive packet routing is available when you select the multiple receive queues in the configuration.

You can route the multicast destination address receive packets that fails the destination address filter on the basis of the receive queue number specified in MAC_RxQ_Ctrl4[MFFQ] when MAC_RxQ_Ctrl4[MFFQE] enables it. MAC_Packet_Filter[RA] = 1 and RXQ#EN field in MAC_RxQ_Ctrl0 enables the corresponding receive queue. This type of receive packet routing is available when you select the multiple receive queues in the configuration.

The receive packet will route through the receive queue 0, if it is not classified in any of the defined packet type for routing.

72.10.6 Receive side arbitration between DMA and MTL

IP controller supports receive side arbitration between DMA and MTL.

After the current packet processing completes, the DMA channel controller fetches the next descriptor and after the descriptor fetching completes, the DMA channel controller evaluates the amount of data to transfer to the Rx buffer on the basis of the programmed PBL and receive buffer length. Accordingly, it requests the MTL to transfer the data.

After servicing the current request, the MTL receive queue arbitration scheme selects receive queue on the basis of the arbitration scheme (MTL_Operation_Mode[RAA]) and the weights programmed in queue <n> receive control register. The arbitration is done among queues for which DMA is ready to service. After the receive queue is selected, PBL amount of data is read out from that queue and route to the receive DMA channel on the basis of the receive channel selection criteria.

The arbitration occur after every PBL data transfer completes and descriptors are ready for processing from at least one DMA channel.

72.10.7 Transit side arbitration between DMA and MTL

IP supports transit side arbitration between DMA and MTL. Transit DMA channels and transit queues are always mapped directly because the number of transit DMA channels are always equal to the number of transit queues in MTL. For instance, each transit DMA pushes data into its respective transit queue assigned to it.

The data inside each transit queue is stored in packets. Therefore, if two DMAs are allowed to transfer data into the same queue, when a transit DMA starts a packet transfer, the other DMA cannot transfer data unless the previous packet is completely pushed-in. This means that the second DMA remains idle until the first packet is transferred. Hence, each DMA is always connected directly to its corresponding transit queue.

72.10.8 Audio video bridging

IP supports the audio video bridging in 100 Mbps mode only, which allows the transmission of time sensitive traffic over network. IP implements these protocol for supporting the AVB feature:

- IEEE 802.1Qbv-2015 (Enhancements to scheduling traffic)
- IEEE 802.3br (Interspersing traffic)
- IEEE 802.1Qbu (Frame preemption)

The queue 0 transmit path supports the strict priority algorithm, and it is used for best-effort traffic when transmit paths of additional queues use the credit-based shaper algorithm to support traffic management. For a queue, the credit-based shaper algorithm determines that a queue is available for transmission if these conditions are true:

- The queue contains one or more packets.
- The credit for the queue is positive per the algorithm
- AV traffic is received on all queues. IP can also receive untagged PTP packets in addition to AV traffic on any queue.

72.10.9 Queue modes

Transit and receive queues both handles the AV traffic.

Queueing is based on WRR (Weighted round robin) or WSP (Weighted strict priority) algorithm for generic traffic. It is based on CBS (Credit Base Shaper) and SP (Strict Priority) algorithm for AV traffic.

The receive queue is configured for generic or AV based routing, which depends on the RXQ#EN field of corresponding queue. Queueing is done on the basis of the VLAN tag priority. The VLAN tag priority must match the PSRQ field of MAC_RxQ_Ctrl2. The receive packets can route to a particular DMA channel on the basis of the DCS field of perfectly-matched MAC address register.

By default, the untagged packets in a generic traffic route to the receive queue specified in MAC_RxQ_Ctrl1[UPQ]. Queue 0 is the default value of MAC_RxQ_Ctrl1[UPQ]. You can override the default value with any other value, for the MAC_RxQ_Ctrl1[UPQ].

The AV control packets (tagged or untagged) route on the basis of MAC_RxQ_Ctrl1[AVCPQ]. The PTP over Ethernet packets route on the basis of MAC_RxQ_Ctrl1[PTPQ].

72.10.10 Queue priorities

You can program the priority of an receive queue in the corresponding field of MAC_RxQ_Ctrl2. Also, you must program the AV queue (high priority) as an higher priority than the best-effort queue (low priority).

72.10.11 Enhancements to scheduled traffic (EST)

The IEEE 802.1Qbv-2015 defines the schedule for each queues on every egress port which makes the implementation aware of traffic arrival schedule. This information blocks the lower priority traffic from transmission in this time window or slot. This ensures that the sender forward the scheduled traffic to receiver through all the network nodes with a deterministic delay.

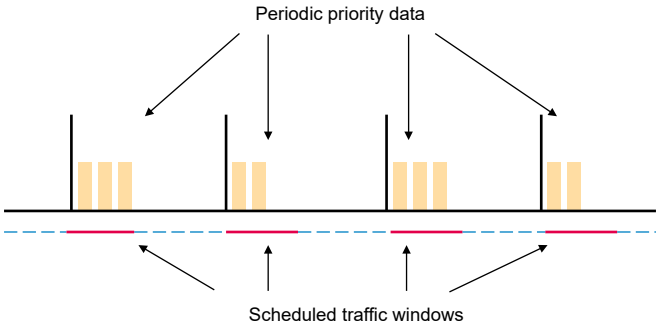

Figure 397. Time aware shaper implementation for traffic scheduling

An important requirement to achieve a low latency is to ensure that there are no interfering frames during the scheduled windows that are reserved for high priority traffic. The use of scheduled traffic imposes limitations when a transmission starts.

As shown in Figure 398 , if an interfering frame begins transmission just before the reserved time period starts, it can extend transmission into the reserved window, and potentially interfere with higher priority traffic. Therefore, a guard band whose size is equal to the largest possible interfering frame is required before the window starts.

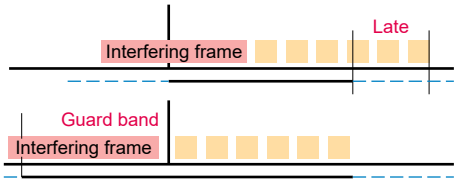

Figure 398. Implementing a guard band to avoid delays due to interfering frames

A larger guard band equates to a less efficient use of network bandwidth. However, this issue is addressed with the implementation of IEEE802.1Qbu (frame preemption). Frame preemption breaks the interfering frame into smaller fragments. Therefore, the guard band must be as large as the largest possible interfering fragment instead of the largest possible interfering frame.

During the guard band, only the frames that can complete the transmission of the entire frame before the next gate close event are permitted. This ensures that the high priority traffic can always start at the beginning of the window reserved for it.

72.10.11.1 Frequently used terms in EST

These are some of the frequently used terms in the EST support and their definitions.

- Gate control list: The list in the hardware memory that hold the gate controls and the associated time intervals.
- Gate controls: For a given schedule (row in gate control list) there is a gate open (O) and gate close (C) state associated with each TC. The set of O or C values, whose width is same as configured TCs is called the gate controls. Example: CCOCOOCO means TC7=C, TC6=C, TC5=O and so on.

- Time interval: Time interval (in nanoseconds) is a 16, 20, or 24-bit configurable field in the gate control list that indicates the time for which the associated gate controls are valid.
- Base time register: Each gate control list is associated with a 64-bit base time register that holds the start time (in PTP format) for the list.

72.10.11.2 Updates to the transmit scheduling to support EST

To support EST, these updates are required to transmit scheduling:

- Implementation of gate control list (GCL)
- Enforcing gate controls in the scheduler
- Utilizing gate open (O) duty cycle in the computation of idleSlope (CBS)

72.10.11.2.1 Implementation of gate control list (GCL)

Figure 399 shows how the gate control list governs the gate close(C) and open(O) events on the basis of the schedule provided for each event. GCL has two parts:

- Time interval: Defines the time in nanoseconds for which the gate controls are valid and must apply before reading the next gate controls from the list. The configurable width of 16, 20 or 24-bit represents a maximum of 64us, 1ms, or 16ms schedule interval respectively. It supports left shift of the time interval upto 7 bits to be able to apply a multiplication factor from 1 to 128ns (in steps of 2(power)n). The maximum value (post shifting) of this field must be 999,999,999 ns.
- Gate control: Defines the open (O) represented by logic 1 or close (C) represented by logic 0 state for the gate of each TC.

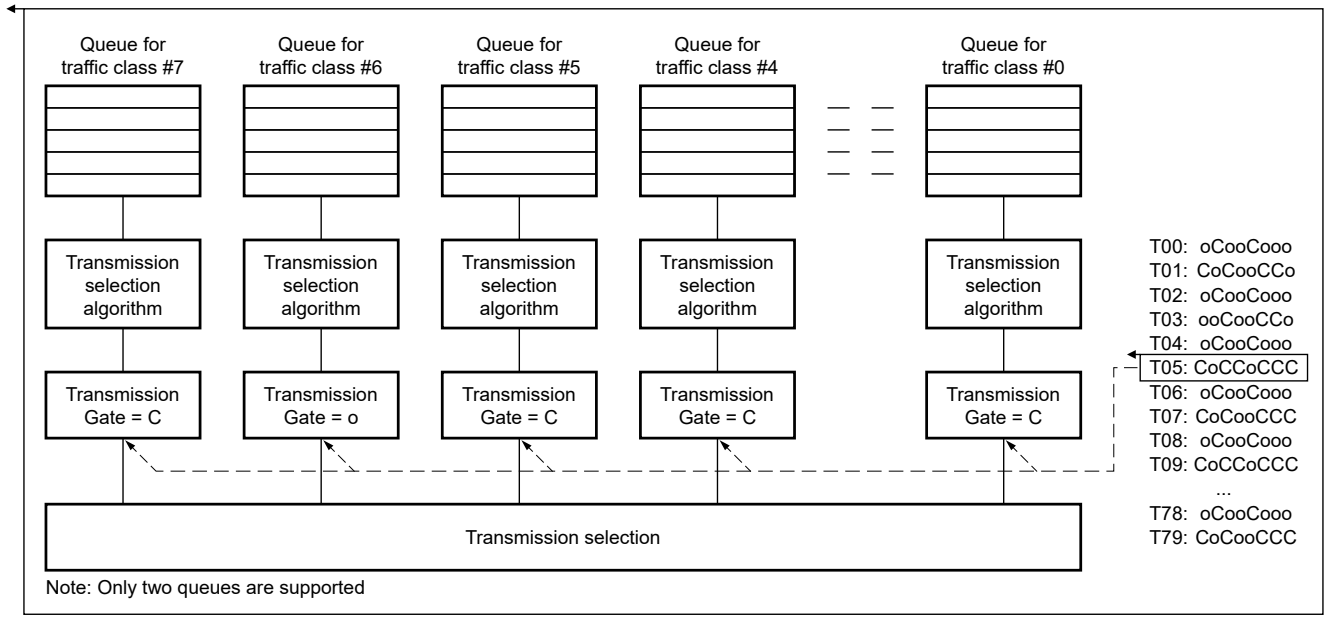

Figure 399. Block diagram from IEEE 802.1 Qbv specification - GCL governing gate close and open events

The implementation of GCL consists of these two gate control lists:

- HWOL - Hardware owned list which is a list for hardware access.
- SWOL - Software owned list which is a list for software access.

