Rev. 1, 02/2023

MWCT2xxxS Reference Manual

Supports MWCT2015S, MWCT2016S, MWCT2D16S, and MWCT2D17S

Contents

Chapter 1
About This Manual

1.1 Audience

This reference manual (RM) is intended for system software, hardware developers, and applications programmers who need to develop products using this chip. It assumes that its users understand operating systems, microprocessor system design, and basic principles of software and hardware.

1.2 Organization

This manual has two main sets of chapters.

- Chapters in the first set contain information that applies to all components on the chip.
- Chapters in the second set are organized into functional groupings that detail particular areas of functionality.
  - Examples of these groupings are clocking, timers, and communication interfaces.
  - Each grouping includes chapters that provide a technical description of individual modules.

1.2.1 Attachments

This manual includes key information in the files attached to it. For example, memory map and I/O details. Use the content in these attachments in conjunction with this manual's content.

NOTE

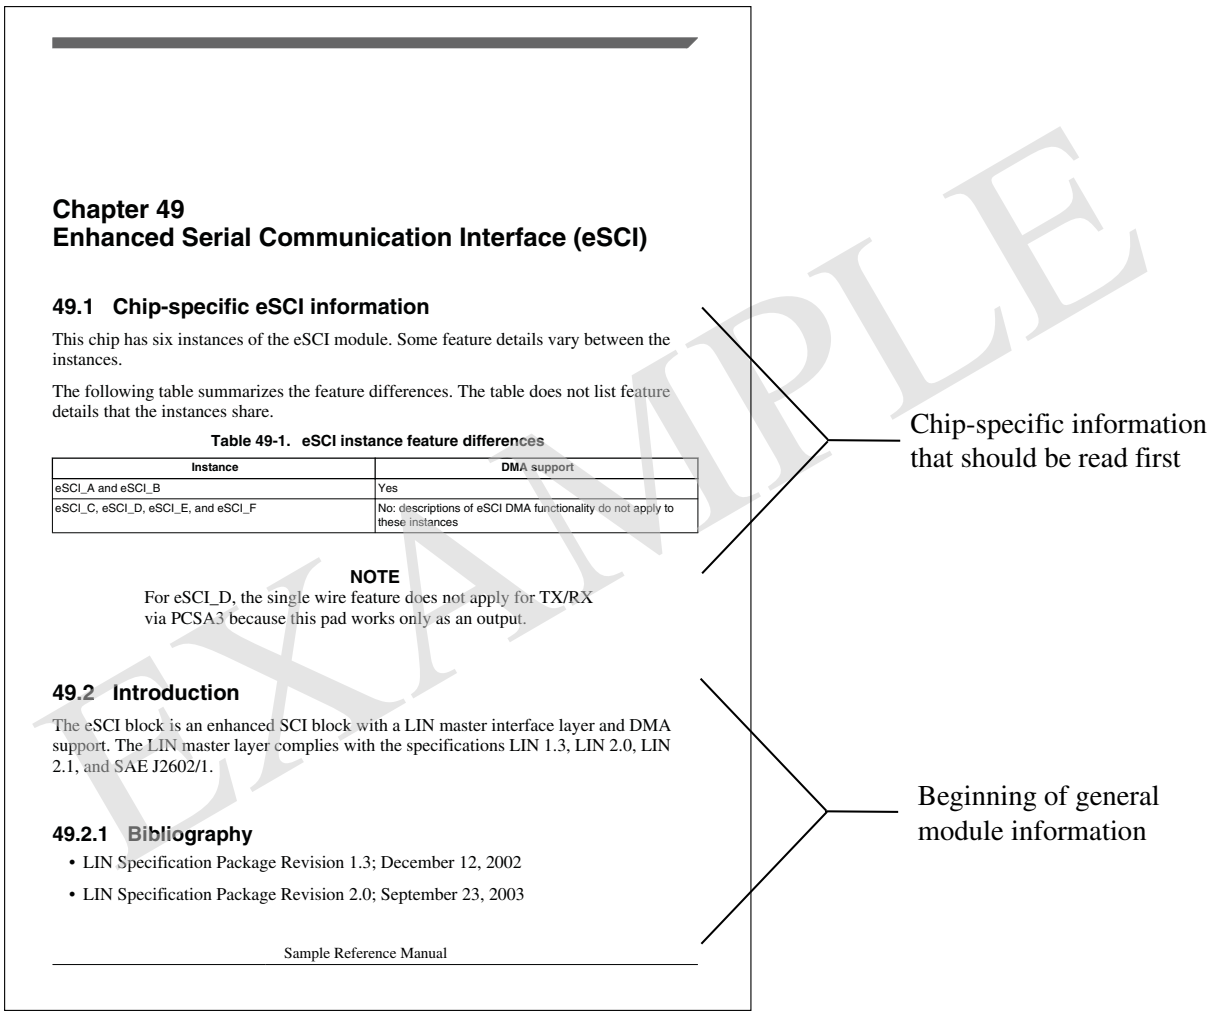
Select the paperclip icon on the left side of the PDF window to see the list of attachments.

1.3 Module descriptions

Each module chapter has two main parts:

- The first section, *chip-specific [module name]* information, provides details such as the number of module instances on the chip and connections between that module and the other ones. Read this section *first* because its content is crucial for understanding the information in the other sections of the chapter.
- The subsequent sections provide general information about the module, including its signals, registers, and functional description.

The following figure shows you an example of this demarcation.



Chapter 49
Enhanced Serial Communication Interface (eSCI)

49.1 Chip-specific eSCI information

This chip has six instances of the eSCI module. Some feature details vary between the instances.

The following table summarizes the feature differences. The table does not list feature details that the instances share.

Table 49-1. eSCI instance feature differences

Instance	DMA support
eSCI_A and eSCI_B	Yes
eSCI_C, eSCI_D, eSCI_E, and eSCI_F	No: descriptions of eSCI DMA functionality do not apply to these instances

NOTE
For eSCI_D, the single wire feature does not apply for TX/RX via PCSA3 because this pad works only as an output.

49.2 Introduction

The eSCI block is an enhanced SCI block with a LIN master interface layer and DMA support. The LIN master layer complies with the specifications LIN 1.3, LIN 2.0, LIN 2.1, and SAE J2602/1.

49.2.1 Bibliography

- LIN Specification Package Revision 1.3; December 12, 2002
- LIN Specification Package Revision 2.0; September 23, 2003

Sample Reference Manual

Figure 1. Example of chapter chip-specific information and general module information

1.3.1 Chip-specific information that clarifies content in the same chapter

The following figure shows an example of chip-specific information that clarifies general module information presented later in the chapter. In this case, the chip-specific register reset values supersede the reset values that appear in the register diagram.

System Integration Unit Lite2 (SIUL2)

Chapter 9
System Integration Unit Lite2 (SIUL2)

9.1 Chip-specific SIUL2 information

9.1.1 Feature configurations

In this device, the SIUL2_0 module instance does not support the following features described in the generic description:

- Interrupts
- DMA channels

9.1.2 Notes for IMCR

Out of reset, PA_00, PA_04, and PA_05 pads have JTAG input functionality selected by default. It should be disabled in the corresponding IMCR registers (IMCR61, IMCR60, and IMCR50 respectively) in order to use other functionality such as GPIO.

9.2 Introduction

9.2.1 Overview

The System Integration Unit Lite2 provides control over all the electrical pin controls and ports with 16 bits of bidirectional, general-purpose input and output signals. One of the most important functions of the SIUL2 is to enable the user to select the functions and electrical characteristics that appear on external device pins. It also controls the multiplexing of internal signals from one module to another and controls chip I/O. It supports as many as 32 external interrupts with trigger event configuration. The following figure is the block diagram of SIUL2 and its interfaces to other system components.

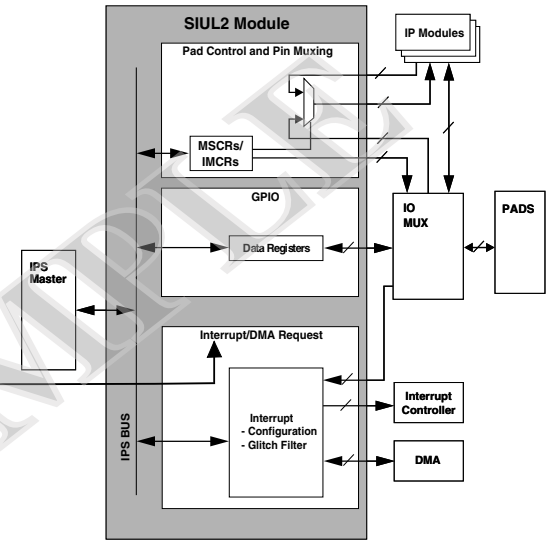


Figure 23. System Integration Unit Lite2 block diagram

This module provides dedicated pad control to general-purpose pads that can be configured as either inputs or outputs. The SIUL2 module provides registers that enable user software to read values from GPIO pads configured as inputs, and write values to GPIO pads configured as outputs:

- When configured as output, you can write to an internal register to control the state driven on the associated output pad.
- When configured as input, you can detect the state of the associated pad by reading the value from an internal register.
- When configured as input and output, the pad value can be read back, which can be used as a method of checking if the written value appeared on the pad.

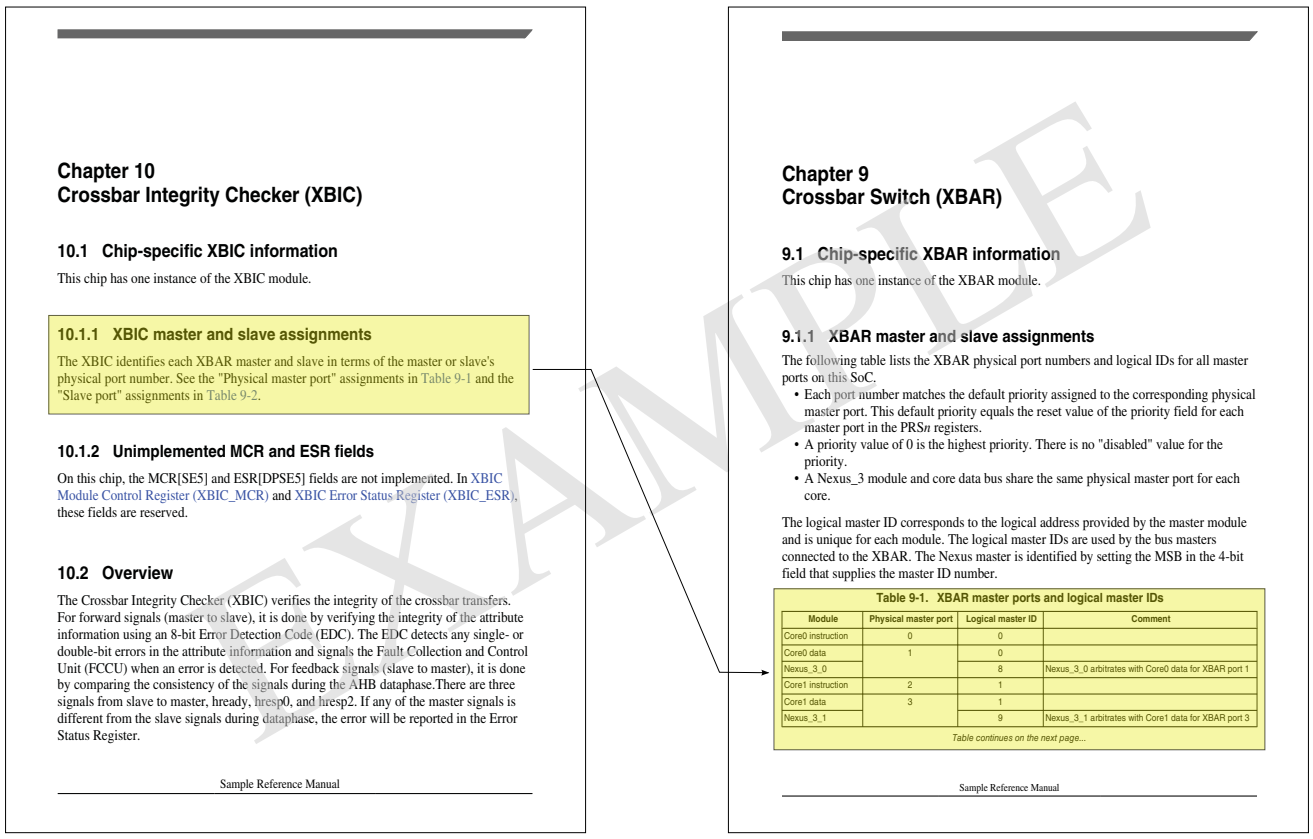
To assist software development, GPIO data registers can be accessed using various mechanisms. These differing mechanisms allow support for port access or for bit manipulation without the need to use read-modify-write operations:

- Access to two 16-bit ports in one access
- Read/write access to a single bit
- A 16-bit port write with a bit mask, using single 32-bit access.

Figure 2. Example of chip-specific information that clarifies content in the same chapter

1.3.2 Chip-specific information that refers to a different chapter

Related chip-specific information may be provided in different chapters of the manual. The following figure shows an example of two such connected pieces of information. In this case, read both before you proceed.



Chapter 10
Crossbar Integrity Checker (XBIC)

10.1 Chip-specific XBIC information

This chip has one instance of the XBIC module.

10.1.1 XBIC master and slave assignments

The XBIC identifies each XBAR master and slave in terms of the master or slave's physical port number. See the "Physical master port" assignments in Table 9-1 and the "Slave port" assignments in Table 9-2.

10.1.2 Unimplemented MCR and ESR fields

On this chip, the MCR[SE5] and ESR[DPSE5] fields are not implemented. In XBIC Module Control Register (XBIC_MCR) and XBIC Error Status Register (XBIC_ESR), these fields are reserved.

10.2 Overview

The Crossbar Integrity Checker (XBIC) verifies the integrity of the crossbar transfers. For forward signals (master to slave), it is done by verifying the integrity of the attribute information using an 8-bit Error Detection Code (EDC). The EDC detects any single- or double-bit errors in the attribute information and signals the Fault Collection and Control Unit (FCCU) when an error is detected. For feedback signals (slave to master), it is done by comparing the consistency of the signals during the AHB dataphase.There are three signals from slave to master, hready, hresp0, and hresp2. If any of the master signals is different from the slave signals during dataphase, the error will be reported in the Error Status Register.

Sample Reference Manual

Chapter 9
Crossbar Switch (XBAR)

9.1 Chip-specific XBAR information

This chip has one instance of the XBAR module.

9.1.1 XBAR master and slave assignments

The following table lists the XBAR physical port numbers and logical IDs for all master ports on this SoC.

- Each port number matches the default priority assigned to the corresponding physical master port. This default priority equals the reset value of the priority field for each master port in the PRS*n* registers.
- A priority value of 0 is the highest priority. There is no "disabled" value for the priority.
- A Nexus_3 module and core data bus share the same physical master port for each core.

The logical master ID corresponds to the logical address provided by the master module and is unique for each module. The logical master IDs are used by the bus masters connected to the XBAR. The Nexus master is identified by setting the MSB in the 4-bit field that supplies the master ID number.

Table 9-1. XBAR master ports and logical master IDs

Module	Physical master port	Logical master ID	Comment
Core0 instruction	0	0	
Core0 data	1	0	
Nexus_3_0		8	Nexus_3_0 arbitrates with Core0 data for XBAR port 1
Core1 instruction	2	1	
Core1 data	3	1	
Nexus_3_1		9	Nexus_3_1 arbitrates with Core1 data for XBAR port 3

Table continues on the next page...

Sample Reference Manual

Figure 3. Example of chip-specific information that refers to a different chapter

1.4 Register descriptions

Module chapters present register information in the following:

- Memory maps, which contain:
  - An offset from the module's base address
  - The mnemonic and name of each register
  - The width of each register (in bits)
  - The reset value of each register
- Register figures
- Field-description tables
- Associated text

The following figure shows register figure conventions used throughout the manual.

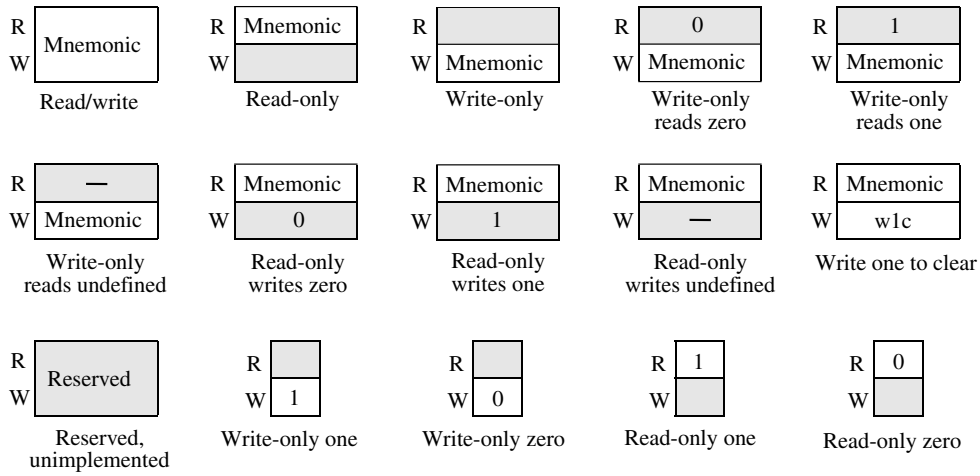


Figure 4. Register figure conventions

NOTE

Reset values of reserved locations documented in this manual are subject to change and must not be used for diagnostic purposes.

1.5 Conventions

1.5.1 Notes and cautions

Specific information is provided as part of notes and cautions throughout this manual.

NOTE

Emphasizes information that deserves extra attention.

CAUTION

Informs you of situations that could lead to highly undesirable outcomes—such as damage to the chip or irreversible malfunction.

1.5.2 Numbering systems

The following suffixes identify different numbering systems:

Table 1. Numbering systems

This suffix	Identifies a
b	Binary number. For example, the binary equivalent of the number 5 is mentioned as 101b. In some cases, *0b* is prefixed to binary numbers.
d	Decimal number. Decimal numbers are followed by this suffix only when there is a possibility of confusion. In general, decimal numbers are used without a suffix.
h	Hexadecimal number. For example, the hexadecimal equivalent of the number 60 is mentioned as 3Ch. In some cases, *0x* is prefixed to hexadecimal numbers.

1.5.3 Typographic notation

The following typographic notations are used throughout this document:

Table 2. Typographic notation

Example	Description
x and other italicized text	The italicized, lowercase *x* is used as a placeholder for replaceable numbers. In general, italicized text is used for titles of publications and for emphasis. Additionally, italics could be used for metasymbols in syntax descriptions. Plain lowercase letters are used as placeholders for single letters and numbers.
`code font`	Fixed-width font (such as Courier) used for code. It is used for a letter, word, or phrase that you want the user to type. For example, "Type `Read` and press Enter." This type of font is also used for instruction mnemonics, directives, symbols, subcommands, parameters, operators, computer-language elements, code listings, commands that appear in running text, and for sample code. Instruction mnemonics and directives in text and tables are mentioned in all caps; for example, BSR.
SR[SCM]	A mnemonic in square brackets represents the name of a register field. This example refers to the Scaling Mode (SCM) field in the Status Register (SR).
REVNO[6:4], XAD[7:0]	Numbers in brackets that are separated by a colon represent either: • A subset of a register's named field For example, REVNO[6:4] refers to bits 6-4 that are part of the COREREV field occupying bits 6-0 of the REVNO register. • A continuous range of individual signals of a bus For example, XAD[7:0] refers to signals 7-0 of the XAD bus.
MOD.REG	A period separates the elements of a hierarchy: subsystem.module.register. For example: • SWT.TO means that the TO register is located in the SWT module. • SMU.XRDC.CR means that the CR register is located in the XRDC module within the SMU subsystem.

1.5.4 Special terms

The following terms have special meanings.

Table 3. Special terms

Term	Meaning
Asserted	Refers to the state of a signal as follows: • An active-high signal is asserted when high (1). • An active-low signal is asserted when low (0).
Deasserted	Refers to the state of a signal as follows: • An active-high signal is deasserted when low (0). • An active-low signal is deasserted when high (1). In some cases, deasserted signals are described as *negated*.
Reserved	Refers to memory space, register, field, or programming setting. Writes to a reserved location can result in unpredictable functionality or behavior. You must:

Table continues on the next page...

Table 3. Special terms (continued)

Term	Meaning
	• Not modify the default value of a reserved programming setting, such as the reset value of a reserved register field. • Consider undefined locations in memory to be reserved. • Not use the reset values of reserved locations documented in this manual for diagnostic purposes. They are subject to change.
Write 1 to clear (w1c)	Refers to the access type of a register field that is used to clear the field by writing the value 1 to it.
Undefined (u)	Refers to undefined reset values

1.6 Editorial changes

Each new release of this document includes editorial improvements such as:

- Spelling
- Grammar
- Punctuation
- Voice
- Tense
- Capitalization
- Formatting
- Presentation
- Navigation

1.7 Glossary

The "Glossary" section provides a list of selected terms and definitions used in a chapter. The glossary, if present, is placed at the end of the chapter.

A glossary contains:

- NXP-specific terms, symbols, and notations, with definitions.
- Terms, symbols, and notations that can have different meanings in different contexts. The glossary defines the way they are used in the chapter—especially if the meaning is different from the meaning in standard references.

A glossary does not contain:

- Field mnemonics
- Register mnemonics
- Module mnemonics
- Signal names
- Industry-standard terms

Chapter 2
Introduction

2.1 Overview

The MWCT2xxS product series further extends the highly-scalable portfolio of Arm ® Cortex ® - M0+/M4F MWCT1xxx chips in the automotive industry with the Arm Cortex-M7 core at higher frequency, more memory, ASIL-B and D rating and advanced security module. With a focus on automotive environment robustness, the MWCT2xxS product series devices are well suited to a wide range of applications in electrical harsh environments, and are optimized for cost-sensitive applications offering new, space saving package options. The MWCT2xxS series offers a broad range of memory, peripherals and performance options. Devices in this series share common peripherals and pin-out, allowing developers to migrate easily within a chip series or among other chip series to take advantage of more memory or feature integration.

CAUTION

MWCT2015S and MWCT2D16S specific information is preliminary until these devices are qualified and may change without notice.

2.2 MWCT2xxxS product series

The MWCT2xxxS series comes to market together with easy-to-use enablement software, application specific software, and various development tools, supported by broad third parties in different development phases.

The portfolio scalability, future proof feature like advanced security, as well as software/tool/third-party development support allows developers to standardize on the MWCT series for their end product platforms, maximizing hardware and software reuse, and reducing time-to-market.

Following are the general features of the MWCT series chips:

- 32-bit Arm Cortex-M7 core with IEEE-754 compliant SPFPU, executing up to 160 MHz
- Scalable memory footprints up to 8 MB flash memory and up to 1 MB SRAM
- Precision mixed-signal capability with low power comparators (LPCMP) and multiple 12-bit ADCs
- Powerful timers for a broad range of applications including motor control, lighting control and body applications
- Serial communication interfaces such as Serial communication interfaces including LPUART, LPSPI, LPI2C, FlexCAN with ISOCAN-FD support, Ethernet and QuadSPI. FXIO configuration allows other communication options including SENT.
- EVITA full and light functionality compliant HSE_B
- Power supply (3.0 – 5.5 V) with fully functional flash memory program/erase/read operations
- Functional safety compliance with ISO26262 levels B or D (features depend on device specification)
  - Lockstep cores
  - Multiple internal watchdogs
  - Voltage monitors
  - Clock monitors
  - Memory protection
  - Data transport checks
  - ECC on memories
  - Cyclic redundancy checking
- Ambient operation temperature range: –40°C to 125°C
- Junction temperature range: –40°C to 150°C

- Tools solutions:
  - MWCT Design Studio IDE
  - NXP GCC compilers for Cortex-M7 and IDE plugins for partner compilers support
  - Low cost debugger with multi-core debug, tracing and profiling support
  - S32 Configuration Tools:
    - Pin wizard with detailed pin configuration report
    - Graphical clock tree for clock configuration
    - Peripheral configuration
  - Model-Based Design Toolbox:
    - Integrated Simulink®-embedded target for direct rapid prototyping and PIL development workflows
    - Peripheral device interface blocks and drivers
    - Target-optimized math and motor control algorithm blocks for efficient execution on the target chip
    - Bit-accurate simulation results in the Simulink® simulation environment
  - FreeMaster
- Software solutions:
  - RTD (Real Time Drivers)
    - Autosar 4.4 compliant MCAL plus complex device drivers for external ICs (e.g. PMIC) and miscellaneous SW components (e.g. inter core communication)
    - Low level drivers covering all device periphery
    - Example projects for each driver
    - Configuration components for Tresos Studio and S32ConfigTools framework
    - Integrated with MWCT Design Studio
  - Stacks/libraries
    - Communication stacks:
      - LIN, TCP/IP, gPTP, AVB, WiFi, AWS IOT
    - Security:
      - mBedTLS
    - Safety:
      - Safety Software Framework
    - Real time control:
      - AMMCLib
    - RTOS:
      - FreeRTOS
    - Firmware:
      - Security firmware for on-chip crypto engine
- Designed to work in conjunction with NXP SBC UJA124x and SBC FS2600

2.3 Feature summary

The MWCT2xxxS product family includes the Arm Cortex-M7 core features described in the following table.

Table 4. MWCT2xxxS chip's feature summary

Feature	Inclusions
Core and architecture	• Arm Cortex-M7 core running up to 160 MHz • Arm core based on the Armv7 architecture and ThumbR-2 ISA with 2.14 DMIPS/MHz • Upto 16 KB data and 16 KB instruction cache for optimizing wait state execution from memories • 96 KB Tightly Coupled Memory associated with each core • On-core MPU for dynamic task protection (16 regions) • SPFPU, IEEE 754 compliant • Harvard bus architecture implementing dedicated instruction and data path • 5-stage pipeline with branch speculation • XRDC integrated with a crossbar switch to provide memory and peripheral protection • DSP • I/O protection (VIRT_WRAPPER) • ETM supporting instruction trace • Arm third-party ecosystem support: software and tools to help minimize development time and cost
DMA	• Up to 2x64-channel DMAMUX • eDMA with up to 32 channels • Complex data transfers performed with minimal intervention from a host processor • Programmable support for scatter-gather DMA processing
System and power management	• Support for simplified power modes (Run and Standby) • Support for clock gating of unused modules; specific peripherals continue to work in low-power modes • Support for external ballast transistor to generate core supply • Fully independent CPU and peripheral clocking scheme • Rapid start-up from a 48 MHz FIRC • Various low-power oscillators such as the 32 kHz SIRC and an external 32 kHz crystal support SXOSC • PMC with LVD and selectable trip points • Support for multiple power modes • NMI
Memory and memory interfaces	• Up to 4 MB program flash memory, up to 128 KB data flash memory, and up to 512 KB SRAM, all with an ECC

Table continues on the next page...

Table 4. MWCT2xxxS chip's feature summary (continued)

Feature	Inclusions
	• 4-bit/8-bit QuadSPI
Clocks	• External 8 MHz–40 MHz crystal oscillator or resonator • External 32 kHz crystal oscillator • Internal clock references — 48 MHz FIRC ±5% — 32 kHz SIRC ±10% • Up to 960 MHz PLL for divided system clock operation
Security and integrity	• Hardware security engine (HSE_B) — Upgradable Firmware delivered by NXP, to be programmed by the user • Security ciphers: — Symmetric: AES-128/192/256 — Cipher modes: ECB, CBC, CMAC, GMAC, CTR, OFB, CCM, and GCM — Asymmetric: RSA (up to 4096 bits) and ECC (up to 521 bits) — Hash: Miyaguchi-Preneel, SHA-2/SHA-3 (up to 512 bits) — Number of keys is configurable and controlled by HSE FW — Random number generator • Security use case supported: — Secure boot — Secure communication — Component protection — Secure storage — Key exchange
Safety ISO26262	• Classification up to ASIL-D • ERM and EIM support • WDOG with an independent clock source • Voltage monitors • Bandgap voltage available as ADC input • External clock source monitoring using an independent reference • PLL lock and loss-of-lock protection • XRDC • ECC on code flash memory, data flash memory, and system RAM

Table continues on the next page...

Table 4. MWCT2xxxS chip's feature summary (continued)

Feature	Inclusions
	• ADC self-test feature • Internal analog monitoring of all supplies available • CRC generation module • FCCU failure output
Analog	• 12-bit ADC — Up to 72 external analog inputs — 1 µs conversion time — Internal bandgap voltage reference channel, supporting automatic compare and an optional hardware trigger — Up to five internal reference inputs — Automatic compare with interrupt — Self-test and self-calibration scheme • ACMP with an internal 8-bit DAC as a reference — ACMP with both positive and negative inputs, separately selectable interrupts on rising and falling comparator output — Ability to cross trigger the timers from both the ADC and ACMP outputs • Temperature Sensor (TempSense) with output measurable by ADC.
Timers	• 16-bit or 24-bit eMIOS timers, offering up to 72 standard channels — Input capture, output compare, and PWM modes — Fault input support with global fault control — Multiple features such as deadtime insertion, configurable polarity, quadrature decoding, and so on • 32-bit PITs, with four channels, for raising interrupts and triggering DMA channels • 32-bit RTC • Motor control and power conversion using combination of eMIOS, LCU , BCTU, and ADC • Up to four STMs, with four channels each
Communications	• LPSPI supporting DMA with full-duplex or single-wire bidirectional communication in Master or Slave mode • FlexIO, with an option to configure it as different communication peripherals, offering support for SENT • LPI2C modules with DMA support, low-power availability, master or slave support, and system management bus

Table continues on the next page...

Table 4. MWCT2xxxS chip's feature summary (continued)

Feature	Inclusions
	• LPUART with DMA support, having an optional 13-bit break, full-duplex non-return- to-zero (NRZ), low-power availability and supports LIN protocol versions 1.3, 2.0, 2.1, 2.2A, and SAE J2602 with using SW LIN driver • FlexCAN modules with ISOCAN-FD and DMA support • SAI capable of supporting stereo audio channels • uSDHC interface to interface with SD/SDIO/MMC cards. • EMAC complex (10/100 Ethernet) that supports 1588 timers, MII/RMII interface, AVB, and TSN support • GMAC (Gigabit Ethernet) with support for AVB (3.3 V only for RGMII) and Time Sensitive Networking (TSN) capability
Debug	• DWT, with four configurable comparators as hardware watchpoints • SWO-synchronous trace data support • ITM with software and hardware trace, plus time stamping • FPB with an ability to patch code and data from code space to system space • Trace of all execution units and bus masters made available through an Arm TPIU over GPIO pins; a very low bandwidth trace option also available via the SWO • Embedded trace FIFO (ETF)—a dedicated trace buffer available for each of the core masters, allowing data to be captured internally before being optionally routed to external trace pins • SWV—trace capability providing displays of reads, writes, exceptions, PC samples, and print
I/O and package	• Pseudo open drain support on LPUART, FlexIO, LPI2C • Package options of 172 MAX QFP, 100 MAX QFP, and 48 LQFP

172-MAX QFP package[4]	No		Yes		
100-MAX QFP package	Yes				No
48-pin LQFP package	Yes		No		

1. Final DMIPS is in range based on compiler setting. Low number is using "ground rules" laid out in the Dhrystone documentation. High number is using inlining of functions.
2. Result depends on specific compiler version, contact NXP sales representative for more details.
3. 4-bit data width
4. 172-MAX QFP-EP (exposed pad)

2.6 Glossary

AES	Advanced encryption standard
ASIL	Automotive safety integrity level. This is a risk classification scheme as defined by ISO 26262 for automotive standard.
AVB	Audio video bridging
CBC	Cipher block chaining
CCM	Counter with CBC MAC (Cipher block chaining message authentication code)
CMAC	Cipher-based message authentication code
CTR	Counter-based block cipher mode
DSP	Digital signal processor
DWT	Debug watchpoint and trace
ECB	Electronic code book
ECC	Elliptic curve cryptography/ Error code correction
ETM	Embedded trace macrocell
ETF	Embedded trace FIFO
EVITA	E-Safety vehicle intrusion protected applications
FPB	Flash patch and breakpoint unit
GCM	Galois/Counter mode, an encryption algorithm
GMAC	Galois message authentication code
GPIO	General purpose input/output
ITM	Instrumentation trace macrocell
ISOCAN-FD	ISO 11898-1 compliant CAN with FD (Flexible datarate)
LVD	Low voltage detection
NMI	Non-maskable interrupt
OFB	Output feedback based block cipher mode
PIL	Processor-in-the-loop
PLL	Phase locked loop oscillator
PWM	Pulse width modulation
RTD	Real-Time Drivers
SDK	Software development kit
SENT	Single edge nibble transmission
SWV	Serial wire viewer
SPFPU	Single precision floating point unit
SWO	Serial wire output
TPIU	Trace port interface unit
TSN	Time sensitive networking

uSDHC	Ultra Secure Digital Host Controller
WDOG	Windowed watchdog

Chapter 3
Memory Map

3.1 Introduction

This chip contains various memories and memory-mapped peripherals that are placed in a 32-bit contiguous memory space, and this chapter describes the memory and peripheral locations within that memory space.

For high-level chip memory map details, see the memory map file attached to this document.

3.2 SRAM memory map

The memory map file attached to this document provides a complete architectural address space definition for various sections that the RAM is partitioned into and across the MWCT2xxxS product series. Based on the physical sizes of the memories and peripherals, the actual address regions used may be smaller. For details see chapter 'Memory and Memory Interfaces'.

3.3 Access-related details of the memory types used in this chip

The Cortex-M7 core can access these memories sequentially:

- ITCM
- DTCM
- I-cache
- D-cache

ITCM and DTCM can be accessed via 32-bit AHBS interface by any master, e.g., different Cortex-M7 cores, eDMA, etc to bootload instructions in ITCM. EMAC is another master that can access DTCM. See 'Block diagram' in the 'Introduction' chapter for details on the transaction path.

Access to SRAM beyond the RAM available on the chip terminates the bus cycle with an error followed by an appropriate response in the requesting bus master.

3.4 TCM as system memory

On multi–core device, all enabled core and non–core masters can use TCMs of the disabled core. In order to allow use of ITCM and DTCM of the disabled core as system memories the following steps must be executed by enabled core:

1. Write 1 to MC_ME's PRTN2_COFB1_CLKEN[REQ62] field for Cortex-M7_0, PRTN2_COFB1_CLKEN[REQ63] field for Cortex-M7_1, PRTN2_COFB2_CLKEN[REQ64] field for Cortex-M7_2, and PRTN2_COFB2_CLKEN[REQ65] field for Cortex-M7_3. This enables the Cortex-M7 core's TCM

   controller clock.
2. . Write 1 to DCM_GPR's DCMRWF4[CM7_0_CPUWAIT] field for Cortex-M7_0, DCMRWF4[CM7_1_CPUWAIT] field for Cortex-M7_1, DCMRWF4[CM7_2_CPUWAIT] field for Cortex-M7_2, and DCMRWF4[CM7_3_CPUWAIT] field for Cortex-M7_3. This configures the core operation in Wait mode.
3. Write 1 to MC_ME's PRTN0_CORE0_PCONF[CCE] field for Cortex-M7_0, PRTN0_CORE1_PCONF[CCE] field for Cortex-M7 _1, PRTN0_CORE4_PCONF[CCE] field for Cortex-M7_2, and PRTN0_CORE3_PCONF[CCE] field for Cortex-M7_3. This enables the Cortex-M7 core's clock.

Table 6. TCM modes of operation

Description	Control bit (Internal signal)	Cortex-M7 and TCM mode

Table continues on the next page...

Table 6. TCM modes of operation (continued)

	PRTN2_COFB*i*_CLKEN[REQ62+n] [1]	DCMRWF4[CM7_n_CPUWAIT]	PRTN0_COREn_PCONF[CCE]	CM7_n mode	CM7_n_TCM backdoor enabled
Application configurations	—	0	1	RUN	Yes
	0	1	1	WAIT	No
	1	1	1	WAIT	Yes
	—	—	0	Disabled	No

1. where *i* represent 1 for Cortex-M7_0/1 and 2 for Cortex-M7_2/3

3.5 Considerations related to TCM's implementation

You must first initialize TCM (ITCM and DTCM) and system RAMs by 64-bit writes before performing read accesses. The system RAM can be initialized using eDMA and core. The ITCM initialization can be performed only by core using either direct or back-door accesses. The DTCM can be initialized also by 32-bit writes performed either using core's direct and back-door accesses as or eDMA. These writes are required to set up the initial ECC code words after chip power-on reset.

Each Cortex-M7 core is equipped with a 32 KB ITCM and 64 KB DTCM with a zero wait-state access. In the lockstep operation, the checker core's TCM is added to the primary core.

See table 'Memory ECC initialization summary' in chapter 'Memory and Memory Interfaces' for details on memory ECC initialization.

3.6 Flash memory map

For details, see the memory map file attached to this document.

3.7 AIPS-Lite memory map

You can access the peripheral memory map via a crossbar slave port. The next table shows the three regions associated with peripheral space.

Table 7. Regions associated with peripheral space

Address of region	Region description
4000_0000h–401F_FFFFh	This 2048 KB region (AIPS_Lite_0) is partitioned into 128 spaces, each 16 KB in size, having 32 on-platform and 96 off-platform spaces. AIPS_Lite generates unique module enables for all the 32 on-platform spaces.
4020_0000h–403F_FFFFh	This 2048 KB region (AIPS_Lite_1) is partitioned into 128 spaces, each 16 KB in size, having 32 on-platform and 96 off-platform spaces. AIPS_Lite generates unique module enables for all the 32 on-platform spaces.
4040_0000h–405F_FFFFh	This 2048 KB region (AIPS_Lite_2) is partitioned into 128 spaces, each 16 KB in size, having 32 on-platform and 96 off-platform spaces. AIPS_Lite generates unique module enables for all the 32 on-platform spaces.

Modules that are disabled via their clock gate control fields in the MC_CGM registers disable the associated AIPS_Lite slots. Access to any address within an unimplemented or disabled peripheral bridge slot results in a transfer error termination.

Multiple instances of same peripherals are connected to different bridges on the interconnect. For details, see the memory map file attached to this document.

3.8 Serialization of memory operations

In particular cases, you must complete the process of writing to a peripheral before the subsequent action occurs. Examples of such situations include:

- Exiting an interrupt service routine
- Changing a mode
- Configuring a function

In these situations, you must perform a read-after-write sequence to achieve the required serialization of memory operations. The following table provides this sequence.

Table 8. Read-after-write sequence for serialization of memory operations

Step	Action
1	Write to the associated peripheral register.
2	Read the register to verify the write process.
3	Continue with the subsequent operations.

3.9 PPB memory map

PPB is a part of the defined Arm bus architecture and provides access to specific processor-local modules. You can access these modules only through the core, and not through other system masters.

Table 9. PPB memory map

Starting hex address	Ending hex address	Size (KB)	Module
E000_0000	E000_0FFF	4	ITM
E000_1000	E000_1FFF		DWT
E000_2000	E000_2FFF		FPB

E00F_F000	E00F_FFFF	4	Cortex-M7 PPB ROM table

3.10 Glossary

CTI	Cross trigger interface
DTCM	Data tightly coupled memory
D-cache	Data cache
DWT	Debug watchpoint and trace
ETM	Embedded trace macrocell
FPB	Flash patch and breakpoints
ITCM	Instruction tightly coupled memory
I-cache	Instruction cache
ITM	Instrumentation trace macrocells
PPB	Private peripheral bus
SCS	System control space
SRAM	Static random access memory
TPIU	Trace port interface unit

Chapter 4
Signal Multiplexing

4.1 Introduction

The signal multiplexing enables the sharing of single pad for multiple functions.

The signal multiplexing unit comprises control signals from SIUL2 and pad interface logic. The signal multiplexing unit consists of several individual sub-units, each handling the signal multiplexing of one pad.

The "SIUL2 Multiplexed Signal Configuration Register (MSCR)" controls the module specific pad settings (pull-up etc.) and the signal present on the external pin. See SIUL2_MSCR for the description of control signals. The pad attributes may vary depending on the pad type.

For the pad attributes of each pad type and their reset values per port, see the IOMUX file attached to this document. The pads specific to the packages and their multiplexing is also documented in the IOMUX file attached to this document.

NOTE

The input functions for the protocols which are not to be used should be appropriated configured as 'disabled low'/'disabled high' with appropriate SIUL2.IMCR configurations corresponding for that function.

4.2 Pad description

Following figure shows the basic representation of a GPIO pad.