The access to these lists is mutually exclusive. Hardware sets the ownership to the list in MTL_EST_Status[SWOL]. Table 481 provides the implementation details of GCL.

Table 481. External memory used for holding the two gate-control lists

Gate control (up to 8 bits)	Time interval (ns) 16, 20, or 24 bits	
OOCCCCCC	T0	HWOL or SWOL
OOOOCCCC	T1	
CCCCOOCC	T2	
CCCCCCOO	T3	
I	I	
I	I	
OCOCOCOO		
OOOOCCCC	T last	
OOOOCCCC	T0	SWOL or HWOL
OOOOCCCC	T1	
OOCCCCCC	T2	
OOOOCCCC	T3	
I	I	
I	I	
OCOCCCCC		
OOCCCCCC	T last	

72.10.11.2.2 Registers related to gate control list

The following are the set of four registers (one for each GCL) related to GCL. These registers are implemented through Indirect addressing using MTL_EST_GCL_Control and MTL_EST_GCL_Data registers.

1. 64-bit Base time register (BTR)

2. 40-bit Cycle time register (CTR)

3. m-bit Time extension register (TER)

4. n-bit [Gate control] List length register (LLR) (n depends of the configured GCL depth)

72.10.11.2.2.1 Base time register (BTR)

This is a 64-bit register that specifies the start time to execute the GCL. The format of the BTR is same as the PTP format (upper 32-bits holds time in seconds and lower 32 bits hold time in nanoseconds). After the execution of a given list starts, the implementation can update the value in BTR to indicate the next list execution start time.

72.10.11.2.2.2 Cycle time register (CTR)

This is a 40-bit register that specifies the time at which the execution of the GCL must repeat. This register consists of an 8-bit value in seconds, and a 32-bit value in nanoseconds (similar to the PTP time format with truncated seconds register). For a given GCL, the start time is "Base Time" + N * "Cycle Time" where N is an integer value that represents the iteration number starting with 0 for first iteration. If the GCL execution takes longer than the cycle time, then the list is truncated at the cycle time and the subsequent loop begins at cycle time.

72.10.11.2.2.3 Time extension register (TER)

This is a m-bit (where m = Configured time interval width + 7) register that specifies the amount of time (in nano seconds) the current GCL can extend before switching to the new GCL. This helps to avoid the execution of the small fragments of the current list before switching to a new list.

72.10.11.2.2.4 List length register (LLR)

This is an n-bit register (when n is 7, 8, 9, 10, or 11 for a GCL configured depth of 64, 128, 256, 512, or 1024 respectively) that specifies the integer value of the length of the GCL (that is the number of valid rows in each GCL). The processing of the GCL stops after the number of rows read equals to the LLR value.

72.10.11.2.3 Transmission gating implementation

A bridge or an end station can enhance to allow transmission from each TC that is yet to be scheduled relative to a known timescale. To achieve this, a transmission gate is associated with each TC; the state of the transmission gate determines if you can select the queued frames for transmission.

For a TC, the transmission gate can be in one of these two states:

1. Open: Select queued frames for transmission, in accordance with the definition of the transmission selection algorithm associated with the TC.
2. Closed: Does not select queued frames for transmission.

A frame on a traffic class queue is not available for transmission if the transmission gate is in the closed state or if there is insufficient time available to transmit the entirety of that frame before the next gate-close event associated with that queue.

The implementation has visibility to the current schedule of gate controls and the immediate next schedule of the gate controls. So the maximum Gate Open period does not exceed the sum of the two Time Intervals. This is because, a frame is selected for transmission only if the gate is currently Open and the duration of gate open interval is greater than the time taken to transfer the entire frame.

The implementation must know the frame size before the transmission, so that you can avoid the transmission overruns and only the frames that can complete are scheduled at all times.

The implementation adequately compensates for the implementation delays in the data transfer from the buffer to the line by offsetting the current time with all the relevant delays (provided by MTL_EST_Control[CTOV]). This ensures that the schedule provided is always accurately implemented at the line.

You must ensure that the GCL slot interval is always greater than the expected packet size and overhead (scheduler delay, inter frame gap (IFG), and preamble, all combined).

72.10.11.3 Idle slope computation updates

When EST is enabled, credit accumulates only when the gate is open therefore, the effective data rate of the idleSlope must increase to reflect the duty cycle for the transmission gate associated with the queue.

The idleSlope is computed on the basis of the gate open time and oper cycle time values. Program the idleSlope registers (implemented one per CBS enabled TC) based on the following equation. The existing MTL register has sufficient field width to accommodate the new values for idleSlope.

idleSlope = (operIdleSlope(N) * OperCycle/GateOpenTime)

72.10.11.3.1 Operational details of GCL

Write 1 to MTL_EST_Control[SSWL], so that the hardware can access the programmed gate control list. The first set of gate controls are applied when the current time is equal to the value in the base time register (BTR) and is held until the programmed "time interval" value.

One additional gate control event is always read ahead from the list, to avoid the transmission overruns. This enables the GCL to determine the next gate close events (if any) for the open TCs.

The scheduling is done on the basis of the gate open state and time interval of only the current and subsequent schedule. An internal accumulator adds the time intervals when gate controls are applied. BTR + Accumulator specifies the time at which the next set of gate controls are applied.

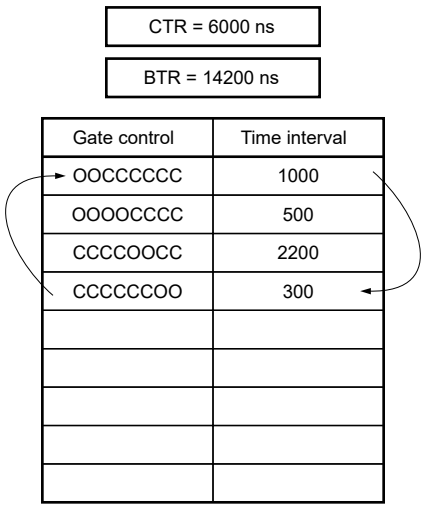

Figure 400. GCL and associated registers - basetime and cycletime

GCL is read progressively from the first row adhering to the schedule. The read operations continue until the list length (from LLR register) is reached and the execution of the list restarts at BTR + CTR time. At this point the value in CTR increments BTR to mark the beginning of a new cycle. In the absence of any gate controls, all the gates are in open state, during the execution of the list.

In cases where the execution time of the list is greater than the cycletime, the list is truncated and the next iteration starts when the current time equals BTR + CTR.

Table 482. GCL and associated registers - BTR and CTR

Current time	Gate control applied	Accumulator value	BTR (with updates)
14200	OOCCCCCC	1000	14200
15200	OOOOCCCC	1500	14200
15700	CCCCOOCC	3700	14200
17900	CCCCCCOO	4000	14200
18200	OOOOOOOO	0	20200
20200	OOCCCCCC	1000	20200
21200	OOOOCCCC	1500	20200

Table 482 describes an example in which the execution starts at 14200 and the first set of gate controls "OOCCCCCC" are applied immediately. The time interval is 1000 ns, so the next set of gate controls are applied at 14200 (BTR) + 1000 (Accumulator) = 15200 ns . The above table shows that there are no gate controls available after the execution of the last gate control and before the next iteration of the loop. The gates are deemed in open state during that time period as depicted at 18200 current time.

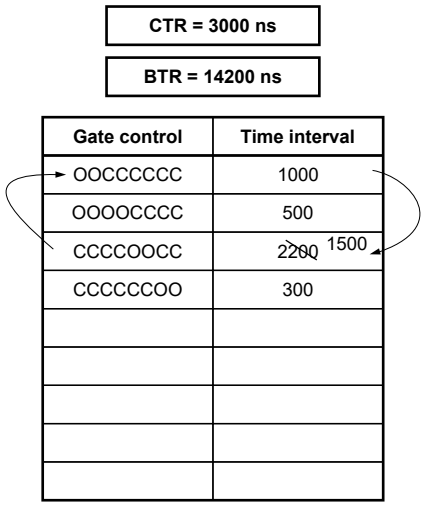

Figure 401. GCL and associated registers - BaseTime and CycleTime list execution time > CycleTime

Table 483 indicates that the list execution takes longer than the allocated CycleTime, so the list is truncated and the list starts from the BTR+CTR.

Table 483. GCL and associated registers - BTR and CTR, execution time > Cycle Time

Current Time	Gate Control Applied	Accumulator Value	BTR (with updates)
14200	OOCCCCCC	1000	14200
15200	OOOOCCCC	1500	14200
15700	CCCCOOCC	3700	14200
17200	OOCCCCCC	1000	17200
18200	OOOOCCCC	1500	17200
18700	CCCCOOCC	3700	17200

When you apply the third set of gate controls, BTR + CycleTime (17200) < BTR + Accumulator (17900), so the list is truncated and execution switches to a new iteration at 17200.

72.10.11.3.2 Installing a new GCL

The switch to the new GCL can happen in one of the following ways when a new software programmed GCL is available and executed at the new BTR value:

- New base time aligned with current schedule
- New base time unaligned with current schedule

72.10.11.3.2.1 New base time aligned with current schedule

If the choice of cycle time for the new gating cycle is unchanged from the cycle time for the current gating cycle, and if the BTR chosen for the new gating cycle (new BTR) is an integer multiple of the current cycle time (+ current BTR), then the new gating cycle exactly lines up with the old gating cycle, that is, the cycle start times for the new gating cycle is same as they would have been for the old configuration. This could be considered to be the ideal case and allows the new gating cycle to be installed and executed with no timing issues. The implementation completes the execution of an iteration of the current list and switches to the new list at the beginning of the BaseTime listed in the new list.