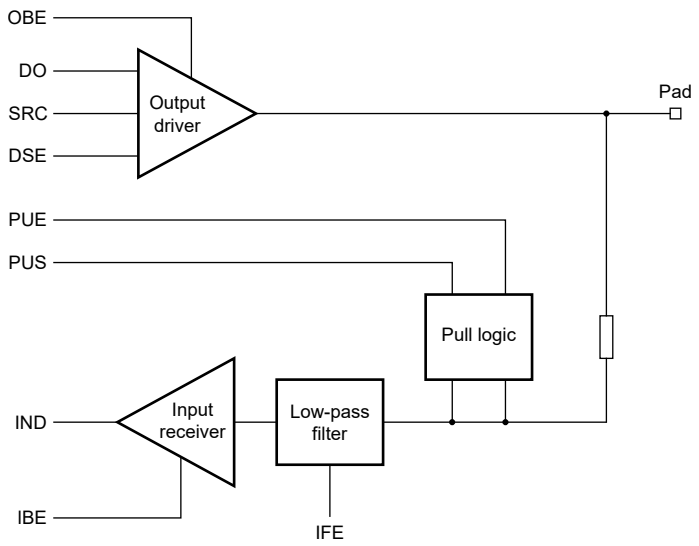

Figure 9. GPIO pad representation

Table 10. Pad Signal description

Signal name	Direction	Description
Pad	I/O	I/O to external world
DO	I	Data coming from the core into the pad
OBE	I	Enable output driver

Table continues on the next page...

Table 10. Pad Signal description (continued)

Signal name	Direction	Description
PUE	I	0: Disable internal pullup or pulldown resistor 1: Enable internal pullup or pulldown resistor
PUS	I	0: Enable internal pulldown resistor if pue is set 1: Enable internal pullup resistor if pue is set
IBE	I	Enable input receiver
IND	O	Data coming out of the pad into the core
SRC	I	Slew Rate Control
PKE	I	Pad keeping enable
IFE	I	Input filter enable
DSE	I	Drive Strength enable

Table 11. Input buffer enable

IBE	Pad	IND	Description
0	X	0	Input buffer disabled, ind gets low
1	0/1	0/1	Input buffer enabled, ind = pad

Table 12. Output buffer enable

OBE	DO	Pad	Description
0	X	Z	Output buffer disabled, pad hi-Z (If not configured as input)
1	0/1	0/1	Output buffer enable, pad = do

Table 13. Input filter enable

IFE	Description
1	Input filter enabled
0	Input filter disabled

Table 14. Pull up/Pull down

PUE	PUS	Pad	Description
0	X	-	Weak pull disabled. Pad retains previous state
1	0	0	Weak pull down enabled
1	1	1	Weak pull up enabled

Table 15. Slew rate control

SRC	Description
0	Slew rate enabled
1	Slew rate disabled

Table 16. Drive strength enable

DSE	Description
1	Drive strength supported
0	Drive strength not supported

Table 17. Pad keeping enable

PKE	Description
0	Pad keeping disabled
1	Pad keeping enabled

NOTE

The default state of GPIO pins on a reset event is high-Z. The high-Z state might settle to active high or active low at chip depending on the supply, temperature and other factors. Hence, it is recommended to use external pulls to ensure safe inactive state in event of a reset.

4.3 Functional description

The signal multiplexing architectural implementation is as shown in the following figure.

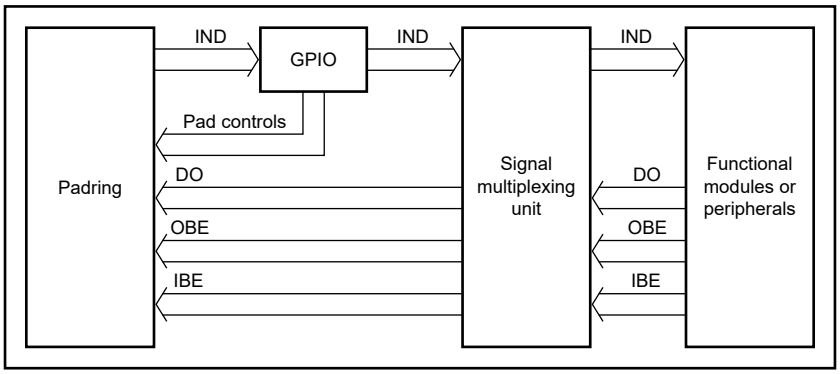

Figure 10. Signal Multiplexing

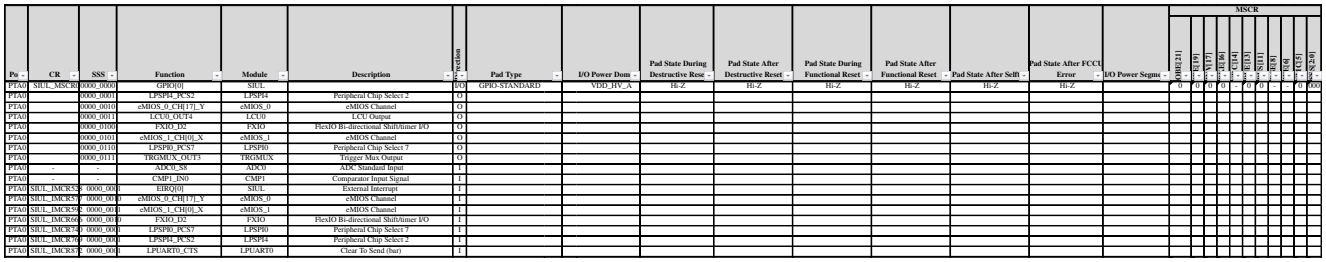
4.4 Signal Multiplexing sheet

IO Signal Description Input Multiplexing sheet(s) attached to the Reference Manual contains information on pins/balls of this device.

The 'IO Signal Table' and 'Input Muxing' tabs in the sheet correspond to the signal multiplexing information. The 'IO Signal Table' consists of all the pin muxing details and the 'Input Muxing' specifies the priority for the input muxing where an input path is driven by more than one pad.

4.4.1 IO Signal Table

Following is an example snippet of IO Signal Table. For selecting any functionality, the pad MSCR register (refer to SIUL2_MSCRn) needs to be configured accordingly.



Pin	CR	SSS	Function	Module	Description	Direction	Pad Type	I/O Power Dom	Pad State During Destructive Reset	Pad State After Destructive Reset	Pad State During Functional Reset	Pad State After Functional Reset	Pad State After SelfTest	Pad State After FCCU Error	I/O Power Segment	MSCR
PTA0	SIUL_MSCR0	0000_0000	GPIO[0]	SIUL		I/O	GPIO-STANDARD	VDD_HV_A	Hi-Z	Hi-Z	Hi-Z	Hi-Z	Hi-Z	Hi-Z		0
PTA0		0000_0001	LPSPI4_PCS2	LPSPI4	Peripheral Chip Select 2	O										
PTA0		0000_0010	eMIOS_0_CH[17]_Y	eMIOS_0	eMIOS Channel	O										
PTA0		0000_0011	LCU0_OUT4	LCU0	LCU Output	O										
PTA0		0000_0100	FXIO_D2	FXIO	FlexIO Bi-directional Shift/timer I/O	O										
PTA0		0000_0101	eMIOS_1_CH[0]_X	eMIOS_1	eMIOS Channel	O										
PTA0		0000_0110	LPSPI0_PCS7	LPSPI0	Peripheral Chip Select 7	O										
PTA0		0000_0111	TRGMUX_OUT3	TRGMUX	Trigger Mux Output	O										
PTA0	-	-	ADC0_S8	ADC0	ADC Standard Input	I										
PTA0	-	-	CMP1_IN0	CMP1	Comparator Input Signal	I										
PTA0	SIUL_IMCR32	0000_0000	EIRQ[0]	SIUL	External Interrupt	I										
PTA0	SIUL_IMCR37	0000_0010	eMIOS_0_CH[17]_Y	eMIOS_0	eMIOS Channel	I										
PTA0	SIUL_IMCR59	0000_0010	eMIOS_1_CH[0]_X	eMIOS_1	eMIOS Channel	I										
PTA0	SIUL_IMCR69	0000_0010	FXIO_D2	FXIO	FlexIO Bi-directional Shift/timer I/O	I										
PTA0	SIUL_IMCR74	0000_0010	LPSPI0_PCS7	LPSPI0	Peripheral Chip Select 7	I										
PTA0	SIUL_IMCR76	0000_0010	LPSPI4_PCS2	LPSPI4	Peripheral Chip Select 2	I										
PTA0	SIUL_IMCR85	0000_0010	LPUART0_CTS	LPUART0	Clear To Send (bar)	I										

Figure 11. IO signal table snippet

The columns of the above figure are described below:

- Port: This field in IO Signal Table specifies the PAD names of the device.
- CR(Control Register): This field specifies the name of MSCR corresponding to the Port field. 'On this device, there are eight port groups (PTA, PTB, PTC, PTD, PTE, PTF and PTG) that are controlled by SIUL2_MSCRn registers. The below table shows the mapping of ports with respect to SIUL2_MSCRn registers.

Table 18. Port/MSCR mapping

Port	SIUL2_MSCRn index
PortA[0-31]	MSCR0 - MSCR31
PortB[0-31]	MSCR32 - MSCR63
PortC[0-31]	MSCR64 - MSCR95
PortD[0-31]	MSCR96 - MSCR127
PortE[0-31]	MSCR128 - MSCR159
PortF[0-31]	MSCR160 - MSCR191
PortG[0-27]	MSCR192 - MSCR219

See SIUL2_MSCR/IMCR (See following Input Muxing section for details on IMCR) for description of MSCR/IMCR fields.

- SSS: This field specifies the ALT mode of operation as per MSCR[Mux_mode]. Not all pins support all pin muxing slots. Unimplemented pin muxing slots are reserved. The corresponding pin is configured in the following pin muxing slot as follows:
  - 000: Alternative 0 (GPIO)
  - 001: Alternative 1 (chip-specific)
  - 010: Alternative 2 (chip-specific)
  - 011: Alternative 3 (chip-specific)
  - 100: Alternative 4 (chip-specific)
  - 101: Alternative 5 (chip-specific)
  - 110: Alternative 6 (chip-specific)
  - 111: Alternative 7 (chip-specific)

NOTE

The analog functionalities are specified with '-' in this field.

- Function: This field specifies the functionality of the pad as per the corresponding ALT mode specified by SSS field.
- Module: The Module field contains the module which is governing the pad for the ALT mode.

- Description: This field mentions a short description of pad functionality.
- Direction: This field specifies the direction (Input, Output or Input/Output) of the pad for the concerned functionality.
- Pad Type: This field mentions the pad type of the corresponding pad.
  - GPIO-Standard:
    - Switching up to 10MHz
    - High drive-strength not supported.
    - Slew-rate control not supported.
  - GPIO-Standard plus:
    - Switching up to 25MHz
    - Supports high drive-strength.
    - Slew-rate control not supported.
  - GPIO-Medium:
    - Switching up to 50MHz
    - Supports high drive-strength.
    - Supports slew-rate control.
  - GPIO-Fast:
    - Switching up to 120MHz
    - Supports high drive-strength.
    - Supports slew-rate control.
- The next columns specify the pin number in the supported packages for the device.
- I/O Power Domain: This field refers to the power domain of associated pad (VDD_HV_A / VDD_HV_B).
- Pad State during/after Reset: These fields represent the pad states during and post different device resets.
- MSCR: This field specifies the default MSCR value for corresponding pad. Refer SIUL2_MSCRn for description of MSCR fields.
- The next two columns specify the reset value and the configurable bit fields of MSCR corresponding to pad.

4.4.2 Input muxing table

As the same function can be multiplexed to several pads by configuring their respective IMCRs, there is priority input muxing. In case of same input being driven from multiple pads, the one with highest priority (1 being the highest) will drive the input. Following is a snippet of Input Muxing Table.

Destination Instance	Destination Function	CR Instance	Input CR#	Input SSS	Source Instance	Source Signal
CAN0	CAN0_RX	SIUL	SIUL_IMCR512	0000_0000	-	disable low
				0000_0001	IO_PAD	PTC2
				0000_0010	IO_PAD	PTA6
				0000_0011	IO_PAD	PTB0
				0000_0100	IO_PAD	PTA28
				0000_0101	IO_PAD	PTF21

Figure 12. Input muxing table snippet

The columns of the figure are briefly described below:

- Destination Instance: This field contains the instance name of the input path to where the signal will propagate from padring.
- Destination Function: This field mentions the function name of the input path.
- Input SSS: This field specifies the IMCR[Mux_mode] value corresponding to the pad specified in source signal column.

- Source Instance: This field specifies the source pad type. A blank is mentioned for the default source when no pad is driving the input path.
- Source Signal: This field mentions the pad name. A ‘disable low’/’disable high’ specifies the signal behavior when none of the pads are driving the input path.
- The next columns specify the pin number in the supported packages for the device.

4.4.3 MSCR/IMCR description/explanation

MSCR assignments

The Implemented SIUL2 Multiplexed Single Configuration Register details is provided in the I/O Signal Description Table attached as excel.

Example:

If user wants to configure PTB0 as CAN0RX and PTB1 as CAN0TX, then the following configuration can be used in SIUL2 registers:

```
//.CAN0.RX.(PTB0):
SIUL2.IMCR0.B.SSS.=.0b011;.//.Select.CAN0-RX
SIUL2.MSCR32.B.IBE.=.1;....//.Enable.the.input.buffer

//.CAN0.TX.(PTB1):
SIUL2.MSCR33.B.SSS.=.0b101;.//.Select.CAN0-TX
SIUL2.MSCR33.B.OBE.=.1;.//.Enable.the.output.buffer
```

MSCR bit fields correspond to pin/pad basis, these are independent of muxing implemented on that specific pin/pad. As an example, pad PTA31 has SSS, SMC, DSE, PUS, PKE, INV, IBE and OBE are implemented with the reset value 0 and SRC is implemented with reset value 1.

In the 'IO Signal Table' tab of the IOMUX file attached, the MSCR register bits shows ‘0’, ‘1’, and ‘-’ for state of all bits associated with different ports. ‘0’ or ’1’ represents the reset state and ‘-’ represents the bit is not supported on the respective port.

NOTE

The GPIOs 38 and 39 are used for direct connections and FXOSC.

4.4.4 Pinout diagrams

See IO Signal Description Input Multiplexing sheet(s) attached to the Reference Manual for pinout diagrams corresponding to available packages.

4.5 Pin States

The tables in the upcoming sections mention the state of pins of the device under various conditions/event like Functional Reset, Destructive Reset, Power Up condition, during Selftest Phase etc. The details of the Reset events can be found in the Reset overview Chapter. The Details of Selftest can be found in the STCU chapter.

4.5.1 Pin numbers

See IOMUX sheet for the pin numbers of the functions mentioned in tables given in following sections.

4.5.2 Power up

This table mentions the pin behavior on power up condition of the device.

Table 19. Power up

Pin function	POWER UP until SW comes up[1]
RESET_B	LOW
JTAG_TMS,JTAG_TCK,JTAG_TDI,JTAG_TDO as JTAG	PULLED Values: (TMS = HIGH, TCK = LOW, TDI =HIGH) TDO: HIGH Z
ETM_TRACE	HIGH Z
FCCU_ERR	HIGH Z
CLKOUT_STANDBY	HIGH Z
GPIOs	HIGH Z
EXTAL	HIGH Z till extal is connected
XTAL	HIGH Z till xtal is connected

1. The IO pad states are undefined until Supply rises sufficiently to enable the POR circuits.

4.5.3 Destructive Reset

This table mentions the Pin behavior when any Destructive Reset event is triggered.

Table 20. Destructive Reset

Pins	ON Destructive Reset until SW comes up
RESET_B	LOW
TMS,TCK,TDI,TDO as JTAG	PULLED Values: (TMS = HIGH TCK = LOW, TDI =HIGH) TDO: HIGH Z
ETM_TRACE (Only on 17trace Pins)	HIGH Z
FCCU_ERR	HIGH Z
CLKOUT_STANDBY	Clkout expose if CLKOUT_STANDBY is configured to be Enabled Else HIGH Z
GPIOs	HIGH Z

4.5.4 Functional Reset including Functional entry sequence

This table mentions the Pin behavior when any functional Reset event is triggered. Also, when the FCCU reaction is configured as Functional Reset , then also the same behavior is achieved.

Table 21. Functional Reset including Functional entry sequence

Pins	Functional Reset Entry	Reset until SW comes up
RESET_B	LOW	LOW

Table continues on the next page...

Table 21. Functional Reset including Functional entry sequence (continued)

Pins	Functional Reset Entry	Reset until SW comes up
TMS,TCK,TDI,TDO as JTAG	TMS,TCK,TDI: PULLED Values if configured as JTAG (TMS = HIGH TCK = LOW, TDI =HIGH) HIGH Z if configured as GPIO TDO: HIGH Z	PULLED Values (TMS = HIGH TCK = LOW, TDI =HIGH) TDO: HIGH Z
ETM_TRACE	Trace if MDMAPCTL[DBGRSTSLOWPAD] or MDMAPCTL[DBGRSTFASTPAD] is configured to be Enabled Else HIGH Z	Trace if MDMAPCTL[DBGRSTSLOWPAD] or MDMAPCTL[DBGRSTFASTPAD] is configured to be Enabled Else HIGH Z
FCCU_ERR	ERR from FCCU if UTEST_MISC[FCCU_EOUT_DEDICATED] is configured to be Enabled Else HIGH Z	ERR from FCCU if UTEST_MISC[FCCU_EOUT_DEDICATED] is configured to be Enabled. Else HIGH Z
CLKOUT_STANDBY	Clkout expose if DCMRWP1[CLKOUT_STANDBY] is configured to be Enabled Else HIGH Z	Clkout expose if DCMRWP1[CLKOUT_STANDBY] is configured to be Enabled Else HIGH Z
GPIOs	HIGH Z	HIGH Z

4.5.5 SELFTEST(MC_RGM.ERCTRL[ERASSERT] configured as 1)

Table 22. SELFTEST(MC_RGM.ERCTRL[ERASSERT] configured as 1)

Pins	Selftest	Reset until SW comes up
RESET_B	LOW if configured as Reset Pin High Z if configured as GPIO	LOW if configured as Reset Pin High Z if configured as GPIO
TMS,TCK,TDI,TDO as JTAG	PULLED Values if configured as JTAG (TMS = HIGH, TCK = LOW, TDI = HIGH) TDO: HIGH Z	PULLED Values (TMS = HIGH, TCK = LOW, TDI = HIGH) TDO: HIGH Z
ETM_TRACE	Trace if MDMAPCTL[DBGRSTSLOWPAD] or MDMAPCTL[DBGRSTFASTPAD] is configured to be Enabled. Else HIGH Z	Trace if MDMAPCTL[DBGRSTSLOWPAD] or MDMAPCTL[DBGRSTFASTPAD] is configured to be Enabled. Else HIGH Z
FCCU_ERR	FCCU Error State if UTEST_MISC[FCCU_EOUT_DEDICAT	FCCU Error State if UTEST_MISC[FCCU_EOUT_DEDICAT

Table continues on the next page...

Table 22. SELFTEST(MC_RGM.ERCTRL[ERASSERT] configured as 1) (continued)

Pins	Selftest	Reset until SW comes up
	ED] is Enabled and DCMRWD2[EOUT_STAT_DUR_STEST] is Enabled Else HIGH Z	ED] is Enabled and DCMRWD2[EOUT_STAT_DUR_STEST] is Enabled Else HIGH Z
CLKOUT_STANDBY	Clkout expose if DCMRWP1[CLKOUT_STANDBY] is configured to be Enabled Else HIGH Z	Clkout expose if DCMRWP1[CLKOUT_STANDBY] is configured to be Enabled Else HIGH Z
GPIOs	HIGH Z	HIGH Z

4.5.6 SELFTEST (RGM_ERCTRL[ERASSERT]=0 and RGM_FRBE[ST_DONE] =0)

Table 23. SELFTEST (RGM_ERCTRL[ERASSERT]=0 and RGM_FRBE[ST_DONE] =0)

Pins	Selftest	Reset after Selftest until SW comes up
RESET_B	Same state as before selftest	Same state as before selftest
TMS,TCK,TDI,TDO as JTAG	Same state as before selftest	PULLED Values (TMS = HIGH, TCK = LOW, TDI = HIGH) TDO: No change
ETM_TRACE	Same state as before selftest	Same state as before selftest
FCCU_ERR	FCCU Error State if UTEST_MISC[FCCU_EOUT_DEDICATED] is Enabled and DCMRWD2[EOUT_STAT_DUR_STEST] is Enabled Else No change	FCCU Error State if UTEST_MISC[FCCU_EOUT_DEDICATED] is Enabled and DCMRWD2[EOUT_STAT_DUR_STEST] is Enabled Else No change
CLKOUT_STANDBY	Same state as before selftest	Same state as before selftest
GPIOs	Same state as before selftest	Same state as before selftest

4.5.7 FCCU fault in RUN mode when the fault reaction is not Reset

NOTE

For any GPIO PAD If SMC=1 then the pad would retain it's state during the fault mode else if SMC=0 then the pad would become high Z during the fault mode.

Table 24. FCCU fault in RUN mode, fault reaction not Reset

Pins	ON FCCU Fault
RESET_B	If RESET_B is assigned as a dedicated PAD then no change in the state of the PAD else if RESET_B is configured as GPIO then it would behave as per the SMC configuration. • Case 1: If dcf_client_reset_pad_dedicated[reset pad dedicated] is configured as 1'b1, the pad functions as per the reset state machine. • Case 2: If dcf_client_reset_pad_dedicated[reset pad dedicated] is configured as 1'b0 and SIUL2.MSCR5[SMC] is configured as 1'b1, the pad functions as per the configured protocol status, the protocol being configured via SIUL2.MSCR5[SSS]. • Case 3: If dcf_client_reset_pad_dedicated[reset pad dedicated] is configured as 1'b0 and SIUL2.MSCR5[SMC] is configured as 1'b0, the pin gets tristated (high-Z).
TMS, TCK, TDI, TDO as JTAG	If the PAD is configured as a JTAG PAD then no change and the pad would continue performing the operation else if it is a GPIO PAD then it would behave as per the SMC configuration. • Case 1: If the pad is configured for JTAG mode and SMC bit of SIUL2's MSCR register of the corresponding pin is configured as 1'b1, the pad functions as per the JTAGC state machine or protocol. • Case 2: If the pad is configured for non-JTAG mode and SMC bit of SIUL2's MSCR register of the corresponding pin is configured as 1'b0, the pins get tristated (high-Z).
ETM_TRACE	If the PAD is configured as a dedicated PAD then no change and the pad would continue performing the operation else if it is a GPIO PAD then it would behave as per the SMC configuration. • Case 1: If the pad is configured for ETM_TRACE functionality and SMC bit of SIUL2's MSCR register of the corresponding pin is configured as 1'b1, the pad functions as per the ETM trace control logic. • Case 2: If the pad is configured for non-ETM_TRACE mode and SMC bit of SIUL2's MSCR register of the corresponding pin is configured as 1'b0, the pins get tristated (high-Z).
FCCU_ERR	If the PAD is configured as a dedicated PAD by programming the UTEST_MISC[FCCU_EOUT_DEDICATED] as well as Eout indication is enabled then it would be indicating error state else if it is a GPIO PAD then it would behave as per the SMC configuration. • Case 1: If dcf_client_utest_misc[FCCU_EOUT_DEDICATED] is configured as 1'b1, the FCCU_ERR pins indicate the error state. • Case 2: If dcf_client_utest_misc[FCCU_EOUT_DEDICATED] is configured as 1'b0 and SMC bit of the SIUL2's corresponding MSCR register is configured as 1'b1, the pin retains its state. • Case 3: If dcf_client_utest_misc[FCCU_EOUT_DEDICATED] is configured as 1'b0 and SIUL2.MSCR5[SMC] is configured as 1'b0, the pin gets tristated (high-Z).
CLKOUT_STANDBY	If the PAD is configured as a dedicated PAD then no change and the pad would continue performing the operation else if it is a GPIO PAD then it would behave as per the SMC configuration. • Case 1: If the pad is configured for CLKOUT_STANDBY functionality and SMC bit of SIUL2's MSCR register of the corresponding pin is configured as 1'b1, the pin continues functioning as the CLKOUT_STANDBY pin. • Case 2: If the SMC bit of SIUL2's MSCR register of the corresponding pin is configured as 1'b0, the pin gets tristated (high-Z).

Table continues on the next page...

Table 24. FCCU fault in RUN mode, fault reaction not Reset (continued)

Pins	ON FCCU Fault
GPIOs	If the PAD is configured as a dedicated PAD then no change and the pad would continue performing the operation else if it is a GPIO PAD then it would behave as per the SMC configuration. • Case 1: If the SMC bit of SIUL2's MSCR register of the corresponding pin is configured as 1'b1, the pin continues its operation. • Case 2: If the SMC bit of SIUL2's MSCR register of the corresponding pin is configured as 1'b0, the pins get tristated (high-Z).

4.5.8 STANDBY (DCMRWF1[STANDBY_IO_CONFIG] must be configured as 1)

- Please refer to Padkeeping Section for steps to configure the various pad states during standby

Table 25. STANDBY

Pins	Standby until SW comes up
RESET_B	Alive / HighZ /LOW/HIGH (Depends on Software configuration before entering STANDBY)
TMS,TCK,TDI,TDO as JTAG	HighZ /LOW/HIGH (Depends on Software configuration before entering STANDBY)
ETM_TRACE	HighZ /LOW/HIGH (Depends on Software configuration before entering STANDBY)
FCUU_ERR	HighZ /LOW/HIGH (Depends on Software configuration before entering STANDBY)
CLKOUT_STANDBY	Alive / HighZ /LOW/HIGH (Depends on Software configuration before entering STANDBY)
GPIOs	HighZ /LOW/HIGH (Depends on Software configuration before entering STANDBY)

4.6 Glossary

Chapter 5
Cortex-M7 Overview

5.1 Introduction

Cortex-M7 is a high-performance embedded processor intended for deeply embedded applications that require fast interrupt response features. The configuration of the processor is based on little-endian format, and you must compile the execution testbench tests in this format too.

Table 26. Cortex-M7 instances

Instances	MWCT2D17S/MWCT2D16S	MWCT2016S/MWCT2015S
CM7_0	Yes	Yes
CM7_1	Yes	No

5.1.1 Features

Cortex-M7 provides:

- Low interrupt latency
- Low-cost debug
- Backwards compatibility with existing Cortex-M profile processors
- In-order superscalar pipeline
- Dual-issue support for load/load and load/store instruction pairs to multiple memory interfaces
- An MPU that you could configure to protect regions of memory
- A NVIC
- A debug and trace unit (CoreSight components)
- Floating-point arithmetic functionality, with support for single-precision arithmetic
- The ability to perform speculative load from any Normal type memory space through its AXIM bus, if D-cache is enabled
- Several memory interfaces that include:
  - Harvard architecture-based instruction and data caches, and an AXIM interface
  - A dedicated low-latency AHBP interface
  - A 64-bit AXI AMBA4 memory interface with a 16 KB instruction cache and a 16 KB data cache for efficient access to external resources. The instruction and data caches are ECC protected.
  - A 32-bit AHBS for interfacing with slaves such as DMA
  - 64-bit and 32-bit memory interfaces for the connection to local Tightly Coupled Memories called ITCM and DTCM. For details see Core configuration

5.1.2 Related information

For detailed information on:

- Cortex-M7 processor, see Arm Cortex-M7 Processor Technical Reference Manual.
- Cortex-M7 peripherals and control, see Arm Cortex-M7 Devices Generic User Guide.
- System memory map, see the memory map file attached to this document.

5.1.3 Buses, interconnects, and interfaces

This table discusses Cortex-M7 buses and their associated interconnects and interfaces.

Table 27. Buses and associated information

Bus name	Description
AXIM	Using the XHB400 module, this bus is first translated to the AHB-Lite bus that interfaces with the AXBS crossbar switch providing high-bandwidth access to on-chip memories and peripherals.
AHBP	This bus connects to the AXBS crossbar switch providing high-bandwidth access to on-chip peripherals.
PPB	This bus provides access to these modules: • Arm modules such as NVIC, ETM, ITM, DWT, and ROM tables • Miscellaneous Control Module (MCM)

NOTE

MWCT2xxxS AHBP bus is enabled after reset. Therefore, accesses of all cores to on-chip peripherals are performed exclusively through this bus.

5.1.4 Core configuration

This table describes Cortex-M7 parameter settings.

Table 28. Core configuration

Parameter	Configuration[1]
FPU	Single precision
DSP extension instructions	• Single cycle 16/32-bit MAC • Single cycle dual 16-bit MAC • 8/16-bit SIMD arithmetic • Hardware divide (2-12 cycles)
Armv8-M security extensions	Not implemented
I-cache	Implemented
D-cache	Implemented
Caches ECC	Implemented
On core MPU region	16
Number of IRQs	240
IRQ priority width configuration	4 (16 interrupt priority levels)
Debug (breakpoint/watchpoint)	Full comparator set: 4 DWT and 8 FPB comparators
Internal trace support	ITM and DWT trace functionality implemented
ETM support	Instruction and data ETM interface implemented
CTI	Implemented

Table continues on the next page...

Table 28. Core configuration (continued)

Parameter	Configuration[1]
WIC support	Not implemented
Dual-redundant core (lock-step) CPU functionality	Not implemented
RAR	All asynchronously reset
I-cache size	Implemented [2]
D-cache size	Implemented [2]
ITCM	• All chips: 32 KB for CM7_0/1, 64 KB for CM7_2
DTCM0	• All chips: 32 KB for CM7_0/1, 64 KB for CM7_2
DTCM1	• All chips: 32 KB for CM7_0/1, 64 KB for CM7_2

1. Armv7-M (Harvard architecture), six-stage superscalar plus branch prediction
2. See chapter 'Memory and Memory Interfaces' for details

5.2 Speculative accesses

The Arm Cortex M7 processor can issue speculative read accesses that may access any location within the complete memory address range. This behavior can be controlled, but not disabled. Corresponding effects must be considered for a proper operation of your system.

Speculative accesses do not cause any processor faults. The processor is aware whether an access is speculative, and ignores any error response signaled by the system due to the speculative access. However, the system that is integrating the processor cannot distinguish speculative accesses from non-speculative accesses.

Addresses used by speculative accesses are not validated against the memory map of the device, and may attempt to also access non-existing memory regions or hardware elements having side effects. For details about corresponding behavior of the Arm Cortex M7 processor see Related information. Important processing aspects are listed in section “Memory Model” within the Generic User Guide.

Speculative accesses can result in improved performance when the related memory regions are properly characterized. It is imperative to properly setup the attributes within the Memory Protection Unit (MPU) to avoid any unwanted impact of a speculative access. Examples for possible, corresponding issues are usually the result of side effects unknown to the processor:

- Speculative access to an uninitialized RAM memory location that causes a double bit error {the related fault processing by the FCCU is performed independently from the processor}.
- Speculative access to a peripheral that causes an unwanted operation; for example, a FIFO read {the corresponding data may be removed from the FIFO without being processed}.
- Speculative access to a peripheral that is not clocked, powered down, or cannot respond {the access may not be terminated, resulting an access that is stalled, system blockage}.
- Speculative access to an address range that causes an unexpected error being reported; for example, a read-while-write error of the embedded flash (indicated by setting MCRS[RWE]) during a flash erase or program operation {which may hide real errors}.

Speculative accesses can be controlled by a proper assignment of memory regions within the MPU:

- Speculative instruction fetches are never made to memory addresses in an Execute Never region.
- Speculative data reads are never made to memory addresses marked as non-accessible in the MPU.
- Speculative cache line-fills are never made to non-cacheable memory addresses.
- Speculative data reads and speculative cache line-fills are never made to memory addresses in a region having a Device or Strongly-ordered attribute.

- Speculative reads are never made on the AHBP interface.
- Speculative writes are never made.

Memory regions mapped to a TCM are always treated as Normal Memory (equivalent to the MPU attribute) and are therefore always subject to speculation. Related issues can be avoided by properly initializing any TCM memory before a corresponding access may occur.

When no speculative accesses should be initiated to a memory region, it is recommended to set all of the following attributes within the MPU for this region: Device or Strongly-ordered, and Execute Never. These attributes are often also used for address ranges associated with peripherals.

Unwanted processing of side effects caused by a speculative access can also be inhibited by disabling the related events while a speculative access may occur. As an example, the FCCU can be enabled after the ECC of the RAM memories has been initialized. As a second example, read accesses to a Flash block can be inhibited by configuring an MPU region while it is being erased.

5.3 Debug facilities

This chip has extensive debug capabilities such as run control and tracing. It includes the standard Arm debug port that supports the JTAG and SWD interfaces.

5.4 Vector fetch behavior on Cortex-M7

In Cortex-M7, the vector fetches are looked up into the I-Cache. if the vector table is located in a region of memory that is cacheable, any load or store to the vector must be treated as self-modifying code and cache maintenance instructions should be used to synchronize the updates to the data and instruction caches. The Cortex-M7 Device Generic User Guide chapter 'Cache maintenance design hints and tips' specifies a recommendation for synchronization of the D-Cache and I-Cache.

If cache maintenance is to be avoided each time when the vector table gets updated, then the vector table must be allocated in the ITCM or DTCM, as those are non-cacheable regions. Alternatively, the I-Cache must be enabled after the vector table has been initialized.

5.5 TCM retry

TCM retry is disabled and software should disable the TCM retry bit at startup by programming the relevant core's CM7_ITCMCR[RETEN] and CM7_DTCMR[RETEN] fields to disable state.

5.6 Glossary

AHBP	AHB-lite peripheral
AHBS	AHB-slave port
AXIM	Advanced extensible interface master
DWT	Data watchpoint and trace unit
ETM	Embedded trace macrocell
FPU	Floating point unit
FPB	Flash patch and breakpoint
ITM	Instrumentation trace macrocell
MAC	Multiplier accumulator (refers to a multiplier accumulator unit as well as multiplier accumulator operation)
NVIC	Nested vectored interrupt controller
RCCU	Redundancy control checking unit
RAR	Reset-all-registers
SIMD	Single instruction multiple data

Chapter 6
Miscellaneous Control Module (MCM)

6.1 Chip-specific MCM information

6.1.1 MCM instances and configuration

This chip supports up to four instances of MCM:

- MCM_0
- MCM_1

Table 29. MCM instances

Instances	MWCT2D16S/ MWCT2D17S	MWCT2016S/MWCT2015S
MCM_0	Yes	Yes
MCM_1	Yes	Yes

Table 30. Memories for all chips

Memory	MWCT2015S/MWCT2016S (Single core)	MWCT2D16S/MWCT2D17S(Dual core)
Icache	8 KB	8 KB (per core)
Dcache	8 KB	8 KB (per core)
ITCM	32 KB	32 KB (per core)
DTCM	64 KB	64 KB (per core)

6.2 Introduction

The Miscellaneous Control Module (MCM) provides miscellaneous control functions and contains Cortex-M7 local memory descriptors. For more information on core related registers, refer to CM7 overview chapter.

6.2.1 Features

The MCM includes the following features:

- Program-visible information on the platform configuration and revision
- Floating Point Exception monitor and interrupt control
- Local memory descriptors:
  - ITCM
  - D0TCM
  - D1TCM
  - ICACHE
  - DCACHE

6.3 Functional description

6.3.1 Interrupts

MCM generates an interrupt if any of the following are true:

- FPU input denormal interrupt is enabled (FIDCE) and an input is denormalized (FIDC).
- FPU inexact interrupt is enabled (FIXCE) and a number is inexact (FIXC).
- FPU underflow interrupt is enabled (FUFCE) and an underflow occurs (FUFC).
- FPU overflow interrupt is enabled (FOFCE) and an overflow occurs (FOFC).
- FPU divide-by-zero interrupt is enabled (FDZCE) and a divide-by-zero occurs (FDZC).
- FPU invalid operation interrupt is enabled (FDZCE) and an invalid operation occurs (FDZC).
- Write abort interrupt is enabled (WABE) and a write abort occurs (CM7 WABORTS INDICATOR).

Determining interrupt source

To determine the exact source of the interrupt for Cortex-M7 core, qualify the interrupt status flags with the corresponding interrupt enable fields.

- MCM_ISCR[31:16] && MCM_ISCR[15:0]
- Search the result for asserted flags, which indicate the exact interrupt sources.

6.4 Memory map/register descriptions

The memory map and register descriptions below describe the registers using byte addresses.

NOTE

Writing in read-only registers at 0x0 results in a bus error.

6.4.1 MCM register descriptions

6.4.1.1 MCM memory map

MCM_0_CM7 base address: E008_0000h

MCM_1_CM7 base address: E008_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	SoC-defined Platform Revision (PLREV)	16	RO	0000h

6.4.1.2 SoC-defined Platform Revision (PLREV)

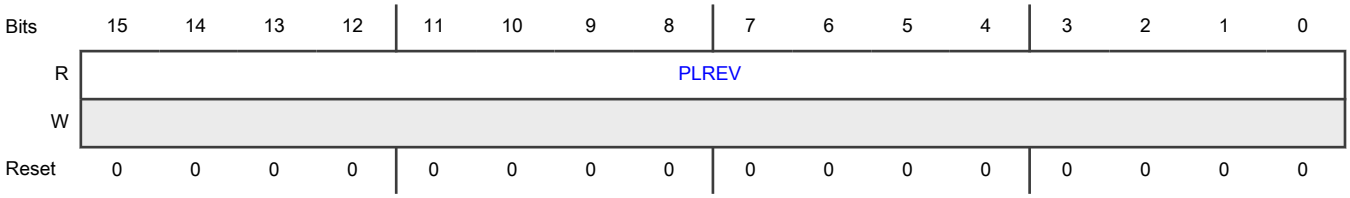
Offset

Register	Offset
PLREV	0h

Function

The PLREV is a 16-bit read-only register specifying an SoC-defined platform revision number. The state of this register is defined by a platform input signal; it can only be read from the IPS programming model. Any attempted write is ignored.

Diagram



Fields

Field	Function
15-0 PLREV	The PLREV[15:0] field is specified by a platform input signal to define a software-visible revision number.

6.4.1.3 Processor Core Type (PCT)

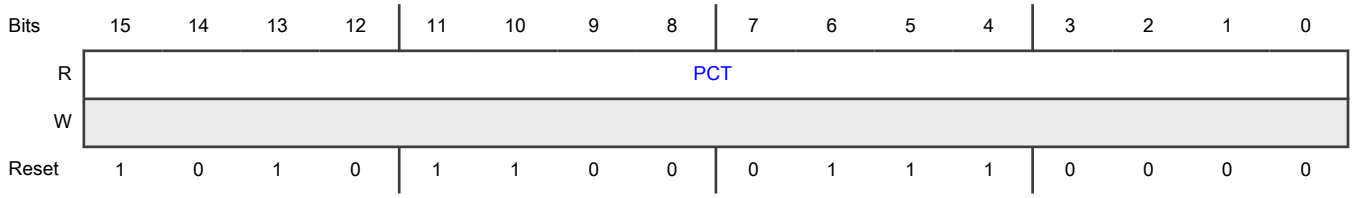
Offset

Register	Offset
PCT	2h

Function

The PCT is a 16-bit read-only register specifying the architecture of the processor core within the platform on the device. The state of this register is defined by a module input signal, which can only be read from the IPS programming model. Any attempted write is ignored.

Diagram



Fields

Field	Function
15-0 PCT	This MCM design supports the Arm Cortex M7 core. The following value identifies this core complex. 1010_1100_0111_0000b - Arm Cortex M7

6.4.1.4 Core Platform Control (CPCR)

Offset

Register	Offset
CPCR	Ch

Function

CR defines the arbitration and protection schemes for the two system RAM arrays.

27 CM7_AHBSPRI	AHB Slave Priority This field indicates the access priority on the AHBS port of the Cortex-M7. **NOTE** This setting has no effect unless enabled by AHBSCR[CTL][1] of the CM7 core. 0b - Uses a round-robin arbitration scheme 1b - AHB-slave access has priority over a core access
26-11 —	Reserved
10 —	Reserved
9 —	Reserved
8-0 —	Reserved

1. For more information see Cortex-M7 documentation: Arm Cortex-M7 Processor Technical Reference Manual at www.arm.com.

6.4.1.5 Interrupt Status and Control (ISCR)

Offset

Register	Offset
ISCR	10h

Function

The MCM_ISCR register defines the configuration of, and reports status for, a number of core-related interrupt exception conditions. It includes:

- Enable and status fields associated with the core's floating-point exceptions
- Bus errors associated with the core's cache write buffer

The individual event indicators are first qualified with their exception enables, and then logically summed to form an interrupt request sent to the core's NVIC.

Bits 15-8 are read-only indicator flags based on the processor's FPSCR register. Attempted writes to these fields are ignored. When these flags are 1, they retain this value until software clears the corresponding FPSCR field. For more information see Cortex-M7 documentation: Arm Cortex-M7 Processor Technical Reference Manual at www.arm.com.

Chapter 7
Miscellaneous System Control Module (MSCM)

7.1 Chip-specific MSCM information

7.1.1 MSCM instance

This chip has one instance of MSCM.

NOTE

The XN_CTRL register is used to restrict execution from SRAM, including TCMs and their backdoors, which will be permanent until next device reset, while still allowing data R/W.

XN_CTRL register is reserved for MWCT2D17S.

7.2 Introduction

MSCM contains registers for:

- CPU configuration
- On-chip memory control
- Interrupt router control
- Message-based interrupt configuration
- Virtual management

7.2.1 Features

- Software-accessible processor core configuration information
- Support for interrupt router control
- Support for message-based interrupt configuration

7.3 Functional description

MSCM provides information of the system cores and can identify the core that is running currently.

7.3.1 MSI routing

MSIs are interrupts that are indirectly broadcast to a target core by writing configuration bits in MSCM. These MSIs can be initiated by one core targeting another core in the system (known as core-to-core interrupts). These MSIs are initiated via writes to Interrupt Router CPn Interrupt Generation (IRCP0IGR0 - IRCP1IGR3) and managed through Interrupt Router CPn Interrupt Status (IRCP0ISR0 - IRCP1ISR3), where *n* indicates the logical core number (0-1) and *m* represents the interrupt number (0-3). CM7_0 and CM7_1 cores can support up to four outstanding core-to-core interrupts.

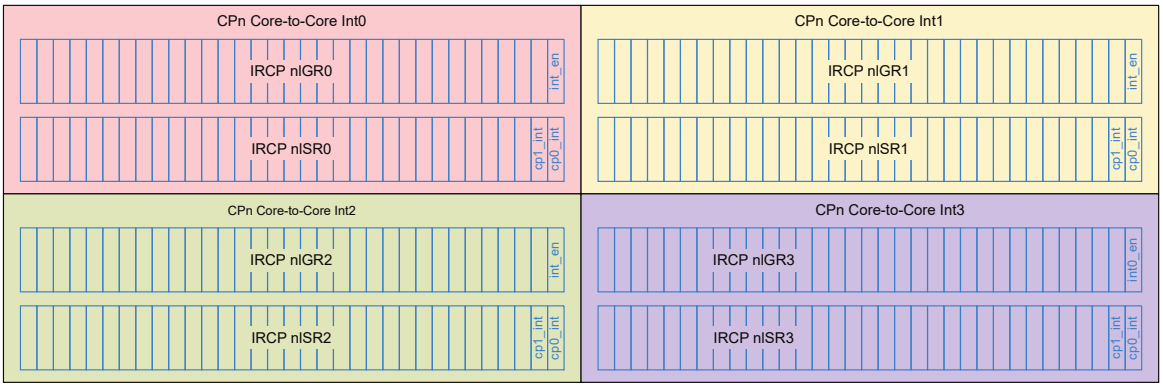

Figure 13. IRCP*n*IGR*m*/IRCP*n*ISR*m* pairs for one core

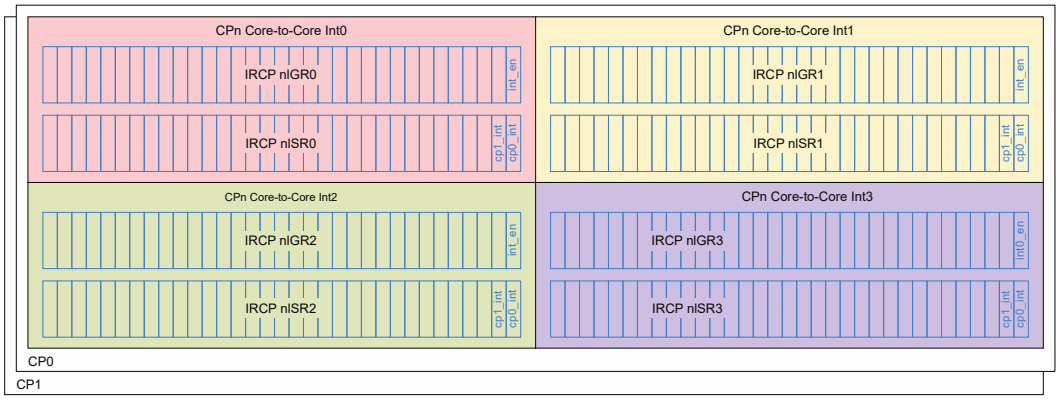

Figure 14. IRCP*n*IGR*m*/IRCP*n*ISR*m* pairs per core

7.3.1.1 Core-to-core MSIs

The next figure depicts the sequence for initiating a core-to-core MSI, in which *m* represents the initiating core, *n* represents the target core, and *x* indicates the MSI number. CP*m* writes to IRCP*n*IGR*x* to initiate an MSI. The outstanding MSI that CP*m* initiates, targeting CP*n*, is reflected in the corresponding bit-mapped field in IRCP*n*ISR*x*.

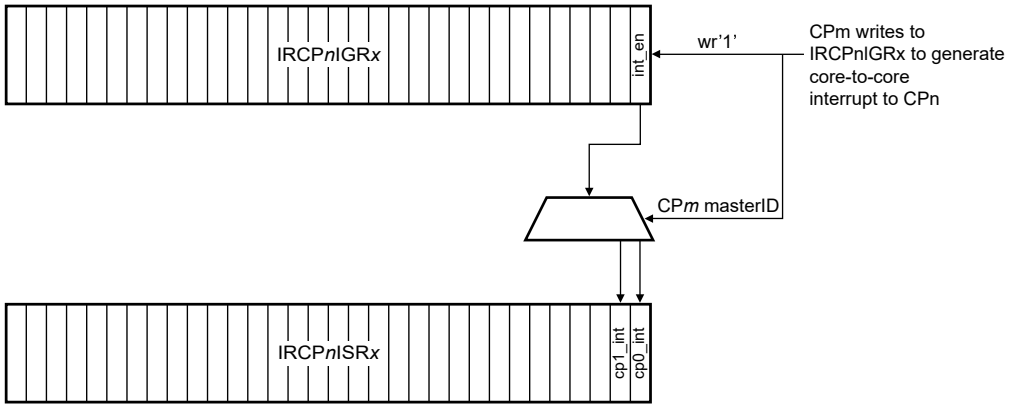

Figure 15. Initiating a core-to-core MSI via IRCP*n*IGR*x*/IRCP*n*ISR*x*

7.3.2 Interrupt steering and semaphores

7.3.2.1 Interrupt handling overview

The interrupt handling mechanisms of the CM7 cores are very similar. These cores have a NVIC tightly coupled to the processor core. The real-time performance of the cores means the NVIC directly provides an appropriate interrupt vector, in the form of the starting instruction address for the interrupt service routine, to the core. These core architectural features directly translate into a faster ISR entry and exit capabilities, coupled with an improved runtime performance. See the Arm modules and Arm core technical reference manuals for details.

In this architecture, a total of 240 IRQs are supported, where this parameter is defined by the realistic limits of the NVIC implementation, both in terms of silicon size and supported frequency of operation. These 240 IRQs are split into a total of four directed requests and 236 shared peripheral requests. Unless noted otherwise, let the directed requests be defined as IRQ[3:0] and the shared peripheral requests as IRQ[239:4]. See the interrupt map file attached to this document for details.

7.3.2.2 MSCM interrupt router functional description

As described in MSCM register descriptions, the interrupt routing registers enable the steering of requests to the processor cores.

7.4 Memory map and register definition

NOTE

The CP1 registers shown in the MSCM memory map section (from offset value 220h to 23Ch) are unavailable for the MWCT2016S and MWCT2015S variants.

7.4.1 Core configuration registers

These read-only registers contain data that defines the core setup for this chip. You can access the registers using 32-bit read references; other access sizes terminate with an error. Attempted write accesses to the read-only core configuration registers also terminate with an error.

The core configuration portion of the MSCM programming model map is organized based on the logical core number, and not on any type of physical port number. The following table shows how the configuration is partitioned.

Table 31. MSCM core configuration partitioning

Offset address range	Purpose
0h–018h	Defines the generic core x configuration information. Only the CM7 cores on the chip can access this region in either User or Privileged mode; reads by non-core bus masters (including the debugger) are treated as read as zero (RAZ) accesses. Write attempts are not permitted and terminate with a system bus error.
020h–038h	Defines the configuration information for core 0 (CP0). Any bus master can access this region in either User or Privileged mode. Write attempts are not permitted and terminate with a system bus error.
040h–058h	Defines the configuration information for core 1 (CP1). A bus master can access this region in either User or Privileged mode. Write attempts are not permitted and terminate with a system bus error.

NOTE

Attempted accesses to reserved locations are not permitted and terminate with a system bus error.

7.4.2 Shared peripheral interrupt (SPI) routing

The SPI router portion of MSCM provides a set of memory-mapped registers defining the interrupt routing for all the SPIs on this chip.

7.4.3 MSCM register descriptions

7.4.3.2 Processor X Type (CPXTYPE)

Offset

Register	Offset
CPXTYPE	0h

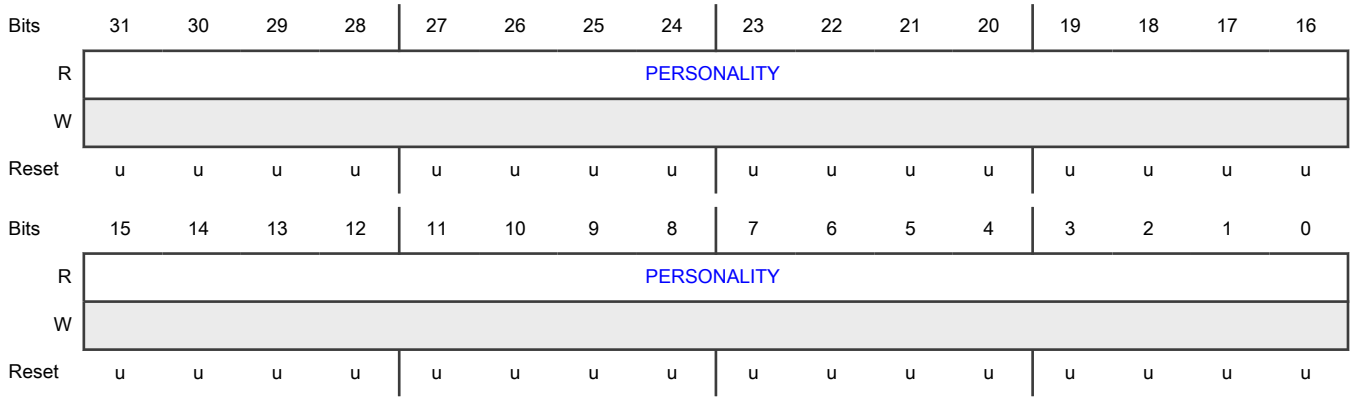
Function

Provides a CPU-specific response indicating the personality of the core making the access. The 32-bit response includes four ASCII characters defining the CPU type (Cortex-M7 cores) along with a byte defining the logical revision number and a byte defining the instance number of the core.

A read from Cortex-M7 returns the appropriate processor information. Reads from any other bus master return all 0s and attempted write accesses terminate with an error.

Access: User or privileged read-only

Diagram



Fields

Field	Function
31-0 PERSONALITY	Personality of CPx Defines the processor personality for CP*x*.

Processor	Personality
CP*x* = Cortex-M7_0	43_4D_37_30h
CP*x* = Cortex-M7_1	43_4D_37_31h

7.4.3.3 Processor X Number (CPXNUM)

Offset

Register	Offset
CPXNUM	4h

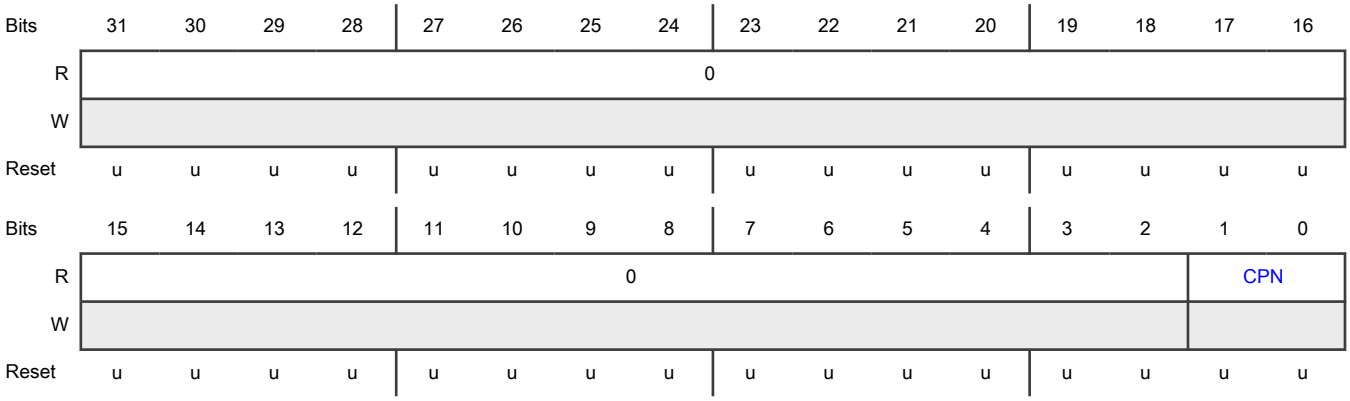
Function

Provides a CPU-specific response indicating the logical processor number of the core making the access.

A read from the Cortex-M7 cores returns the appropriate processor information. Reads from any other bus master return all 0s and attempted write accesses terminate with an error.

Access: User or privileged read-only

Diagram



Fields

Field	Function
31-2 —	Reserved
1-0 CPN	Processor Number This zero-filled word defines the logical processor number for CP*x*. **NOTE** CPN in MSCM indicates only the on-platform cores and not the HSE core. CPN = 0 represents Cortex-M7_0 if it is a lockstep or dual core. In Lockstep mode, CPN = 1 does not read from Processor X Number (CPXNUM). 00b - Cortex-M7 core 0 01b - Cortex-M7 core 1

7.4.3.4 Processor X Revision (CPXREV)

Offset

Register	Offset
CPXREV	8h

Function

Provides a CPU-specific response indicating the logical revision number of the core.

A read from the Cortex-M7 cores returns the appropriate processor information. Reads from any other bus master return all 0s and attempted write accesses terminate with an error.

Access: User or privileged read-only

Fields

Field	Function
31-8 —	Reserved
7-0 RYPZ	Processor Revision Defines the processor revision for CP*x*. For the Cortex-M7 cores in this chip, RYPZ = 12h corresponding to the r1p2 core release.

7.4.3.5 Processor X Configuration 0 (CPXCFG0)

Offset

Register	Offset
CPXCFG0	Ch

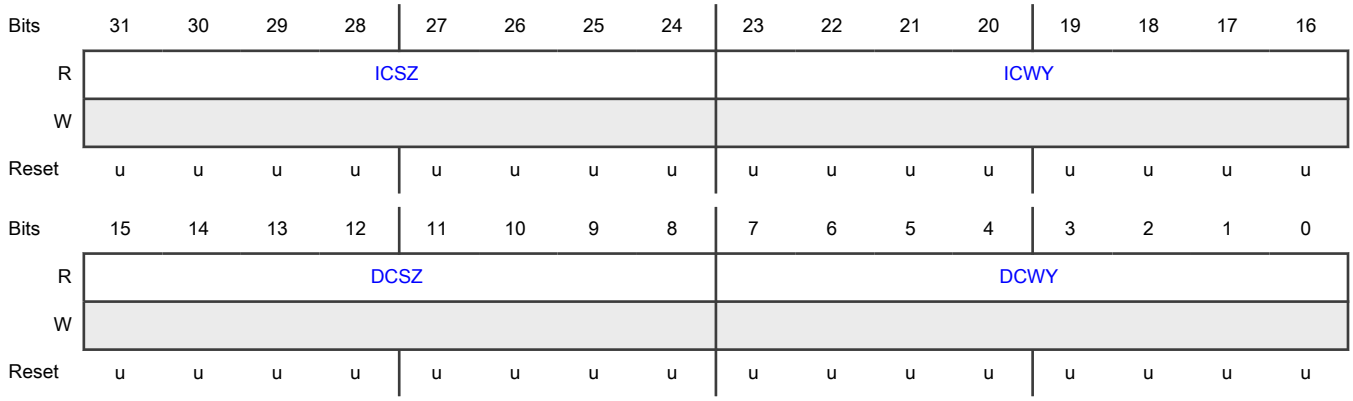
Function

Provides a CPU-specific response detailing configuration information. In this case, it is information on Level 1 (L1) cache, if present.

A read from Cortex-M7 returns the appropriate processor information. Reads from any other bus master return all 0s and attempted write accesses terminate with an error.

Access: User or privileged read-only

Diagram



Fields

Field	Function
31-24 ICSZ	Level 1 Instruction Cache Size Provides an encoded value of the instruction cache size. The capacity of the memory is derived using the formula $2^{(8+SZ)}$ and expressed as bytes. Here, ICSZ is a non-zero value and ICSZ = 0 indicates that the memory is not present. For the Cortex-M7 cores in this chip, ICSZ = 5h (8 KB).
23-16 ICWY	L1 Instruction Cache Ways Provides the number of cache ways for the instruction cache. For Cortex-M7 cores in this chip, ICWY = 2h (2-way set-associative).
15-8 DCSZ	L1 Data Cache Size Provides an encoded value of the data cache size. The capacity of the memory is derived using the formula $2^{(8+SZ)}$ and expressed as bytes. Here, DCSZ is a non-zero value and DCSZ = 0 indicates that the memory is not present. For Cortex-M7 cores in this chip, DCSZ = 5h (8 KB).
7-0 DCWY	L1 Data Cache Ways Provides the number of cache ways for the data cache. For the Cortex-M7 cores in this chip, DCWY = 4h (4-way set-associative).

7.4.3.6 Processor X Configuration 1 (CPXCFG1)

Offset

Register	Offset
CPXCFG1	10h

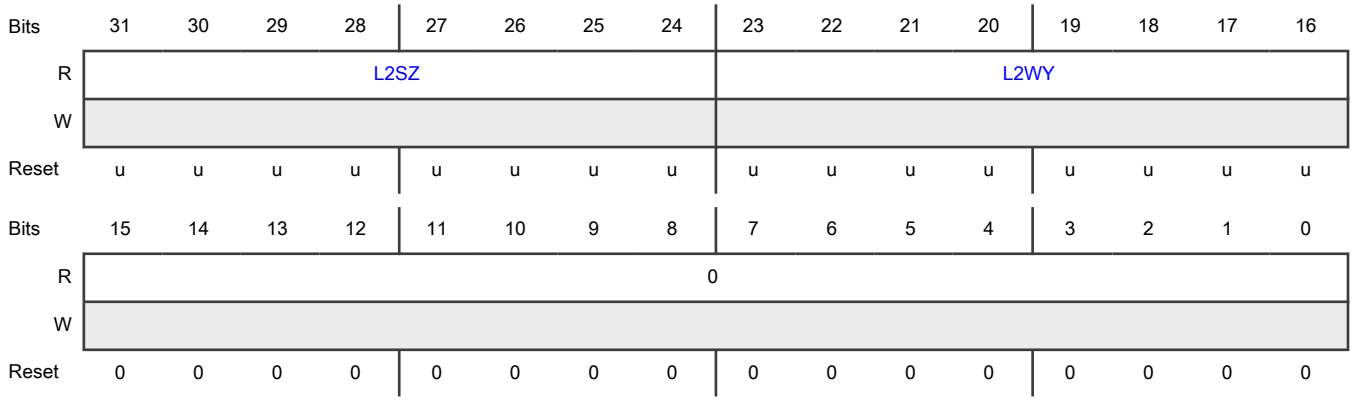
Function

Provides a CPU-specific response detailing configuration information. In this case, it is information on Level 2 (L2) cache, if present.

A read from the Cortex-M7 cores returns the appropriate processor information. Reads from any other bus master return all 0s and attempted write accesses terminate with an error.

Access: User or privileged read-only

Diagram



Fields

Field	Function
31-24 L2SZ	L2 Cache Size Provides an encoded value of the L2 cache size. The capacity of the memory is derived using the formula $2^{(8+SZ)}$ and expressed as bytes. Here, L2SZ is a non-zero value, and L2SZ = 0 indicates that the memory is not present. For the Cortex-M7 cores in this chip, L2SZ = 0h (not present).
23-16 L2WY	L2 Cache Ways Provides the number of cache ways for the L2 cache. For the Cortex-M7 cores in this chip, L2WY = 0h (not present).
15-0 —	Reserved

7.4.3.7 Processor X Configuration 2 (CPXCFG2)

Offset

Register	Offset
CPXCFG2	14h

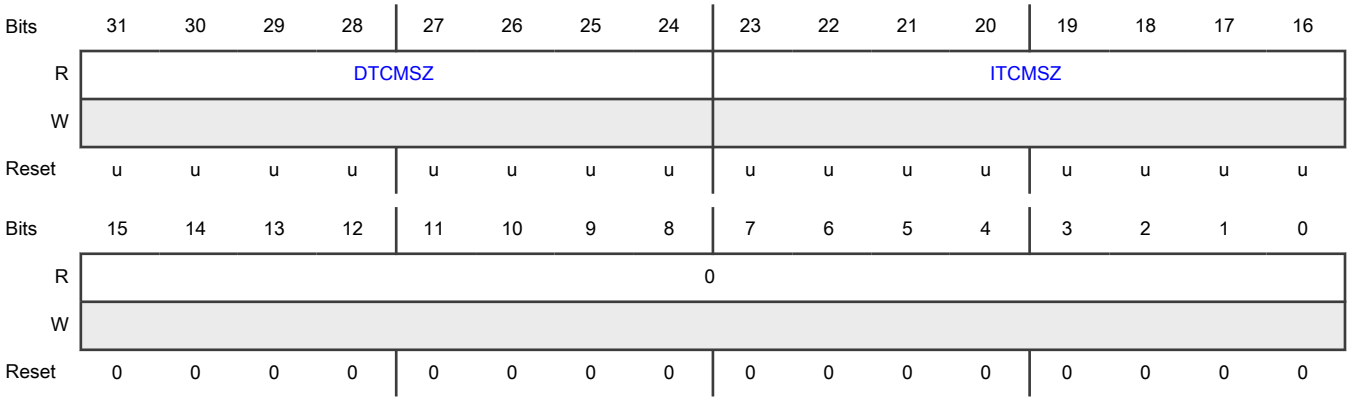
Function

Provides a CPU-specific response detailing configuration information. In this case, it is information on tightly coupled local memories, if present.

A read from the Cortex-M7 cores returns the appropriate processor information. Reads from any other bus master return all 0s and attempted write accesses terminate with an error.

Access: User or privileged read-only

Diagram



Fields

Field	Function
31-24 DTCMSZ	Tightly Coupled Data Memory Size Provides an encoded value of the tightly coupled local data memory size. The capacity of the memory is derived using the formula $2^{(8+SZ)}$ and expressed as bytes. Here, DTCMSZ is a non-zero value and DTCMSZ = 0 indicates that the memory is not present. For the Cortex-M7 cores in this chip: • DTCMSZ = 08 in Decoupled mode (64 KB) • DTCMSZ = 09 for Cortex-M7_0 in Lockstep mode (128 KB)
23-16 ITCMSZ	Instruction Tightly Coupled Memory Size Provides an encoded value of the tightly coupled local instruction memory size. The capacity of the memory is derived using the formula $2^{(8+SZ)}$ and expressed as bytes. Here, ITCMSZ is a non-zero value, and ITCMSZ = 0 indicates that the memory is not present. For the Cortex-M7 cores in this chip: • ITCMSZ = 07 in Decoupled mode (32 KB) • ITCMSZ = 08 for Cortex-M7_0 in Lockstep mode (64 KB)
15-0 —	Reserved

7.4.3.8 Processor x Configuration 3 (CPXCFG3)

Offset

Register	Offset
CPXCFG3	18h

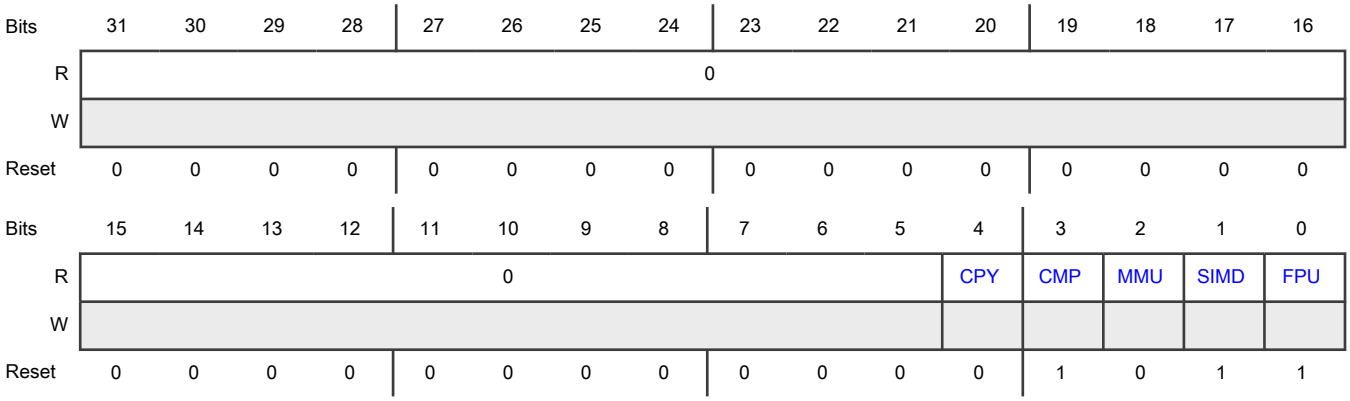
Function

Provides a CPU-specific response detailing configuration information. In this case, it is information on processor options.

A privileged read from Cortex-M7 returns the appropriate processor information. Reads from any other bus master return all 0s and attempted write accesses terminate with an error.

Access: User or privileged read-only

Diagram



Fields

The capacity of the memory is derived using the formula $2^{(8+SZ)}$ and expressed as bytes. Here, TMLSZ is a non-zero value, and TMLSZ = 0 indicates that the memory is not present. For the Cortex-M7 cores in this chip: • DTCMSZ = 8h in Decoupled mode (64 KB) • DTCMSZ = 9h in Lockstep mode (128 KB)
23-16 ITCMSZ	Instruction Tightly Coupled Memory Size Provides an encoded value of the tightly coupled local instruction memory size. The capacity of the memory is derived using the formula $2^{(8+SZ)}$ and expressed as bytes. Here, TMUSZ is a non-zero value, and TMUSZ = 0 indicates that the memory is not present. For the Cortex-M7 cores in this chip: • ITCMSZ = 7h in Decoupled mode (32 KB) • ITCMSZ = 8h in Lockstep mode (64 KB)
15-0 —	Reserved

7.4.3.15 Processor 0 Configuration 3 (CP0CFG3)

Offset

Register	Offset
CP0CFG3	38h

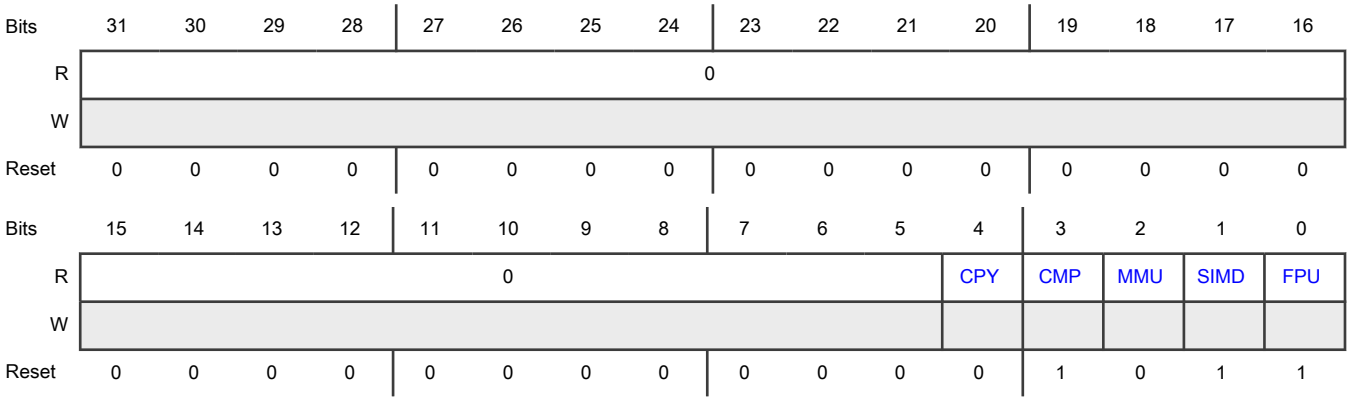
Function

Defines the configuration information for processor 0 (CP0). It has the same field definitions and functionality as provided in Processor x Configuration 3 (CPXCFG3).

A privileged read from any bus master returns the appropriate processor information and attempted write accesses terminate with an error.

Access: User or privileged read-only

Diagram



Fields

Field	Function
31-5 —	Reserved
4 CPY	Cryptography Indicates if the cryptography extensions are supported in the core. For the Cortex-M7 cores in this chip, CPY = 0h. 0b - Not supported 1b - Supported
3 CMP	Core Memory Protection Unit Indicates if the core memory protection hardware is included in this core. For the Cortex-M7 cores in this chip, CMP = 1h.

Table continues on the next page...

Table continued from the previous page...

Field	Function

2 MMU	Memory Management Unit Indicates if virtual management capabilities are supported in this core. For the Cortex-M7 cores in this chip, MMU = 0h. 0b - Not supported 1b - Supported
1 SIMD	SIMD/NEON Instruction Support Indicates if the instruction set extensions supporting SIMD and/or NEON capabilities are included in the processor. For the Cortex-M7 cores in this chip, SIMD = 1h. 0b - Not included 1b - Included
0 FPU	Floating Point Unit Indicates if hardware support for floating point capabilities is provided in the processor. For the Cortex-M7 cores in this chip, FPU = 1h. 0b - Not provided 1b - Provided

7.4.3.16 Processor 1 Type (CP1TYPE)

Offset

Register	Offset
CP1TYPE	40h

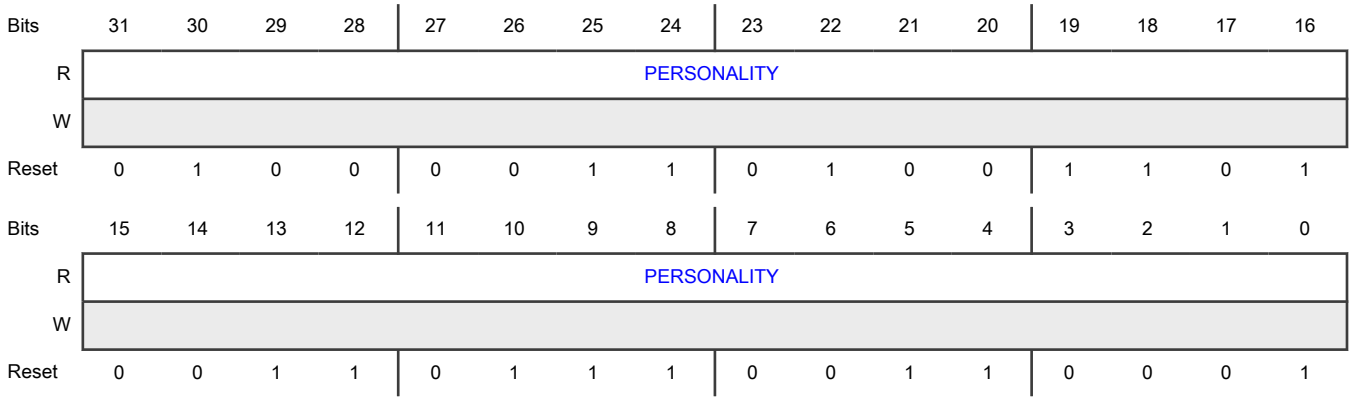
Function

Defines the configuration information for processor 1 (CP1). It has the same field definitions and functionality as provided in Processor X Type (CPXTYPE).

A read from any bus master returns the appropriate processor information and attempted write accesses terminate with an error.

Access: User or privileged read-only

Diagram



Fields

Field	Function
31-0 PERSONALITY	Personality Processor Defines the processor personality for CP1. CP1 = Cortex-M7 core 1 and processor personality = 43_4D_37_31h.

7.4.3.17 Processor 1 Number (CP1NUM)

Offset

Register	Offset
CP1NUM	44h

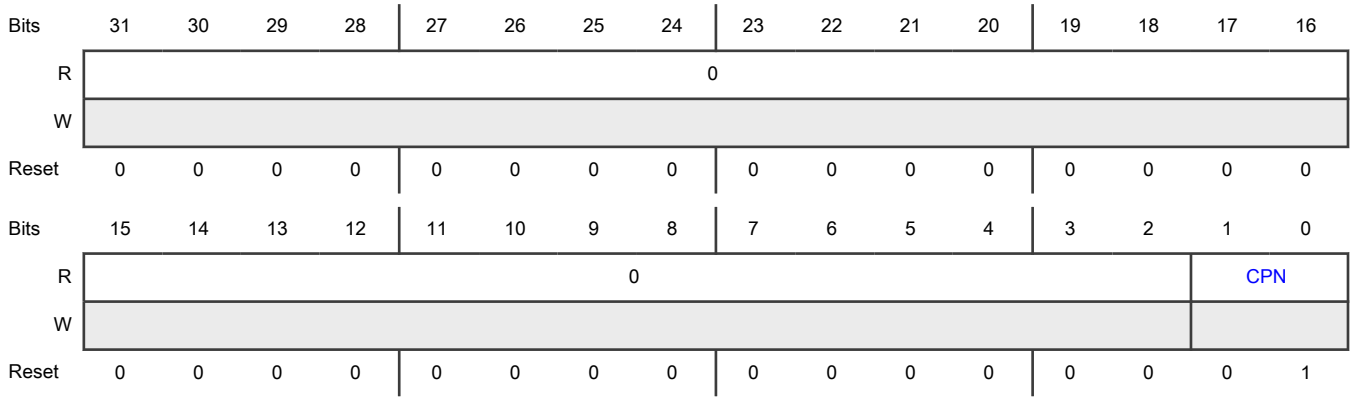
Function

Defines the configuration information for processor 1 (CP1). It has the same field definitions and functionality as provided in Processor X Number (CPXNUM).

A read from any bus master returns the appropriate processor information and attempted write accesses terminate with an error.

Access: User or privileged read-only

Diagram



Fields

Field	Function
31-2 —	Reserved
1-0 CPN	Processor Number This zero-filled word defines the logical processor number for CP1. For the Cortex-7 core 1 processor, the processor number = 1.

7.4.3.18 Processor 1 Count (CP1REV)

Offset

Register	Offset
CP1REV	48h

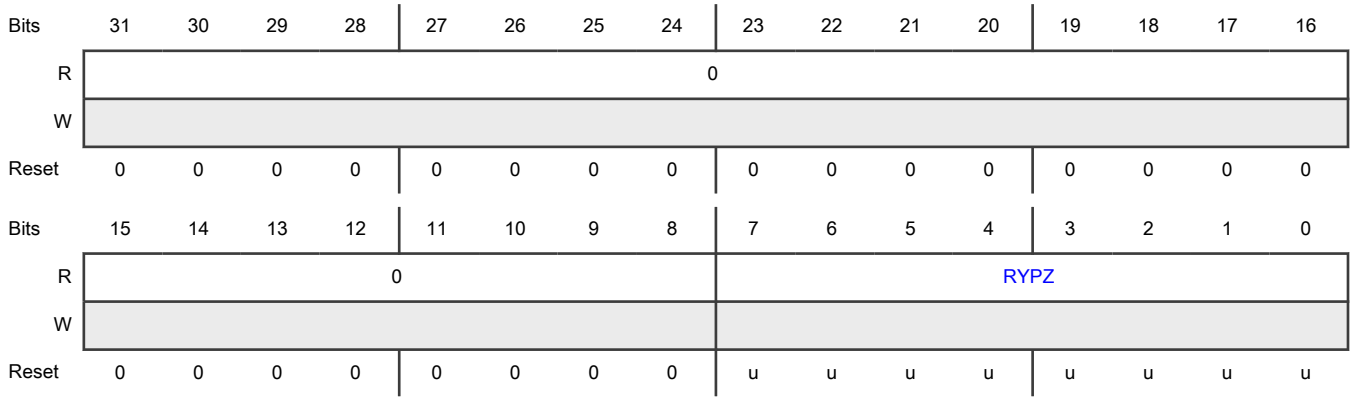
Function

Defines the configuration information for processor 1 (CP1). It has the same field definitions and functionality as provided in Processor X Revision (CPXREV).

A read from any bus master returns the appropriate processor information and attempted write accesses terminate with an error.

Access: User or privileged read-only

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 RYPZ	Processor Revision Defines the processor revision for CP1. For the Cortex-M7 processor, RYPZ = 12h corresponding to the r1p2 core release.

7.4.3.19 Processor 1 Configuration 0 (CP1CFG0)

Offset

Register	Offset
CP1CFG0	4Ch

Function

Defines the configuration information for processor 1 (CP1). It has the same field definitions and functionality as provided in Processor X Configuration 0 (CPXCFG0).

A privileged read from any bus master returns the appropriate processor information and attempted write accesses terminate with an error.

Access: User or privileged read-only

7.4.3.23 Interrupt Router CPn Interrupt Status (IRCP0ISR0 - IRCP1ISR3)

Offset

For n = 0 to 1; m = 0 to 3:

Register	Offset
IRCPnISRm	200h + (n × 20h) + (m × 8h)

Function

Provides an interrupt bit map, where each bit defines the state of a unique MSI based on the initiating core. An MSI interrupt clears in an interrupt service routine by writing 1 to the appropriate field in IRCP*n*ISR*m*.

In this discussion, CP*m* represents the initiating core and CP*n* represents the target core for a core-to-core interrupt. For more information on interrupt source mapping, see the interrupt map file attached to this document.

For read access:

- Reads to IRCP*n*ISR*m* are only accessible in Privileged mode using 32-bit (word) accesses.
- Privileged 32-bit read accesses from non-core (and non-debugger) bus masters are treated as RAZ.

- Attempted accesses in User mode or the ones using a size other than 32 bits are not permitted. They terminate with an error.
- When CP*n* requests to read IRCP*n*ISR*m*, MSCM returns the entire content of IRCP*n*ISR*m*.
- When a trusted core, as indicated by Interrupt Router Configuration (IRCPCFG), requests to read IRCP*n*ISR*m*, MSCM returns the entire content of IRCP*n*ISR*m*.
- When the debugger requests to read IRCP*n*ISR*m*, MSCM returns the entire content of IRCP*n*ISR*m*.
- When CP*m* requests to read IRCP*n*ISR*m*, MSCM returns the value of the corresponding status, CP*m*_INT, while not exposing all the other pending interrupts that the cores initiated.
- When CP*m* requests to read IRCP*n*ISR*m*, MSCM returns the value of the corresponding status, CP*m*_INT, in bit position 0, reflecting how CP*m* set the MSI when it wrote to IRCP*n*IGR*m*. All the other fields on the returned read value are zero-filled.

For write access:

- Writes to IRCP*n*ISR*m* are only accessible in Privileged mode using 32-bit (word) accesses.
- Attempted accesses in User mode or the ones using a size other than 32 bits are not permitted. They terminate with an error.
- Writes to IRCP*n*ISR*m* follow the Write 1 to Clear (W1C) protocol, whereby writing 1 causes the corresponding field to become 0, and writing 0 is ignored.
- The target core, CP*n*, has full access to write to all the fields of IRCP*n*ISR*m*.
- A trusted core, as indicated by Interrupt Router Configuration (IRCPCFG), has full access to write to all the fields of IRCP*n*ISR*m*.
- When CP*m* is different from CP*n*, the W1C action by CP*m* only clears IRCP*n*ISR*m*[CP*m*_INT].
- The CP*m* field must present W1C in bit position 0 to clear its corresponding interrupt. Write data bits 1-31 that CP*m* presents are ignored.
- Privileged write accesses from the non-core (and non-debugger) bus masters are treated as Writes Ignored (WI).
- Privileged write accesses from the debugger are treated as WI.

Access: Privileged mode only

Table continued from the previous page...