If (New base time > = Current time)

ConfigChangeTime = New BaseTime

Else If (New base time < Current time)

1. Set the BTRError

2. ConfigChangeTime = (New BaseTime + N* New CycleTime)

where N is the smallest integer for which the relation ConfigChangeTime >= CurrentTime and (N =< 8) is true.

When N > 8 the hardware cannot auto recover and the loop count value in BTRError reporting is set to 1111 requires the software to reprogram the new base time.

Figure 402 illustrates the installation of the new GCL along with the timelines.

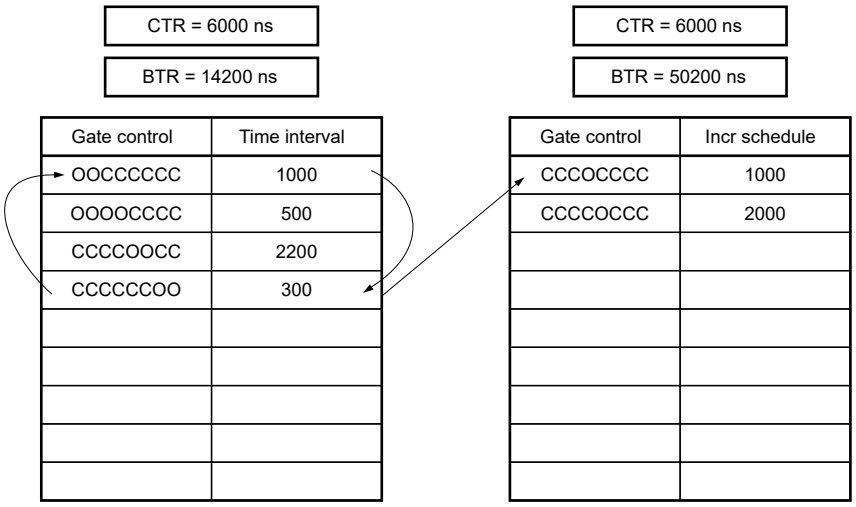

Figure 402. Switching to a new configuration that is aligned with the existing configuration

In the above example, after the sixth iteration of the first GCL, the BTR values of the old and new GCL are equal. At that point the new GCL is processed as a natural extension to the existing GCL.

Table 484. GCL and associated registers - BTR and CTR

Current time	Gate control applied	Accumulator value	BTR (with updates)
44200	OOCCCCCC	1000	44200
45200	OOOOCCCC	1500	44200
45700	CCCCOOCC	3700	44200

Table continues on the next page...

Table 484. GCL and associated registers - BTR and CTR (continued)

Current time	Gate control applied	Accumulator value	BTR (with updates)
47900	CCCCCCOO	4000	44200
48200	OOOOOOOO	0	50200
50200	CCCOCCCC	1000	50200
51200	CCCCOCCC	3000	50200
53200	OOOOOOOO	0	56200

72.10.11.3.2.2 New base time unaligned with current schedule

If the new cycletime differs from the current cycletime or new basetime in the future and is not an integer multiple of current cycletime, then the old and new cycles do not line up. When new basetime is reached (when the new configuration is installed and starts to execute), the last old cycle is normally truncated to start the first new cycle. This could be undesirable if it results in a very short last old cycle; arguably it would be better to simply extend the penultimate old cycle by that small amount, rather than starting a very short cycle. The Cycle Time Extension Register (related to the current config list) allows this extension of the last old cycle to be done in a defined way; if the last complete old cycle ends normally in less than current Cycle Time Extension (TER) ns before the new base time, then the last complete cycle before new BaseTime is reached is extended so that it ends at new BaseTime.

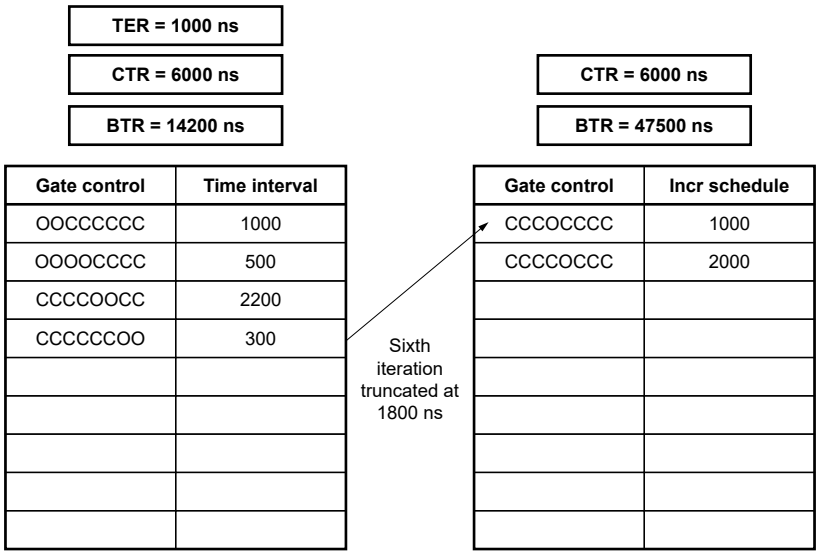

Figure 403. Switching to new list truncating the current list

At the end of the fifth iteration the Current time + Cycle time extension (TER) < New BTR so the sixth iteration of current configuration is started. During the sixth iteration of the current list when the new BTR value is smaller than the next schedule in the current list, it switches to the new list.

Table 485. Extending to new list by truncating the current list

Current time	Gate control applied	Accumulator value	BTR (with updates)
44200	OOCCCCCC	1000	44200

Table continues on the next page...

Table 485. Extending to new list by truncating the current list (continued)

Current time	Gate control applied	Accumulator value	BTR (with updates)
45200	OOOOCCCC	1500	44200
45700	CCCCOOCC	3700	44200
47500	CCCOCCCC	4000	44200
48500	CCCCOCCC	0	50200
50500	OOOOOOOO	1000	50200

Below is an example where the current config list is extended instead of starting a new iteration as the extension time of 800 ns is less than the allowed cycle extension time (TER) of 1000 ns.

Figure 404. Switching to new list by extending the current list

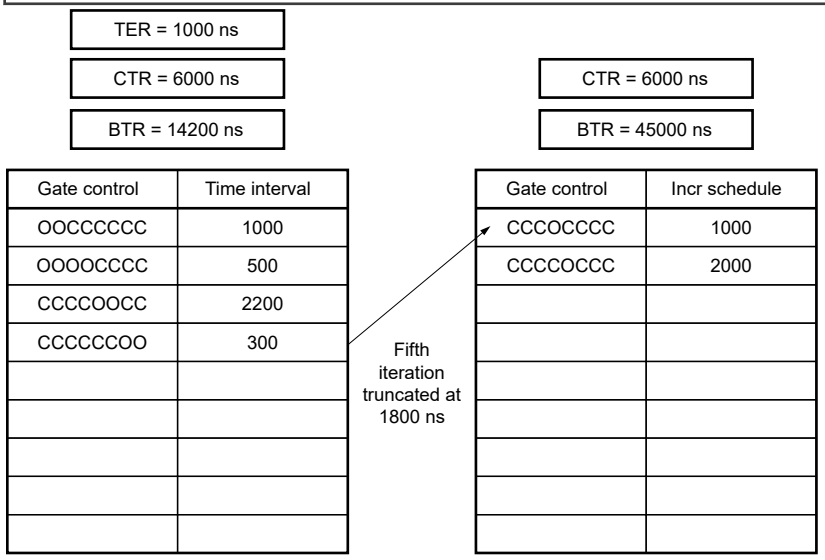

Table 486. Switching to new list by extending the current list

Current time	Gate control applied	Accumulator value	BTR (with updates)
38200	OOCCCCCC	1000	38200
39200	OOOOCCCC	1500	38200
39700	CCCCOOCC	3700	38200
41900	CCCCCCOO	4000	38200
42200	OOOOOOOO	0	44200
45000	CCCOCCCC	1000	45000

Table continues on the next page...

Table 486. Switching to new list by extending the current list (continued)

Current time	Gate control applied	Accumulator value	BTR (with updates)
46000	CCCCOCCC	3000	45000
48000	OOOOOOOO	0	51000

72.10.11.4 Impact of Transmit Scheduling Algorithms on EST

When EST is used in isolation, the Gate Control List manages the final open/close state of the Queues along with the checks carried out by the Transmission Selection Algorithm in MTL. As the Gate Controls operate on a predefined repetitive schedule, it is recommended to use Strict Priority or Credit Based Shaper (CBS) scheduling algorithms.

Other algorithms such as the Weighted Round Robin (WRR), Deficit Weighted Round Robin (DWRR) and Weighted Fair Queuing (WFQ) implement masking of the queues based on the current winning queue. The algorithm is applied only among the group of queues that open simultaneously. To ensure Queues whose gates are "Open" get priority, these algorithms are modified to treat "gate open" queues and "gate closed" queues as separate groups giving priority to gate open queues.

For example, consider 4 queues (Q3, Q2, Q1, Q0) with weights 4:3:2:1; Q3 and Q2 are in Open state in slot one slot, while Q1 and Q0 are in Open state in another slot. In this case, the scheduler works as follows:

1. In the first slot, the Q3 and Q2 are serviced in the ratio of 4:3 for the duration the slot is open.
2. In the second slot, the queues Q1 and Q0 are serviced in the ratio of 2:1.
3. Fresh arbitration is started every time a slot is opened.

In other words, the traffic does not get distributed in the intended ratio of 4:3:2:1; but as two groups with different ratios and only for the duration of the slot when the gates are open continuously

NOTE

See Programming guidelines for EST

72.10.12 Frame preemption (FPE)

Frame preemption breaks the interfering frame into smaller fragments. Therefore, the guard band needs to be only as large as the largest possible interfering fragment instead of the largest possible interfering frame. During the guard band, only the frames that can complete the transmission of the entire frame before the next gate close event are permitted. This ensures that the high priority traffic can always start at the beginning of the window reserved for it.

Preemption allows one or more higher priority (express) frames to interrupt the transmission of a lower priority (preemptable) frame; the preemptable frame transmission is resumed and completed after the express frame transmission is complete. To support frame preemption, the following two abstractions of the MAC are used:

- A preemptable MAC, called pMAC, which carries the preemptable traffic.
- An express MAC, called eMAC, which carries the express traffic.