Field	Function
—	
1 CP1_INT	CP1-to-CPn Interrupt Generates a directed interrupt initiated by core 1 targeting core *n*, if the appropriate interrupt routing bit is enabled. The interrupt is negated when the target core, a trusted core, or core 1 writes 1 to clear the field. 0b - No interrupt is asserted to CPn 1b - Interrupt to CPn is asserted
0 CP0_INT	CP0-to-CPn Interrupt Generates a directed interrupt initiated by core 0 targeting core *n*, if the appropriate interrupt routing bit is enabled. The interrupt is negated when the target core, a trusted core, or core 0 writes 1 to clear the field. 0b - No interrupt asserted to CPn 1b - Interrupt to CPn asserted

7.4.3.24 Interrupt Router CPn Interrupt Generation (IRCP0IGR0 - IRCP1IGR3)

Offset

For n = 0 to 1; m = 0 to 3:

Register	Offset
IRCPnIGRm	204h + (n × 20h) + (m × 8h)

Function

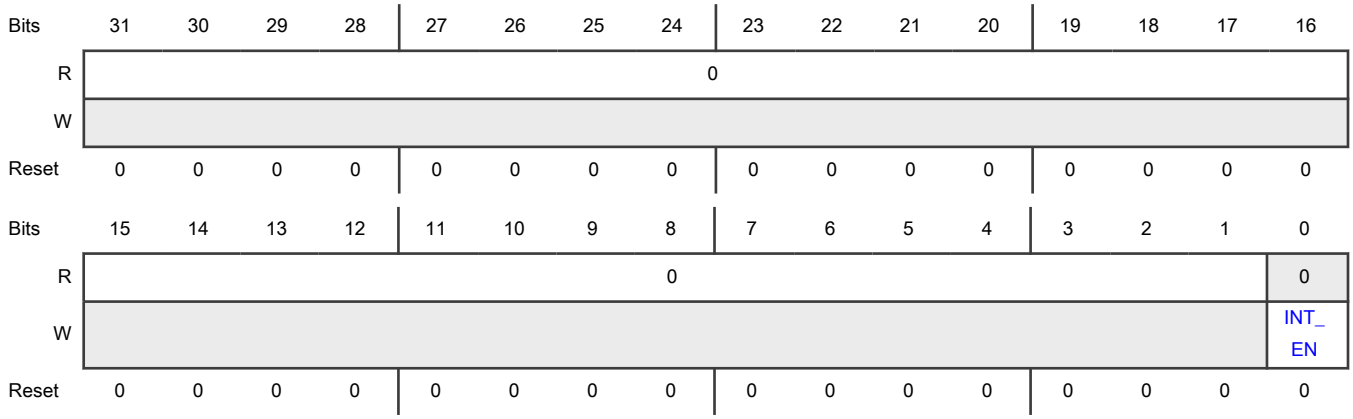
Provides a mechanism for cores to initiate an MSI to another core in the system.

Privileged, 32-bit accesses from the:

- Cortex-M7 cores are treated as RAZ/W.
- Debugger are treated as RAZ/WI.
- Non-core (and non-debugger) bus masters are treated as RAZ/WI.

Access: Privileged mode only. Attempted accesses in User mode or the ones using a size other than 32 bits are not permitted and terminate with an error.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 INT_EN	Interrupt Enable Initiates a core-to-core interrupt targeting CP*n*, if CP*m* writes to this field. See MSI routing.

7.4.3.25 Interrupt Router Configuration (IRCPCFG)

Offset

Register	Offset
IRCPCFG	400h

Function

Provides a mechanism to designate specific cores in the system as trusted. These trusted cores are allowed to access and manage outstanding MSIs.

Privileged, 32-bit accesses from the:

- Cortex-M7 cores are treated as R/W.
- Debugger are treated as R/WI.
- Non-core (and non-debugger) bus masters are treated as RAZ/WI.

Attempted accesses in User mode or the ones using a size other than 32 bits are not permitted. They terminate with an error.

Access: Privileged mode only

7.4.3.28 Interrupt Router Shared Peripheral Routing Control (IRSPRC0 - IRSPRC239)

Offset

For n = 0 to 239:

Register	Offset
IRSPRCn	880h + (n × 2h)

Function

Provides an array of 16-bit registers, where each register defines the routing control for the corresponding interrupt request. Starting from IRQ = 0 (first on-platform interrupt vector). See the interrupt map file attached to this document for details.

For this chip, each interrupt request can be either routed to a subset or to all the cores using the bit-mapped fields in IRSPRC*n*. If all the CP*x*E*n* fields are cleared, the interrupt request is disabled. Each routing control halfword can be locked by writing 1 to the LOCK field.

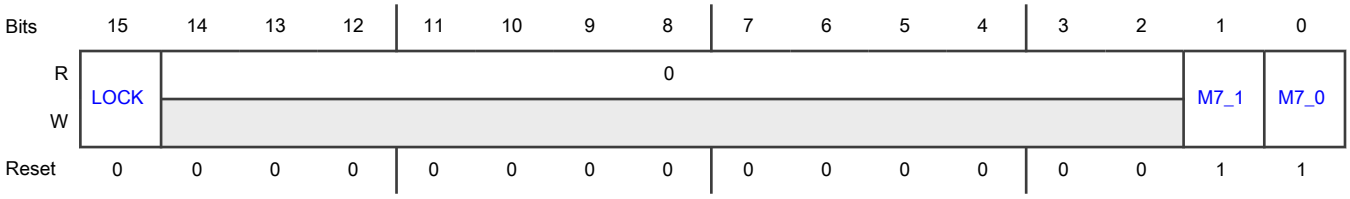
Privileged accesses from non-core (and non-debug) bus masters are treated as RAZ/WI, and any attempted User mode reference terminates with an error. Attempted accesses using a size other than a 16-bit halfword also terminate with an error.

If you write 1 to all the CP*x*En bits, all the cores service the interrupt. It is up to software to ensure that no conflicts arise from this setup either via the interrupt handler or through programming core level interrupt routing (the NVIC/GIC).

Reads and writes to this register beyond IRSPRC207 lead to unpredictable results.

Access: Privileged mode only

Diagram



Fields

Field	Function
15 LOCK	Lock Provides a mechanism to lock the routing of the corresponding interrupt request. After you write 1 to this field, attempted writes to IRSPRC*n* are ignored until the next reset writes 0 to the field. 0b - Writes to IRSPRCn allowed 1b - Writes to IRSPRCn ignored
14-2 —	Reserved
1 M7_1	Enable Cortex-M7_1 Interrupt Steering Enables or disables the corresponding interrupt request to route to Cortex-M7_1. 0b - Routing disabled 1b - Routing enabled
0 M7_0	Enable Cortex-M7_0 Interrupt Steering Enables or disables the corresponding interrupt request to route to Cortex-M7_0. 0b - Routing disabled 1b - Routing enabled

Chapter 8
Virtualization Wrapper (VIRT_WRAPPER)

8.1 Chip-specific VIRT_WRAPPER information

8.1.1 System overview of PDAC scheme

This figure shows the interaction of XRDC (containing PDACs), related to different cores (domain IDs), with VIRT_WRAPPER.

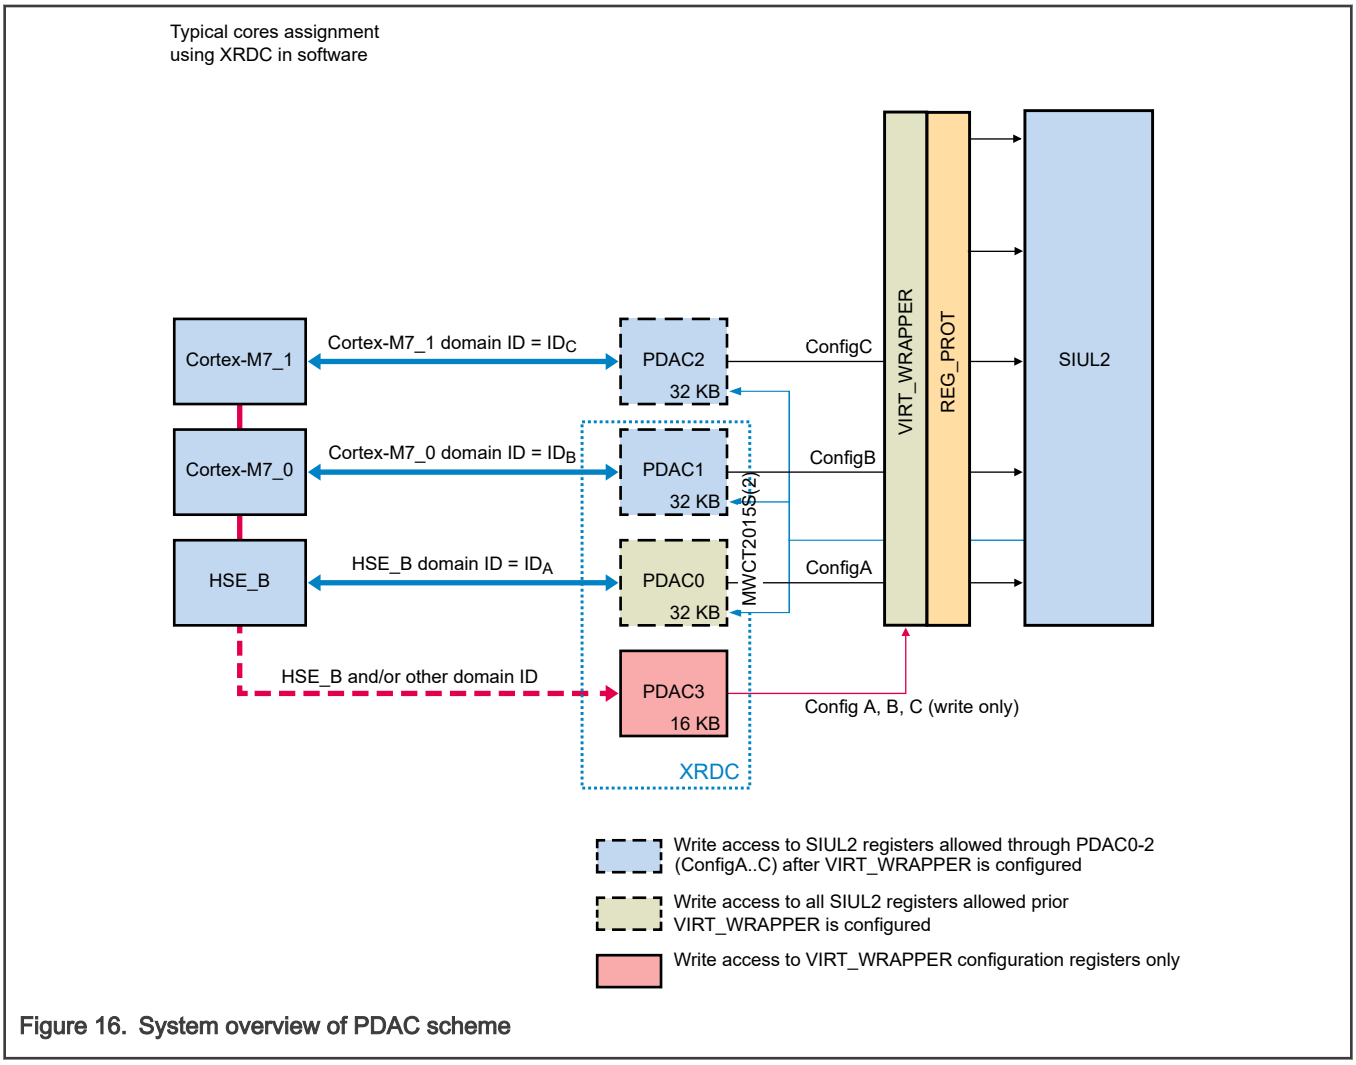

Figure 16. System overview of PDAC scheme

8.1.2 Initial VIRT_WRAPPER operation

Initially, VIRT_WRAPPER:

- Protects the "ConfigB-C" paths to SIUL2. You must configure VIRT_WRAPPER to define the SIUL2 R/W control registers that you can access through the "ConfigB-C" VIRT_WRAPPER access paths.
- Does not protect the direct path to SIUL2. It allows write accesses to all the SIUL2 R/W control registers. If PDAC0 is set to allow write access only to master core, for example HSE-B core (variant supported by the chip), then other masters cannot program the SIUL2 register. However, if these non-HSE_B masters program SIUL2 registers using other PDAC slots, a transfer error occurs. Any core can act as master core.

- Protects the "ConfigB-D" paths to SIUL2. You must configure VIRT_WRAPPER to define the SIUL2 R/W control registers that you can access through the "ConfigB-D" VIRT_WRAPPER access paths.

8.1.3 Additional VIRT_WRAPPER details

See the "SIUL2 memory map overview and protection" table, later in this chapter, for an overview of the SIUL2 registers and their protection attributes.

By default, any core can access SIUL2 registers through PDAC0. This process is called ANY_MASTER. However, after XRDC configuration, HSE_B:

- Assigns PDACs to the respective cores or domain IDs
- Locks the XRDC configuration
- Programs VIRT_WRAPPER registers for pad assignments

HSE_B accesses PDAC0 solely for the pads having 11b as the value in their corresponding registers. Also, HSE_B retains the same value for the pads that it stores. In case HSE_B needs to take control of some pins, it can still configure PDAC*n* to be accessible not only from a specific core master, but also from HSE_B, before it allows other cores to execute.

PDAC3 protects the IPS register portal of VIRT_WRAPPER configuration registers that any master can access but only via the memory slot assigned to PDAC3. The configuration via IPS register portal can be locked to prevent any further changes until the next functional reset. PDAC3 implements this locking.

The protection information of the parallel port output registers is inherited from the protection information of the included pads, according to these rules:

- When all the pads assigned to a GPIO port share the same protection information, the corresponding parallel port output register for this port inherits the same protection information.
- When at least one of the pads assigned to a GPIO port has different protection information than the other pads assigned to this GPIO port, access to the corresponding parallel port output register for this port is disabled for all the masters. Because of the aforementioned protection group mapping, the data bits of a register encode the protection control information related to one full GPIO port, or a chunk of 16 pads.
- You can assign the following SIUL2 registers to individual PDAC control:
  - DISR0
  - DIRER0
  - DIRSR0
  - IREER0
  - IFEER0
  - IFER0
  - IFMCR0–31
  - IFCPR

  Then, you can access all these registers only through the assigned PDAC because the VIRT_WRAPPER_REG_C1039_1024 register controls the SIUL2 interrupt registers.
- You cannot access the SIUL2 R/W control registers configured through PDAC3 to be accessible through the ConfigA VIRT_WRAPPER access path, using the ConfigB VIRT_WRAPPER access path.
- You cannot access any of the SIUL2 R/W control registers through ConfigB-C VIRT_WRAPPER access paths prior to VIRT_WRAPPER configuration. By default, any core can access SIUL2 registers through PDAC0 after reset.
- The same PDAC that accesses the main SIUL2 registers is used to access the SIUL2-mirrored registers and soft-lock-bit registers. This is because these registers are a part of the same 16 KB space.
- Access to mirrored SIUL2 registers sets the bit in Soft lock bit as an inherent property of register protection. See the "Register Protection" chapter for details on the soft lock bit behavior, when accessing the mirrored region.

- You cannot access any of the SIUL2 R/W control registers through ConfigB-D VIRT_WRAPPER access paths prior to VIRT_WRAPPER configuration. By default, any core can access SIUL2 registers through PDAC0 after reset.

8.2 Introduction

Virtualization refers to the various techniques, methods, or approaches of creating a virtual (rather than actual) version of something, such as a virtual hardware platform, operating system (OS), storage device, or network resources. The term "hardware virtualization" refers to the creation of a virtual machine that acts like a real computer with an operating system. The underlying hardware resources separate the software executed on these virtual machines (named "guest program"). In many cases, the specifically modified guest programs are required to run in such a virtual environment.

There are different types of hardware virtualization. One of them is para-virtualization. The para-virtualization is a non-simulated hardware environment. However, a guest program is executed in its own isolated domain, as if it is running on a separate system. Such a behavior is especially beneficial for the software targeted toward functional safety, because it allows freedom of interference for certain aspects of this software.

The hardware-assisted virtualization is a way of improving the efficiency of hardware virtualization. It involves employing specially designed CPUs and hardware components that help improve the performance of a guest environment. VIRT_WRAPPER, described in this chapter, is such a hardware component.

8.2.1 Overview

VIRT_WRAPPER is an extension of the Register Protection (REG_PROT) wrapper methodology. It works in parallel with an existing REG_PROT wrapper by virtualizing registers within the virtualized module. In this chip, SIUL2 is the virtualized module. Virtualized module is the module instance associated with VIRT_WRAPPER. Virtualization is implemented by protecting (for example, granting or inhibiting) the access to a register within the virtualized module, dependent on the specific criteria. It also virtualizes registers within REG_PROT when associated with registers within the virtualized module.

Registers within virtualized module or the REG_PROT wrapper are virtualized by granting, or inhibiting the access to different PDACs as encoded within virtualization pad assignments in VIRT_WRAPPER configuration registers. For this purpose, the virtualization information is programmed into VIRT_WRAPPER configuration registers that specify the grouping of registers within virtualized module. Upon an access to virtualized module through the peripheral interface, the grouping information is exercised to identify whether the corresponding transaction should be granted, or inhibited. A corresponding signal is forwarded to the REG_PROT wrapper that then grants, or inhibits the transaction. The following figure depicts the usage of VIRT_WRAPPER in combination with the REG_PROT wrapper and virtualized module.

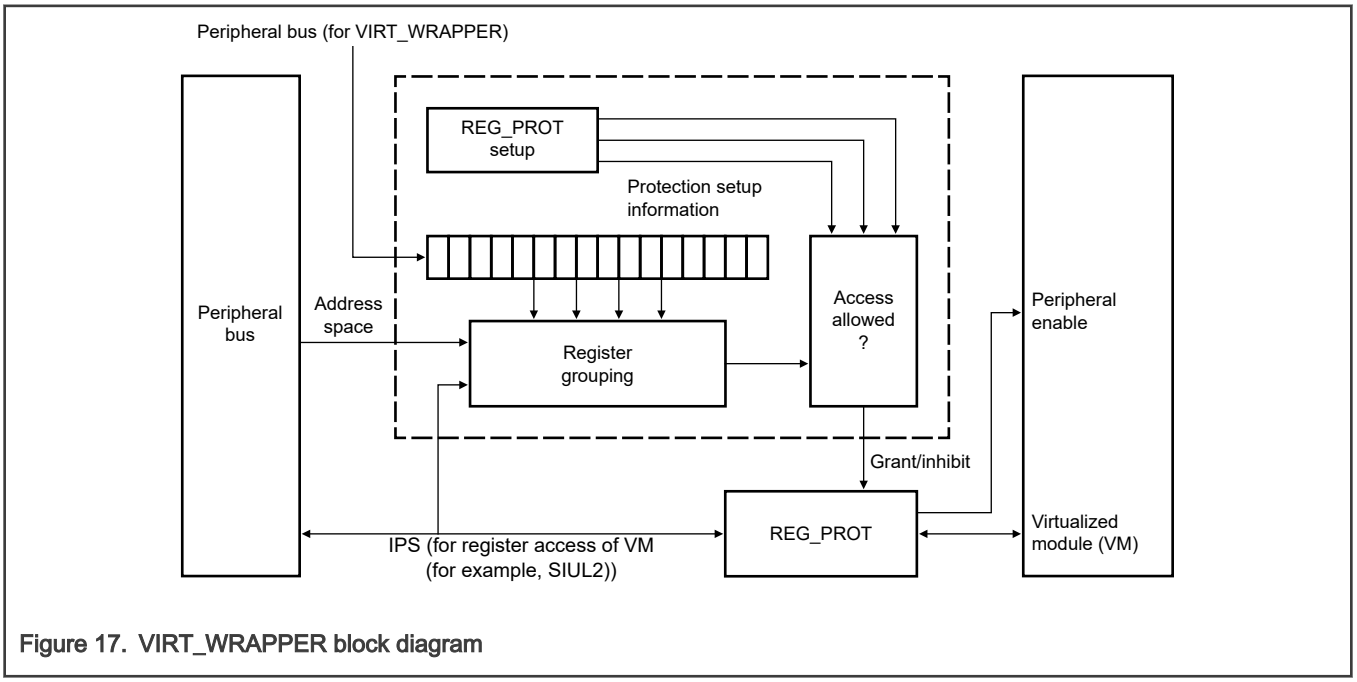

Figure 17. VIRT_WRAPPER block diagram

On a high level, VIRT_WRAPPER is an extension of the REG_PROT wrapper along those lines:

- There are a set of GPRs that receive data over peripheral bus of the VIRT_WRAPPER module. The output of these clients is a quasi-static bus providing the "Protection Control Information" to the remaining logic; this information is kept stable)that is programmed by PDAC4 after boot-up. PDAC4 should be accessed only by that master(s) that is accessing PDAC0. This is taken care by XRDC programming at the SoC.
- The remaining functionality added by VIRT_WRAPPER module consists of two sub-blocks:
  - A first sub-block (the "Grouping PLA") defines the grouping of the registers within the virtualized module. This sub-block is module specific and generated, since this information is specific for the virtualized module, It receives the address information from the peripheral bus and selects the corresponding data from the "Protection Control Information".
  - A second sub-block (the "Protection" sub-block) encodes the previously selected "Protection Control Information" and combines it with the information about the received access request. The current protection methodology allows to inhibit only write accesses for a specific master or set of masters. For this purpose, this sub-block evaluates the received access information; especially the byte enables and the PDAC of the accessing master. The output of this sub-block is an internal signal "access granted" that is used to flag an access inhibited by the virtualization information.

8.2.2 Features

VIRT_WRAPPER includes these features:

- A programmable chip-specific virtualization setup, capable to select a subset of the available masters in combination with up to four available address spaces
- Virtualizing accesses to the registers within a VM by inhibiting accesses to a subset of these registers under control of the specified virtualization information. Only write accesses can be inhibited for a specific master or set of masters.
- Inhibiting accesses to registers within REG_PROT associated with VM; in cases, these registers are associated with a register in the VM to which the access is also inhibited. Additionally, accesses to the global control register (GCR) within REG_PROT can be protected separately.

8.2.3 Modes of operation

VIRT_WRAPPER is operable when the VM is operable. For details about the availability of the VM, see the chapter of the corresponding module. When there is no virtualization information specified for the VIRT_WRAPPER module, if XRDC is not configured, PDAC0 is open as the default value of configuration register is 11b that is assigned with PDAC0 and any master can access through it.

8.3 Functional description

This section describes the following topics:

- PDAC-based protection scheme
- Register group mapping considering SIUL2
- Access errors

8.3.1 PDAC-based protection scheme

VIRT_WRAPPER uses a protection scheme of the PDACs sub-blocks of XRDC. Each PDAC is assigned to one or more cores (by domain ID assignment in XRDC) as shown in Chip-specific VIRT_WRAPPER information section. Only the write accesses are protected by the virtualization feature. Read accesses are not impacted.

For any protection group defined within the register, two bits specify the protection control information according to the following table.

Table 32. Protection control information for a single group

Value	Mnemonic	Protection	Description
00	PDAC1	Restricted access of registers, MSCR, IMCR, and INTINT, and GCR to PDAC1	Protection setup information for PDAC 1 is used.
01	PDAC2	Restricted access of registers, MSCR, IMCR, and INTINT, and GCR to PDAC2	Protection setup information for PDAC 2 is used.
11	PDAC0	By default, any core can access SIUL2 registers through PDAC0. This process is called ANY_MASTER.	Protection setup information for PDAC 0 is used.

8.3.2 Register group mapping for SIUL2

For the SIUL2 instance, the corresponding virtualization information within the VIRT_WRAPPER module is defined on a per-pad basis. Additionally, the virtualization information protects the control registers (controlling the input multiplexing scheme).

8.3.2.1 Virtualization of pad output registers

Any functional pad (controlled by the SIUL2 instance) is assigned to a separate protection group. This scheme excludes the pads that a MSCR register does not control within an SIUL2 instance (for example, power supply pads). As a result, the protection granularity defined by the virtualization information is a single pad. The control information associated with this protection group affects all the registers related to this pad.

The protection control information for pad *i* is specified within the protection group *i*; thus, it enables a very simple assignment scheme for the related protection control data that is hard-coded. The protection control information for pad *i* affects all the registers related to this pad, in the MSCR*i* and the GPDO*i* registers (in case such registers exist).

SIUL2 can control up to 512 pads that the MSCR, GPDO, and GPDI registers can access individually. The actual number of pads associated with a SIUL2 instance is specific to implementation. GPIO pads are also organized in GPIO ports consisting of a maximum of 16 pads that the parallel port registers (PGPDO, PGPDI, MPGPDO) can access.

Only the pad control and pad output registers are protected. Accesses to the read-only registers GPDI and PGPDI are not affected by virtualization.

As the protection granularity is a single pad, any virtualization information associated with this pad affects the corresponding MCSR and GPDO registers directly. Additionally, any consequence that an illegal access has on the registers implemented within the REG_PROT wrapper is inhibited. For this purpose, any access to the mirrored address space and the corresponding Soft Lock Bit Register (SLBR) is also observed.

The parallel port output registers (PGPDO, MPGPDO) inherit the protection information from the protection information of the included pads according to the following rules:

- When all pads assigned to a GPIO port share the same protection information, the corresponding parallel port output register for this port inherits the same protection information.
- When at least one of the pads assigned to a GPIO port has a different protection information than the other pads assigned to this GPIO port, the write access to the corresponding parallel port output register (PGPDO and MPGPDO) for this port is disabled for all the masters through all the PDACs and a transfer error is generated.

Due to the aforementioned protection group mapping, the data bits of a register encode the protection control information related to one full GPIO port, or a chunk of 16 pads.

8.3.2.2 Virtualization of input multiplexing control registers

Additionally, the SIUL2 instance supports the control of an input multiplexer (INMUX) scheme. This scheme provides the capability to select one of a set of the input pads to be the source of an input function for some of the peripheral modules. Any INMUX controlled by the SIUL2 instance is assigned to a separate protection group. It therefore provides an equivalent protection granularity within the virtualization information.

The protection group 512+*i* specifies the protection control information for the input multiplexer INMUX *i*. This enables a very simple assignment scheme for the related protection control data that is hard-coded. The protection control information for INMUX *i* affects the input multiplexing control register related to this input—namely, IMCR*i*.

SIUL2 can control up to 512 MSCRs and 512 IMCRs input multiplexers that the IMCRs can access individually. GPIO inputs are not affected by the input multiplexer scheme. Therefore, the associated virtualization information does not affect the corresponding pad input registers.

As the protection granularity is a single INMUX, any virtualization information associated with this INMUX affects the corresponding IMCR directly. Additionally, any consequence that an illegal access has on the registers implemented within the REG_PROT wrapper is inhibited. For this purpose, any access to the mirrored address space and the corresponding SLBR is also observed.

8.3.2.3 Virtualization of interrupt control registers

Additionally, the complete set of interrupt control registers within SIUL2 (address offset range 0010h–00C3h) can be protected as a separate group (protection group #1024).

Another additional protection group (protection group #1055) is defined for the global control register (GCR) of the related REG_PROT wrapper.

The following table shows an overview of the SIUL2 registers and their protection attributes.

Table 33. SIUL2 memory map overview and protection

Offset range	Register	Size (bits)	Protected	Description
0000–000Fh	MIDR1, MIDR2	32	N	Read-only registers, not protected
0010–00C3h	Interrupt registers	32	Y	Protected as a single group—no individual protection of related registers
0240–A3Fh [1]	MSCR	32	Y	Amount of registers defines maximum number of PADs to be controlled and protected
0A40–0123Fh	IMCR	32	Y	Amount of registers defines maximum number of INMUXes to be controlled and protected
1300–14FFh	GPDO GPDO[0] (8-bit) register controls single PAD[0] pad means that if PAD[0] is assigned to PDAC1 then PDAC1 can write to GPDO[0] (8-bit).	8	Y	There are fewer GPDO registers than MSCR registers, as some PADs are not made available as GPIO PADs, but their electrical characteristics can still be programmed
1500–16FFh	GPDI	8	N	PAD input register, not protected
1700–173Fh	PGPDO PGPDO[0] (16-bit) register controls PAD[0-15]	16	Y	Writable with 8-, 16-, and as a pair with 32-bit accesses

Table continues on the next page...

Table 33. SIUL2 memory map overview and protection (continued)

Offset range	Register	Size (bits)	Protected	Description
	pads meaning if only all the PADs[0-15] are assigned to PDAC1, then PDAC1 can write to PGPDO[0] (16-bit).			
1740–177Fh	PGPDI	16	N	PAD input register, not protected
1780–17FFh	MPGPDO MPGPDO[0] (32-bit) register controls PAD[0-15] pads meaning if only all the PADs[0-15] are assigned to PDAC1, then PDAC1 can write to MPGPDO[0] (32-bit).	32	Y	Only writable with 32-bit accesses
2010–20C3h	Interrupt registers (mirror) The DISR0 DIRER0 DIRSR0 IREER0 IFEER0 IFER0 IFMCR0-31 IFCPR0 can be assigned to individual PDAC control, then all these registers are only accessible through assigned PDAC.[2]	32	Y	Mirrored access to interrupt registers in SIUL2 instance
2240–2A3Fh	MSCR (mirror)[3]	32	Y	Mirrored access to MCSRs in SIUL2 instance
2A40–323Fh	IMCR (mirror)[3]	32	Y	Mirrored access to IMCRs in SIUL2 instance
3300–34FFh	GPDO (mirror)[4]	8	Y	Mirrored access to GPDOs in SIUL2 instance
4000–47FFh	SLBR[5]	8	Y	Soft lock bit registers within REG_PROT wrapper for this SIUL2 instance
4800–48FFh	GCR	32	Y	Global configuration register within REG_PROT wrapper for this SIUL2 instance. There is a single register in configuration space that is area 4 of REG_PROT. The size mentioned is to make the whole area a multiple of 4 KB. See the table "Address accesses as a function of PROT_MEM" in the REG_PROT chapter to know the exact area for GCRs.

1. The SIUL2 block guide specifies the support of a maximum of 512 MSCRs.

2. Access to mirrored register address range results in a change of the related SLBR within the REG_PROT wrapper if REG_PROT protects the register. For registers unprotected by REG_PROT, a write to a register mirror has the same impact as a write to the register.
3. Access to mirrored register address range results in a change of the related SLBR within the REG_PROT wrapper if REG_PROT protects the register. For registers unprotected by REG_PROT, write to register mirror has the same impact as write to register.
4. Access to mirrored register address range results in a change of the related SLBR within the REG_PROT wrapper if REG_PROT protects the register. For registers unprotected by REG_PROT, a write to a register mirror has the same impact as a write to the register.
5. Only SLBRs protecting accesses to the interrupt registers, IMCRs, and the MSCR registers are protected. See the register protection sheet attached to the reference manual for a complete list of SIUL2 registers that REG_PROT protects.

8.4 VIRT_WRAPPER memory map register descriptions

NOTE

Access to reserved spaces outside the register bank generates the transfer error. However, access to the reserved spaces within the register bank does not have any effect.

Function

This register set is for PAD0-511. They control MSCR, GPDO, PGPDO, and MPGPDO. Two bits assigned per PDAC have attributes of one of the implemented PDACs:

- 00-SIUL2_VIRTWRAPPER_PDAC1
- 01-SIUL2_VIRTWRAPPER_PDAC2
- 10-Reserved
- 11-SIUL2_VIRTWRAPPER_PDAC0

NOTE

After reset, when XRDC is not configured, any master can access SIUL2 registers through PDAC0 without getting transfer error. However, if SIUL2 registers are accessed through other PDAC slots, a transfer error will be generated.

Register	Offset
REG_B1007_992	F8h
REG_B1023_1008	FCh

Function

Controls access to pads 0 to 255 specific for IMCR registers. Two bits assigned per IMCR register have attributes of one of the implemented PDACs:

- 00-SIUL2_VIRTWRAPPER_PDAC1
- 01-SIUL2_VIRTWRAPPER_PDAC2
- 10-Reserved
- 11-SIUL2_VIRTWRAPPER_PDAC0

NOTE

After reset, when XRDC is not configured, any master can access SIUL2 registers through PDAC0 without getting transfer error. However, if SIUL2 registers are accessed through other PDAC slots, a transfer error will be generated.

PDAC	Peripheral domain access control

Chapter 9
System Integration Unit Lite2 (SIUL2)

9.1 Chip-specific SIUL2 information

9.1.1 Feature availability

This chip:

- Supports input filter enable (MSCR5[IFE]) only for the reset pad (PTA5). For details, see the "Pad signal description" table in the "Signal Multiplexing" chapter.
- Does not implement the open-drain feature. LPI2C directly configures only the pads related to the I2C and LPUART functions in pseudo open-drain when these functions are muxed to the pads. See the LPI2C and LPUART chapters for more information.
- Reserves GPDO[25:24] and PGPDO1[7:6] because PTA24 and PTA25 are input-only pins.

NOTE

EIRQ[0-15] can be used either for interrupt or DMA request. EIRQ[16-31] can only be used for interrupt request.

9.1.2 Mapping of MSCR and IMCR instances

- CR numbers 0-511 correspond to the MSCR instances.
- CR numbers 512-1023 correspond to the IMCR instances. IMCRs defined in the attached IOMUX file have an offset of 512 with respect to the IMCR number defined in SIUL2 memory map section.

NOTE

IMCR register only supports 32 bit access, any other access might result in unexpected data. See IOMUX file attached to this document for the reset value and exact number of IMCR and MSCR register instances.

9.2 Introduction

9.2.1 Overview

SIUL2 provides control over all electrical pin controls and ports with 16 bits of bidirectional, general-purpose input and output signals. SIUL2 enables you to select the functions and electrical characteristics that appear on external chip pins. It also controls the multiplexing of internal signals from one module to another and controls chip I/O. It supports as many as 32 external interrupts with trigger event configuration.

The block diagram shows the functional blocks of the module and its interfaces to other system components.

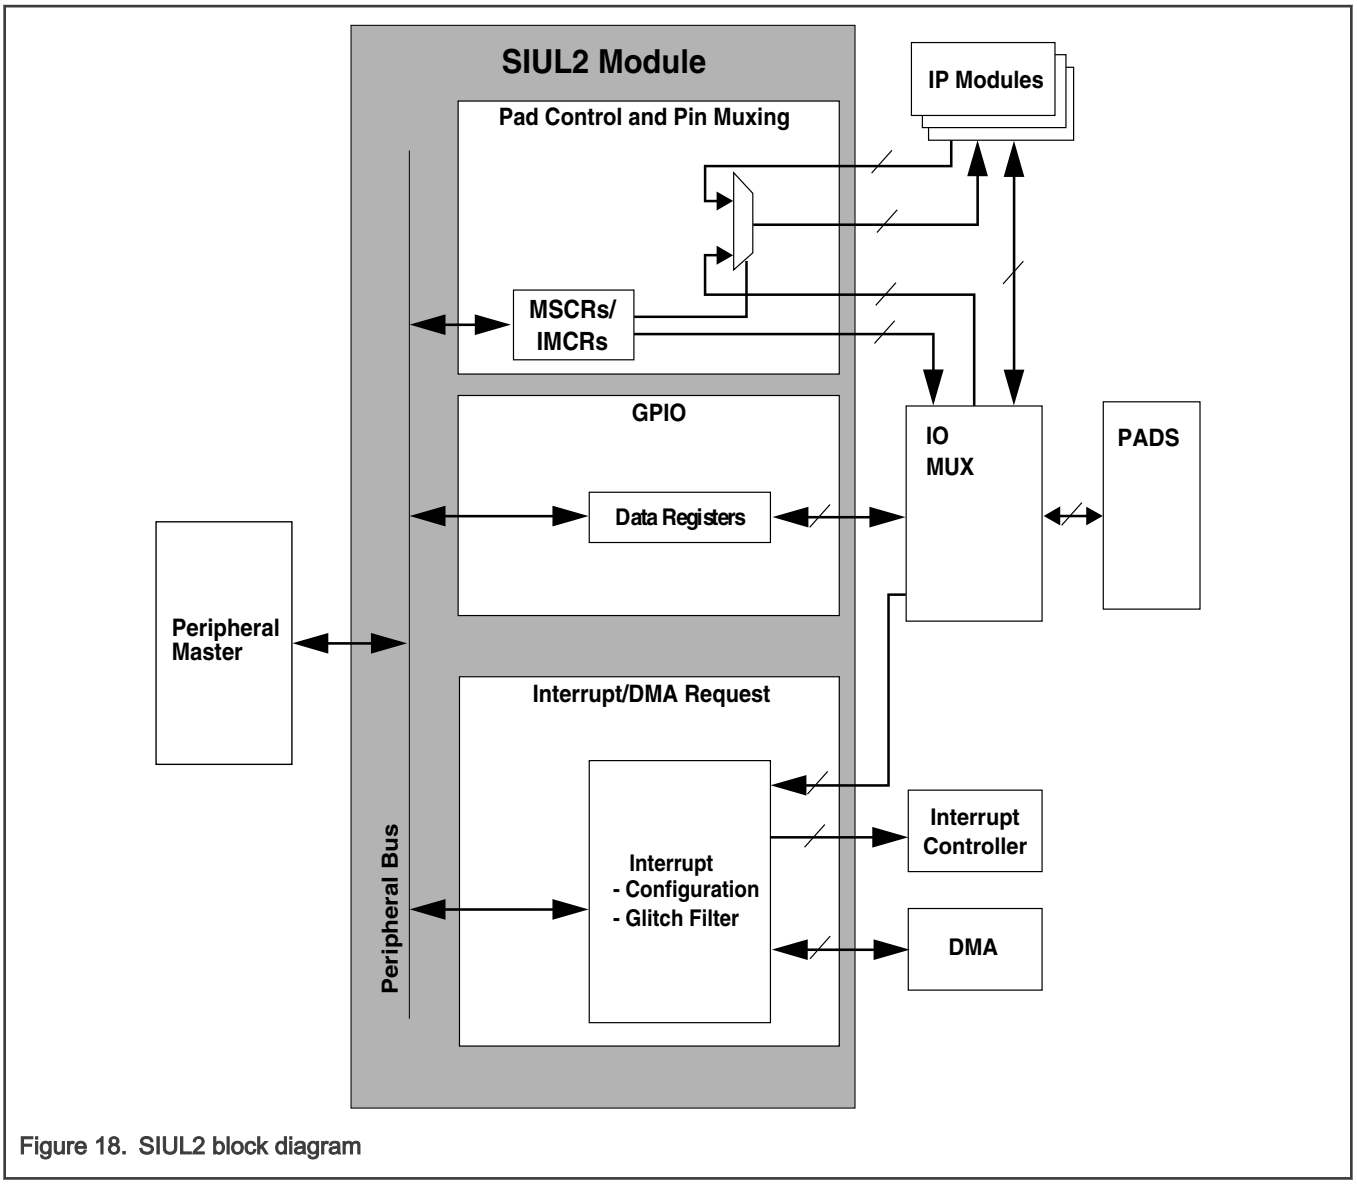

Figure 18. SIUL2 block diagram

SIUL2 provides dedicated pad control to general-purpose pads that can be configured as either inputs or outputs. It provides registers for you to read values from GPIO pads configured as inputs and to write values to GPIO pads configured as outputs:

- When configured as output, you can write to an internal register to control the state driven on the associated output pad.
- When configured as input, you can detect the state of the associated pad by reading the value from an internal register.
- When configured as input and output, the pad value can be read back to check if the written value appeared on the pad.

You can access GPIO data registers in various ways to allow port access and bit manipulation without read-modify-write operations:

- Access to two 16-bit ports in one access
- Read/write access to a single bit
- A 16-bit port write with a bit mask using single 32-bit access

You can configure external interrupt sources at the chip level to be used with any chip pad. You can configure interrupt sources to have a digital filter to reject short glitches on the inputs. The external interrupt/DMA requests map to the REQ pins in the chip packages.

9.2.2 Features

SIUL2 supports:

- One to 32 GPIO ports with data control
  - Drives data to as many as 16 independent I/O channels
  - Samples data from as many as 16 independent I/O channels
- Read or write of two 16-bit registers with one access for a 32-bit port
- External interrupt/DMA requests:
  - One to 32 programmable digital glitch filters, one for each REQ pin
  - Edge detection
- Multiplexed Signal Configuration Registers (MSCR) to configure the electrical parameters and settings for as many as 512 functional pads.

See the interrupt map file and the DMAMUX map file attached to this document for mapping of interrupt and DMA sources to interrupt vectors and DMA channels.

9.3 Functional description

9.3.1 Pad Control

SIUL2 can control the electrical characteristics of as many as 512 pads. It provides a consistent interface for all pads, both on a by-port and a by-bit basis.

The setting of each pad out of reset is fixed per chip but can be configured individually. This way you can select special pull settings or peripheral pad ownership.

You can configure each pad independently of all other pads on the chip or other pads grouped within a single port. Thus you can group different pad types together in ports and operate the pads individually. Grouping the various functions for each pad into a single register allows you to configure each pad with a single write to a register, which further allows you to duplicate software for similar pads with index changes.

9.3.2 General Purpose Input and Output pads (GPIO)

SIUL2 allows each pad to be configured as either of the following:

- General Purpose Input or Output pad (GPIO)
- A pad for one or more alternate functions (input or output) determined by the peripheral that uses the pad

GPIO pads can also be implemented without any alternate function.

SIUL2 can manage as many as 512 GPIO pads organized as ports that can be accessed for data reads and writes as 8-bit, 16-bit, or 32-bit.

All port accesses are identical, with each read or write performed only at a different location to access a different port width:

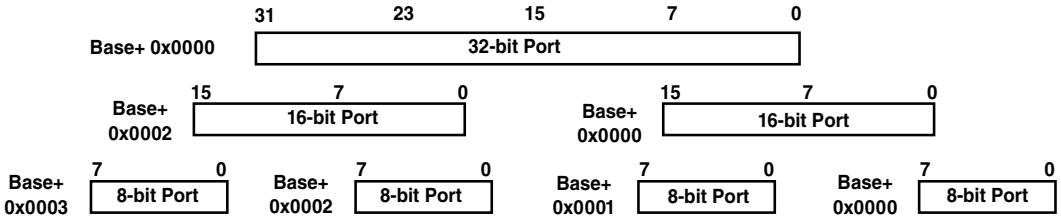

Figure 19. Data Port example arrangement showing configuration for different port width accesses

SIUL2 has separate data input and data output registers for all pads. You can thus directly read back an input or output value of a pad to validate what is actually present on the pad instead of confirming the value that was written to the data input registers.

- The data output registers support both read and write operations.
- The data input registers support read access only.

When a pad is configured to use one of its alternate functions, the data input values reflect the respective value of the pad. If a write operation is performed to the data output register for a pad configured as an alternate function (non-GPIO), this write will not be reflected by the pad value until re-configured to GPIO. All general purpose pads are implemented as bidirectional.

If bidirectional operation impacts performance or is not required for a pad function, you can limit the functionality of the pad to input only.

9.3.3 External interrupts/DMA requests (REQ Pins)

SIUL2 supports one to 32 external interrupts allocated to pads by the chip.

See the interrupt map file and the DMAMUX map file attached to this document for mapping of interrupt and DMA sources to interrupt vectors and DMA channels.

SIUL2 supports one to four interrupt vectors to the interrupt controller of the chip. Each interrupt vector can support as many as eight external interrupt sources from the chip pads.

All the external interrupt pads within a single group have equal priority. You are responsible for searching through the group of sources in the appropriate way for the application.

NOTE

Glitch filters appplied to external interrupts require a running internal oscillator clock. If such a clock is not available, enabling the glitch filter on an external interrupt will disable the interrupt.

The external interrupt signals from a pad have internal synchronizers. Therefore, the width of the interrupt signals should be at least 2.5/3 times the IRC clock cycles to correctly capture the interrupts.

9.3.3.1 External interrupt initialization

Follow these steps to enable external interrupts:

NOTE

If you do not follow these steps you may get a false interrupt flag during interrupt initialization.

1. Clear the DIRER0[EIRE*n*] bits to mask interrupts.
2. Set the appropriate IREER0[IREE*n*] bits and IFEER0[IFEE*n*] bits as needed to select the pin polarity.
3. Configure the appropriate bits in the MSCR register instances for the external interrupt pin(s):
    a. Clear the OBE and ODE bits to disable output.
    b. Set the IBE bit to enable the input buffer of the pin.
    c. If you are using the internal pullup or pulldown, configure the appropriate PUE and PUS fields.
4. Write the appropriate DIRSR0[DIRS*n*] bits to select a request between DMA or interrupt.
5. Select the desired glitch filter setup for the pins:
    a. Write the appropriate value to IFMCR*n*[MAXCNT] register for the respective external interrupt to the filter counter.
    b. Write the appropriate value to IFCPR[IFCP] to set the filter clock prescaler.
    c. Set the appropriate IFER0[IFE*n*] bits to enable the glitch filter for the external interrupt pins.
6. Write to the appropriate DISR0[EIF*n*] bits to clear any flags.
7. Set the appropriate DIRER0[EIRE*n*] bits to enable the interrupt pins.

9.3.3.2 External interrupt management

You can enable or disable each interrupt independently using a single rolled up register, DIRER0.

You can configure a pad defined as an external interrupt to recognize interrupts with an active rising edge, an active falling edge, or both, using the IREER and IFEER registers.

NOTE

You must not disable both edge events of a given interrupt.

Each external interrupt has an individual flag, held in the DISR0 register. DISR0 is a clear-by-write-1 register, which prevents inadvertent overwriting of other flags in the same register.

This figure provides an overview of the external interrupt implementation:

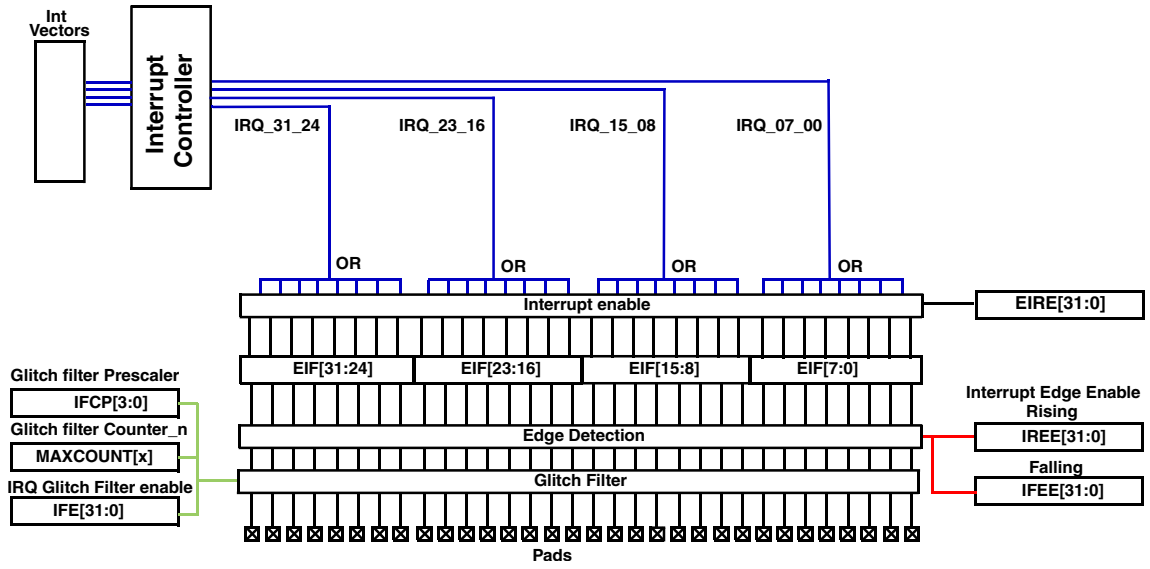

Figure 20. External interrupt pad diagram

9.3.3.3 External interrupt request

The REQ input pins on the chip are sources for interrupt or DMA requests. The chip provides four possible interrupt vectors for the SIUL2. The 32 interrupt request sources map to vectors and channels as follows:

Table 34. Interrupt source mapping to SIUL2 interrupt request output for 32 interrupt sources

Vector/Channel #	Interrupt vector source
0	REQ[07] | REQ[06] | REQ[05] | REQ[04] | REQ[03] | REQ[02] | REQ[01] | REQ[00]
1	REQ[15] | REQ[14] | REQ[13] | REQ[12] | REQ[11] | REQ[10] | REQ[09] | REQ[08]
2	REQ[23] | REQ[22] | REQ[21] | REQ[20] | REQ[19] | REQ[18] | REQ[17] | REQ[16]
3	REQ[31] | REQ[30] | REQ[29] | REQ[28] | REQ[27] | REQ[26] | REQ[25] | REQ[24]

9.3.3.4 DMA requests

The REQ pins on the chip map to independent DMA request channels in the DMA controller.

9.4 SIUL2 register descriptions

This section describes the SIUL2 registers.

NOTE

- Undocumented register spaces in the SIUL2 memory map, including addresses shown as blanks, are Reserved.
  - Reserved registers or spaces are read as 0.
  - Writes to Reserved registers or spaces generate a transfer error.
- Writes to read-only registers generate a transfer error.

NOTE

- For the array of 8-bit registers GPDO*n* and GPDI*n*:
  - An 8-bit access to an unimplemented address (a "hole") within the array region will generate a transfer error.
  - However, if you do a 16-bit or a 32-bit access and if any register instance is implemented within the accessed range, a transfer error will not be generated even if the range includes a hole.
- For the array of 16-bit registers PGPDO*n* and PGPDI*n*:
  - A 16-bit access to an unimplemented address (a "hole") within the array region will generate a transfer error.
  - However, if you do a 32-bit access and if a register instance is implemented on the other 16-bit range, a transfer error will not be generated even if the range includes a hole.

1. In this array, the index and offset values of the registers do not increment in direct alignment. For details, see the register description.

9.4.2 SIUL2 MCU ID Register #1 (MIDR1)

Offset

Register	Offset
MIDR1	4h

Function

This register holds identification information about the device.

NOTE

This register supports only 32-bit accesses. Byte and half-word accesses are not supported.

9.4.4 SIUL2 DMA/Interrupt Status Flag Register0 (DISR0)

Offset

Register	Offset
DISR0	10h

Function

DISR0 contains flag bits that record an event on the external IRQ pins. When an event as defined in IREER0 and IFEER0 occurs, the corresponding flag bit is set. The IRQ flag bit is set regardless of the state of the corresponding DIRER0[EIRE*n*] bit. The IRQ flag bit remains set until you clear it or is cleared by servicing of a DMA request. The IRQ flag bits are cleared by writing a 1 to the bits. A write of 0 has no effect.

This register supports 8-, 16-, and 32-bit accesses.

9.4.5 SIUL2 DMA/Interrupt Request Enable Register0 (DIRER0)

Offset

Register	Offset
DIRER0	18h

Function

DIRER0 enables the assertion of DMA or interrupt request to the interrupt controller if the corresponding DISR0[EIF*n*] bit is set. The type of request is determined by the corresponding DIRSR0[DIRSR*n*] bit.

This register supports 8-, 16-, and 32-bit accesses.

NOTE

Once DIRSR0 selects a DMA request, you cannot enable or disable it.

9.4.6 SIUL2 DMA/Interrupt Request Select Register0 (DIRSR0)

Offset

Register	Offset
DIRSR0	20h

Function

DIRSR0 selects between the DMA or interrupt request. The DIRSR0[DIRSR*n*] bit determines whether DMA or an interrupt request asserts the corresponding DISR0[EIF*n*] bit.

This register supports 8-, 16-, and 32-bit accesses.

9.4.7 SIUL2 Interrupt Rising-Edge Event Enable Register 0 (IREER0)

Offset

Register	Offset
IREER0	28h

Function

IREER0 enables the rising-edge triggered events on the corresponding interrupt pads.

This register supports 8-, 16-, and 32-bit accesses.

NOTE

If both the IREE and IFEE bits are cleared for the same interrupt source, the interrupt status flag for the corresponding external interrupt will never be set.

9.4.8 SIUL2 Interrupt Falling-Edge Event Enable Register 0 (IFEER0)

Offset

Register	Offset
IFEER0	30h

Function

IFEER0 enables falling-edge triggered events on the corresponding interrupt pads.

This register supports 8-, 16-, and 32-bit accesses.

NOTE

If both the IREE and IFEE bits are cleared for the same interrupt source, the interrupt status flag for the corresponding external interrupt will never be set.

9.4.9 SIUL2 Interrupt Filter Enable Register 0 (IFER0)

Offset

Register	Offset
IFER0	38h

Function

IFER0 enables a digital filter counter on the corresponding interrupt pads to filter out glitches on the inputs.

This register supports 8-, 16-, and 32-bit accesses.

9.4.10 SIUL2 Interrupt Filter Maximum Counter Register (IFMCR0 - IFMCR31)

Offset

For a = 0 to 31:

Register	Offset
IFMCRa	40h + (a × 4h)

Function

IFMCR*n* registers configure the filter counter associated with each digital glitch filter.

NOTE

These registers support only 32-bit accesses. Byte and half-word accesses are not supported.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-4 —	Reserved
3-0 MAXCNT	Maximum Interrupt Filter Counter setting MAXCNT can be 0d to 15d.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• A value of 0d, 1d, or 2d sets the filter as an all pass filter. • A value of 3d to 15d sets the filter period to TCK × MAXCNT + *n* × TCK, where: — *n* is 0, 1, 2, 3, or 4. — TCK is the prescaled filter clock period, which is the IRC clock prescaled to the IFCP value specified in IFCPR. n accounts for the uncertainty factor in filter period calculation.

9.4.11 SIUL2 Interrupt Filter Clock Prescaler Register (IFCPR)

Offset

Register	Offset
IFCPR	C0h

Function

IFCPR configures the clock prescaler which selects the clock for all digital filters. A prescaler is applied to the input clock to SIUL2, which is the peripheral clock counter in the SIUL2.

NOTE

This register supports only 32-bit accesses. Byte and half-word accesses are not supported.

Function

MSCR*n* registers select the source signal connected to the register's associated destination, which is a chip output pin or a chip pin that can be configured as an output.

MSCR*n* also specifies the electrical properties of the associated pin.

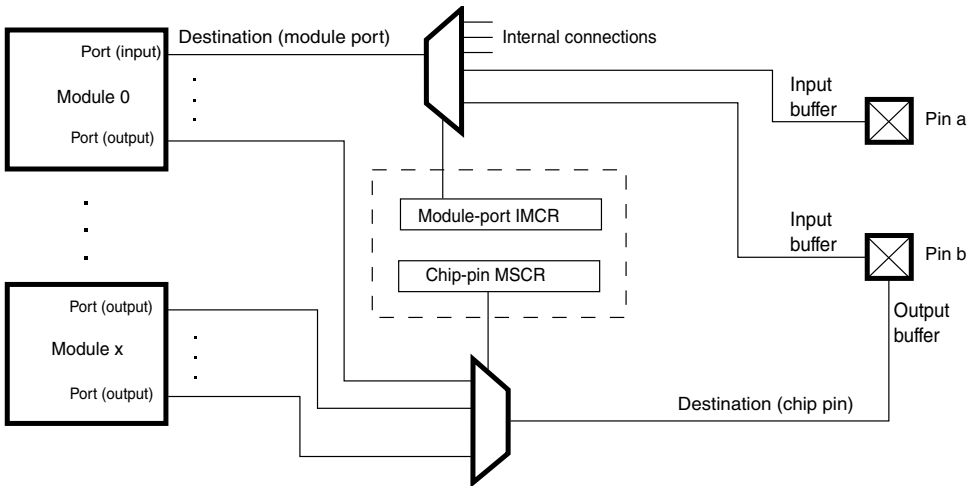

Figure 21. MSCR and IMCR port and pin connection

For chip-pin MSCR assignments and pin types, see the IOMUX file attached to this document.

NOTE

- MSCR*n* registers support only 32-bit accesses. Byte and half-word write accesses are not supported.
- MSCR*n* registers must be configured only during application initialization and must not be modified during application runtime.
- Accessing a reserved MSCR*n* register generates a transfer error.

Fields

Field	Function
31-22 —	Reserved
21 OBE	GPIO Output Buffer Enable Applies only to digital pins. Otherwise this bit is reserved. 0b - Output driver disabled 1b - Output driver enabled
20 —	Reserved
19 IBE	Input Buffer Enable Used only when the associated destination is a chip pin. Enables the associated pin's input buffer. 0b - Disabled 1b - Enabled
18 —	Reserved
17 INV	Invert Inverts the signal selected by SSS before transmitting it to the associated destination (chip pin or module port). 0b - Don't invert 1b - Invert
16 PKE	Pad keeping enable Pad keeping enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disabled 1b - Enabled
15 —	Reserved
14 SRC	Slew Rate Control 0b - Fastest setting 1b - Slowest setting
13 PUE	Pull Enable Enables the pull function. Used only when the associated destination is a chip pin. 0b - Disabled 1b - Enabled
12 —	Reserved
11 PUS	Pull Select Determines whether the pull function is a pullup or pulldown when the pull function is enabled by the PUE field. Used only when the associated destination is a chip pin. 0b - Pull down 1b - Pull up
10-9 —	Reserved
8 DSE	DSE Drive strength enable 0b - Disabled 1b - Enabled
7 —	Reserved
6 IFE	IFE Input filter enable **NOTE** This field is supported for RESET pad only (PTA5).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disabled 1b - Enabled
5 SMC	Safe Mode Control Used only when the associated destination is a chip pin. Specifies whether the chip disables the pin's output buffer when the chip enters Safe mode. 0b - Disable (The output buffer returns to its previous state when the chip leaves Safe mode.) 1b - Don't disable
4-3 —	Reserved
2 SSS_2	Source Signal Select_2 Selects a function for the pad. Refer to “SSS” column of the ‘IO Signal Table' tab of the IOMUX spreadsheet attachment.
1 SSS_1	Source Signal Select_1 Selects a function for the pad. Refer to “SSS” column of the ‘IO Signal Table' tab of the IOMUX spreadsheet attachment.
0 SSS_0	Source Signal Select_0 Selects a function for the pad. Refer to “SSS” column of the ‘IO Signal Table' tab of the IOMUX spreadsheet attachment.

Function

IMCR*n* registers select the source signal connected to the register's associated destination, which is an internal module port that is an input port or can be configured as an input.

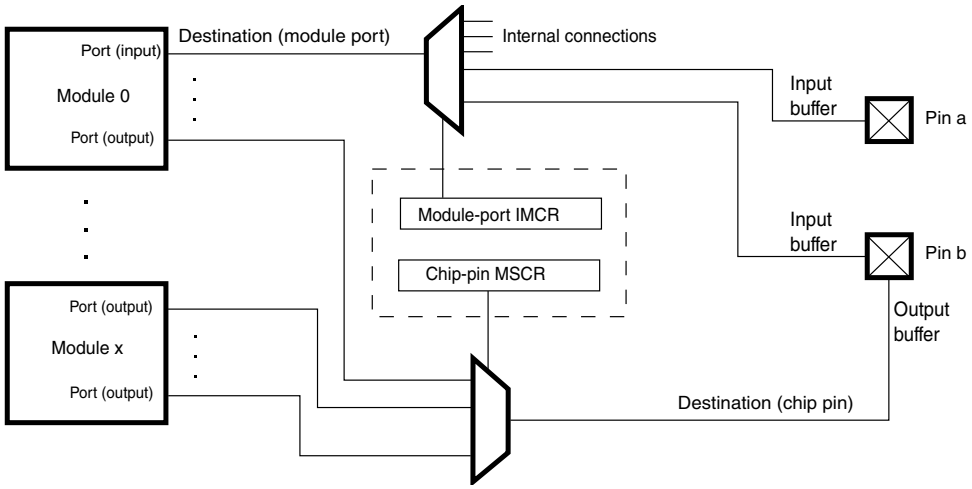

Figure 22. MSCR and IMCR port and pin connection

For IMCR assignments and field values, see the IOMUX file attached to this document.

NOTE

- IMCR*n* registers support only 32-bit accesses. Byte and half-word write accesses are not supported.
- IMCR*n* registers must be configured only during application initialization and must not be modified during application runtime.
- Accessing a reserved IMCR*n* register generates a transfer error.

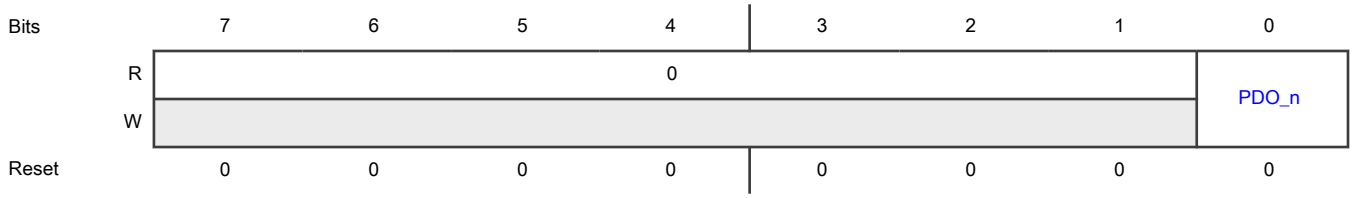
GPDOn	1300h + (n + 3 - 2 × (n mod 4))

Function

Each GPDO*n* register sets or clears a single GPIO pad with a byte access.

These registers support 8-, 16-, and 32-bit accesses.

Diagram



Fields

Field	Function
7-1 —	Reserved
0 PDO_n	Pad Data Out Stores the data to be driven out on the external GPIO pad controlled by this register when the pad is configured as an output. PDO_*n* represents PDO[*n*], where *n* is the instance of the register. 0b - Pad Data Out Low. Logic low value 1b - Pad Data Out High. Logic high value

9.4.17 SIUL2 GPIO Pad Data Input Register (GPDI0 - GPDI219)

Offset

For n = 0 to 37; n = 40 to 219:

Register	Offset
GPDIn	1500h + (n + 3 - 2 × (n mod 4))

Function

Each GPDI*n* register reads the GPIO pad data with a byte access.

These registers support 8-, 16-, and 32-bit accesses.

Diagram

Fields

Field	Function
7-1 —	Reserved
0 PDI_n	Pad Data In Stores the value of the external GPIO pad associated with this register. PDI_*n* represents PDI[*n*], where *n* is the instance of the register. 0b - Pad Data In Low. Logic low 1b - Pad Data In High. Logic high

9.4.18 SIUL2 Parallel GPIO Pad Data Out Register (PGPDO0 - PGPDO3)

Offset

Register	Offset
PGPDO1	1700h
PGPDO0	1702h
PGPDO3	1704h

Function

Each PGPDO*n* register sets or clears the respective pads of the chip.

PGPDO*n* registers can set the values of all output pins assigned to a chip port with a single 16-bit register write, while the GPDO*n* registers set the value on a specific pin with byte writes.

Each bit writes or reads the data register that stores the value to be driven on the pad in output mode. Access to this register location is coherent with access to the bit-wise GPDO*n*.

For a given PGPDO*x*[PPDO*y*] where *x* is the register instance index and *y* is the field index, the following equation shows the equivalent GPDO*n*[PDO_*n*] bit:

PGPDO*x*[PPDO*y*] = GPDO(*x* × 16) + (15 - *y*)[PDO_(*x* × 16) + (15 - *y*)]

Some examples of the mapping:

- PGPDO0[PPDO15] = GPDO0[PDO_0]

- PGPDO2[PPDO15] = GPDO32[PDO_32]
- PGPDO31[PPDO0] = GPDO511[PDO_511]

PGPDO*n* registers access the same physical resource as the PDO and MPGPDO address locations.

These registers support 8-, 16-, and 32-bit accesses.

Chapter 10
Touch Sensing Pin Coupling (TSPC)

10.1 Chip-specific TSPC information

10.1.1 TSPC instances and configuration

This chip has one instance of TSPC module. The GPIO pads being used for TSPC should be configured with Source Signal Select (SSS) = 0. TSPC module works in conjunction with SIUL2.

NOTE

TSPC clock shall be enabled to control the I/Os assigned to TSPC.

For the GPIOs and ADC pads supporting TSPC, see the IOMUX file attached to this document. There are two groups of pads which can be configured via TSPC:

1. Group 1 consists of 32 ADC channels and 14 GPIOs
2. Group 2 consists of 32 ADC channels and 6 GPIOs

NOTE

Use preferably the same type of I/O pins for driving each electrode. Such I/O pins matching will improve resolution of the capacitance sensing. For more information about types of I/O pins, see the IOMUX file attached to this document.

10.2 Introduction

TSPC provides simultaneous transitioning of a group of pads into high impedance to support a more robust recognition of touch sense.

10.2.1 Block diagram

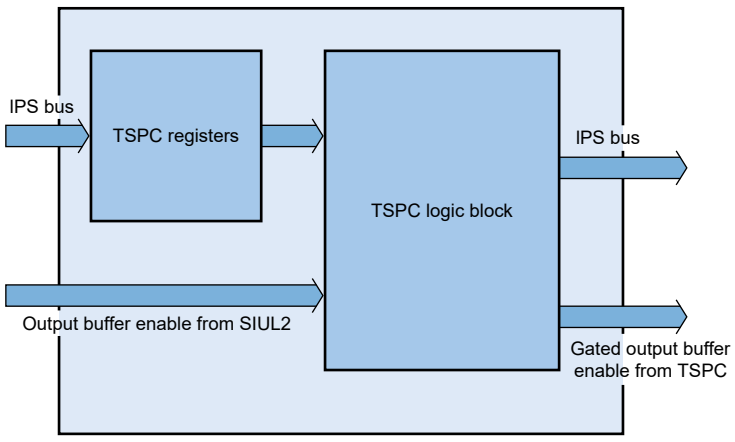

Figure 23. TSPC block diagram

10.2.2 Features

TSPC provides a set of control registers for pairing up GPIO pads for the touch sensing pairing operation. These control registers select the set of GPIO pads to pair with the set of ADC channels of an ADC instance. TSPC supports the following features:

- Up to 512 GPIO pads allow grouping

- OBE of all the grouped pads transitions from high to low simultaneously if SIUL2 transitions a pad's OBE from high to low
- Programming of group registers defines grouping

10.3 Logic block

This block takes the information from register fields to produce gated OBEs.

The simultaneous transition of grouped OBEs occurs when the GRP*n*_EN field in Group Enable (GRP_EN) for the respective group becomes 1.

The logic diagram below shows that if the GRP_EN is high for a particular group, and one of the output buffer enable (ipp_obe_in_b) from SIUL2 belonging to that group transitions from high to low, then all the other output buffer enables belonging to that group also transitions from high to low. If the GRP_EN is set low, the transitions in OBE do not affect the other OBE's belonging to that group.

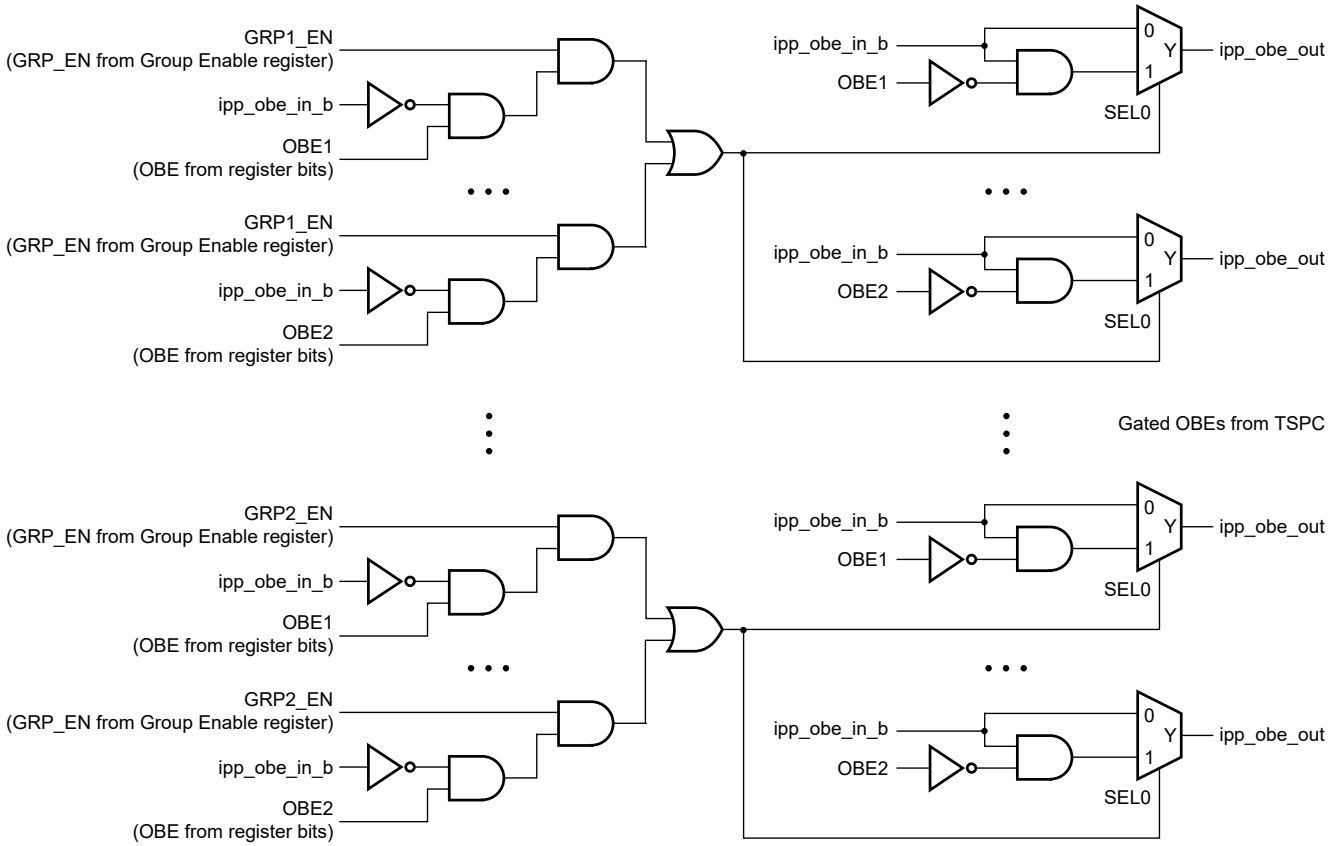

Figure 24. Logic block diagram

10.4 Functional description

TSPC contains these types of registers:

- Group enable: Each field of this register enables the respective group's OBE register—that is, if any OBE within a group transitions from high to low, it enables that group of OBEs for simultaneous transition from high to low. For example, GRP1_EN is the enable field for group 1 OBE registers. The number of fields in this register is equal to the number of groups.
- Group *n* OBE register *n*: The number of registers for a particular group *n* depends on the number of grouped OBEs in the respective group. For example, if the number of OBEs in group 1 is 36, then two registers of 32 fields each exist. Each field of this register represents an OBE pad. If you write 1 to the field, it indicates the OBE's participation in the grouping. If one of

the pad's OBEs transitions from high to low, all the participating OBEs transition from high to low. The remaining OBEs that are not participating in the grouping are not affected.

The register programming sequence is as follows:

1. Reset all the registers.
2. Write 1 to the GRP*n*_OBE*x*[OBE*n*] of the OBEs that participate in grouping.
3. Program the corresponding group enable field participating in grouping in Group Enable (GRP_EN).

You must write 0 to the corresponding GRP_EN field when you configure the group *n* OBE fields. You must write 1 to the OBE*n* field in Group OBE (GRP1_OBE1 - GRP2_OBE1) and then write 1 to the corresponding GRP_EN field in Group Enable (GRP_EN).

11.2 Introduction

This section provides information on the layout, configuration, and programming of the crossbar switch.

The crossbar switch connects bus masters and bus slaves using a crossbar switch structure. This structure allows all bus masters to access different bus slaves simultaneously, while providing arbitration among the bus masters when they access the same slave. A variety of bus arbitration methods and attributes may be programmed on a slave-by-slave basis.

11.2.1 Features

- Symmetric crossbar bus switch implementation
  - Allows concurrent accesses from different masters to different slaves

— Slave arbitration attributes configured on a slave-by-slave basis

- Up to single-clock 64-bit transfer
- Support for burst transfers of up to 64 bits of data
- Support for low-power park mode
- Master high-priority elevation
- 64-bit AHB crossbar bus switch compatible with ARM's AMBA Specification v2.0

11.3 Functional description

Information about general operation and arbitration is provided in this section.

11.3.1 General operation

When a master accesses the crossbar switch, the access is immediately taken. If the targeted slave port of the access is available, then the access is immediately presented on the slave port. Single-clock or zero-wait-state accesses are possible through the crossbar. If the targeted slave port of the access is busy or parked on a different master port, the requesting master sees wait states inserted until the targeted slave port can service the master's request. The latency in servicing the request depends on each master's priority level and the responding slave's access time.

Because the crossbar switch appears to be just another slave to the master device, the master device has no knowledge of whether it actually owns the slave port it is targeting. The master waits while it does not have control of the slave port it is targeting.

After the master acquires control of the slave port, it controls the port until it relinquishes the port by running an IDLE cycle or by targeting a different slave port for its next access.

The master can also lose control of the slave port if another higher-priority master makes a request to the slave port. However, if the master is running a fixed-length burst transfer, it retains control of the slave port until that transfer completes.

The crossbar terminates all master IDLE transfers, as opposed to allowing the termination to come from one of the slave buses. Additionally, when no master is requesting access to a slave port, the crossbar drives IDLE transfers onto the slave bus, even though a default master may be granted access to the slave port.

When a slave bus is being idled by the crossbar, it can park the slave port on the master port indicated by CRS*n*[PARK]. This is done to save the initial clock of arbitration delay that otherwise would be seen if the same master had to arbitrate to gain control of the slave port. The slave port can also be put into low-power park mode to save power, by using CRS*n*[PCTL].

11.3.2 Register coherency

The operation of the crossbar is affected as soon as a register is written. The values of the registers do not track with slave-port-related master accesses, but instead track only with slave accesses.

11.3.3 Arbitration

The crossbar switch supports two arbitration algorithms:

- Fixed priority
- Round-robin

The arbitration scheme is independently programmable for each slave port.

11.3.3.1 Fixed-priority operation

When operating in fixed-priority mode, each master is assigned a unique priority level in the priority registers (PRS*n*). If two masters request access to the same slave port, the master with the highest priority in the selected priority register gains control over the slave port.

NOTE

In this arbitration mode, a higher-priority master can monopolize a slave port, preventing accesses from any lower-priority master to the port.

When a master makes a request to a slave port, the slave port checks whether the new requesting master's priority level is higher than that of the master that currently has control over the slave port, unless the slave port is in a parked state. The slave port performs an arbitration check at every clock edge to ensure that the master, if any, has control of the slave port.

The following table describes possible scenarios based on the requesting master port.

Table 38. Methods of how the crossbar switch grants control of a slave port to a master

When	Then the crossbar switch grants control to the requesting master
Both of the following are true: • The current master is not running a transfer. • The new requesting master's priority level is higher than that of the current master.	At the next clock edge
Both of the following are true: • The current master is running a fixed length burst transfer or a locked transfer. • The requesting master's priority level is higher than that of the current master.	At the end of the burst transfer or locked transfer
The requesting master's priority level is lower than the current master.	At the conclusion of one of the following cycles: • An IDLE cycle • A non-IDLE cycle to a location other than the current slave port

11.3.3.2 Round-robin priority operation

When operating in round-robin mode, each master is assigned a relative priority based on the master port number. This relative priority is compared to the master port number (ID) of the last master to perform a transfer on the slave bus. The highest priority requesting master owns the slave bus at the next transfer boundary, accounting for locked and fixed-length burst transfers. Priority is based on how far ahead the ID of the requesting master is to the ID of the last master.

After a master is granted access to a slave port, a master may perform as many transfers as desired to that port until another master makes a request to the same slave port. The next master in line is granted access to the slave port at the next transfer boundary, or possibly on the next clock cycle, if the current master has no pending access request.

As an example of arbitration in round-robin mode, assume that the crossbar is implemented with master ports 0, 1, 4, and 5. If the last master of the slave port was master 1, and masters 0, 4, and 5 make simultaneous requests, they are serviced in this order: 4,5, and then 0.

Parking may continue to be used in a round-robin mode, but does not affect the round-robin pointer unless the parked master performs a transfer. Handoff occurs to the next master in line after one cycle of arbitration. If the slave port is put into low-power park mode, the round-robin pointer is reset to point at master port 0, giving it the highest priority.

11.3.3.3 Priority assignment

Each master port must be assigned a unique 3-bit priority level. If an attempt is made to program multiple master ports with the same priority level within the priority registers (PRS*n*), the crossbar switch responds with a bus error and the registers are not updated.

11.4 Initialization/application information

No initialization is required for the crossbar switch.

Hardware reset ensures that all the register bits used by the crossbar switch are properly initialized to a valid state. However, the following settings and priorities may be programmed to achieve the maximum system performance:

- During the configuration of the crossbar switch, all other masters must be idle.
- To prevent reconfiguration of the crossbar switch, write 1 to CRS*n*[RO].

11.5 Memory map and register definition

Each slave port of the crossbar switch contains configuration registers. Read- and write-transfers require two bus clock cycles. The registers can be read from and written to only in supervisor mode. Additionally, these registers can be read from or written to only by 32-bit accesses.

A bus error response is returned if an unimplemented location is accessed within the crossbar switch.

The CRS*n* and PRS*n* registers can be programmed as read-only to prevent changes to their configuration. After being read-only protected, future writes to them terminate with a data storage error.

NOTE

This section shows the registers for all eight master and slave ports. If a master or slave is not used on this particular chip, then unexpected results occur when writing to its registers. See the chip configuration details for the exact master and slave assignments for your chip.

All references to the crossbar switch registers are based on the physical port connections.

PRS3	300h
PRS4	400h
PRS5	500h
PRS6	600h

Function

The priority slave registers(PRS*n*) set the priority of each master port on a per slave port basis and reside in each slave port. The priority register can be accessed only with 32-bit accesses. After the CRS*n*[RO] bit is set, the PRS*n* register can only be read; attempts to write to it have no effect on PRS*n* and result in a bus-error response to the master initiating the write.

Two available masters must not be programmed with the same priority level. Attempts to program two or more masters with the same priority level result in a bus-error response and the PRS*n* is not updated.

NOTE

Valid values for the M*n* priority fields depend on which masters are available on the chip. This information can be found in the chip-specific information for the crossbar.

- If the chip contains fewer than three masters, only one bit is valid.
- If the chip contains fewer than five masters, only two bits are valid.
- If five or more masters are present, all three bits of the priority field are used.

11.5.1.3 Control Register (CRS0 - CRS6)

Offset

Register	Offset
CRS0	10h
CRS1	110h
CRS2	210h
CRS3	310h
CRS4	410h
CRS5	510h
CRS6	610h

Function

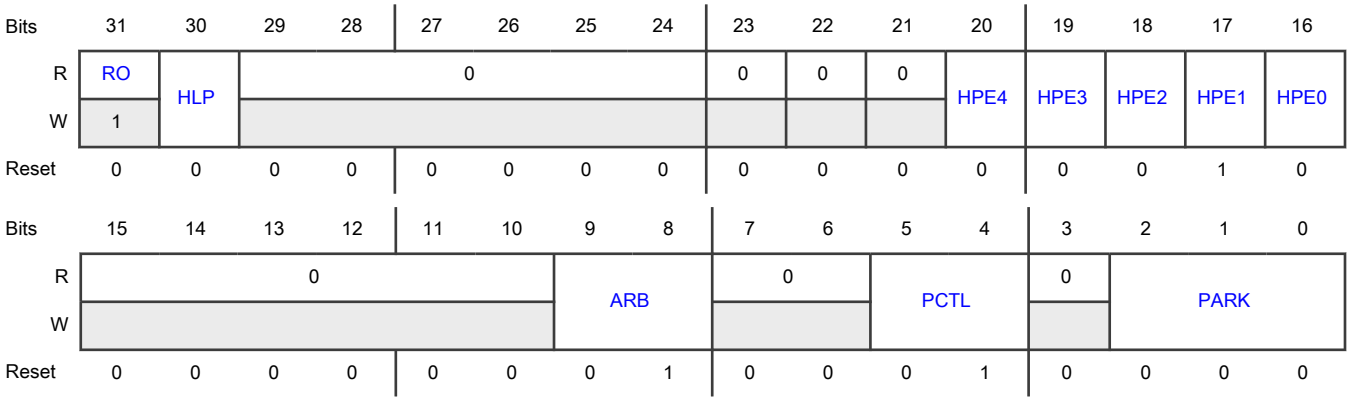
These registers control several features of each slave port and must be accessed using 32-bit accesses. After CRS*n*[RO] is set, the PRS*n* can only be read; attempts to write to it have no effect and result in an error response.

NOTE

See the chip-specific crossbar information for the reset value of this register.

Not all HPE *n* fields may be active. See the chip-specific crossbar information for which masters support master high-priority elevation. Setting a field corresponding to a master that does not support master high-priority elevation has no effect.

Diagram



Fields

Field	Function
31 RO	Read Only Forces the PRS*n* and CRS*n* registers to be read-only. After being set, only a hardware reset clears this field. 0b - The CRS*n* and PRS*n* registers are writeable 1b - The CRS*n* and PRS*n* registers are read-only and cannot be written (attempted writes have no effect on the registers and result in a bus error response).
30 HLP	Halt Low Priority This field sets the initial arbitration priority for low power-mode requests . Setting this bit will not affect the ,request for low power-mode from attaining highest priority after it has control of the slave ports. 0b - The low-power mode request has the highest priority for arbitration on this slave port. 1b - The low-power mode request has the lowest initial priority for arbitration on this slave port.