In the implementation, only parts of the MAC that holds the state during preemption is replicated and represented as pMAC and eMAC. The MAC uses the following two ways to puts on hold, the transmission of the preemtable traffic, in the presence of express traffic:

- The MTL scheduler interrupts the preemptable traffic that is currently being transmitted. When the preemption capability is active, the MAC interrupts the transmission and reception of preemptable frames. A preempted fragment can be followed by zero or more express frames, before the continuation fragments. The preemptable frame can be fragmented any number of times, however, the minimum final and non-final fragment length criterion must be is met. However, interleaving of more than 1 preemptable packet is not permitted. This implies that if a preemptable packet is fragmented by an express packet, another preemptable packet cannot be transferred until all the remaining fragments of the first preempted packet are transferred.

- The MTL scheduler prevents starting the transmission of preemptable traffic. When the preemption capability is inactive, the pMAC entity is disabled and only express traffic is transmitted or received. Frame preemption feature can be enabled by setting EFPE field of the MAC_FPE_CTRL_STS register.

If you are unable to schedule fragmented packets after a certain number of attempts because of some reason, there is a possibility that the remaining fragmented packets are dropped. For this, software can program MTL_EST_Control[LCSE] to increase number of iterations or MTL_EST_Control[DFBS] to disable dropping of packet.

NOTE

EST and FPE cannot be used at the same time.

72.10.12.1 GCL Modification to Support FPE

In the EST-only configuration, the GCL entry has up to 24 bits of Time Interval and up to 8 high order bits representing the Gate Open/Close state requirements as shown in the following figure.

Gate control (up to 8 bits)	Time interval (ns) 16, 20 or 24 bits
OOCCCCCC	T0
OOOOCCCC	T1
CCCCOOCC	T2
CCCCCCOO	T3
|	|
|	|
OCOCOCOO	T126
OOOOCCCC	T127

Figure 405. Gate Control List When FPE is Disabled

EST only supports SetGate operation, which implies that the gates are set to either open or close at a given time interval. However, when both Frame Preemption (FPE) and EST are enabled, the GCL also supports Set-and-Hold-MAC and Set-and-Release-MAC operations, in addition to the SetGate operation. To enable the support of hold and release operations, the format of the GCL is slightly changed while configuring and enabling the FPE. The first Queue (Q0) is always programmed to carry preemption traffic and therefore it is always Open. The bit corresponding to Q0 is renamed as Release/Hold MAC control. The TX Queues whose packets are preemptable are indicated by setting the PEC field of the MTL_FPE_CTRL_STS register. The GCL bit of the corresponding Queue are ignored and considered as always "Open". So, even if the software writes a "0" ("C"), it is ignored for such queues.

Gate control (up to 7 bits)	Release or hold indication	Time interval (ns) 16, 20 or 24 bits
CCCOOOO	0	T0
CCCCOOO	0	T1
OCCCOOO	1	T2
COCCOOO	1	T3
CCOCOOO	1	T4
CCCOOOO	0	T5
CCCCOOO	0	T6

Figure 406. Gate Control List When FPE is Enabled

When the Release/Hold bit transitions from a '0' to '1', a Set-and-Hold-MAC operation is performed. This marks the cease of the preemptable traffic. This is achieved by sending a Hold request to MTL "ha" ns in advance (where ha is the time interval mentioned in the Hold Advance (HADV) field of the MTL_FPE_Advance register). When the Release/Hold bit transitions from a '1' to '0' a Set-and-Release-MAC operation is performed. This marks the resuming of the preemptable traffic. This is achieved by sending a Release request to MTL "ra" ns in advance (where ra is the time interval mentioned in the Release Advance (RADV) field of the MTL_FPE_Advance register). The preemptable traffic is blocked for the time duration the Release/Hold bit is set to a '1' in the Gate Control List.

72.10.12.2 Impact of Preemption on CBS

In Credit Base Shaper(CBS), the definition of "Transmit" is as follows:

- TRUE for the duration of frame transmission from the queue.
- FALSE when frame transmission from the queue is complete.
- When CBS algorithm is used along with frame preemption, the value of "Transmit" is TRUE only while the frame is being transmitted by the MAC. If the frame transmission is delayed or interrupted (for instance, a preemptable frame transmission is interrupted to allow the transmission of an express frame from a different queue, or the start of express frame is delayed because a preemptable frame is being transmitted) the value of "Transmit" is FALSE until transmission of the frame commences or is resumed.

Also, the value of "Transmit" is FALSE during the transmission of any overhead that is a consequence of frame preemption. For example, additional frame overhead (mCRC, Fragment Count) that is added to the preemptable frame.

At any given time, if there are no frames in the queue, and the value of Transmit is FALSE, and credit is positive value, the credit value is set to zero if here is no preemptable frame from the queue for which transmission is in progress but has been interrupted.

72.10.12.3 mPacket Format

When the preemption capability is active, MAC sends mPackets to the PHY. An mPacket can be one of the following:

1. A express packet
2. A preemptable packet
3. An initial fragment of a preemptable packet
4. A continuation fragment of a preemptable packet

Start mPacket Delimiter (SMD)

The value of the SMD indicates whether the mPacket contains an express packet, the start of a preemptable packet (initial fragment or complete packet), or any of continuation fragments of a preemptable packet. Following table shows the valid SMD values.

Table 487. Possible SMD Values of mPacket

mPacket Type	Notation	Frame Count	Value
verify packet	SMD-V	-	0x07
respond packet	SMD-R	-	0x19
express packet	SMD-E	-	0xD5
preemptable packet start	SMD-S0	0	0xE6
	SMD-S1	1	0x4C

Table continues on the next page...

Table 487. Possible SMD Values of mPacket (continued)

mPacket Type	Notation	Frame Count	Value
	SMD-S2	2	0x7F
	SMD-S3	3	0xB3
continuation fragment	SMD-C0	0	0x61
	SMD-C1	1	0x52
	SMD-C2	2	0x9E
	SMD-C3	3	0x2A

frag_count

A frag_count is a modulo-4 counter that increments for each continuation fragment of the preemptable packet. The frag_count protects against mPacket reassembly errors by enabling detection of the loss of up to 3 packet fragments.

The frag_count field is present only in mPackets with SMD-C notation (continuation fragment). The frag_count is zero in the first continuation fragment of each preemptable packet.

Table 488. Possible frag_count Values

frag_count	Value
0	0xE6
1	0x4C
2	0x7F
3	0xB3

mData

The contents of the packet from the MAC, starting with the first byte after the SFD to the last byte before the FCS are sent in the mData fields of one or more mPackets for that frame. The minimum size of the mData field is 60 bytes.

CRC The CRC field contains a cyclic redundancy check (CRC) and has an indication of the final mPacket of a frame. In the final mPacket of a frame, the CRC field contains the last 4 octets of the MAC frame (the FCS field).

For other mPackets, the CRC field contains an mCRC value. The mCRC is calculated on the octets of the packet from the first octet of the frame (the octet following the SFD of preemption frames) to the last octet of the packet transmitted in that mPacket by performing an XOR of the calculated 32 bit CRC value of the fragment and a value of 0x0000FFFF.

Summary of Packet Formats

- Express Packet: 7bytes of PREAMBLE, SMD-E, Data, and CRC
- Complete Preemptable Packet: 7 bytes of PREAMBLE, <Current Preemptable packet SMD>, Data, CRC
- Initial Fragment (non-final) of Preemptable Packet: 7 bytes of PREAMBLE, <Current Preemptable packet SMD>, Data, mCRC
- Continuation fragments (non-final) of Preemptable packet: 6 bytes of PREAMBLE, <Current Preemptable continuation fragment SMD>, <Current Preemptable continuation fragment FC>, Data, mCRC

- Final fragment of Preemptable packet: 6 bytes of PREAMBLE, <Current Preemptable continuation fragment SMD>, <Current Preemptable continuation fragment FC>, Data, CRC

72.10.12.4 Transmit Preemption

When FPE is enabled (setting EFPE=1 in MAC_FPE_CTRL_STS register), the MTL preempts a preemptable frame, when a "hold" request is asserted (EST/Qbv configured and enabled) express frames are available for transmission, that is, frame is present in MTL FIFO and is qualified for arbitration, after ensuring that the minimum mPacket mData field size is met. Therefore, preemption occurs only if at least 60 bytes of the preemptable frame have been transmitted and at least 64 bytes (including the frame CRC) remain to be transmitted.

The earliest starting position of preemption is controlled by the AFSZ field of the MTL_ FPE_CTRL_STS Register. Preemption does not occur until at least 64 * (1+ AFSZ) - 4 bytes of the preemptable frame have been sent.

When preemption occurs, all the preemptable queues are blocked and only the express queues are allowed to arbitrate (if more than one express queue has traffic) and transmit.

Continuation fragment of the preempted frame is the first frame to be transmitted after "release" request is asserted (EST/Qbv configured and enabled) and all the express traffic transmission completes.

NOTE

All the PTP packets should be transmitted as express packets

MTL communicates the following frame-type information to the MAC using a 2-bit preemption control signal on the MTI interface qualified by SoF and EoF.

- Express Frame
- Preemption Frame (Full or Fragment)
- Continuation Fragment (non-Final or Final)

Table 491. Preemption Control Values on MTI Interface for Various Frame Types

Qualifier	Preemption Control Value	Frame Type
SoF	00	Start Express
SoF	01	Start Preemption
SoF	10	Continuation Fragment
SoF	11	Reserved
EoF	00	End of Frame
EoF	01	End of Fragment

MTL should wait for the previous fragment status to be received before resuming the continuation fragments of a preempted frame. Fragment status is described in detail in the Tx Fragment Status section.

72.10.12.4.1 MAC Tx Preemption

MAC supports preemption by implementing the functionality needed to generate the mPackets as described in “mPacket Format”.

Based on the Preemption Control value received on the MTI interface (qualified with SoF and EoF), MAC determines the frame type (shown in the above table 'Preemption Control Values on MTI Interface for Various Frame Types') and generates mPackets accordingly.

When the preemption capability is active, MAC replaces the SFD of a preemption packet with an SMD-S value. A 2-bit rolling frame count is encoded in the SMD-S value.

The SMD-E value is the same as the SFD value so the SFD of an express packet does not need to be replaced.

72.10.12.4.1.1 Tx Fragment Status

MAC sends Tx fragment status to indicate successful transmission of fragmented mPackets.

In case of a transmission error (underflow, jabber, and so on) the frame status is sent (and not a fragment status) with an error indication along with all other relevant status fields. In case of receiving an error status for a transmitted fragment, the MTL drops the remaining fragments and does not send any more continuation fragments.