Chapter 12
Peripheral Bridge (AIPS_Lite)

12.1 Chip-specific AIPS_Lite information

12.1.1 AIPS_Lite instances

The following table summarizes AIPS_Lite instances on MWCT2xxxS product series to support simultaneous data transfers to different peripherals. See the memory map file attached to this document to find information related to these peripherals that are associated with AIPS_Lite instances.

Table 39. AIPS_Lite instances

Instance	MWCT2D17S, MWCT2D16S	MWCT2016S, MWCT2015S
AIPS_0	Yes	Yes
AIPS_1	Yes	Yes
AIPS_2	Yes	No

12.2 Introduction

AIPS_Lite converts the crossbar switch interface to an interface that can access most of the slave peripherals on this chip.

This peripheral bridge occupies 64 MB of the address space, which is divided into peripheral slots of 16 KB each. All the peripherals may not be used. See the memory map chapter for details on slot assignments. The bridge includes separate clock enable inputs for each of the slots to accommodate slower peripherals.

12.2.1 Features

Following are the key features of the peripheral bridge:

- Supports peripheral slots with 8-, 16-, and 32-bit datapath width
- Supports a pair of 32-bit transactions for selected 64-bit memory accesses

12.2.2 General operation

The slave devices connected to the peripheral bridge are modules that contain a programming model of control and status registers. The system masters read and write these registers through the peripheral bridge.

The register maps of the peripherals are located on 16 KB boundaries. Each peripheral is allocated one or more 16-KB block(s) of the memory map.

12.3 Functional description

The peripheral bridge functions as a bus protocol translator between the crossbar switch and the slave peripheral bus. Support is provided for generating a pair of 32-bit slave accesses when performing certain 64-bit peripheral accesses.

The peripheral bridge manages all transactions for the attached slave devices and generates select signals for modules on the peripheral bus by decoding accesses within the attached address space.

12.3.1 Access support

All combinations of access size and peripheral data port width are supported. An access that is larger than the target peripheral's data width is decomposed to multiple, smaller accesses. Bus decomposition is terminated by a transfer error caused by an access to an empty register area.

12.4 Memory map and register definition

The AIPS module(s) on this chip do(es) not contain any user-programmable registers.

12.5 Glossary

ID	Master port number

Chapter 13
Direct Memory Access Multiplexer (DMAMUX)

13.1 Chip-specific DMAMUX information

13.1.1 DMAMUX instances

This chip has two instances of DMAMUX: DMAMUX_0 and DMAMUX_1. See the DMAMUX map file attached to this document to find information related to the slot number for each DMA trigger source.

NOTE

- For MWCT2014S, MWCT2015S, and MWCT2016S: DMAMUX_0 channels 0-5 and DMAMUX_1 channels 0-5 are mapped to eDMA Transfer Control Descriptor(TCD) 0-5 and eDMA Transfer Control Descriptor(TCD) 6-11, respectively. Programming of DMAMUX_0 channels 6-15 and DMAMUX_1 channels 6-15 is not therefore expected however if programmed then any access will terminate with either error response for channels 8-15 or without error response for channels 6-7.
- For remaining MWCT2xxxS devices: DMAMUX_0 channel 0-15 and DMAMUX_1 channel 0-15 are mapped to eDMA Transfer Control Descriptor(TCD) 0-15 and eDMA Transfer Control Descriptor(TCD) 16-31, respectively.

13.1.2 Periodic DMA triggering

PIT generates periodic trigger events to DMAMUX as shown in this table.

Table 40. PIT channel assignment for periodic DMA triggering through DMAMUX

DMAMUX0/1 ports	PIT channel
pit_dma_trigger[0]	PIT0 channel 0
pit_dma_trigger[1]	PIT0 channel 1
pit_dma_trigger[2]	PIT0 channel 2
pit_dma_trigger[3]	PIT0 channel 3

13.2 Introduction

13.2.1 Overview

The Direct Memory Access Multiplexer (DMAMUX) routes DMA sources, called slots, to any of the 16 DMA channels. See the chip-specific information to know the detailed source numbers. This process is illustrated in the following figure.

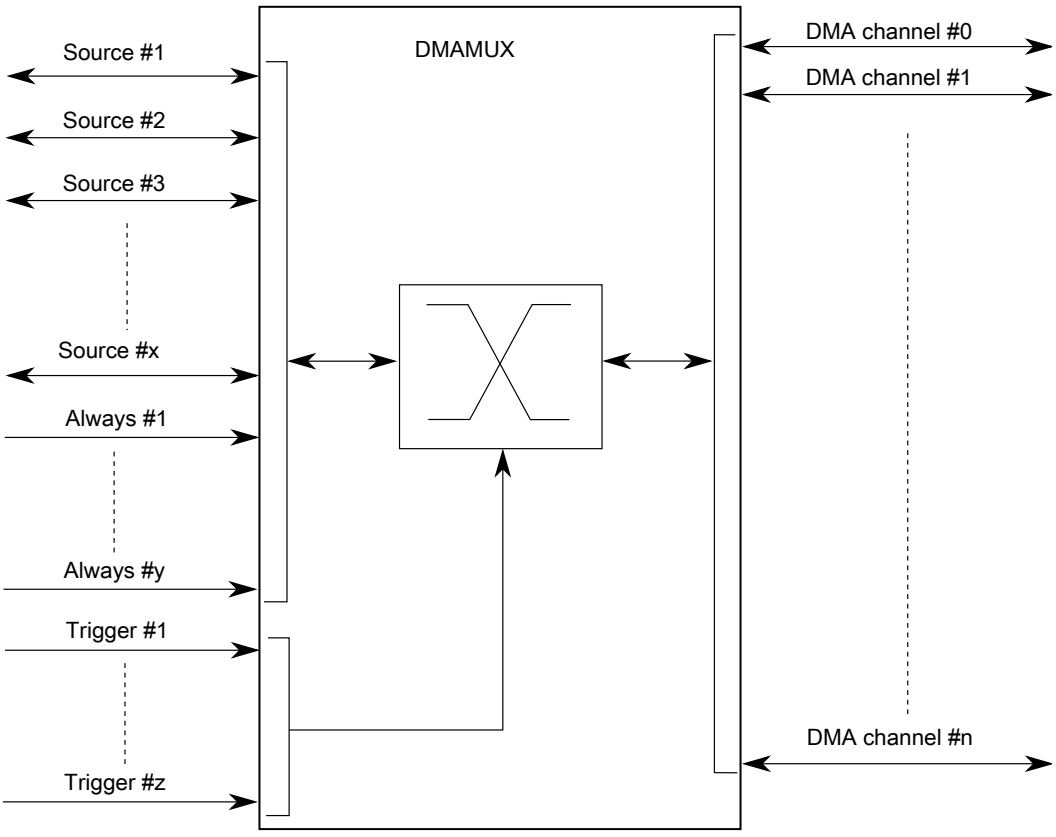

Figure 25. DMAMUX block diagram

13.2.2 Features

Following are the features of DMAMUX module.

- Up to 61 peripheral slots and up to 2 always-on slots can be routed to 16 channels.
- 16 independently selectable DMA channel routers.
  - The first 4 channels additionally provide a trigger functionality.
- Each channel router can be assigned to one of the possible peripheral DMA slots or to one of the always-on slots.

13.2.3 Modes of operation

The DMAMUX module supports the following operating modes.

- Disabled mode: In this mode, the DMA channel is disabled. Because disabling and enabling of DMA channels is done primarily via the DMA configuration registers, this mode is used mainly as the reset state for a DMA channel in the DMA channel MUX. It may also be used to temporarily suspend a DMA channel while reconfiguration of the system takes place, for example, changing the period of a DMA trigger.
- Normal mode: In this mode, a DMA source is routed directly to the specified DMA channel. The operation of the DMAMUX in this mode is completely transparent to the system.
- Periodic Trigger mode: In this mode, a DMA source may only request a DMA transfer, such as when a transmit buffer becomes empty or a receive buffer becomes full, periodically.

  Configuration of the period is done by an external periodic interrupt timer (PIT). This mode is available only for channels 0–3.

13.3 Functional description

The primary purpose of the DMAMUX is to provide flexibility in the system's use of the available DMA channels. As such, configuration of the DMAMUX is intended to be a static procedure done during execution of the system boot code. However, if the procedure outlined in Enabling and configuring sources is followed, the configuration of the DMAMUX may be changed during the normal operation of the system.

Functionally, the DMAMUX channels may be divided into two classes:

- Channels that implement the normal routing functionality plus periodic triggering capability
- Channels that implement only the normal routing functionality

13.3.1 DMA channels with periodic triggering capability

Besides the normal routing functionality, the first 4 channels of the DMAMUX provide a special periodic triggering capability that can be used to provide an automatic mechanism to transmit bytes, frames, or packets at fixed intervals without the need for processor intervention.

The trigger is generated by an external periodic interrupt timer (PIT); as such, the configuration of the periodic triggering interval is done by configuring the external periodic timer.

NOTE

Because of the dynamic nature of the system (due to DMA channel priorities, bus arbitration, interrupt service routine lengths, etc.), the number of clock cycles between a trigger and the actual DMA transfer cannot be guaranteed.

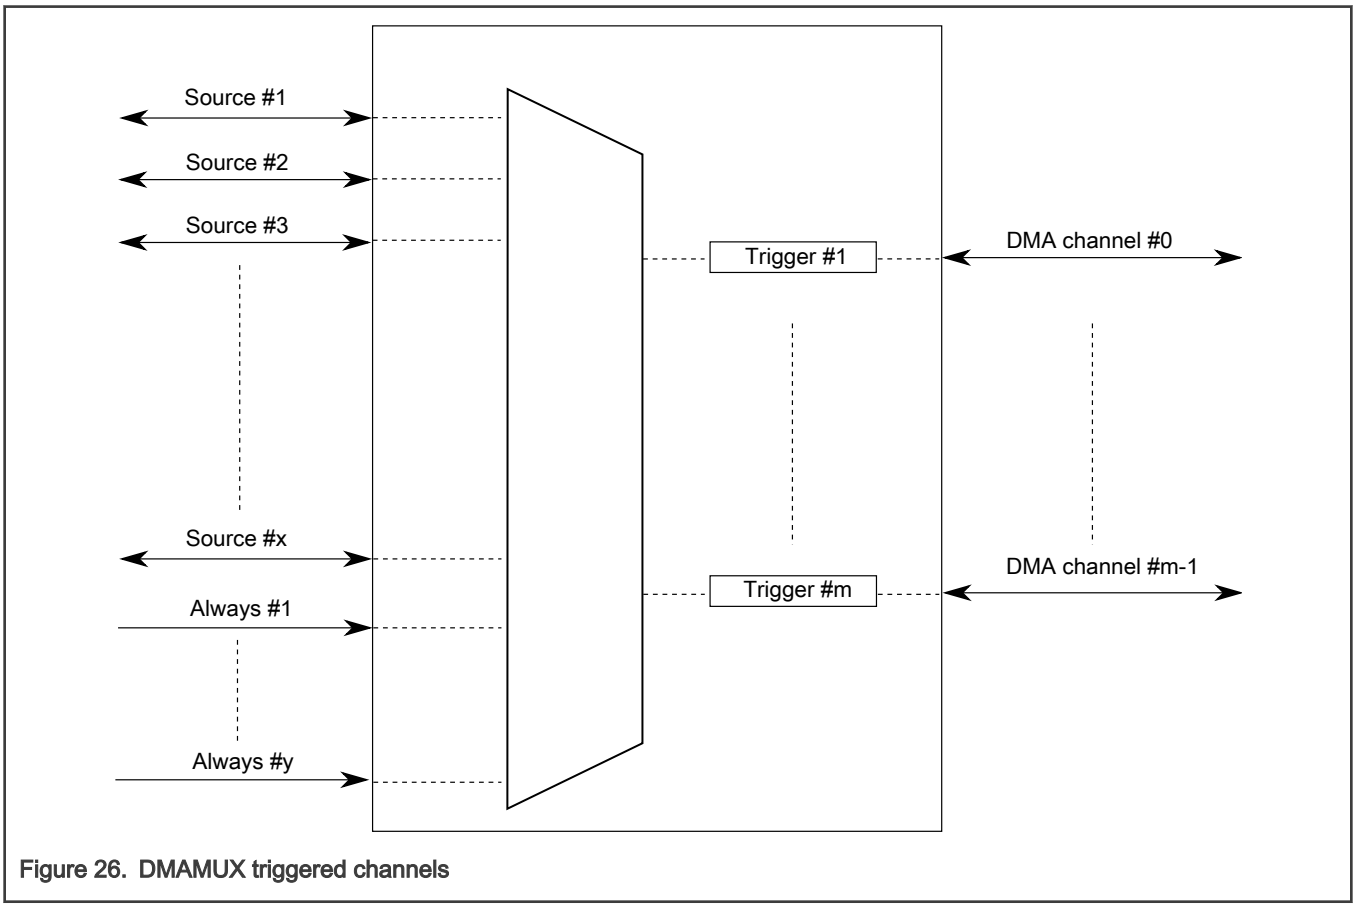

Figure 26. DMAMUX triggered channels

The DMA channel triggering capability allows the system to schedule regular DMA transfers, usually on the transmit side of certain peripherals, without the intervention of the processor. This trigger works by gating the request from the peripheral to the DMA until a trigger event has been seen. This is illustrated in the following figure.

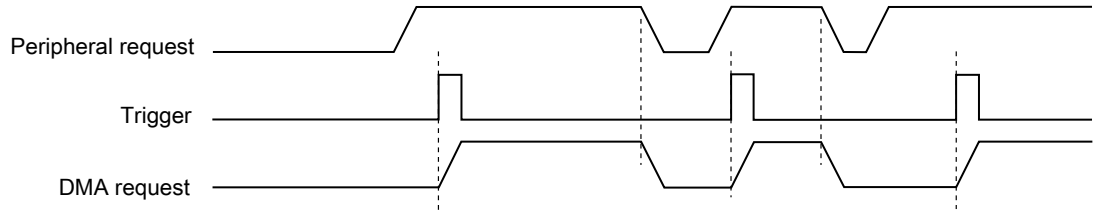

Figure 27. DMAMUX channel triggering: normal operation

After the DMA request has been serviced, the peripheral negates its request, effectively resetting the gating mechanism until the peripheral reasserts its request and the next trigger event is seen. This means that if a trigger is seen, but the peripheral is not requesting a transfer, then that trigger will be ignored. This situation is illustrated in the following figure.

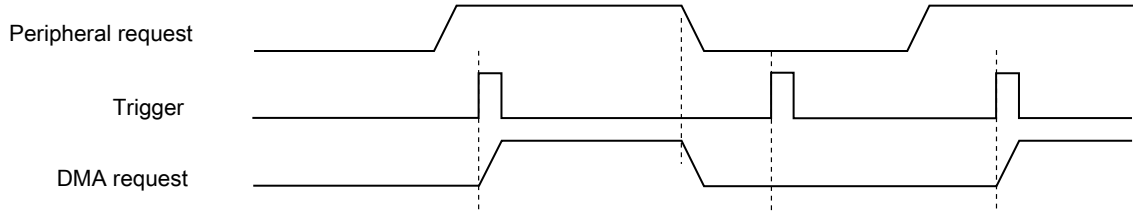

Figure 28. DMAMUX channel triggering: ignored trigger

This triggering capability may be used with any peripheral that supports DMA transfers, and is most useful in the following two situations.

- Periodically polling external devices on a particular bus: As an example, the transmit side of an SPI is assigned to a DMA channel with a trigger, as described above. After it has been set up, the SPI requests DMA transfers, presumably from memory, as long as its transmit buffer is empty. By using a trigger on this channel, the SPI transfers can be automatically performed every 5 µs (as an example). On the receive side of the SPI, the SPI and DMA can be configured to transfer receive data into memory, effectively implementing a method to periodically read data from external devices and transfer the results into memory without processor intervention.
- Using the GPIO ports to drive or sample waveforms: By configuring the DMA to transfer data to one or more GPIO ports, it is possible to create complex waveforms using tabular data stored in on-chip memory. Conversely, using the DMA to periodically transfer data from one or more GPIO ports, it is possible to sample complex waveforms and store the results in tabular form in on-chip memory.

13.3.2 DMA channels with no triggering capability

The other channels of the DMAMUX provide the normal routing functionality as described in Modes of operation.

13.3.3 Always-enabled DMA sources

In addition to the peripherals that can be used as DMA sources, there are 2 additional DMA sources that are always enabled. Unlike the peripheral DMA sources, where the peripheral controls the flow of data during DMA transfers, the sources that are always enabled provide no such "throttling" of the data transfers. These sources are most useful in the following cases:

- Performing DMA transfers to/from GPIO—Moving data from/to one or more GPIO pins, either unthrottled (that is, as fast as possible), or periodically (using the DMA triggering capability).
- Performing DMA transfers from memory to memory: Moving data from memory to memory, typically as fast as possible, sometimes with software activation.
- Performing DMA transfers from memory to the external bus, or vice-versa: Similar to memory to memory transfers, this is typically done as quickly as possible.
- Any DMA transfer that requires software activation: Any DMA transfer that should be explicitly started by software.

In cases where software should initiate the start of a DMA transfer, an always-enabled DMA source can be used to provide maximum flexibility. When activating a DMA channel via software, subsequent executions of the minor loop require that a new start event be sent. This can either be a new software activation, or a transfer request from the DMA channel MUX. The options for doing this are as follows.

- Transfer all data in a single minor loop: By configuring the DMA to transfer all of the data in a single minor loop (that is, major loop counter = 1), no reactivation of the channel is necessary. The disadvantage to this option is the reduced granularity in determining the load that the DMA transfer will impose on the system. For this option, the DMA channel must be disabled in the DMA channel MUX.
- Use explicit software reactivation: In this option, the DMA is configured to transfer the data using both minor and major loops, but the processor is required to reactivate the channel by writing to the DMA registers after every minor loop. For this option, the DMA channel must be disabled in the DMA channel MUX.
- Use an always-enabled DMA source: In this option, the DMA is configured to transfer the data using both minor and major loops, and the DMA channel MUX does the channel reactivation. For this option, the DMA channel should be enabled and pointing to an "always enabled" source. Note that the reactivation of the channel can be continuous (DMA triggering is disabled) or can use the DMA triggering capability. In this manner, it is possible to execute periodic transfers of packets of data from one source to another, without processor intervention.

13.4 Initialization/application information

This section provides instructions for initializing the DMA channel MUX.

13.4.1 Reset

The reset state of each individual bit is shown in Memory map/register definition. In summary, after reset, all channels are disabled and must be explicitly enabled before use.

13.4.2 Enabling and configuring sources

To enable a source with periodic triggering:

1. Determine the DMA channel with which the source will be associated. Note that only the first 4 DMA channels have periodic triggering capability.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] fields of the DMA channel.
3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point.
4. Configure the corresponding timer.
5. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the CHCFG[ENBL] and CHCFG[TRIG] fields are set.

NOTE

The following is an example. See the chip-specific information for the number of this device's DMA channels that have triggering capability.

To configure source #5 transmit for use with DMA channel 1, with periodic triggering capability:

1. Write 0x00 to CHCFG1.
2. Configure channel 1 in the DMA, including enabling the channel.
3. Configure a timer for the desired trigger interval.
4. Write 0xC5 to CHCFG1.

The following code example illustrates steps 1 and 4 above:

```
In File registers.h:
#define DMAMUX_BASE_ADDR     0x40021000/* Example only ! */
/* Following example assumes char is 8-bits */
volatile unsigned char *CHCFG0 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0003);
volatile unsigned char *CHCFG1 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0002);
volatile unsigned char *CHCFG2 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0001);
volatile unsigned char *CHCFG3 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0000);
volatile unsigned char *CHCFG4 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0007);
volatile unsigned char *CHCFG5 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0006);
volatile unsigned char *CHCFG6 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0005);
volatile unsigned char *CHCFG7 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0004);
volatile unsigned char *CHCFG8 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000B);
volatile unsigned char *CHCFG9 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000A);
volatile unsigned char *CHCFG10= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0009);
volatile unsigned char *CHCFG11= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0008);
volatile unsigned char *CHCFG12= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000F);
volatile unsigned char *CHCFG13= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000E);
volatile unsigned char *CHCFG14= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000D);
volatile unsigned char *CHCFG15= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000C);

In File main.c:
#include "registers.h"
:
:
*CHCFG1 = 0x00;                                 /* Clear all the fields of CHCFG1 register */
*CHCFG1 = 0xC5;                                 /* ENBL = 1  DMA Channel is enabled */
                                                /* TRIG = 1  Triggering is enabled */
                                                /* SOURCE = 5  DMA Source 5 is selected */
```

To enable a source, without periodic triggering:

1. Determine the DMA channel with which the source will be associated. Note that only the first 4 DMA channels have periodic triggering capability.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] fields of the DMA channel.
3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point.
4. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that CHCFG[ENBL] is setwhile CHCFG[TRIG] is cleared.

NOTE

The following is an example. See the chip configuration details for the number of this device's DMA channels that have triggering capability.

To configure source #5 transmit for use with DMA channel 1, with no periodic triggering capability:

1. Write 0x00 to CHCFG1.
2. Configure channel 1 in the DMA, including enabling the channel.
3. Write 0x85 to CHCFG1.

The following code example illustrates steps 1 and 3 above:

```
In File registers.h:
#define DMAMUX_BASE_ADDR     0x40021000/* Example only ! */
/* Following example assumes char is 8-bits */
volatile unsigned char *CHCFG0 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0003);
volatile unsigned char *CHCFG1 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0002);
volatile unsigned char *CHCFG2 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0001);
volatile unsigned char *CHCFG3 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0000);
volatile unsigned char *CHCFG4 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0007);
volatile unsigned char *CHCFG5 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0006);
volatile unsigned char *CHCFG6 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0005);
volatile unsigned char *CHCFG7 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0004);
volatile unsigned char *CHCFG8 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000B);
volatile unsigned char *CHCFG9 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000A);
volatile unsigned char *CHCFG10= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0009);
volatile unsigned char *CHCFG11= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0008);
volatile unsigned char *CHCFG12= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000F);
volatile unsigned char *CHCFG13= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000E);
volatile unsigned char *CHCFG14= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000D);
volatile unsigned char *CHCFG15= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000C);

In File main.c:
#include "registers.h"
:
:
*CHCFG1 = 0x00;                                 /* Clear all the fields of CHCFG1 register */
*CHCFG1 = 0x85;                                 /* ENBL = 1  DMA Channel is enabled */
                                                /* TRIG = 0  Triggering is disabled */
                                                /* SOURCE = 5  DMA Source 5 is selected */
```

To disable a source:

A particular DMA source may be disabled by not writing the corresponding source value into any of the CHCFG registers. Additionally, some module-specific configuration may be necessary. See the eDMA chapter for more details.

To switch the source of a DMA channel:

1. Disable the DMA channel in the DMA and reconfigure the channel for the new source.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] bits of the DMA channel.
3. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the CHCFG[ENBL] and CHCFG[TRIG] fields are set.

To switch DMA channel 8 from source #5 transmit to source #7 transmit:

1. In the DMA configuration registers, disable DMA channel 8 and reconfigure it to handle the transfers to peripheral slot 7. This example assumes channel 8 doesn't have triggering capability.
2. Write 0x00 to CHCFG8.
3. Write 0x87 to CHCFG8. (In this example, setting CHCFG[TRIG] would have no effect due to the assumption that channel 8 does not support the periodic triggering functionality.)

The following code example illustrates steps 2 and 3 above:

```
In File registers.h:
#define DMAMUX_BASE_ADDR     0x40021000/* Example only ! */
```

```
/* Following example assumes char is 8-bits */
volatile unsigned char *CHCFG0 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0003);
volatile unsigned char *CHCFG1 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0002);
volatile unsigned char *CHCFG2 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0001);
volatile unsigned char *CHCFG3 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0000);
volatile unsigned char *CHCFG4 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0007);
volatile unsigned char *CHCFG5 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0006);
volatile unsigned char *CHCFG6 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0005);
volatile unsigned char *CHCFG7 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0004);
volatile unsigned char *CHCFG8 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000B);
volatile unsigned char *CHCFG9 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000A);
volatile unsigned char *CHCFG10= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0009);
volatile unsigned char *CHCFG11= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0008);
volatile unsigned char *CHCFG12= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000F);
volatile unsigned char *CHCFG13= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000E);
volatile unsigned char *CHCFG14= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000D);
volatile unsigned char *CHCFG15= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000C);

In File main.c:
#include "registers.h"
:
:
*CHCFG8 = 0x00;                                 /* Clear all the fields of CHCFG1 register */
*CHCFG8 = 0x87;                                 /* ENBL = 1  DMA Channel is enabled */
                                                /* TRIG = 0  Triggering is disabled */
                                                /* SOURCE = 7  DMA Source 7 is selected */
```

13.5 Memory map/register definition

This section provides a detailed description of all memory-mapped registers in the DMAMUX.

13.5.1 DMAMUX register descriptions

13.5.1.1 DMAMUX memory map

DMAMUX_0 base address: 4028_0000h

DMAMUX_1 base address: 4028_4000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Channel Configuration register (CHCFG3)	8	RW	00h
1h	Channel Configuration register (CHCFG2)	8	RW	00h
2h	Channel Configuration register (CHCFG1)	8	RW	00h
3h	Channel Configuration register (CHCFG0)	8	RW	00h
4h	Channel Configuration register (CHCFG7)	8	RW	00h

Table continues on the next page...

Table continued from the previous page...

Offset	Register	Width (In bits)	Access	Reset value
5h	Channel Configuration register (CHCFG6)	8	RW	00h
6h	Channel Configuration register (CHCFG5)	8	RW	00h
7h	Channel Configuration register (CHCFG4)	8	RW	00h

13.5.1.2 Channel Configuration register (CHCFG0 - CHCFG15)

Offset

For n = 0 to 15:

Register	Offset
CHCFGn	0h + (n + 3 - 2 × (n mod 4))

Function

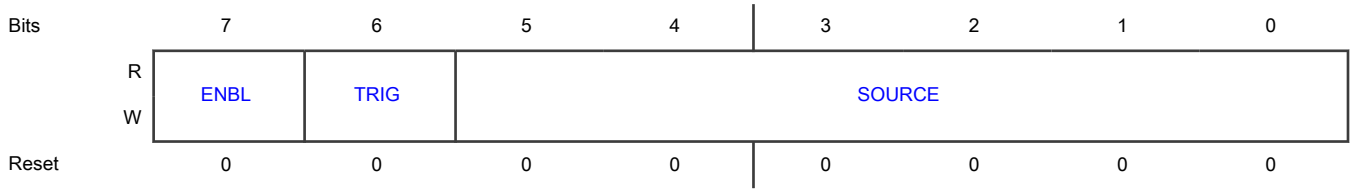
Each of the DMA channels can be independently enabled/disabled and associated with one of the DMA slots (peripheral slots or always-on slots) in the system.

NOTE

Setting multiple CHCFG registers with the same source value will result in unpredictable behavior. This is true, even if a channel is disabled (ENBL==0).

Before changing the trigger or source settings, a DMA channel must be disabled via CHCFGn[ENBL].

Diagram



Fields

Field	Function
7 ENBL	DMA Channel Enable Enables the DMA channel. 0b - DMA channel is disabled. This mode is primarily used during configuration of the DMAMUX. The DMA has separate channel enables/disables, which should be used to disable or reconfigure a DMA channel. 1b - DMA channel is enabled
6 TRIG	DMA Channel Trigger Enable Enables the periodic trigger capability for the triggered DMA channel. 0b - Triggering is disabled. If triggering is disabled and ENBL is set, the DMA Channel will simply route the specified source to the DMA channel. (Normal mode) 1b - Triggering is enabled. If triggering is enabled and ENBL is set, the DMAMUX is in Periodic Trigger mode.
5-0 SOURCE	DMA Channel Source (Slot) Specifies which DMA source, if any, is routed to a particular DMA channel. See the chip-specific DMAMUX information for details about the peripherals and their slot numbers.

Chapter 14
Enhanced Direct Memory Access (eDMA)

14.1 Chip-specific eDMA information

14.1.1 DMA channels

See the following table for number of DMA channels across MWCT2xxxS product series.

Table 41. DMA channels

Chip	No. of DMA channels
MWCT2D17S/MWCT2014S/MWCT2D16S	32
MWCT2015S/MWCT2016S	12

NOTE

TCD_CH[12-31] are not available in MWCT2014S, MWCT2015S and MWCT2016S, so the registers corresponding to these channels are not available. See the memory map file attached to this document for details.

14.2 Introduction

The enhanced direct memory access (eDMA) controller is capable of performing complex data transfers with minimal intervention from a host processor. The hardware microarchitecture includes:

- A DMA engine that performs:
  - Source address and destination address calculations
  - Data-movement operations
- Local memory containing transfer control descriptors for each of the 32 channels

14.2.1 eDMA system block diagram

Figure 29 illustrates the components of the eDMA system, including the eDMA module (engine).

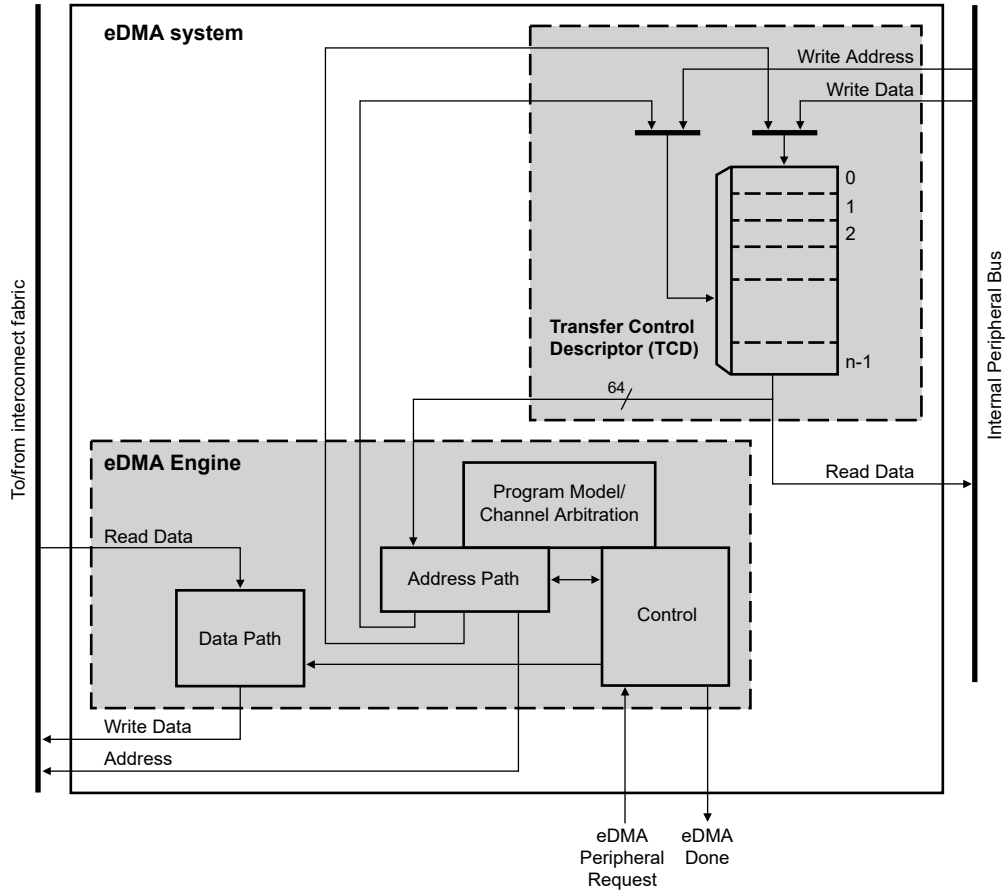


Figure 29. eDMA system block diagram

14.2.2 Block parts

The eDMA module is partitioned into two major modules: the eDMA engine and the transfer control descriptor local memory.

The eDMA engine is further partitioned into four submodules:

Table 42. eDMA engine submodules

Submodule	Function
Address path	This block: • Implements a primary channel and secondary (preempt) channel • Manages all master bus-address calculations All the channels provide the same functionality. This structure allows data transfers associated with one channel to be preempted after the completion of a read/write sequence if a higher priority channel activation is asserted while the primary channel is active. After a channel is activated, it runs until the minor loop is completed, unless preempted by a higher priority channel. This provides a mechanism (enabled by CH*n*_PRI[ECP]) where a large data transfer can be preempted to minimize the time another channel is blocked from execution.

Table continues on the next page...

Table 42. eDMA engine submodules (continued)

Submodule	Function
	When any channel is selected to execute, the contents of its TCD are read from local memory and loaded into the address path channel x registers for a normal start and into channel y registers for a preemption start. After the minor loop completes execution, the address path hardware writes the new values for the TCD*n*_{SADDR, DADDR, CITER} back to local memory. If the major iteration count is exhausted, additional processing is performed, including the final address pointer updates, reloading the TCD*n*_CITER field, and a possible fetch of a new TCD*n* from memory as part of a scatter/gather operation. See Dynamic scatter/gather for more details.
Data path	This block implements the bus master read/write data path. It includes a data buffer and the necessary multiplex logic to support any required data alignment. The internal read data bus is the primary input, and the internal write data bus is the primary output. The address and data path modules directly support the 2-stage pipelined internal bus. The address path module represents the first stage of the bus pipeline (address phase), and the data path module implements the second stage of the pipeline (data phase).
Program model/channel arbitration	This block implements the first section of the eDMA programming model as well as the channel arbitration logic. The programming model registers are connected to the internal peripheral bus. The eDMA peripheral request inputs and interrupt request outputs are also connected to this block (via control logic).
Control	This block provides all the control functions for the eDMA engine. For data transfers where the source and destination sizes are equal, the eDMA engine performs a series of source read/destination write operations until the number of bytes specified in the minor loop byte count has been moved from the source to the destination. For descriptors where the sizes are not equal, multiple accesses of the smaller size data are required for each reference of the larger size. As an example, if the source size references 16-bit data and the destination is 32-bit data, the eDMA performs two reads, then one 32-bit write.

The transfer control descriptor local memory is further partitioned into:

Table 43. Transfer control descriptor memory

Submodule	Description
Memory controller	This logic implements the required dual-ported controller, and manages accesses from the eDMA engine as well as references from the internal peripheral bus. As noted earlier, in simultaneous accesses, the eDMA engine is given priority and the peripheral transaction is stalled.
Memory array	TCD storage for each channel's transfer profile.

14.2.3 Features

The eDMA is a highly programmable data-transfer engine optimized to minimize any required intervention from the host processor. It is intended for use in applications where the data size to be transferred is statically known and not defined within the transferred data itself. The eDMA module features:

- All data movement via dual-address transfers: read from source, write to destination
  - Programmable source and destination addresses and transfer size
  - Support for complex address calculations
- 32-channel implementation that performs complex data transfers with minimal intervention from a host processor
  - Internal data buffer, used as temporary storage for all transfers

  - Connections to the crossbar switch for bus mastering the data movement
- TCD organized to support two-deep, nested transfer operations
  - 32-byte TCD stored in local memory for each channel
  - An inner data transfer loop defined by a minor byte transfer count
  - An outer data transfer loop defined by a major iteration count
- Channel activation via one of three methods:
  - Explicit software initiation
  - Initiation via a channel-to-channel linking mechanism for continuous transfers
  - Peripheral-paced hardware requests, one per channel
- Fixed-priority and round-robin channel arbitration
- Channel completion reported via programmable interrupt requests
  - One interrupt per channel, which can be asserted at completion of major iteration count
  - Programmable error terminations per channel that are logically summed together to form one error interrupt to the interrupt controller
- Programmable support for scatter/gather DMA processing
- Support for complex data structures

In the discussion of this module, *n* is used to reference the channel number.

14.3 Modes of operation

The eDMA operates in the following modes:

Table 44. Modes of operation

Mode	Description
Normal	In Normal mode, eDMA transfers data between a source and a destination. The source and destination can be a memory block or an I/O block capable of operation with eDMA. A service request initiates a transfer of a specific number of bytes (NBYTES) as specified in the TCD. The minor loop is the sequence of read-write operations that transfers these NBYTES per service request. Each service request executes one iteration of the major loop, which transfers NBYTES of data.
Debug	eDMA operation is configurable in Debug mode via the control register: • If CSR[EDBG] is cleared to 0, eDMA continues to operate. • If CSR[EDBG] is set to 1, eDMA stops transferring data. If Debug mode is entered when a channel is active, eDMA continues operation until the channel retires.

14.4 Functional description

The operation of eDMA is described in the following subsections.

14.4.1 eDMA basic data flow

The basic flow of a data transfer can be partitioned into three segments.

As shown in the following diagram, the first segment involves the channel activation:

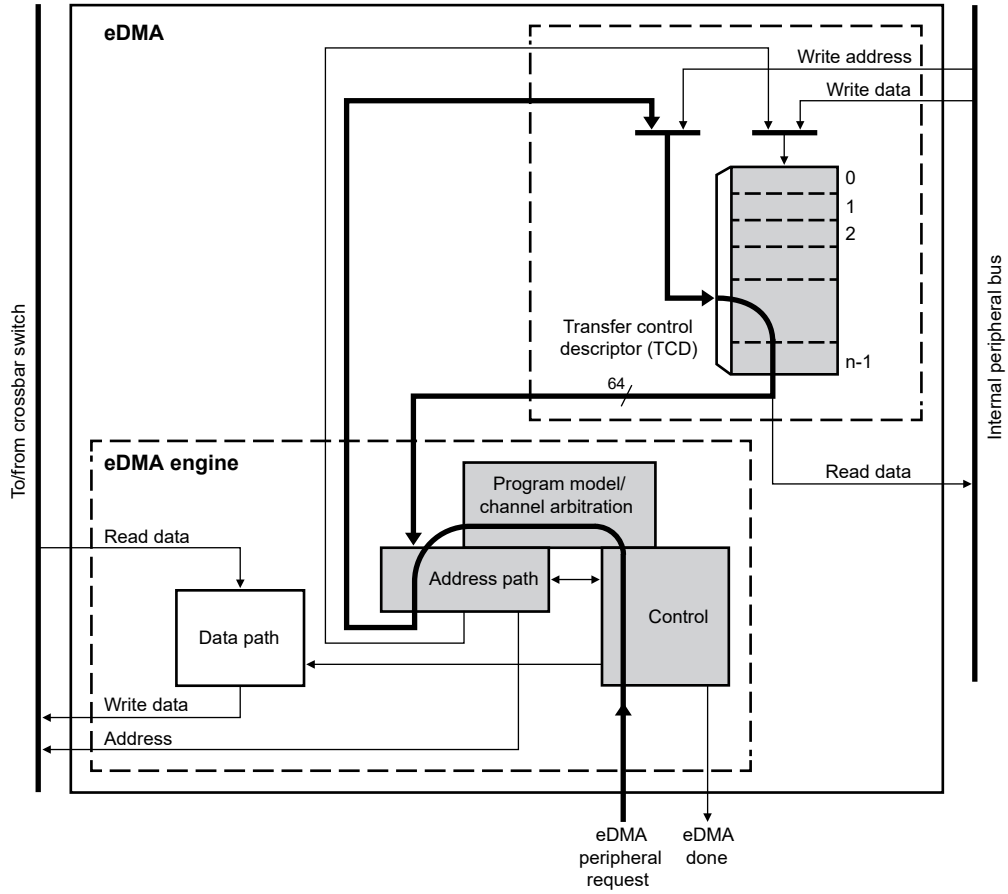

Figure 30. eDMA operation, part 1

This example uses the assertion of the eDMA peripheral request signal to request service for channel *n*. Channel activation via software and the TCD*n*_CSR[START] field follows the same basic flow as peripheral requests. The eDMA request input signal is registered internally and then routed through the eDMA engine: first through the control module, then into the program model and channel arbitration.

In the next cycle, the channel arbitration begins using fixed-priority plus the optional round-robin algorithm. After arbitration is complete, the activated channel number is sent through the address path and converted into the required address to access the local memory for TCD*n*. Next, the TCD memory is accessed and the required descriptor is read from the local memory and then loaded into the eDMA engine address path's primary or secondary channel execution registers. The TCD memory is 64 bits wide to minimize the time needed to fetch the activated channel descriptor and load it into the address path registers.