72.10.12.5 Receive Preemption

72.10.12.5.1 MAC Receive Preemption

When FPE is enabled, the MAC Receiver pases the incoming packets and differentiates between Express packets and preemptable packets. An SMD containing an SMD-E indicates express packet, and SMD containing an SMD-S indicates the first mPacket of a preemptable packet.

If an mPacket containing an SMD-S is received when MAC has not completed receiving the previous preempted packet, MAC sets a CRC Error status for the previously received partial packet.

When an SMD-S is detected, MAC records the frame count indicated by the SMD and then begins sending data on the MRI interface.

The MAC checks the last four bytes of the mPacket . If the last four bytes of the mPacket do not match CRC, that indicates the end of the packet with or without a CRC error as per the CRC check result. If the last four octets of the mPacket match, that indicates that the packet was preempted.

An SMD containing an SMD-C indicates an mPacket that continues the data for a preempted packet. Upon receiving an SMD value of SMD-C, MAC checks the following:

1. A preempted packet is in progress
2. The frame count indicated by the SMD matches the frame count of the packet in progress
3. The frag_count value indicates the next fragment count.

If any of the above check fails, the mPacket is discarded and MAC sets a CRC Error status for the partially received packet.

If all the checks pass, the next fragment count is incremented modulo 4.

When a packet is preempted, the MAC saves the state of the partially received packet (filter check status, timestamp, length fields etc.) and will be able to process any received Express packets before the continuation fragment is received.

The MAC Receiver sends a "dummy status" for all the mPacket fragments successfully received and sends the Rx status with the final fragment. If an error is detected during any of the fragments the Rx status is sent and the fragment is marked as final fragment. All subsequent continuation fragments received for this packet are dropped in the MAC.

The MAC communicates the following frame type information to the MTL using a 2-bit preemption control signal.

1. Express Frame
2. Preemption Frame (Full or Fragment)
3. Continuation Fragment (non-Final or Final)

Table 492. Preemption Control Values on MRI Interface for Various Frame Types

Qualifier	Preemption Control Value	Frame Type
SoF	00	Start Express
SoF	01	Start Preemption
SoF	10	Continuation Fragment
SoF	11	Reserved
EoF	00	End of Frame
EoF	01	End of Fragment

72.10.12.5.1.1 Data Alignment

When a received frame cannot be fragmented on any byte boundary, MAC retains the unaligned bytes of data in the previous fragment and resends them with the next fragment as shown in the following figure.

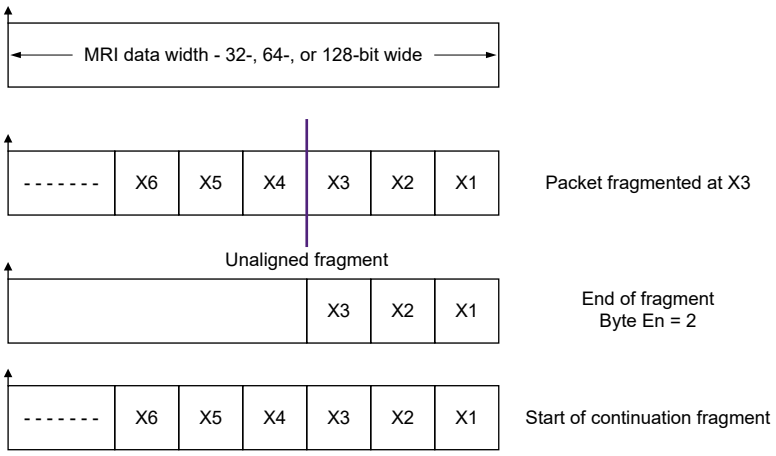

Figure 407. Data Alignment Feature of MAC

72.10.12.5.1.2 MTL Receive Preemption

The MTL Rx must have at least 2 Rx queues to support FPE function as the preemptable packets and the express packets must be routed to separate Rx queues. The destination Rx queue of a received packet is controlled by MAC_RxQ_Ctrl[n] registers. Program these registers such that Preemptable traffic and express traffic are not routed to the same Rx queue. As the queue mapping for tagged packets is based on VLAN user-priority field, this implies that priority of preemptable and express packets are mutually exclusive. In other words, packets of a certain priority (traffic class) are either express or preemptable but cannot be both.

For the preemptable frames, in addition to the PSRQ (Priority Selected in Rx queue) based queue routing, a programmable "Frame Preemption Residue Queue" (FPRQ) is supported to route all other Preemption Packets received (Untagged, SA/ DA or VLAN Filter Fails forwarded due to RA being set or VTFE being reset).

Table 493. Preemption Control Values on MRI Interface for Various Frame Types

Preemption Packet Type	Queue Routing
AV Tagged Packets passing the SA/DA and VLAN filters	PSRQ*
DCB/Generic Tagged Packets passing the SA/DA and VLAN filters	PSRQ**
Tagged Packets failing the SA/DA and VLAN filters without setting the Receive All (RA = 0) or setting VTFE = 1	Dropped
All other packets OR when RA = 1	FPRQ

72.10.12.5.1.3 MTL Receive Arbitration

On the ARI Interface, data is fetched from the MTL Rx FIFO based on the arbitration selected in the MTL_Operation_Mode register. Frame based arbitration can be used only when all the MTL Preemption Queues are operating in Store and Forward mode, else there will be loss of bandwidth on the ARI interface because all the fragments of a preemptable packet is not available. Therefore, any express packets received between the fragments are blocked until all the fragments are received and transferred; this defeats the purpose of express traffic.

When operating in either Threshold (cut through) or Store and forward modes of operation, PBL based arbitration is recommended over Frame based arbitration. In case of PBL based arbitration, the watermark check is always performed and the arbitration/ transfer of data in terms of chunks of "PBL" size of data which is almost similar to the concepts of "fragments". Therefore the express queue packets get blocked for less time as well as the ARI interface transfers the data without loss of efficiency.

72.10.12.6 Verify and Respond mPackets

When FPE function is present, the MAC can receive and detect the Verify and Respond mPackets, even when FPE is not enabled by software. When MAC detects valid Verify/Respond mPackets, it notifies the software by setting the RVER and RRSP fields of MAC_FPE_CTRL_STS register respectively. Optionally an interrupt can be generated. As such packets have empty (all-zero) data payload, they are dropped inside the MAC and not forwarded to the MRI.

Software can set the SVER and SRSP fields of MAC_FPE_CTRL_STS register to request MAC to transmit Verify and Respond mPackets respectively. Upon successful transmission of these frames, MAC clears the SVER/SRSP bits and sets the TVER & TRSP fields of MAC_FPE_CTRL_STS register. Optionally an interrupt can be generated when these events occur.

Software must ensure that frame preemption verify and response packet are not triggered at the same time. Trigger either of the packets and then wait for its completion before triggering another packet.

72.10.12.7 Frame Preemption and MMC Counter and Interrupt Registers

The following MMC counters and associated Interrupt registers are instantiated/present in the MAC when Frame Preemption feature is enabled.

Table 494. MMC Counters and Associated Interrupt Registers

Frame Assembly Error Counter	Description	Associated MMC Counter
Frame Assembly Error Counter	A 32-bit counter that provides the number of MAC frames with reassembly errors on the Receiver, due to mismatch in the Fragment Count value.	MMC_Rx_Packet_Assembly_Err_Cntr

Table continues on the next page...

Table 494. MMC Counters and Associated Interrupt Registers (continued)

Frame Assembly Error Counter	Description	Associated MMC Counter
Frame SMD Error Counter	A 32-bit counter that provides the number of received MAC frames rejected due to arriving with an SMD-C when there was no preceding preempted frame.	MMC_Rx_Packet_SMD_Err_Cntr
Frame Assembly OK Counter	A 32-bit counter that provides the number of MAC frames that were successfully reassembled.	MMC_Rx_Packet_Assembly_Ok_Cntr
MAC Rx Fragment Counter	A 32-bit counter that provides the number of additional mPackets received due to preemption.	MMC_Rx_FPE_Fragment_Cntr
MAC Tx Fragment Counter	A 32-bit counter that provides the number of additional mPackets transmitted due to preemption.	MMC_Tx_FPE_Fragment_Cntr
Hold Request Counter	A 32-bit counter that maintains the count of number of times a hold request is given to MAC.	MMC_Tx_Hold_Req_Cntr

72.10.12.7.1 Additional Registers Associated With MMC Interrupts

Following are the additional registers associated with MMC interrupts for the MMC error counters:

- MMC_FPE_Tx_Interrupt
- MMC_FPE_Tx_Interrupt_Mask
- MMC_Rx_Interrupt
- MMC_FPE_Rx_Interrupt_Mask

72.10.13 Time-Based Scheduling

Time-based scheduling feature is suitable for traffic whose periodicity and rate are predictable. To improve the quality-of-service of such traffic,

- The transmit DMA fetches the packet from the host memory for transmission at designated time. This helps the software to setup the Transmit descriptors in advance even before packet is ready/available. It reduces the overhead on the software and avoids constant monitoring of the time and preparing descriptors just in time when the packet is targeted to be transmitted.
- The MAC transmits the packet only at the designated/pre-determined time even if the packets are fetched in advance. This helps in maintaining a constant transmission rate that can be consumed by the receiver station; therefore avoiding congestion and excessive buffering in the network.

The time-based scheduling feature supports fetching and launching an Ethernet packet at (or after) a pre-determined time. The time-based scheduling is supported only in the following modes/configurations:

- Full duplex mode
- Link speed is 100Mbps or higher

The following figure shows the time-based scheduling flow.

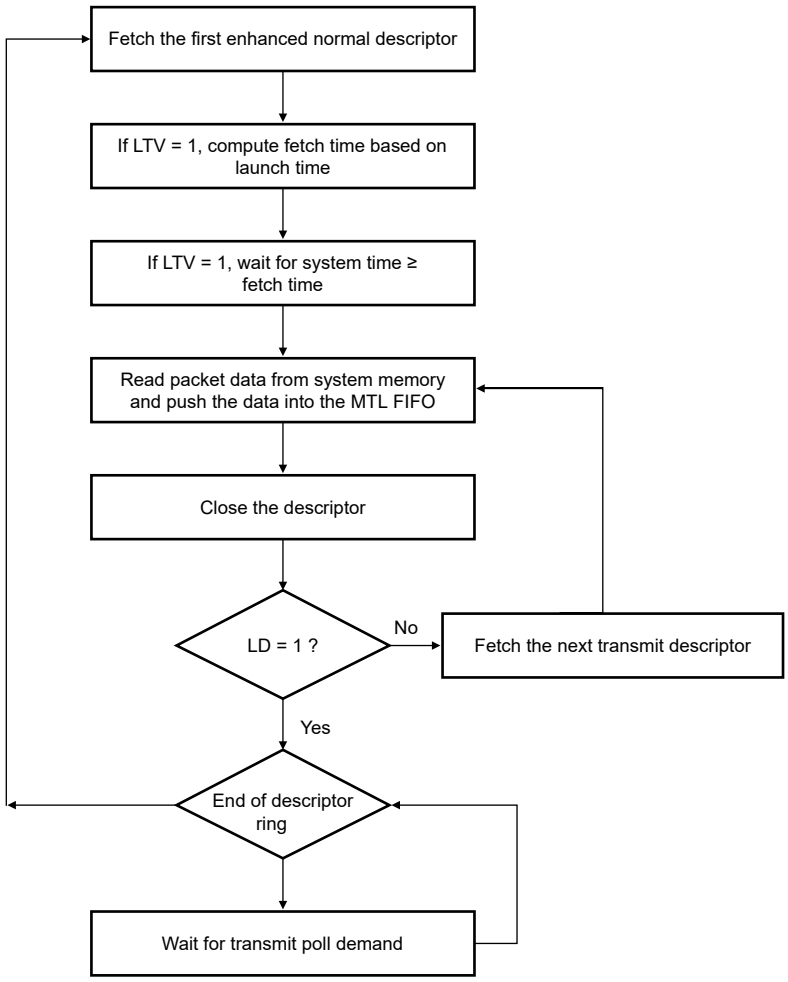

Figure 408. Time-Based Scheduling Flow

Following are the definitions specific to the time-based scheduling feature:

72.10.13.1 Launch time

The time beyond which MTL can schedule the packet for transmission. The launch time resets after the transmission of one frame. These are the two formats of the launch time.

Normal or absolute format:

In this format, the launch time is interpreted in the normal or absolute format if the ESTM bit of the MTL_TBS_CTRL register is set to 0.

The launch time is a 32-bit value, where most-significant 8-bits represent the time in seconds and the rest 24-bits represent the time in 256 ns. The launch time is compared against the IEEE 1588 based system or PTP time (bits[39:8]) and rolls over after 256 seconds.

The maximum value of the lower 32-bits of system time is 999,999,999 decimal (0x3B9AC9FF) and it wraps to 0 when reaching this value (representing a full second). Therefore, the maximum value of the lower 24-bits of the launch time (after multiplying by 256) must be 0x3B9AC9.

As the maximum value of launch time is 256 seconds,

- Launch time is greater than current system time when its value is between system time[39:8] and System time[39:8] + 128 sec.

- Launch time is less than current system time when its value is between System Time[39:8] + 128sec and System Time[39:8] + 256 sec, because this is a modulo 256 computation.

EST or offset format

In this format, the launch time is a offset value relative to the time which the BTR of the GCL list provided in the GCL slot number (GSN) indicates. The value in the BTR is always updated to the start time of the current loop of the GCL.

For each packet, the GSN value and the launch time value are specified in the enhanced transmit descriptor in the DMA configurations, or as control word in the MTL configurations.

The launch time offset is a 32-bit value; the upper 8-bits represent the time in seconds and the rest 24 bits represent the time in 256 ns, which is added to the BTR value corresponding to GCL slot number. The value of the launch time offset must be smaller than the value of the cycle time (specified in the CTR register that is implemented when EST is enabled). If the CTR is greater than or equal to 1s, the maximum value of the lower-24 bits of launch time offset must be 999,999,999 decimal (0x3B9AC9FF).

In this format, the launch time is a 64-bit value, which is interpreted as, Launch time = Launch GSN BTR[63:0] + (Launch time offset[31:0] << 8), which is compared with the system time [63:0].

GSN BTR is the Base Time value at which the Launch GSN loop started execution.

GCL slot number (GSN) A modulo 16 count of the GCL loop count is implemented and it is known as GSN. The count is incremented for every new GCL loop. Installation of new GCL list does not impact the count. Read MTL_EST_Status[CGSN] to obtain the current GCL slot number.

The maximum value of GSN is 15. Therefore the GSN values between MTL_EST_Status[CGSN] and MTL_EST_Status[CGSN]+8 represent current or future slots and all other GSN values are interpreted as elapsed slots or past slots. So, for the correct interpretation of time, GSN value must be between MTL_EST_Status[CGSN] and MTL_EST_Status[CGSN]+8.

72.10.13.2 Launch expiry time

Normal or Absolute Mode

In this mode, when MTL_TBS_CTRL[LEOV] = 1, MTL_TBS_CTRL[LEOS] determines the maximum amount of time a frame is eligible for launch, starting from the time the frame becomes eligible for launch.

The launch expiry offset is a 24-bit value defined in 256 ns units, with a maximum possible value of 999,999,999 ns (0x3B9AC9FF).

Launch expiry time = (Launch time[39:8] + LEOS[32:8]) * 256 ns

The packet with a specific launch time is considered as eligible for transmission when the launch time is less than the system time and (if MTL_TBS_CTRL[LEOV] = 1) the system time is less than the launch expiry time.

When the system time is greater than the launch expiry time, the frame is categorized as expired and it drops from the MTL FIFO.

NOTE

- For correct interpretation and meaningful operation, the fetch, launch, and launch expiry time must never set to a value larger than the Current system time + 128 sec; such a value is interpreted as time that has already elapsed.
- In Full Duplex mode, the frames dropped from the MTL FIFO have error summary (Bit 15) and excessive deferral (bit 3) of TxStatus set.

EST/Offset Mode

In EST mode, when MTL_TBS_CTRL[LEOV] = 1, MTL_TBS_CTRL[LEGOS] and MTL_TBS_CTRL[LEOS] determines the maximum amount of time a frame remains eligible for launch, starting from the time the frame becomes eligible for launch.

Launch Expiry Offset = (LEGOS: LEOS)

LEGOS holds the GSN offset (multiples of CTR time) and LEOS holds maximum value of CTR (sub CTR values) in ns.

Launch expiry offset is a 24-bit value defined in the units of 256 ns, with a maximum possible value of the smaller of 999,999,999 ns or CTR-1 ns.

The Launch expiry GSN is computed as follows:

Launch expiry GSN = (Launch GSN + LEGOS + CCMA) where, CCMA is the CTR carry due to modulo addition. This value is 1 if ((Launch time offset + LEOS) << 8) is equal to or greater than CTR.

When CCMA = 1, Launch expiry offset = (Launch time offset+ LEOS) - CTR

When CCMA = 0,

Launch expiry offset = (Launch time offset + LEOS).

Launch expiry time = Launch expiry GSN BTR [63:0] + Launch expiry time offset.

When MTL_TBS_CTRL[LEOV] is not 1, the launch expiry time is not checked.

When MTL_TBS_CTRL[LEOV] = 1, and

- the system time is greater than the launch expiry time, the frame drops from MTL FIFO. Then the frame is considered as expired.
- the launch time is smaller than the system time and the launch expiry time is greater than the system time, then the frame is considered eligible for launch.

NOTE

- Max value of MTL_TBS_CTRL[LEGOS] is 7. This indicates that when MTL_TBS_CTRL[LEOV] = 1, the frame has a maximum life time of <8 GCL loop iterations after it becomes eligible for launch.
- The slot number of the first GCL list that executes each time after EST is enabled, is zero.

72.10.13.3 Fetch time

This accounts for all possible delays in the DMA fetch operation and ensures that the frame is present in the MTL FIFO before the launch time.

If DMA_TBS_CTRL[FTOV] is 1, it indicates the fetch time for each packet. If DMA_TBS_CTRL[FTOV] is not 1, it indicates that the fetch time offset is not valid and DMA fetches packets without any time constraints.

Normal/Absolute mode

In this mode fetch time is derived or calculated by reducing the time specified in DMA_TBS_CTRL[FTOS] from the given launch time.

In Normal mode, the fetch launch time is computed as:

Fetch Time[39:8] = (Launch Time[39:8] - FTOS[31:8])

The fetch time is 32-bits and is compared against the system time[39:8] to determine whether it is eligible for fetching the frame:

- The fetch time is defined as greater than system time if the fetch time is in the range of system time[39:8]" and system time[39:8] + 128 sec. The frame is considered as not-eligible for fetch.
- The fetch time is defined as smaller than the system time if the fetch time is in the range of system time[39:8] + 128 sec and system time[39:8] + 256 sec. The frame is considered as eligible for fetch.

This is a modulo 256 computation.

EST/Offset mode

In this mode, the fetch GSN offset (DMA_TBS_CTRL[FGOS]) provides the slot number offset to deduct from the launch GSN. In this case the FTOS value must be smaller than 999,999,999 ns or CTR-1 ns.

If (Launch time offset >= FTOS):

Fetch time offset = ((Launch time offset - FTOS) * 256ns)

CBFS(CTR borrow for fetch subtraction) = 0

If (Launch time offset < FTOS) Fetch time offset = CTR + ((Launch time offset - FTOS) * 256ns)

CBFS (CTR borrow for fetch subtraction) = 1

The fetch GSN is computed as follows:

Fetch GSN = Launch GSN - FGOS - CBFS

Fetch time = Fetch GSN BTR[63:0] + Fetch time offset

The frame is eligible for DMA fetch when the fetch time is smaller than the system time.

DMA operations sequence

This is the sequence of operation when FTOV = 1:

1. Fetch the first enhanced normal descriptor (FD = 1).
2. Compute the fetch time on the basis of the launch time and wait for the system time to be greater than fetch time, if LTV = 1 and fetch is enabled.
3. Read the frame (data) from the host memory and transfer to MTL FIFO.
4. Close the normal descriptor.
5. Fetch the next normal descriptor (if the previous descriptor was not the last).
6. Repeat steps 4 to 6, until the last descriptor of the frame (LD = 1).

After the last descriptor of a frame, program the next enhanced normal descriptor with a new launch time and with LTV = 1. Otherwise, process the subsequent frames without any time restrictions.

See Programming the launch time in time-based scheduling for more information.

72.11 TCP/IP Offloading Features

This section and all other sections, along with respective sub-sections are Synopsys Proprietary. Used with permission.