The following diagram illustrates the second part of the basic data flow:

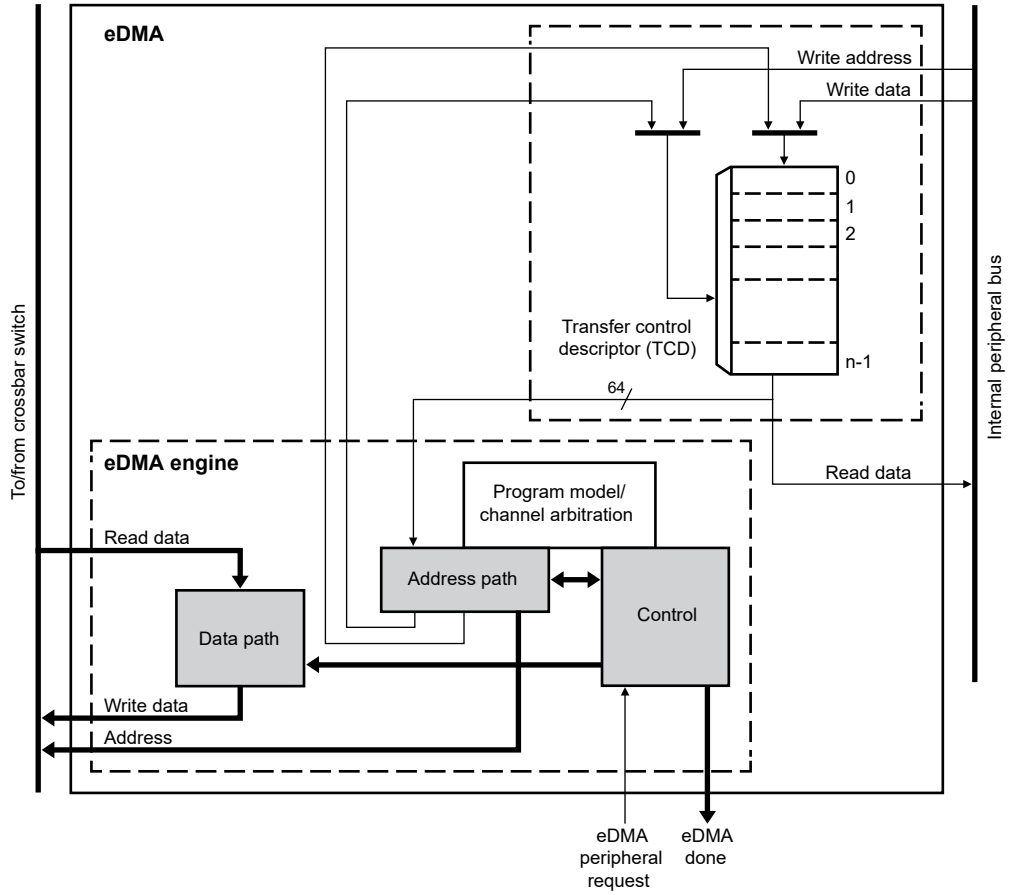

Figure 31. eDMA operation, part 2

The modules associated with the data transfer (address path, data path, and control) go through the required sequence of source reads and destination writes to perform the actual data movement. The source reads are initiated, and the fetched data is temporarily stored in the data path block until it is gated onto the internal bus during the destination write. This source read/destination write processing continues until the byte count, NBYTES, has been transferred.

After NBYTES of data has been moved, the final phase of the basic data flow is performed. In this segment, the address path logic performs the required updates to certain fields in the appropriate TCD (for example, SADDR, DADDR, CITER). If the major iteration count is exhausted, additional operations are performed. These include the final address adjustments and reloading of the BITER field into the CITER field. Assertion of an optional interrupt request also occurs at this time, as does a possible fetch of a new TCD from memory using the scatter/gather address pointer included in the descriptor (if scatter/gather is enabled). The updates to the TCD memory and the assertion of an interrupt request are shown in the following diagram.

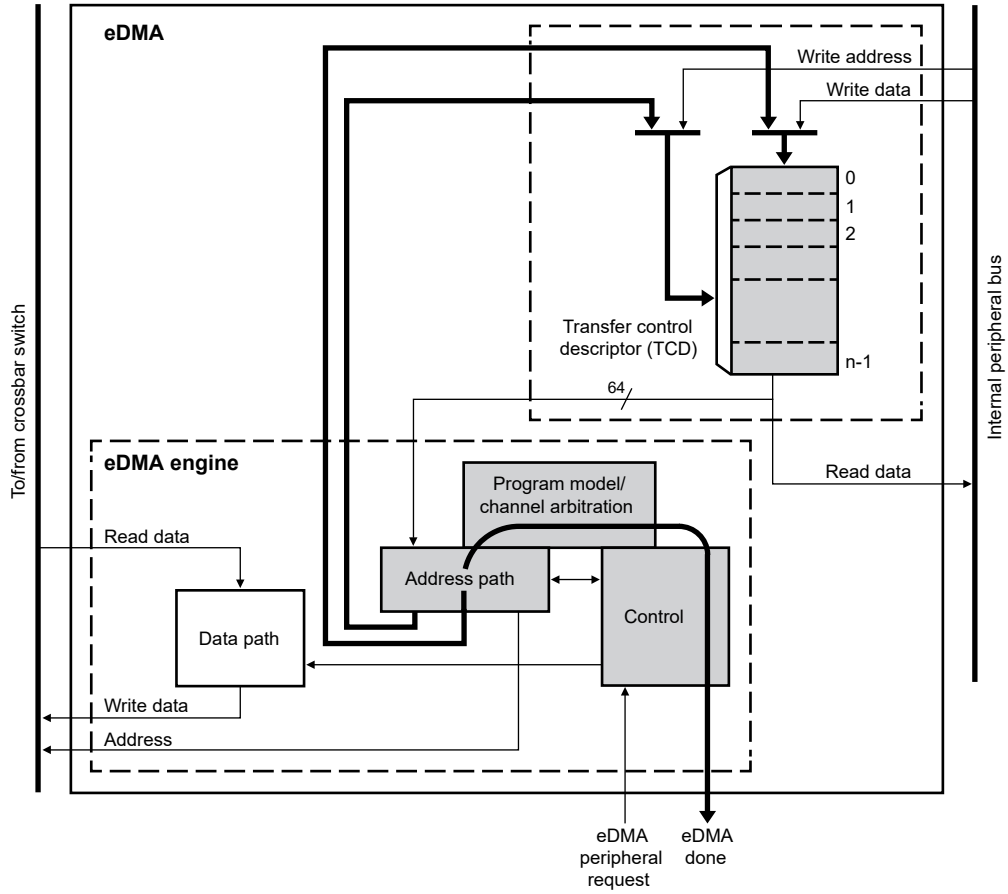

Figure 32. eDMA operation, part 3

14.4.2 Fault reporting and handling

Channel errors are reported in the Error Status register (CHn_CSR and TCDn_CSR) and can be caused by any of the following:

- A configuration error, which is an illegal setting in the transfer control descriptor
- An active channel canceled via a "cancel transfer with error" hardware or software request
- A TCD memory error
- An error termination to a bus master read or write cycle

A configuration error is reported when an inconsistent state is represented by one of these factors:

- Starting source or destination address
- Source or destination offsets
- Minor loop byte count
- Transfer size

Each of these possible causes is detailed below:

- The addresses and offsets must be aligned on zero-modulo-transfer-sized boundaries.
- The minor loop byte count must be a multiple of the source and destination transfer sizes.
- All source reads and destination writes must be configured to the natural boundary of the programmed transfer size.

NOTE

To aid in debugging, set the Halt After Error field in the DMA's Control Status register, CSR[HAE]. Upon any error condition, the DMA is halted after the error is recorded. The DMA remains halted and does not process any channel service requests. After the error is fixed, the DMA may be enabled again by clearing the Halt field, CSR[HALT].

- If a scatter/gather operation is enabled upon channel completion, a configuration error is reported if the scatter/gather address (DLAST_SGA) is not aligned on a 32-byte boundary.
- If minor loop channel linking is enabled upon channel completion, a configuration error is reported when the link is attempted if the TCDn_CITER[ELINK] field does not equal the TCDn_BITER[ELINK] field.

If enabled, all configuration error conditions, except the scatter/gather and minor-loop link errors, are reported as the channel activates and asserts an error interrupt request. A scatter/gather configuration error is reported when the scatter/gather operation begins at major loop completion if properly enabled. A minor loop channel link configuration error is reported when the link operation is serviced at minor loop completion.

The occurrence of any error causes the eDMA engine to stop normal processing of the active channel immediately (it goes to its error processing states and the transaction to the system bus still has pipeline effect), and the appropriate channel field in the eDMA error register is set to 1. At the same time, the details of the error condition are loaded into the Error Status register (CHn_CSR and TCDn_CSR). The major loop complete indicators, setting the transfer control descriptor DONE flag, and the possible assertion of an interrupt request are not affected when an error is detected.

After the error status has been updated, the eDMA engine continues operating by servicing the next appropriate channel. A channel that experiences an error condition is not automatically disabled. If a channel is terminated by an error and then issues another service request before the error is fixed, that channel executes and terminates with the same error condition.

The error status fields are read-only. These error indicators are sticky and cannot be cleared. They show the last recorded error until the DMA is reset. The valid field (VLD) is used to determine if a new error condition exists. This field is the logical OR of each channel's error interrupt field (ERR).

After the software has resolved any errors and cleared all of the error interrupt fields, the valid field is cleared to 0 but the cause of the last error is still indicated.

14.4.3 Channel preemption

Channel preemption is enabled on a per-channel basis by setting the CHn_PRI[ECP] field. Channel preemption allows the executing channel's data transfers to temporarily suspend in favor of starting a higher-priority channel. After the preempting channel has completed all of its minor loop data transfers, the preempted channel is restored and resumes execution.

After the restored channel completes one read/write sequence, it is again eligible for preemption. If any higher priority channel is requesting service, the restored channel is suspended, and the higher-priority channel is serviced. Nested preemption, that is, attempting to preempt a preempting channel, is not supported. After a preempting channel begins execution, it cannot be preempted.

A channel's ability to preempt another channel can be disabled by setting CHn_PRI[DPA] to 1. When a channel's preempt ability is disabled, that channel cannot suspend a lower-priority channel's data transfer, regardless of the lower-priority channel's ECP setting. This allows for a pool of low-priority, large-data-moving channels to be defined.

You can configure these low-priority channels to not preempt each other, thus preventing a low-priority channel from consuming the preempt slot normally available to a true high-priority channel. When you enable round-robin channel arbitration mode (CSR[ERCA] is set to 1), any channel with a priority level equal to 0 (CHn_PRI[APL] = 0) has preemption disabled and cannot preempt another channel.

14.5 Initialization/application information

The following sections discuss initialization of the eDMA and programming considerations.

14.5.1 eDMA initialization

To initialize the eDMA:

1. Write to the CSR if a configuration other than the default is wanted.
2. Write the channel priority levels to the CHn_PRI registers and group priority levels to the CHn_GRPRI registers if a configuration other than the default is wanted.
3. Enable error interrupts in the CHn_CSR[EEI] registers if they are wanted.
4. Write the 32-byte TCD for each channel that may request service.
5. Enable any hardware service requests via the CHn_CSR[ERQ] registers.
6. Request channel service via either:
   - Software: setting TCDn_CSR[START]
   - Hardware: slave device asserting its eDMA peripheral request signal

After any channel requests service, a channel is selected for execution based on the arbitration and priority levels written into the programmer's model. The eDMA engine reads the entire TCD, including the TCD control and status fields, as shown in Table 45, for the selected channel into its internal address path module.

As the TCD is read, the first transfer is initiated on the internal bus, unless a configuration error is detected. Transfers from the source, defined by TCDn_SADDR, to the destination, defined by TCD_DADDR, continue until the number of bytes specified by TCDn_NBYTES are transferred.

When the transfer is complete, the eDMA engine's local TCDn_SADDR, TCDn_DADDR, and TCDn_CITER are written back to the main TCD memory and any minor loop channel linking is performed, if enabled. If the major loop is exhausted, then eDMA executes further post-processing, such as interrupts, major loop channel linking, and scatter/gather operations, if enabled.

Table 45. TCD control and status (TCDn_CSR) fields

TCDn_CSR field name	Description
START	Control field to start the channel explicitly when using a software-initiated DMA service (automatically cleared by hardware)
EEOP	Control field to enable end-of-packet processing
ESDA	Control field to enable storing of the destination address to system memory after the major loop completes
DREQ	Control field to disable hardware-initiated DMA service requests after major loop completion
BWC	Control field for throttling the bandwidth control of a channel
ESG	Control field to enable the scatter-gather feature
INTHALF	Control field to enable interrupt when major loop is half-complete
INTMAJOR	Control field to enable interrupt when major loop completes

Table 46. Channel control and status (CHn_CSR) fields

CHn_CSR field name	Description
ACTIVE	Status field indicating the channel is currently in execution
DONE	Status field indicating major loop completion (cleared by software when a channel begins execution)
EEI	Control field to enable error interrupts

Table continues on the next page...

Table 46. Channel control and status (CHn_CSR) fields (continued)

CHn_CSR field name	Description
EARQ	Control field to enable external, asynchronous wakeup event in conjunction with the ERQ field
ERQ	Control field to enable hardware service requests

The following figure shows how each DMA request initiates one minor-loop transfer, or iteration, without CPU intervention. DMA arbitration can occur after each minor loop, and one level of minor loop DMA preemption is allowed. The number of minor loops in a major loop is specified by the beginning iteration count (BITER).

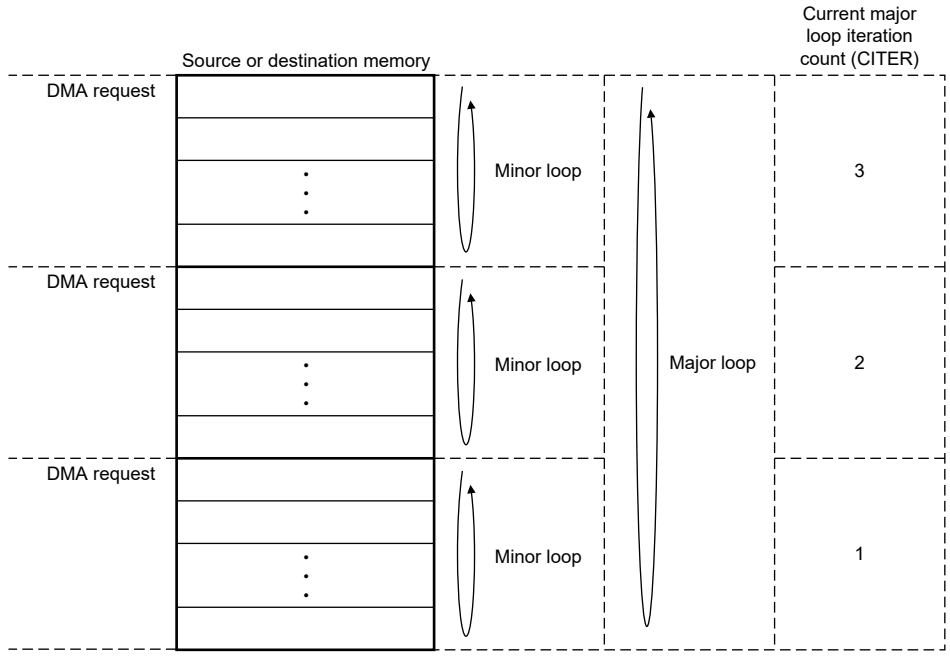

Figure 33. Example of multiple loop iterations

The following figure lists the memory array terms and how the TCD settings are related.

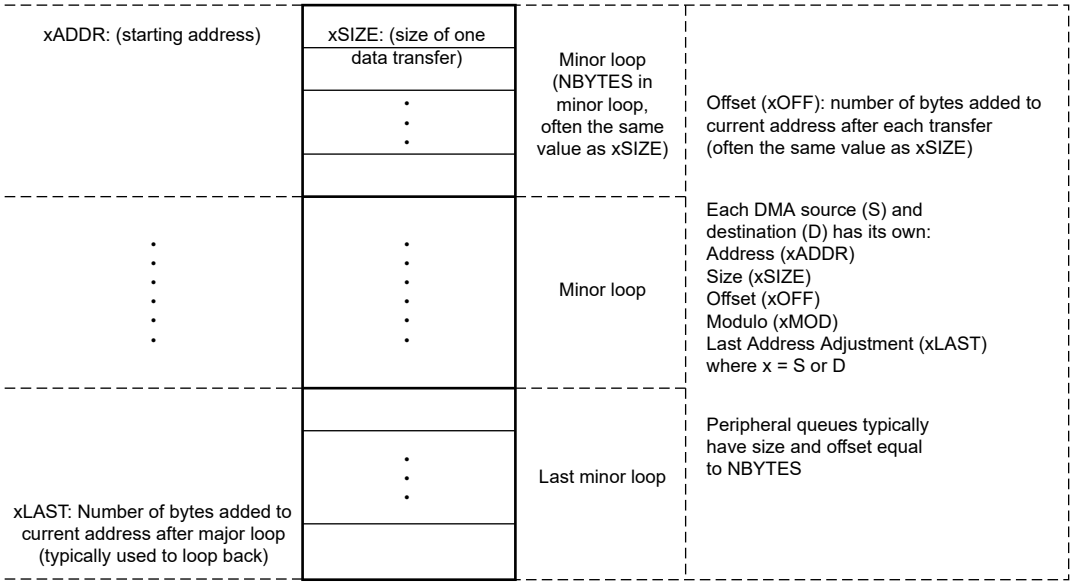

Figure 34. Memory array terms

14.5.2 eDMA arbitration

The eDMA uses a layered arbitration scheme composed of multiple priority levels. The eDMA uses a fixed-priority arbitration scheme with optional round-robin arbitration under specific conditions. The priorities are evaluated in the following order:

Table 47. eDMA arbitration priorities

Priority	Scheme	Description
1 (Highest)	Arbitration group priority	Each channel is assigned an arbitration group via the CHn_GRPRI registers. Priority is given to the highest value (31 being the highest possible value) down to the lowest value (zero, the default).
2	Channel priority	Each channel is assigned a channel priority level via the CHn_PRI registers. The channel priority is a relative priority level within an arbitration group. Priority is given to the highest value (seven being the highest possible value) down to the lowest value (zero, the default). Channel priorities within each arbitration group need not be unique. If multiple channels have the same channel priority level, the channel number will be used to determine priority as defined in row three.
3	Channel number	When two or more channels have the same arbitration group priority and channel priority, the channel number (CHn_NUM) is used to determine the highest priority. Priority is giver to the

Table continues on the next page...

Table 47. eDMA arbitration priorities (continued)

Priority	Scheme	Description
		highest channel number. Lowest priority is channel 0. The channel numbers are static and cannot be changed in the programmer's model.
4 (Lowest)	Round-robin	When round-robin is enabled, any channel configured for round-robin operation has lowest priority within an arbitration group. Round-robin is enabled by setting the CSR[ERCA] field to 1. After being enabled, channels with a channel priority of zero (CHn_PRI=0) will use round-robin arbitration. Round-robin arbitration will rotate the channel selection among the channels requesting service with CHn_PRI=0 within the arbitration group. Any non-zero channel within the arbitration group will continue to use fixed-priority arbitration, and if requesting service will be selected over any round-robin channels.

For fixed arbitration, the overall priority can be considered a number composed of three concatenated priority levels: CHn_GRPRI:CHn_PRI:CH_NUM. The largest number has the highest priority and the lowest number has the lowest priority.

For round-robin arbitration, the priority number is CHn_GRPRI:0:X. The module rotates through the CHn_PRI=0 channels requesting service without regard to priority among these channels. Any channel within the arbitration group for which CHn_PRI is greater than 0 will be serviced before the round-robin channels.

14.5.3 Programming errors

The eDMA performs various tests on the transfer control descriptor to verify consistency in the descriptor data.

The channel number causing the error is recorded in the Error Status register (CHn_CSR and TCDn_CSR). If the error source is not removed before the next activation of the problematic channel, the error is detected and recorded again. Setting the halt after error field, CSR[HAE], will halt the DMA and prevent reoccurrence of the error.

14.5.4 Arbitration mode considerations

This section discusses arbitration considerations for eDMA.

14.5.4.1 Fixed group arbitration, fixed channel arbitration

In this mode, eDMA selects for execution the channel service request from the highest-priority channel in the highest-priority group. If eDMA is programmed so that the channels within a high-priority group have a high number of requests or large data transfers, that group may consume all the bandwidth of the eDMA controller. That is, no lower-priority groups are serviced if there is always at least one DMA request pending on a channel in the highest-priority group when the controller arbitrates the next DMA request. The advantage of this scenario is that latency can be small for channels that need to be serviced quickly.

14.5.4.2 Fixed group arbitration, round-robin channel arbitration

The highest-priority group with a request is serviced. Lower-priority groups are serviced if no pending requests exist in the higher-priority groups.

Within each group, channels are serviced starting with the highest non-zero channel priority. For all channels with a channel priority programmed to 0, selection begins with the highest channel number requesting service and then rotates through to the lowest channel number requesting service. The round-robin channel arbitration can provide a fairness mechanism to lower-priority channels.

This scenario could cause the same bandwidth consumption problem as indicated in Fixed group arbitration, fixed channel arbitration, but all the channels in the highest-priority group will be serviced. Service latency is short on the highest-priority group, but could potentially be very much longer as the group priority decreases.

14.5.5 Performing DMA transfers

This section presents examples on how to perform DMA transfers with the eDMA.

14.5.5.1 Single request

To perform a simple transfer of n bytes of data with one activation, set the major loop to one (TCD*n*_CITER = TCD*n*_BITER = 1). The data transfer begins after the channel service request is acknowledged and the channel is selected to execute. After the transfer is complete, the CH*n*_CSR[DONE] field is set to 1 and an interrupt is generated if properly enabled.

For example, the following TCD entry is configured to transfer 16 bytes of data. The eDMA is programmed for one iteration of the major loop transferring 16 bytes per iteration. The source memory has a byte-wide memory port located at 0x1000. The destination memory has a 32-bit port located at 0x2000. The address offsets are programmed in increments to match the transfer size: one byte for the source, and four bytes for the destination. The final source and destination addresses are adjusted to return to their beginning values.

```
TCDn_CITER = TCDn_BITER = 1
TCDn_NBYTES = 16
TCDn_SADDR = 0x1000
TCDn_SOFF = 1
TCDn_ATTR[SSIZE] = 0
TCDn_SLAST = -16
TCDn_DADDR = 0x2000
TCDn_DOFF = 4
TCDn_ATTR[DSIZE] = 2
TCDn_DLAST_SGA= -16
TCDn_CSR[INTMAJ] = 1
TCDn_CSR[START] = 1 (should be written last after all other fields have been initialized)
All other TCDn fields = 0
```

This generates the following event sequence:

1. User write to the TCD*n*_CSR[START] field requests channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes:
   - CH*n*_CSR[DONE] = 0
   - TCD*n*_CSR[START] = 0
   - CH*n*_CSR[ACTIVE] = 1
4. eDMA engine reads: channel TCD data from local memory to internal register file.
5. The source-to-destination transfers are executed as follows:
   a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
   b. Write 32 bits to location 0x2000 → first iteration of the minor loop.
   c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
   d. Write 32 bits to location 0x2004 → second iteration of the minor loop.

e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.

f. Write 32 bits to location 0x2008 → third iteration of the minor loop.

g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.

h. Write 32 bits to location 0x200C → last iteration of the minor loop → major loop complete.

6. The eDMA engine writes: TCD*n*_SADDR = 0x1000, TCD*n*_DADDR = 0x2000, TCD*n*_CITER = 1 (TCD*n*_BITER).
7. The eDMA engine writes: CH*n*_CSR[ACTIVE] = 0, CH*n*_CSR[DONE] = 1, CH*n*_INT[INT] = 1.
8. The channel retires and the eDMA goes idle or services the next channel.

14.5.5.2 Multiple requests

The following example transfers 32 bytes via two hardware requests, but is otherwise the same as the previous example. The only fields that change are the major loop iteration count and the final address offsets. The eDMA is programmed for two iterations of the major loop, transferring 16 bytes per iteration. After the channel's hardware requests are enabled via the CHn_CSR[ERQ] register field, the slave device initiates channel service requests.

```
TCDn_CITER = TCDn_BITER = 2
TCDn_SLAST = -32
TCDn_DLAST_SGA = -32
```

This would generate the following sequence of events:

1. First hardware (eDMA peripheral) requests channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: CH*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, CH*n*_CSR[ACTIVE] = 1.
4. eDMA engine reads: channel TCD*n* data from local memory to internal register file.
5. The source-to-destination transfers are executed as follows:
   a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
   b. Write 32 bits to location 0x2000 → first iteration of the minor loop.
   c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
   d. Write 32 bits to location 0x2004 → second iteration of the minor loop.
   e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
   f. Write 32 bits to location 0x2008 → third iteration of the minor loop.
   g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
   h. Write 32 bits to location 0x200C → last iteration of the minor loop.
6. eDMA engine writes: TCD*n*_SADDR = 0x1010, TCD*n*_DADDR = 0x2010, TCD*n*_CITER = 1.
7. eDMA engine writes: CH*n*_CSR[ACTIVE] = 0.
8. The channel retires, which concludes one iteration of the major loop. The eDMA goes idle or services the next channel.
9. Second hardware (eDMA peripheral) requests channel service.
10. The channel is selected by arbitration for servicing.
11. eDMA engine writes: CH*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, CH*n*_CSR[ACTIVE] = 1.
12. eDMA engine reads: Channel TCD data from local memory to internal register file.
13. The source-to-destination transfers are executed as follows:
    a. Read byte from location 0x1010, read byte from location 0x1011, read byte from 0x1012, read byte from 0x1013.

b. Write 32 bits to location 0x2010 → first iteration of the minor loop.

c. Read byte from location 0x1014, read byte from location 0x1015, read byte from 0x1016, read byte from 0x1017.

d. Write 32 bits to location 0x2014 → second iteration of the minor loop.

e. Read byte from location 0x1018, read byte from location 0x1019, read byte from 0x101A, read byte from 0x101B.

f. Write 32 bits to location 0x2018 → third iteration of the minor loop.

g. Read byte from location 0x101C, read byte from location 0x101D, read byte from 0x101E, read byte from 0x101F.

h. Write 32 bits to location 0x201C → last iteration of the minor loop → major loop complete.

14. eDMA engine writes: TCD*n*_SADDR = 0x1000, TCD*n*_DADDR = 0x2000, TCD*n*_CITER = 2 (TCD*n*_BITER).
15. eDMA engine writes: CH*n*_CSR[ACTIVE] = 0, CH*n*_CSR[DONE] = 1, CH*n*_INT[INT] = 1.
16. The channel retires, which concludes with the major loop complete. The eDMA goes idle or services the next channel.

14.5.5.3 Using the modulo feature

The modulo feature of the eDMA allows implementation of a circular data queue in which the size of the queue is a power of 2. xMOD is a 5-bit field for the source and destination in the TCD, and it specifies which lower address bits increment from their original value after the address+offset calculation. All upper address bits remain the same as in the original value. A setting of 0 for this field disables the modulo feature. Modulo addressing applies to cases where the minor loop offset is enabled; that is, the upper address bits remain the same after the minor loop offset is added to the source or destination address.

The following table shows how the transfer addresses are specified based on the setting of the MOD field. Here a circular buffer is created where the address wraps to the original value but the 28 upper address bits (0x1234567*x*) retain their original value. In this example, the source address is set to 0x12345670, the offset is set to four bytes, and the MOD field is set to four, which allows for a 2^4 byte (16 byte) queue size.

Table 48. Modulo example

Transfer number	Address
1	0x12345670
2	0x12345674
3	0x12345678
4	0x1234567C
5	0x12345670
6	0x12345674

14.5.6 Monitoring transfer descriptor status

This section discusses how to monitor eDMA status.

14.5.6.1 Testing for minor loop completion

There are two methods to test for minor loop completion when using software-initiated service requests.

1. The first method is to read the TCDn_CITER field and test for a change.
2. The second method, extracted from the sequence shown below, is to test the TCDn_CSR[START] field and the CHn_CSR[ACTIVE] field. The minor-loop-complete condition is indicated by both fields reading 0 after TCDn_CSR[START] is set to 1. Polling the CHn_CSR[ACTIVE] field only may be inconclusive because the active status may be missed if the channel execution is short in duration.

The CHn_CSR and TCDn_CSR status fields execute the following sequence for a software-activated channel:

Stage	TCDn_CSR field	CHn_CSR fields		State
	START	ACTIVE	DONE	
1	1	0	0	Initiate channel service request via software.
2	0	1	0	Channel is executing.
3a	0	0	0	Channel has completed the minor loop and is idle.
3b	0	0	1	Channel has completed the major loop and is idle.

The best method to test for minor-loop completion when using hardware-initiated (that is, peripheral-initiated) service requests is to read the TCDn_CITER field and test for a change. The hardware request and acknowledge handshake signals are not visible in the programmer's model.

The TCD status fields execute the following sequence for a hardware-activated channel:

Stage	TCDn_CSR field	CHn_CSR fields		State
	START	ACTIVE	DONE	
1	0	0	0	Initiate channel service request via hardware (peripheral request asserted).
2	0	1	0	Channel is executing.
3a	0	0	0	Channel has completed the minor loop and is idle.
3b	0	0	1	Channel has completed the major loop and is idle.

For both activation types, the major-loop-complete status is explicitly indicated via the CHn_CSR[DONE] field.

The TCDn_CSR[START] field is cleared to 0 automatically when the channel begins execution, regardless of how the channel activates.

14.5.6.2 Reading the transfer descriptors of active channels

The eDMA reads back the true TCDn_SADDR, TCDn_DADDR, and TCDn_NBYTES values if they are read when a channel executes. The true values of SADDR, DADDR, and NBYTES are the values the eDMA engine currently uses in its internal register file, and not the values in the TCD local memory for that channel. The addresses, SADDR and DADDR, and NBYTES (which decrements to zero as the transfer progresses), can give an indication of the progress of the transfer. All other values are read back from the TCD local memory.

14.5.6.3 Checking channel preemption status

A preemptive situation is one in which a preempt-enabled channel is executing and a higher-priority request becomes active. When round-robin channel arbitration mode is enabled, all channels with their channel priority set to 0 lose their preempt ability. Channel priorities of 0 are treated as equal, that is, they are constantly rotating, when round-robin arbitration mode is enabled.

The CHn_CSR[ACTIVE] field for the preempted channel remains asserted throughout the preemption. The preempted channel is temporarily suspended when the preempting channel executes one major loop iteration. If two CHn_CSR[ACTIVE] fields are set simultaneously in the global TCD map, a higher-priority channel is actively preempting a lower-priority channel.

14.5.7 Channel linking

Channel linking (or chaining) is a mechanism in which one channel sets the TCDn_CSR[START] field of another channel (or itself), thus initiating a service request for that channel. When properly enabled, the eDMA engine automatically performs this operation at the major or minor loop completion.

The minor loop channel linking occurs at the completion of the minor loop (or one iteration of the major loop). The TCDn_CITER[ELINK] field determines whether a minor loop link is requested. When enabled, the channel link is made after each iteration of the major loop except for the last. When the major loop is exhausted, only the major loop channel link fields are used to determine if a channel link should be made. For example, using an initial field setting of:

```
TCDn_CITER[ELINK] = 1
TCDn_CITER[LINKCH] = 0xC
TCDn_CITER[CITER] value = 0x4
TCDn_CSR[MAJORELINK] = 1
TCDn_CSR[MAJORLINKCH] = 0x7
```

executes as:

1. Minor loop done → set TCD12_CSR[START] field
2. Minor loop done → set TCD12_CSR[START] field
3. Minor loop done → set TCD12_CSR[START] field
4. Minor loop done, major loop done→ set TCD7_CSR[START] field

When minor loop linking is enabled (TCDn_CITER[ELINK] = 1), the TCDn_CITER[CITER] field uses a nine-bit vector to form the current iteration count. When minor loop linking is disabled (TCDn_CITER[ELINK] = 0), the TCDn_CITER[CITER] field uses a 15-bit vector to form the current iteration count. The bits associated with the TCDn_CITER[LINKCH] field are concatenated onto the CITER value to increase the range of the CITER.

NOTE

The TCDn_CITER[ELINK] field and the TCDn_BITER[ELINK] field must be equal — if they are not, a configuration error is reported. The CITER and BITER vector widths must be equal to calculate the major loop halfway done interrupt point.

The following table summarizes how a DMA channel can link to another DMA channel, that is, use another channel's TCD, at the end of a loop.

Table 49. Channel linking parameters

Wanted link behavior	TCD control field name	Description
Link at end of minor loop	TCDn_CITER[ELINK]	Enable channel-to-channel linking on minor loop completion (current iteration)
	TCDn_CITER[LINKCH]	Link channel number when linking at end of minor loop (current iteration)
Link at end of major loop	TCDn_CSR[MAJORELINK]	Enable channel-to-channel linking on major loop completion
	TCDn_CSR[MAJORLINKCH]	Link channel number when linking at end of major loop

14.5.8 Dynamic programming

This section provides recommended methods to change the programming model during channel execution.

14.5.8.1 Dynamically changing the channel priority

To change group or channel priority levels:

1. Halt the DMA by writing 1 to the CSR[HALT] field.
2. Change the group or channel priorities as wanted.
3. Enable normal DMA operations by writing 0 to the CSR[HALT] field.

14.5.8.2 Dynamic channel linking

Dynamic channel linking is the process of setting the TCDn_CSR[MAJORELINK] field during channel execution (see the diagram in TCD structure). This field is read from the TCD local memory at the end of channel execution, thus allowing you to enable the feature during channel execution.

Because you are allowed to change the configuration during execution, you need a coherency model. Consider the scenario where you attempt to execute a dynamic channel link by enabling the TCDn_CSR[MAJORELINK] field at the same time the eDMA engine is retiring the channel. TCDn_CSR[MAJORELINK] would be set in the programmer's model, but it would be unclear whether the actual link was made before the channel retired.

We recommend that you use the following coherency model when executing a dynamic channel link request.

1. Write 1 to the TCDn_CSR[MAJORELINK] field.
2. Read back the TCDn_CSR[MAJORELINK] field.
3. Test the TCDn_CSR[MAJORELINK] request status:
   - If TCDn_CSR[MAJORELINK] = 1, the dynamic link attempt was successful.
   - If TCDn_CSR[MAJORELINK] = 0, the attempted dynamic link did not succeed (the channel was already retiring).

For this request, the TCD local memory controller forces the TCDn_CSR[MAJORELINK] field to 0 on any writes to a channel's TCDn_CSR[7:0] after that channel's CHn_CSR[DONE] field is set to 1, indicating the major loop is complete.

NOTE

You must clear the CHn_CSR[DONE] field to 0 before writing to the TCDn_CSR[MAJORELINK] field. The CHn_CSR[DONE] field is cleared to 0 automatically by the eDMA engine after a channel begins execution.

14.5.8.3 Dynamic scatter/gather

Scatter/gather is the process of automatically loading a new TCD into a channel. It allows a DMA channel to use multiple TCDs; this enables a DMA channel to scatter the DMA data to multiple destinations or gather it from multiple sources. When scatter/gather is enabled and the channel has finished its major loop, a new TCD is fetched from system memory and loaded into that channel's descriptor location in the eDMA programmer's model, thus replacing the current descriptor.

Because you are allowed to change the configuration during execution, you need a coherency model. Consider the scenario where you attempt to execute a dynamic scatter/gather operation by enabling the TCDn_CSR[ESG] field at the same time the eDMA engine is retiring the channel. The TCDn_CSR[ESG] field would be set in the programmer's model, but it would be unclear whether the actual scatter/gather request was honored before the channel retired.

Two methods are recommended for executing a dynamic scatter/gather request. Whenever the TCDn_CSR is written, the TCD local memory controller forces the TCDn_CSR[ESG] field to 0 on any writes to a channel's TCDn_CSR[7:0] after that channel's CHn_CSR[DONE] field has been set to 1, indicating the major loop is complete. If attempting to set the ESG, ensure the DONE field is cleared to 0.

NOTE

You must clear the CHn_CSR[DONE] field to 0 before writing the TCDn_CSR[MAJORELINK] or TCDn_CSR[ESG] fields. The CHn_CSR[DONE] field is cleared to 0 automatically by the eDMA engine after a channel begins execution and is set to 1 upon major loop completion.

14.5.8.3.1 Method 1 (channel not using major loop channel linking)

For a channel not using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request.

When the TCDn_CSR[MAJORELINK] field is 0, the TCDn_CSR[MAJORLINKCH] field is not used by the eDMA. In this case, the TCDn_CSR[MAJORLINKCH] bits may be used for other purposes. This method uses the TCDn_CSR[MAJORLINKCH] field as a TCDn_CSR identification (ID).

When the descriptors are built, write a unique TCDn_CSR ID in the TCDn_CSR[MAJORLINKCH] field for each TCDn_CSR associated with a channel using dynamic scatter/gather.

1. Write a 1 to the TCDn_CSR[DREQ] field. Should a dynamic scatter/gather attempt fail, setting the TCDn_CSR[DREQ] field to 1 will prevent future hardware activation of this channel. This stops the channel from executing with a destination address (daddr) that was calculated using a scatter/gather address (written in the next step) instead of a DLAST final offset value.
2. Write the TCDn_DLAST_SGA field with the scatter/gather address.
3. Write a 1 to the TCDn_CSR[ESG] field.
4. Read back the 16-bit TCDn_CSR control/status field.
5. Test the TCDn_CSR[ESG] request status and TCDn_CSR[MAJORLINKCH] value:
   - If ESG = 1, the dynamic scatter/gather attempt was successful.
   - If ESG = 0 and the MAJORLINKCH (ID) did not change, the dynamic scatter/gather attempt was not successful (the channel was already retiring).
   - If ESG = 0 and the MAJORLINKCH (ID) changed, the dynamic scatter/gather attempt was successful (the new TCDn_CSR's ESG value cleared the ESG field to 0).

14.5.8.3.2 Method 2 (channel using major loop channel linking)

For a channel using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request. This method uses the TCDn_DLAST_SGA field as a TCD identification (ID).

1. Write a 1 to the TCDn_CSR[DREQ] field. Should a dynamic scatter/gather attempt fail, setting the DREQ field to 1 will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (DADDR) that was calculated using a scatter/gather address (written in the next step) instead of a DLAST final offset value.
2. Write the TCDn_DLAST_SGA field with the scatter/gather address.
3. Write a 1 to the TCDn_CSR[ESG] field.
4. Read back the TCDn_CSR[ESG] field.
5. Test the TCDn_CSR[ESG] request status:
   - If ESG = 1, the dynamic scatter/gather attempt was successful.
   - If ESG = 0, read the 32-bit TCDn_DLAST_SGA field.
   - If ESG = 0 and the TCDn_DLAST_SGA did not change, the dynamic scatter/gather attempt was not successful (the channel was already retiring).
   - If ESG = 0 and the TCDn_DLAST_SGA changed, the dynamic scatter/gather attempt was successful (the new TCDn_CSR's ESG value cleared the ESG field to 0).

14.5.9 Suspend/resume a DMA channel with active hardware service requests

The DMA allows you to move data from memory or peripheral registers to another location in memory or to peripheral registers without CPU interaction. After the DMA and peripherals are configured and active, it is rare but supported to suspend a peripheral's service request dynamically. In this scenario, there are certain restrictions to disabling a DMA hardware service request. For

coherency, you must follow a specific procedure. This section provides guidance on how to coherently suspend and resume a Direct Memory Access (DMA) channel when the DMA is triggered by a slave module such as the Serial Peripheral Interface (DSPI), Sigma Delta Analog to Digital Convertor (SDADC), or other module.

14.5.9.1 Suspend an active DMA channel

To suspend an active DMA channel:

1. Stop the DMA service request at the peripheral first. Confirm it has been disabled by reading back the appropriate register in the peripheral.
2. Check the DMA's Hardware Request Status (HRS) to ensure there is no service request to the DMA channel being suspended. Then disable the hardware service request by clearing the ERQ field to 0 on the appropriate DMA channel.

For example, assume the DSPI is set as a master for transmitting data via a DMA service request when the TXFIFO has an empty slot. The DMA will transfer the next command and data to the TXFIFO upon the request. If you need to suspend the DMA/DSPI transfer loop, perform the following steps:

1. Disable the DMA service request at the source by writing 0 to DSPI_RSER[TFFF_RE]. Confirm that DSPI_RSER[TFFF_RE] is 0.
2. Ensure there is no DMA service request from the DSPI by verifying that HRS[HRS] is 0 for the appropriate channel. If no service request is present, disable the DMA channel by clearing the channel's ERQ field to 0. If a service request is present, wait until the request has been processed and the HRS field reads 0.

14.5.9.2 Resume a DMA channel

To resume a DMA channel:

1. Enable the DMA service request on the appropriate channel by setting its ERQ field to 1.
2. Enable the DMA service request at the peripheral.