72.11.1 Transmit Checksum Offload Engine

The MAC has a Checksum Offload Engine (COE) to support checksum calculation and insertion in the Transmit path, using which, the software can offload the task of checksum insertion to the hardware. In the transmit path MAC calculates the checksum and inserts it in the Tx packet. This feature helps in reducing the load on the software and can improve the overall throughput of the system. This feature is supported for only Q0 queue.

The checksum offload engine module supports two types of checksum calculation and insertion. The checksum engine can be controlled for each packet by setting the CIC bits (TDES3 Bits[17:16]).

Note: The checksum for TCP, UDP, or ICMP is calculated over a complete packet, and then inserted into its corresponding header field. Because of this requirement, when this function is enabled, the Tx FIFO automatically operates in the store-and-forward mode even if IP is configured for Threshold (cut-through) mode.

72.11.1.1 IP Header Checksum Engine

In IPv4 datagrams, the integrity of the header fields is indicated by the 16-bit Header Checksum field (the eleventh and twelfth bytes of the IPv4 datagram). The COE detects an IPv4 datagram when the Type field of Ethernet packet has the value 0x0800 and the Version field of IP datagram has the value 0x4. The checksum field of the input packet is ignored during calculation and replaced with the calculated value.

NOTE

IPv6 headers do not have a checksum field. Therefore, the COE does not modify the IPv6 header fields.

The result of this IP header checksum calculation is indicated by the IP Header Error status bit in the Transmit status (Bit 0 in Table 19-12 on page 1330). This status bit is set whenever the values of the Ethernet Type field and the Version field of IP header are not consistent, or when the Ethernet packet does not have enough data, as indicated by the IP header Length field. In other words, this bit is set when an IP header error is asserted under the following circumstances:

- For IPv4 datagrams:
  - The received Ethernet type is 0x0800, but the Version field of IP header is not equal to 0x4.
  - The IPv4 Header Length field indicates a value less than 0x5 (20 bytes).
  - The total packet length is less than the value given in the IPv4 Header Length field.
- For IPv6 datagrams:
  - The Ethernet type is 0x86dd but the IP header Version field is not equal to 0x6.
  - The packet ends before the IPv6 header (40 bytes) or extension header (as given in the corre-sponding Header Length field in an extension header) is completely received.

72.11.1.2 TCP/UDP/ICMP Checksum Engine

The TCP/UDP/ICMP Checksum Engine processes the IPv4 or IPv6 header (including extension headers) and determines whether the encapsulated payload is TCP, UDP, or ICMP. The checksum is calculated for the TCP, UDP, or ICMP payload and inserted into its corresponding field in the header. The Tx COE can work in the following two modes:

- The TCP, UDP, or ICMPv6 pseudo-header is not included in the checksum calculation and is assumed to be present in the Checksum field of the input packet. This engine includes the Checksum field in the checksum calculation, and then replaces the Checksum field with the final calculated checksum.
- The engine ignores the Checksum field, includes the TCP, UDP, or ICMPv6 pseudo-header data into the checksum calculation, and overwrites the checksum field with the final calculated value.

NOTE

For ICMP-over-IPv4 packets, the Checksum field in the ICMP packet must always be 16'h0000 in both modes, because pseudo-headers are not defined for such packets. If it does not equal 16'h0000, an incorrect checksum may be inserted into the packet.

The result of this operation is indicated by the Payload Checksum Error status bit in the Transmit Status vector (Bit 12 in Table 19-3 on page 1324). This engine sets the Payload Checksum Error status bit when it detects that the packet has been forwarded to the MAC Transmitter engine in the store-and-forward mode without the end of packet (EOP) being written to the FIFO, or when the packet ends before the number of bytes indicated by the Payload Length field in the IP Header is received. When the packet is longer than the indicated payload length, the COE ignores them as stuff bytes, and no error is reported. When this engine detects the first type of error, it does not modify the TCP, UDP, or ICMP header. For the second error type, it still inserts the calculated checksum into the corresponding header field. Following table describes the functions supported by Transmit Checksum Offload engine based on the packet type. When the MAC does not insert the checksum, it is indicated as "No" in the table.

NOTE

You should not enable checksum insertion for IPv4 or IPv6 packets that are greater than the frame size constraint specified in Description of Transmit Checksum Offload Engine because it may result in incorrect checksum insertion or unexpected behavior.

Table 495. Transmit Checksum Offload Engine Functions for Different Packet Types

Packet Type	Hardware IP headerchecksum insertion	Hardware TCP/ UDPchecksum insertion
Non-IPv4 or IPv6 packet	No	No
IPv4 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in MAC) but less than or equal to the frame size constraint specified in Transmit Checksum Offload Engine.	Yes	Yes

Table continues on the next page...

Table 495. Transmit Checksum Offload Engine Functions for Different Packet Types (continued)

Packet Type	Hardware IP headerchecksum insertion	Hardware TCP/ UDPchecksum insertion
IPv6 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in MAC) but less than or equal to the frame size constraint specified in Transmit Checksum Offload Engine.	Not Applicable	Yes
IPv4 with TCP, UDP, or ICMP	Yes	Yes
IPv4 packet has IP options (IP header is longer than 20 bytes)	Yes	Yes
Packet is an IPv4 fragment	Yes	No
IPv6 packet with the following next header fields in main or extension headers: • Hop-by-hop options (in IPv6 main header) • Hop-by-hop options (in IPv6 extension header) • Destinations options • Routing (with segment left 0) • Routing (with segment left > 0) • TCP, UDP, or ICMP • Authentication • Any other next header field in main or extension headers	• Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable	• Yes • No • Yes • No • No • Yes • No • No
IPv4 packet has TCP header with Options fields	Yes	Yes
IPv4 Tunnels: • IPv4 packet in an IPv4 tunnel • IPv6 packet in an IPv4 tunnel	• Yes (IPv4 tunnel header) • Yes (IPv4 tunnel header)	• No • No
IPv6 Tunnels: • IPv4 packet in an IPv6 tunnel • IPv6 packet in an IPv6 tunnel	• Not applicable • Not applicable	• No • No
IPv4 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled).	Yes	Yes
IPv6 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled).	Not applicable	Yes
IPv4 frames with security features (such as encapsulated security payload)	Yes	No
IPv6 frames with security features (such as encapsulated security payload)	Not applicable	No

72.11.2 Receive Checksum Offload Engine

IP provides the Checksum Offload Engine that is used to detect any error in an IPv4 or IPv6 packet in the receive path. The MAC verifies the checksum field of the received packet with the internally calculated checksum and provides the status.

The Receive Checksum Offload engine is used to detect errors in IP packets by calculating the header checksum and further matching it with the received header checksum. This engine also identifies a TCP, UDP, or ICMP payload in received IP packets and calculates the checksum of such payloads appropriately.

Here, both IPv4 and IPv6 packet in the received Ethernet packets are detected and processed for data integrity. The MAC receiver identifies IPv4 or IPv6 packets by checking for value 0x0800 or 0x86DD, respectively, in the Type field of the received Ethernet packet. This identification is applicable to single VLAN-tagged packets. It is also applicable to double VLAN-tagged packets when the Enable Double VLAN Processing option is selected and the EDVLP bit of the MAC_VLAN_Tag register is set.

The Rx COE calculates the IPv4 header checksums and checks that they match the received IPv4 header checksums. The result of this operation (pass or fail) is given to the RFC module for insertion into the receive status word. The IP Header Error bit is set for any mismatch between the indicated payload type (Ethernet Type field) and the IP header version, or when the received packet does not have enough bytes, as indicated by the Length field of the IPv4 header (or when fewer than 20 bytes are available in an IPv4 or IPv6 header).

This engine also identifies a TCP, UDP, or ICMP payload in the received IP datagrams (IPv4 or IPv6) and calculates the checksum of such payloads properly, as defined in the TCP, UDP, or ICMP specifications. This engine includes the TCP, UDP, or ICMPv6 pseudo-header bytes for checksum calculation and checks whether the received checksum field matches the calculated value. The result of this operation is given as a Payload Checksum Error bit in the receive status word. This status bit is also set if the length of the TCP, UDP, or ICMP payload does not match the expected payload length given in the IP header.

Following table describes the functions supported by the Rx COE based on the packet type. When the payload of an IP packet is not processed (indicated as "No" in the table), the information (whether the checksum engine is bypassed or not) is given in the receive status.

NOTE

The MAC does not append any payload checksum bytes to the received Ethernet packets.

Table 496. Receive Checksum Offload Engine Functions for Different Packet Types

Packet type	Hardware IP header checksum checking	Hardware TCP/UDP/ICMP checksum checking
Non-IPv4 or IPv6	No	No
IPv4 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in the MAC)	Yes	Yes
IPv6 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in the MAC)	Not Applicable	Yes
IPv4 with TCP, UDP, or ICMP	Yes	Yes
IPv4 header's protocol field contains a protocol other than TCP, UDP, or ICMP	Yes	No

Table continues on the next page...

Table 496. Receive Checksum Offload Engine Functions for Different Packet Types (continued)

Packet type	Hardware IP header checksum checking	Hardware TCP/UDP/ICMP checksum checking
IPv4 packet has IP options (IP header is longer than 20 bytes)	Yes	Yes
Packet is an IPv4 fragment	Yes	No
IPv6 packet with the following next header fields in main or extension headers: • Hop-by-hop options (in IPv6 main header) • Hop-by-hop options (in IPv6 extension header) • Destinations options • Routing (with segment left 0) • Routing (with segment left > 0) • TCP, UDP, or ICMP • Any other next header field in main or extension headers	• Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable	• Yes • No • Yes • Yes • No • Yes • No
IPv4 packet has TCP header with Options fields	Yes	Yes
IPv4 Tunnels: • IPv4 packet in an IPv4 tunnel • IPv6 packet in an IPv4 tunnel	• Yes (IPv4 tunnel header) • Yes (IPv4 tunnel header)	• No • No
IPv4 Tunnels: • IPv4 packet in an IPv6 tunnel • IPv6 packet in an IPv6 tunnel	• Not Applicable • Not Applicable	• No • No
IPv4 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled)	Yes	Yes
IPv6 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled)	Not Applicable	Yes
IPv4 frames with security features (such as encapsulated security payload)	Yes	No

Packet type	Hardware IP header checksum checking	Hardware TCP/UDP/ICMP checksum checking
IPv6 frames with security features (such as encapsulated security payload)	Not Applicable	No

Set the IPC bit of the MAC_Configuration register for enabling Receive Checksum offload.

72.12 MAC Management Counters

This section is Synopsys Proprietary. Used with permission.

IP supports storing the statistics about the received and transmitted packets in registers that are accessible through the application/software. The MMC module maintains a set of registers for gathering statistics on the received and transmitted packets. The MMC counters are free running.

For MMC register details, see registers "MMC_Control" to "MMC_Rx_FPE_Fragment_Cntr" in EMAC register descriptions.

72.13 Flow Control

This section and its sub-sections are Synopsys Proprietary. Used with permission.

72.13.1 Transmit Flow Control

The Transmit Flow Control involves transmitting Pause packets in full-duplex mode and backpressure in half-duplex mode to control the flow of packets from the remote end.

72.13.1.1 Flow control in Full duplex mode

IP supports the IEEE802.3x Pause Packets.

Pause packet structure is shown in the following table.

Table 497. Pause Packet Fields

Field	Description
DA	Contains the special multicast address
SA	Contains the MAC address 0
Type	Contains 8808
MAC Control opcode	Contains 0001 for IEEE 802.3x Pause Control packets; 0101 for PFC packets
PT	Contains Pause time specified in the PT field of the MAC_Q#_Tx_Flow_Ctrl register

72.13.1.2 Pause Packet Control

When the FCB bit is set, the MAC generates and transmits a single Pause packet. If the FCB bit is set again after the Pause packet transmission is complete, the MAC sends another Pause packet irrespective of whether the pause time is complete or not. To extend the pause or terminate the pause prior to the time specified in the previously-transmitted Pause packet, the application should program the Pause Time register with appropriate value and then again set the FCB bit.

72.13.1.3 Flow Control in Half-Duplex Mode

In half-duplex mode, the MAC uses the deferral mechanism for the flow control (backpressure). When the application requests to stop receiving packets, the MAC sends a JAM pattern of 32 bytes when it senses a packet reception, provided the transmit flow control is enabled. This results in a collision and the remote station backs off. If the application requests a packet to be transmitted, it is scheduled and transmitted even when the backpressure is activated. If the backpressure is kept activated for a long time (and more than 16 consecutive collision events occur), the remote stations abort the transmission because of excessive collisions.

Following table describes the flow control in the Tx path for Queue 0 based on the setting of the following bits:

- EHFC bit of MTL_RxQ0_Operation_Mode register
- TFE bit of MAC_Q0_Tx_Flow_Ctrl register
- DM bit of MAC_Configuration register

Flow control is similar for all queues.

Table 498. Tx MAC Flow Control

EHFC	TFE	DM	Description
x	0	x	The MAC transmitter does not perform the flow control or backpressure operation.
0	1	0	The MAC transmitter performs back-pressure when Bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set or the sideband signal sbd_flowctrl_i is 1.
1	1	0	The MAC transmitter performs back-pressure when Bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set or the sideband signal sbd_flowctrl_i is 1. In addition, the MAC Tx performs back-pressure when Rx Queue level crosses the threshold set by Bits[10:8] of MTL_RxQ0_Operation_Mode register.
0	1	1	The MAC transmitter sends the Pause packet when Bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set or the sideband signal sbd_flowctrl_i is 1.
1	1	1	The MAC transmitter sends the Pause packet when Bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set or the sideband signal sbd_flowctrl_i is 1. In addition, the MAC Tx sends a Pause packet when Rx Queue level crosses the threshold set by Bits[10:8] of MTL_RxQ0_Operation_Mode register.

72.13.1.4 Enabling Transmit Flow Control

To independently enable Transmit Flow Control for each Tx queue, set the TFE bit in the MAC_Q#_Tx_Flow_Ctrl register.

72.13.2 Receive Flow Control

In the Receive path, the Flow Control is functional only in the full-duplex mode. If any Pause packet is received in the half-duplex mode, the packet is considered as a normal control packet.

NOTE

Receive pause packets should have a frame size of 64 bytes.

The Receive Flow Control is implemented by the MAC based on the bit value of the respective register, and the destination address and different fields of the received packet.

Following table describes the flow control in the Rx path based on the setting of the following bits:

- RFE bit of MAC_Rx_Flow_Ctrl register
- DM bit of MAC_Configuration register

Table 499. Rx MAC Flow Control

RFE	DM	Description
0	x	The MAC receiver does not detect the received Pause packets.
1	0	The MAC receiver does not detect the received Pause packets but recognizes such packets as Control packets.
1	1	The MAC receiver detects or processes the Pause packets and responds to such packets by stopping the MAC transmitter.

72.13.2.1 Enabling Receive Flow Control

To enable Pause Flow Control, set the RFE bit in the MAC_Rx_Flow_Ctrl register.

72.14 Loopback Mode

This section is Synopsys Proprietary. Used with permission.

The MAC supports Loopback of transmitted packets to its receiver.

The following are some guidelines for using the loopback mode:

- Enable loopback only with the full-duplex mode. In half-duplex mode, the carrier sense signal (crs) or collision (col) signal inputs get sampled which may result into issues such as packet dropping.
- If the loopback mode is enabled without connecting a PHY chip (for example, in FPGA setup), you should externally generate the Tx and Rx clocks and provide these clocks to the MAC.
- Do not loop back big packets. Big packets (>1522 bytes) may get corrupted in the loopback FIFO.

To enable this feature, program the LM bit of the MAC_Configuration register.

You can enable loopback for all PHY interfaces. The data is always looped back through internal asynchronous FIFO on to the internal Receive MII or GMII interface, irrespective of which PHY interface is selected. The loopback data is also passed through the corresponding transmit PHY interface block, on to the Ethernet line.

72.15 Automotive Safety Features

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

IP supports the automotive safety feature.

72.15.1 Error Correction Code (ECC) Protection for Memories

The Error Correction Code (ECC) block can correct single-bit error and detect double-bit error.

At the write interface, ECC checkbits are generated by computing ECC on the contents of the data bus and respective address is appended with the data that is written to the memory.

At the read interface, ECC checkbits are recomputed on the content of the read data and the respective address is compared with the received checkbits in the memory.

Following figure shows the block diagram of ECC protection for memories

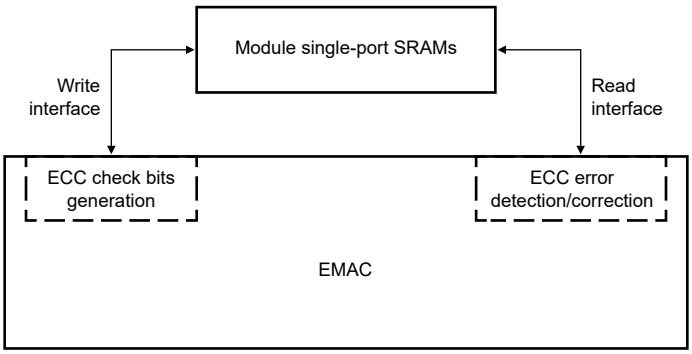

Figure 409. Block Diagram of ECC Protection for Memories

72.15.1.1 Handling the Address Mismatch

The ECC is calculated over the sum of memory data and memory location address. However only data is written in the memory along with the ECC(address is excluded).

On the read interface, the ECC is checked over the sum of memory DATA, memory ECC, and Internally generated address. When an ECC correctable error is detected over the range of the address bit position, it is treated as an uncorrectable error. This is because data might have been read from a different location.

72.15.1.2 Diagnostic Support for the Error Management

Following statistics are provided for monitoring the error behavior on each of the memory blocks.

- Error status provided to management
  - A separate status for correctable, uncorrectable, and address mismatch is specified in the MTL_EC-C_Interrupt_Status register.
  - Memory locations at which correctable and uncorrectable errors are detected is specified in the MTL_ECC_Err_Addr_Status register. In addition, a control bit (MEEAO field of MTL_ECC_Control register) decides, whether the first errored memory address is reported or the latest errored memory address is reported.
  - MTL_ECC_Err_Cntr_Status register has separate counters to count the number of correctable and uncorrectable errors
- Interrupts provided to management
  - Separate interrupts are generated for correctable and uncorrectable errors.
  - sbd_sfty_ue_intr_o interrupt is generated when uncorrectable errors are detected and these errors cannot be masked.
  - sbd_sfty_ce_intr_o interrupt is generated when correctable errors are detected. The module sets the respective interrupt enable bits (in the DMA/MTL_ECC_Interrupt_enable register).
  - To find the root cause of the error, read the DMA/MTL_Safety_Interrupt_Status and DMA/MTL_ECC_Interrupt_Status registers.
  - To clear the interrupt, write 1 in the respective interrupt status bit in DMA/MTL_ECC_Inter-rupt_Status registers.

NOTE

- The status/counters/interrupts are generated per memory.
- MTL Tx and Rx memory is logically divided into multiple queues. But, ECC diagnostics (status/counter/interrupts) are common to all queues.

72.15.1.3 ECC Error Injection Capabilities

IP supports error injection capabilities for each memory as a static configuration. The position where the errors are injected in the data word is random. For each memory, 3 control bits are provided to inject errors. The 3 bits are:

- A single bit to enable error injection
- Two bits to indicate the type of error to be injected ❑ 00: 1 bit error
  - 01: 2 bit error
  - 10: 3 bit error
  - 11: 1 bit error in address field

The control bit descriptions for

- MTL Tx/Rx and DMA TSO memory are specified in the MTL_DBG_CTL register, for and for R.
- MTL EST memory are specified in the MTL_EST_GCL_Control register
- Rx parser memory are specified in the MTL_RXP_Indirect_Acc_Control_Status register

NOTE

While using debug mode for ECC error injection:

- There should be no traffic in the module
- When multiple CSR writes are required for writing single data word into the memory, the application should ensure that all the CSR writes corresponding to one memory write main-tains the same value for the error injection control word.
- See Programming guidelines for ECC protection for memories

72.15.2 Finite State Machine(FSM) Parity and Timeout Protection

The FSM protection feature supports FSM parity and time out protection.

72.15.2.1 FSM State Parity Protection

Odd parity is implemented on all the FSM state register bits. Parity is monitored for every clock, after the reset is de-asserted. When a bit flips due to transient errors or permanent faults, the erroneous FSM is set to its default state and an uncorrectable error is indicated.

When the FSM state parity protection is enabled, by setting PRTYEN field of MAC_FSM_Control Register, the FSM state error is indicated by setting the FSMPES field of the MAC_DPP_FSM_Interrupt_Status register. Also, the Safety Interrupt (sbd_sfty_ue_intr_o) is asserted when an FSM Error is detected.