14.6 Memory map/register definition

The eDMA programming model is partitioned into three parts:

1. The first part defines a number of registers providing overall control functions and is known as the management page.
2. The second part corresponds to the channel (CH) control, status, and configuration.
3. The third part corresponds to the local TCD memory.

TCD memory

Each channel requires a 32-byte transfer control descriptor for defining the data movement operation. Each TCDn definition is presented as 11 registers of 16 or 32 bits.

TCD initialization

The TCD memory is in an unknown state after reset. Only the TCD START bit is initialized to 0. Prior to activating a channel, you must initialize its TCD with the appropriate transfer profile.

TCD structure

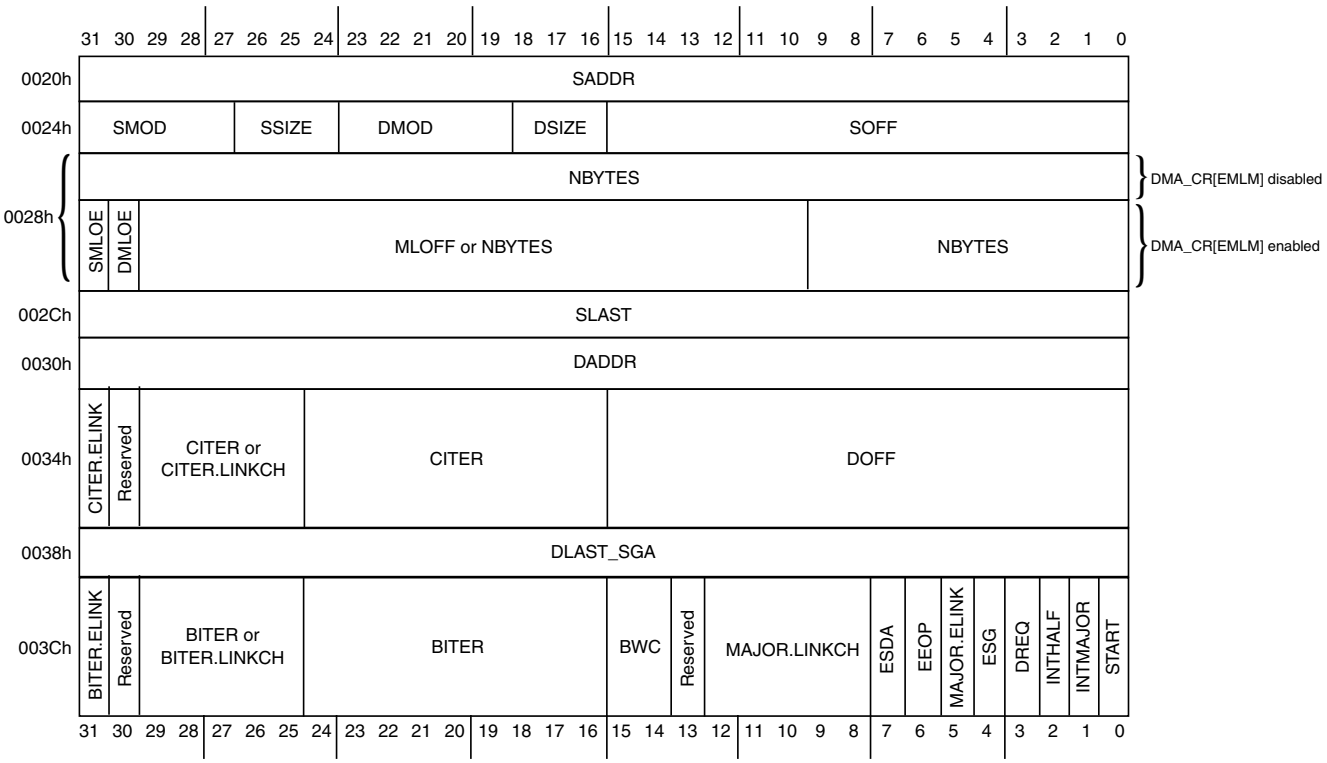

Figure 35. TCD structure

Accesses to reserved memory and fields

- Reading reserved fields in a register returns the value of zero.
- Writes to reserved fields in a register are ignored.
- Reading or writing a reserved memory location generates a bus error.

14.6.1 eDMA register descriptions

14.6.1.1 eDMA memory map

eDMA base address: 4020_C000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Management Page Control (CSR)	32	RW	0030_0000h
4h	Management Page Error Status (ES)	32	RO	0000_0000h
8h	Management Page Interrupt Request Status (INT)	32	RO	0000_0000h
Ch	Management Page Hardware Request Status (HRS)	32	RO	0000_0000h
100h - 17Ch	Channel Arbitration Group (CH0_GRPRI - CH31_GRPRI)	32	RW	0000_0000h

14.6.1.2 Management Page Control (CSR)

Offset

Register	Offset
CSR	0h

Function

The Management Page Control register defines the basic operating configuration of the DMA.

Arbitration uses a two-tier priority system; group and channel priority. The eDMA assigns each channel to a priority group. Group arbitration is fixed-priority and cannot be changed. Channel arbitration uses fixed priority and may be configured to use a selective round-robin scheme for specified channels within each priority group. For fixed-priority arbitration, eDMA selects for execution the highest priority channel requesting service in the highest priority arbitration group.

The channel priority registers assign the relative priorities within each arbitration group; see CHn_PRI. All channels with a non-zero CHn_PRI value use fixed-priority arbitration.

When you enable round-robin arbitration, all channels with channel priority set to zero do not have a priority and, of those channels requesting service, are cycled through (from high to low channel number) without regard to priority relative to each other within the same priority group. Any channel with a non-zero CHn_PRI value automatically has a higher priority over the round-robin channels. A channel's priority group is assigned in Channel Arbitration Group (CH0_GRPRI - CH31_GRPRI).

NOTE

For correct operation, changes to the CSR[ERCA, GCLC, GMRC] fields must be performed when the DMA channels are inactive; that is, when the CSR[ACTIVE] field is 0.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31 ACTIVE	DMA Active Status 0b - eDMA is idle 1b - eDMA is executing a channel

Table continues on the next page...

Table continued from the previous page...

Field	Function
30-29 —	Reserved
28-24 ACTIVE_ID	Active Channel ID This field identifies the channel number that is executing when the ACTIVE bit is 1.
23-16 —	Reserved
15-10 —	Reserved
9 CX	Cancel Transfer When set to 1, this field cancels the remaining data transfer, stops the executing channel, and forces the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. CX clears itself to 0 after the cancel has been honored. This cancel retires the channel normally as if the minor loop had been completed. 0b - Normal operation 1b - Cancel the remaining data transfer
8 ECX	Cancel Transfer With Error Cancellation of the remaining data transfer is similar to that of the CX field. Execution of the the channel is stopped and the minor loop is forced to finish. The cancellation takes effect after the last write of the current read/write sequence. The ECX field clears itself to 0 after the cancel is honored. In addition to cancelling the transfer, ECX treats the cancel as an error condition, thus updating Management Page Error Status (ES) and generating an optional error interrupt. 0b - Normal operation 1b - Cancel the remaining data transfer
7 GMRC	Global Master ID Replication Control **NOTE** If master ID replication is disabled, the privileged protection level (Supervisor mode) for DMA transfers is used. 0b - Master ID replication disabled for all channels 1b - Master ID replication available and controlled by each channel's CHn_SBR[EMI] setting
6 GCLC	Global Channel Linking Control 0b - Channel linking disabled for all channels 1b - Channel linking available and controlled by each channel's link settings
5	Halt DMA Operations

Table continues on the next page...

Table continued from the previous page...

Field	Function
HALT	This field stalls the start of any new channels. Executing channels are allowed to complete. Channel execution resumes when this field is cleared to 0. 0b - Normal operation 1b - Stall the start of any new channels
4 HAE	Halt After Error When this field is set to 1, any error causes the HALT field to be set to 1. Then all service requests are ignored until the HALT field is cleared to 0. 0b - Normal operation 1b - Any error causes the HALT field to be set to 1
3 —	Reserved
2 ERCA	Enable Round Robin Channel Arbitration 0b - Round-robin channel arbitration disabled. Fixed priority arbitration used for channel selection within each group 1b - Round-robin channel arbitration enabled. Round-robin arbitration used for channel selection within each group
1 EDBG	Enable Debug When in debug mode, the DMA stalls the start of a new channel. Executing channels are allowed to complete. DMA resumes channel execution when the system exits debug mode or clears the EDBG field to 0. 0b - Debug mode disabled. When in debug mode, the DMA continues to operate 1b - Debug mode is enabled. When in debug mode, the DMA stalls the start of a new channel
0 —	Reserved

14.6.1.3 Management Page Error Status (ES)

Offset

Register	Offset
ES	4h

Function

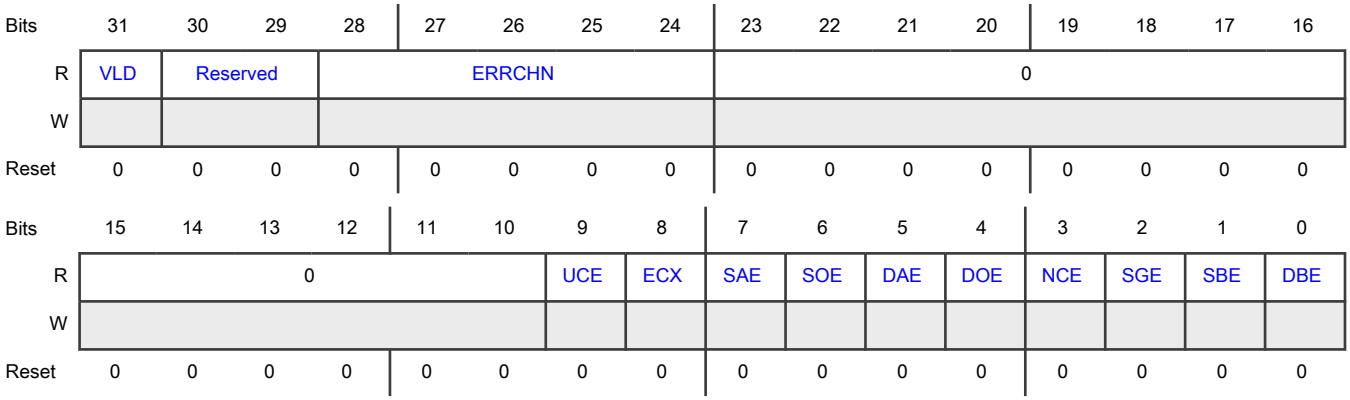
The ES provides information concerning the last recorded channel error. Channel errors can be caused by:

- An illegal setting in the transfer control descriptor
- An error termination to a bus master read or write cycle

- An uncorrectable error that occurred when the device was accessing the TCD SRAM
- A "cancel transfer with error" request was made via the corresponding cancel transfer field or input signal

Upon any error condition, the software must initialize the TCD of the channel that contains the error, as it is in an incomplete state after an error. See Fault reporting and handling for more details.

Diagram



Fields

Field	Function
31 VLD	Valid Logical OR of all ERR status fields. 0b - No ERR fields are set to 1 1b - At least one ERR field is set to 1, indicating a valid error exists that software has not cleared
30-29 —	Reserved
28-24 ERRCHN	Error Channel Number or Canceled Channel Number The channel number of the last recorded error or last recorded error-canceled transfer.
23-10 —	Reserved
9 UCE	Uncorrectable TCD Error During Channel Execution UCE is set to 1 only when an uncorrectable ECC error occurs on an access generated by the DMA. If a CPU access to the TCD causes an uncorrectable ECC error, then that access receives a bus error response. **NOTE** When the eDMA sees a RAM error on an IPS access (when you are accessing a TCD), it reports the error as a bus abort. When the DMA engine receives a RAM error (the execution engine is accessing a TCD) it is recorded in the Error Status register, ES[UCE], along with the channel number.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No uncorrectable ECC error 1b - Last recorded error was an uncorrectable TCD RAM error
8 ECX	Transfer Canceled The ECX operation is a management page function. When employed, the targeted channel's CHn_ES register reports an unspecified error; that is, only the ERR field is set to 1. The management page has full view of the error condition. 0b - No canceled transfers 1b - Last recorded entry was a canceled transfer by the error cancel transfer input
7 SAE	Source Address Error When this field is 1, it indicates that TCDn_SADDR is inconsistent with TCDn_ATTR[SSIZE]. 0b - No source address configuration error 1b - Last recorded error was a configuration error detected in the TCDn_SADDR field
6 SOE	Source Offset Error When this field is 1, it indicates that TCDn_SOFF is inconsistent with TCDn_ATTR[SSIZE]. 0b - No source offset configuration error 1b - Last recorded error was a configuration error detected in the TCDn_SOFF field
5 DAE	Destination Address Error When this field is 1, it indicates that TCDn_DADDR is inconsistent with TCDn_ATTR[DSIZE]. 0b - No destination address configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DADDR field
4 DOE	Destination Offset Error When this field is 1, it indicates that TCDn_DOFF is inconsistent with TCDn_ATTR[DSIZE]. 0b - No destination offset configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DOFF field
3 NCE	NBYTES/CITER Configuration Error This error indicates that one of the following has occurred: • TCDn_NBYTES is not a multiple of TCDn_ATTR[SSIZE] and TCDn_ATTR[DSIZE] • TCDn_CITER[CITER] is equal to zero • TCDn_CITER[ELINK] is not equal to TCDn_BITER[ELINK] 0b - No NBYTES/CITER configuration error 1b - The last recorded error was NBYTES equal to zero or a CITER not equal to BITER error. Last recorded error was a configuration error detected in the TCDn_NBYTES or TCDn_CITER fields

Table continues on the next page...

Table continued from the previous page...

Field	Function
2 SGE	Scatter/Gather Configuration Error When this field is 1, it indicates that TCDn_DLAST_SGA is not on a 32-byte boundary. This field is checked at the beginning of a scatter/gather operation after major loop completion if TCDn_CSR[ESG] is enabled. 0b - No scatter/gather configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DLAST_SGA field
1 SBE	Source Bus Error 0b - No source bus error 1b - Last recorded error was a bus error on a source read
0 DBE	Destination Bus Error 0b - No destination bus error 1b - Last recorded error was a bus error on a destination write

14.6.1.4 Management Page Interrupt Request Status (INT)

Offset

Register	Offset
INT	8h

Function

This register shows the current state of the interrupt service requests for all eDMA channels.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	INT															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	INT															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 INT	Interrupt Request Status The INT register presents the interrupt request status for each eDMA channel. Depending on the appropriate field setting in the transfer control descriptors, the eDMA engine generates an interrupt on data transfer completion or an error condition. The eDMA routes channel interrupt requests to the interrupt controller. During the interrupt service routine associated with any given channel, it is the software's responsibility to clear the appropriate field in the channel's interrupt request register, CHn_INT, thus negating the interrupt request. 0b - Interrupt request for corresponding channel not present 1b - Interrupt request for corresponding channel present

14.6.1.5 Management Page Hardware Request Status (HRS)

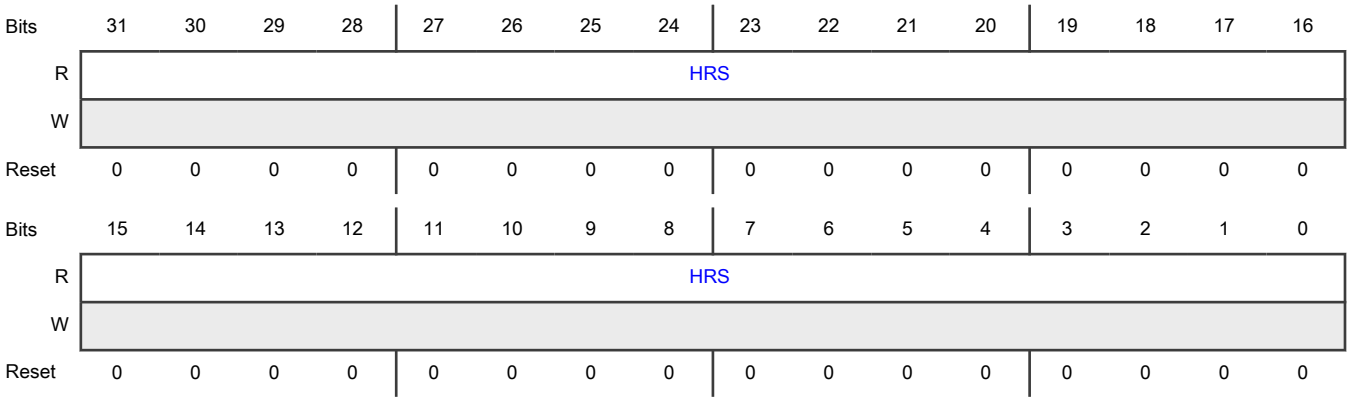
Offset

Register	Offset
HRS	Ch

Function

The hardware request status register (HRS) shows the current state of the hardware service request signaling as seen by eDMA's arbitration logic.

Diagram



Fields

Field	Function
31-0 HRS	Hardware Request Status

Table continues on the next page...

Field	Function
	The HRS bit for its respective channel remains asserted for the period when a hardware request is present on the channel. After the request is completed and the channel is free, the hardware automatically clears the corresponding HRS bit to 0. 0b - Hardware service request for corresponding channel is not present 1b - Hardware service request for corresponding channel is present

14.6.1.6 Channel Arbitration Group (CH0_GRPRI - CH31_GRPRI)

Offset

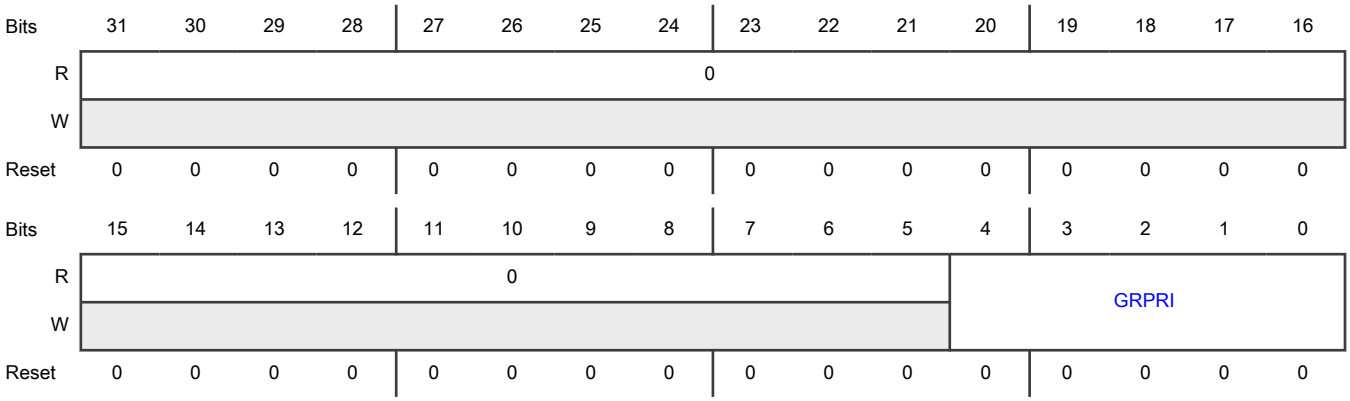
For n = 0 to 31:

Register	Offset
CHn_GRPRI	100h + (n × 4h)

Function

The contents of this register define the arbitration group associated with each channel. Using a fixed-priority group arbitration scheme, eDMA evaluates the arbitration group priorities by numeric value from highest group number to lowest; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, and so on. The range of the group priority values is limited to the values of 0 through 31. Within each arbitration group, the channel priority assignment CH*n*_PRI determines the highest-priority channel.

Diagram



Fields

Field	Function
31-5 —	Reserved
4-0 GRPRI	Arbitration Group For Channel n Fixed-priority arbitration group number.

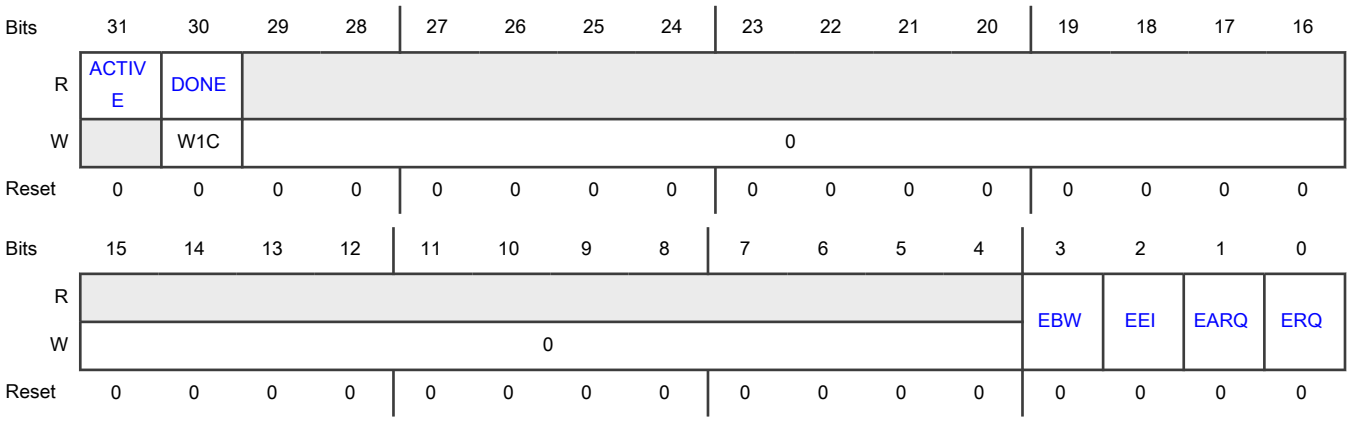
Function

This register contains several fields related to hardware and interrupt requests, configuration, and status for the given channel.

Diagram



Fields

Field	Function
31 ACTIVE	Channel Active The ACTIVE field indicates the channel was selected by arbitration and is executing the prescribed transfers. The eDMA sets it to 1 when channel service begins, and clears it to 0 as the minor loop completes or when any error condition is detected. Except for dynamic scatter/gather or dynamic channel linking, you must not modify the transfer control descriptor when a channel is active.
30 DONE	Channel Done

Table continues on the next page...

Table continued from the previous page...

Field	Function
	The DONE field indicates the eDMA has completed the major loop. The eDMA engine sets this field as the CITER count reaches zero. If enabled, the eDMA generates an interrupt request corresponding to this completed channel. The software clears it, or the hardware clears it when the channel is activated. **NOTE** This field must be cleared to 0 before writing the MAJORELINK or ESG fields.
29-4 —	Reserved
3 EBW	Enable Buffered Writes When buffered writes are enabled, all writes except for the last write sequence of the minor loop are signaled by the eDMA as bufferable. 0b - Buffered writes on system bus disabled. Buffered writes on system bus disabled 1b - Buffered writes on system bus enabled. Bufferable write signal asserted on all system bus writes except during last write sequence
2 EEI	Enable Error Interrupt The EEI field enables the error interrupt signal for the channel. The DMA error indicator and the error interrupt enable flag must be asserted before an error interrupt request for a given channel is asserted to the interrupt controller. 0b - Error signal for corresponding channel does not generate error interrupt 1b - Assertion of error signal for corresponding channel generates error interrupt request
1 EARQ	Enable Asynchronous DMA Request In Stop Mode For Channel The enable asynchronous DMA request field (EARQ) does not affect DMA operations. When set to 1, this field allows the hardware service request enable field (ERQ) to propagate out of the DMA to the power controller. When cleared to 0, this field masks the hardware service request enable field to the power controller. 0b - Disable asynchronous DMA request for the channel 1b - Enable asynchronous DMA request for the channel
0 ERQ	Enable DMA Request Disable a channel's hardware service request at the source before clearing the channel's ERQ field. The DMA hardware request input signal and the enable request field (ERQ) must be asserted before a channel's hardware service request is accepted. The state of the eDMA enable request field does not affect a channel service request made explicitly through software or channel linking. The state of the ERQ field does not affect the channel's START field. 0b - DMA hardware request signal for corresponding channel disabled 1b - DMA hardware request signal for corresponding channel enabled

Register	Offset
CH30_ES	24_8004h
CH31_ES	24_C004h

Function

The ES provides information concerning the last recorded channel error. Channel errors can be caused by:

- An illegal setting in the transfer control descriptor
- An error termination to a bus master read or write cycle

The ERR field signals the presence of an error for the channel. The eDMA engine signals the occurrence of an error condition by setting the appropriate field in this register. The outputs of this register are enabled by the contents of the CHn_CSR[EEI] field, then logically summed across all channels to form an error interrupt request, which may be routed to the interrupt controller. In addition, this enabled error status is logically OR'd onto the channel done interrupt, CHn_INT[INT], thus forming a done or error interrupt on a per channel basis.

During the execution of the interrupt service routine associated with any DMA errors, it is software's responsibility to clear the appropriate bit, negating the error-interrupt request. The normal DMA channel completion indicators (setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request) are not affected when eDMA detects an error. The contents of this ERR register field can also be polled because a non-zero value indicates the presence of a channel error, regardless of the state of the EEI mask.

The state of any given channel's error indicators is affected by writes to this register. Writing a 1 to the ERR field clears the channel's error status, and writing a 0 has no effect.

An unspecified error, where only the ERR field is set to 1, indicates that either a transfer was cancelled with an error or else an uncorrectable TCD error occurred. The Management Page Error Status register has full view of the error condition.

See Fault reporting and handling for more details.

Function

The INT field signals the presence of an interrupt request for the channel. Depending on the appropriate bit setting in the transfe control descriptors, the eDMA engine generates an interrupt on data transfer completion or an error condition.

The outputs of this register are directly routed to the interrupt controller. During the interrupt service routine associated with any given channel, it is the software's responsibility to clear the appropriate bit, negating the interrupt request. On writes to INT, a 1 clears the channel's interrupt request. A zero has no effect on the channel's current interrupt status.

Function

The Channel System Bus register places identification and attribute information on the system bus interface for the eDMA.

The ATTR register outputs the register values onto the system bus interface for further decoding by the security system.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-20 —	Reserved
19-17 ATTR	Attribute Output DMA's system bus attribute output value.
16	Enable Master ID Replication

Table continues on the next page...

Table continued from the previous page...

Field	Function
EMI	The eDMA master ID replication field allows the eDMA to use the same protection level and system bus ID of the master programming the eDMA's TCD. When enabled, the eDMA uses the master ID and protection level stored in the CHn_SBR registers, instead of the eDMA's default values. When a master (for example a core) programs a TCD, its master ID and protection level are captured when the TCD*n*_CSR control attributes are written. A scatter/gather operation does not affect the CHn_SBR registers. You can write the EMI only if CSR[GMRC] = 1, which means Global Master ID Replication Control is enabled; otherwise, the EMI is forced to zero. **NOTE** If master ID replication is disabled, the privileged protection level (Supervisor mode) for DMA transfers is used. 0b - Master ID replication is disabled 1b - Master ID replication is enabled
15 PAL	Privileged Access Level This field controls DMA's protection level on the system bus when the channel is active. **NOTE** When you enable master ID replication, the value captured in this register is the privilege level of the core or other master writing the channel's transfer control descriptor, which is the lower byte of TCD*n*_CSR. 0b - User protection level for DMA transfers 1b - Privileged protection level for DMA transfers
14-4 —	Reserved
3-0 MID	Master ID This field controls the DMA's master ID on the system bus when the channel is active. **NOTE** The ID captured in this register reflects the master ID of the core or other master writing the channel's control attributes, which are in the lower byte of TCD*n*_CSR.

CH28_PRI	24_0010h
CH29_PRI	24_4010h
CH30_PRI	24_8010h
CH31_PRI	24_C010h

Function

The contents of these registers define unique priorities associated with each channel within the same channel group. Channel grouping is programmed via Channel Arbitration Group (CH0_GRPRI - CH31_GRPRI).

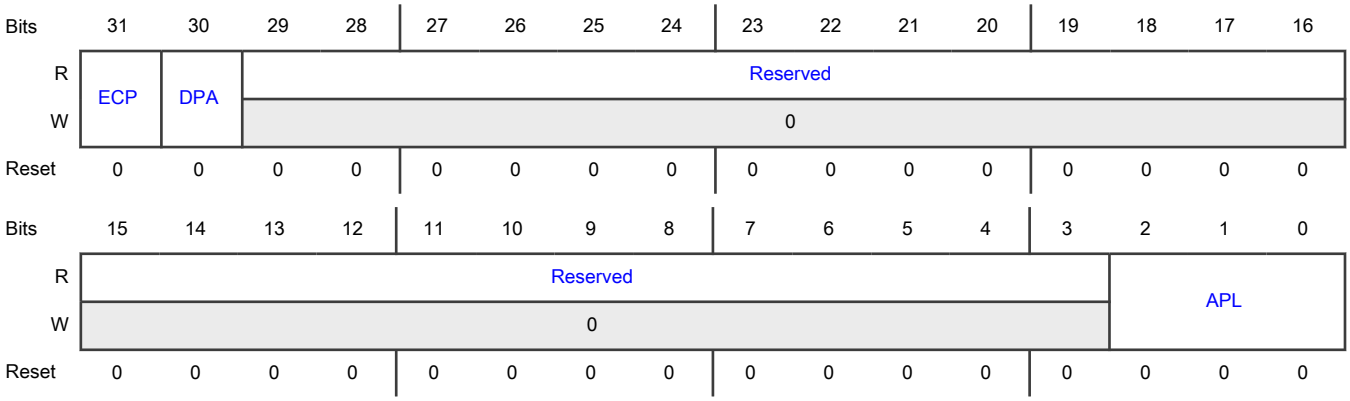
The channel priorities within a group are evaluated by numeric value; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, and so on. Software must program the channel priorities with unique values; otherwise, channel numbers with the same, non-zero value, will be selected based on channel number with the higher channel number having higher priority.

If more than one channel in a group has an arbitration priority level value of zero, then the arbitration mode field CSR[ERCA] is used to determine the arbitration scheme for all channels with APL=0 within a group.

When you enable round-robin channel arbitration (CSR[ERCA] = 1), all channels with APL=0 within a group will use a round-robin arbitration scheme, which rotates among these channels requesting service without regard to priority. Round-robin provides a fairness mechanism within an arbitration group.

When you enable fixed-priority channel arbitration (CSR[ERCA] = 0), eDMA selects channels with APL=0 based on channel number, with the higher channel number having higher priority.

Diagram



Fields

Field	Function
31 ECP	Enable Channel Preemption 0b - Channel cannot be suspended by a higher-priority channel's service request 1b - Channel can be temporarily suspended by a higher-priority channel's service request
30 DPA	Disable Preempt Ability 0b - Channel can suspend a lower-priority channel 1b - Channel cannot suspend any other channel, regardless of channel priority
29-3 —	Reserved
2-0 APL	Arbitration Priority Level Channel priority level for arbitration within the assigned arbitration group.

Fields

Field	Function
15-11 SMOD	Source Address Modulo This field defines a specific address range, which is the value after the SADDR + SOFF calculation is performed on the original register value. Setting this field makes it easy to implement a circular data queue. For data queues requiring power-of-2-sized bytes, the queue must start at a 0-modulo-size address and the SMOD field must be set to the appropriate value for the queue, freezing the required number of upper address bits. The value programmed into this field specifies the number of lower address bits that are allowed to change. For a circular queue application, you typically set TCDn_SOFF[SOFF] to the transfer size to implement post-increment addressing, with the SMOD function constraining the addresses to a 0-modulo-size range. 0_0000b - Source address modulo feature disabled 0_0001b - Source address modulo feature enabled for any non-zero value [1-31]
10-8 SSIZE	Source Data Transfer Size 000b - 8-bit 001b - 16-bit 010b - 32-bit 011b - 64-bit 100b - 16-byte 101b - 32-byte 110b - 64-byte

Function

The TCDn_NBYTES field defines the number of bytes to transfer per service request.

Minor loop offsets are address offset values added to the final source address (TCDn_SADDR), or destination address (TCDn_DADDR), upon minor loop completion. Minor loop completion is when the channel has finished the service request and has transferred NBYTES. When minor loop offsets are enabled, the minor loop offset value (TCDn_NBYTES_MLOFFYES[MLOFF]) is added to the final source address (TCDn_SADDR), to the final destination address (TCDn_DADDR), or to both, prior to the addresses being written back to the TCD. If the major loop is complete, the minor loop offset is ignored and the major loop address offsets (TCDn_SLAST_SDA and TCDn_DLAST_SGA) are used to compute the next TCDn_SADDR and TCDn_DADDR values.

When minor loop mapping is enabled (SMLOE or DMLOE is 1), TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES is redefined. A portion of TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES is used to specify multiple fields:

- A source enable bit (SMLOE) to specify the minor loop offset must be applied to the source address (TCDn_SADDR) upon minor loop completion
- A destination enable bit (DMLOE) to specify the minor loop offset must be applied to the destination address (TCDn_DADDR) upon minor loop completion
- The sign extended minor loop offset value (MLOFF)

The same offset value (MLOFF) is used for both source and destination minor loop offsets. When either minor loop offset is enabled (SMLOE set or DMLOE set), the NBYTES field is reduced to 10 bits. If both minor loop offsets are disabled (SMLOE cleared and DMLOE cleared), the NBYTES field is a 30-bit vector.

One of two register profiles (this register or TCDn_NBYTES_MLOFFYES), defines the number of bytes to transfer per request. Which register to use depends on whether source or destination minor loop mapping is enabled.

TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES is defined as follows:

- If SMLOE = 0 and DMLOE = 0, then see the TCDn_NBYTES_MLOFFNO register description.
- If either SMLOE or DMLOE is 1, then see the TCDn_NBYTES_MLOFFYES register description.

Fields

Field	Function
31 SMLOE	Source Minor Loop Offset Enable Selects whether the minor loop offset is applied to the source address upon minor loop completion. 0b - Minor loop offset not applied to SADDR 1b - Minor loop offset applied to SADDR
30 DMLOE	Destination Minor Loop Offset Enable Selects whether the minor loop offset is applied to the destination address upon minor loop completion. 0b - Minor loop offset not applied to DADDR 1b - Minor loop offset applied to DADDR
29-0 NBYTES	Number of Bytes To Transfer Per Service Request Number of bytes to be transferred for each service request of the channel. When a channel activates, the module loads the appropriate TCD contents into the eDMA engine and performs the appropriate reads and writes until the byte transfer count has been reached. This process is normally an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the byte count is exhausted, the SADDR and DADDR values are written back into the TCD memory, and the major loop iteration count (CITER) is decremented by one and written back to the TCD memory. If the major iteration count is complete, additional processing is performed.

Function

The TCDn_NBYTES field defines the number of bytes to transfer per service request.

Minor loop offset is an address offset value added to the final source address (TCDn_SADDR) or destination address (TCDn_DADDR) upon minor loop completion. Minor loop completion occurs when the channel has finished the service request and has transferred NBYTES. Minor loop offsets are enabled by setting either the source enable bit (SMLOE) or the destination enable bit (DMLOE).

The source enable bit (SMLOE) specifies the minor loop offset value (MLOFF) that is to be applied to the source address (TCDn_SADDR) upon minor loop completion. The destination enable bit (DMLOE) specifies the minor loop offset (MLOFF) that is to be applied to the destination address (TCDn_DADDR) upon minor loop completion.

If the major loop is complete, the minor loop offsets are ignored and the major loop address offsets (TCDn_SLAST_SDA and TCDn_DLAST_SGA) are used to compute the next TCDn_SADDR and TCDn_DADDR values.

When you enable the minor loop offset overlay (either SMLOE or DMLOE is 1), eDMA redefines TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES. A portion of TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES specifies the sign-extended minor loop offset value (MLOFF). The same offset value (MLOFF) applies to both source and destination minor loop offsets. When the minor loop offset is enabled, you must align it to the transfer size of the source or destination it is associated with. When either minor loop offset is enabled (SMLOE set or DMLOE set), the NBYTES field is reduced to 10 bits. If both minor loop offsets are disabled (SMLOE cleared and DMLOE cleared), the NBYTES field is a 30-bit vector.

One of two register profiles (this register or TCDn_NBYTES_MLOFFNO) defines the number of bytes to transfer per request. Which register to use depends on whether source or destination minor loop mapping is enabled.

TCDn_NBYTES_MLOFFYES is defined as follows:

- If either minor loop offset is enabled (SMLOE or DMLOE = 1), then see the TCDn_NBYTES_MLOFFYES register description.
- If SMLOE and DMLOE are both 0, then see the TCDn_NBYTES_MLOFFNO register description.

Fields

Field	Function
31-0 SLAST_SDA	Last Source Address Adjustment / Store DADDR Address Source last address adjustment or the system memory address for destination address (DADDR) storage. If (TCDn_CSR[ESDA] = 0), then: • Adjustment value is added to the source address at the completion of the major iteration count. This value can be used to restore the source address to the initial value or adjust the address to reference the next data structure. • This field uses two's complement notation for the final source address adjustment. Otherwise: • This address points to the 32-bit-aligned memory location where the destination address (DADDR) is to be stored in system memory. By saving the final destination address in system memory via the ESDA feature, you are able to compute the size of a variable destination data buffer by simply subtracting the beginning DADDR from the final, saved DADDR. This feature is used together with the scatter/gather operation to prevent the loss of the final DADDR, which is overwritten during the scatter/gather operation. The "Store Destination Address" (SDA) value must be a 32-bit-aligned location because the eDMA forces the lower two address bits of the SLAST_SDA field to zero when ESDA is enabled. The module performs this write operation when the major loop is done; that is, when the major iteration count (CITER) decrements to zero.

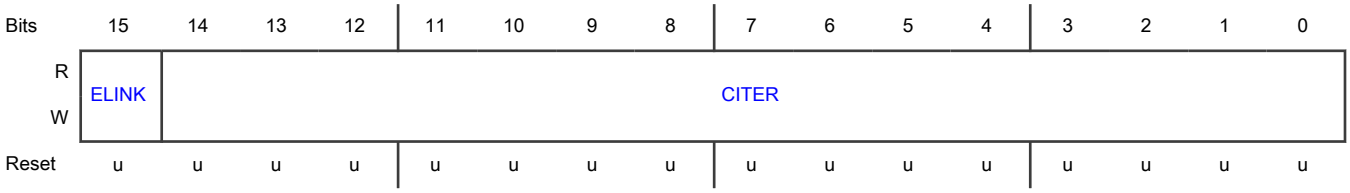
Function

If TCDn_CITER[ELINK] is 0, the TCDn_CITER register is defined as follows.

Diagram



Fields

Field	Function
15 ELINK	Enable Link As the channel completes the minor loop, this flag enables linking to another channel as defined by the relevant LINKCH field. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel to 1. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of MAJORELINK channel linking. **NOTE** This field must be equal to the BITER[ELINK] field; otherwise, a configuration error is reported. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
14-0 CITER	Current Major Iteration Count This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the channel finishes a service request and is written back to TCD memory. After the major iteration count is exhausted, the channel performs a number of operations — for example, final source and destination address calculations — and optionally generates an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field. **NOTE** When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. **NOTE** If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

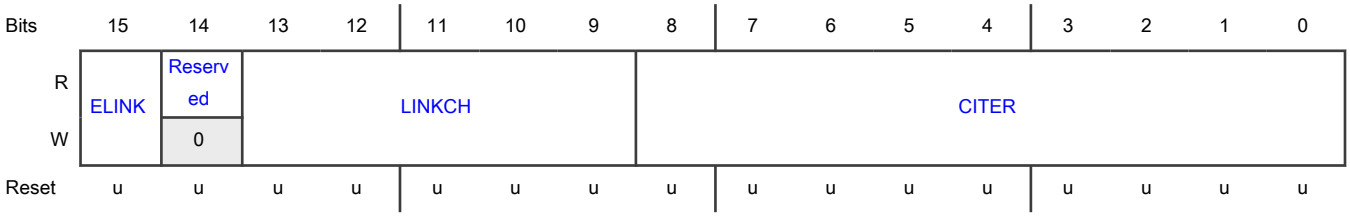
Function

If TCDn_CITER[ELINK] is 1, the TCDn_CITER register is defined as follows.

Diagram



Fields

Field	Function
15 ELINK	Enable Link As the channel completes the minor loop, this flag enables linking to another channel as defined by the relevant LINKCH field. When enabled, an internal mechanism sets the TCDn_CSR[START] field of the specified channel (LINKCH) upon minor loop completion. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of MAJORELINK channel linking. **NOTE** This field must be equal to the BITER[ELINK] field; otherwise, a configuration error is reported. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
14 —	Reserved
13-9 LINKCH	Minor Loop Link Channel Number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted the eDMA engine initiates a channel service request to the channel defined by this field by writing that channel's TCDn_CSR[START] field to 1.
8-0 CITER	Current Major Iteration Count This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the channel finishes a service request and is written back to the TCD memory. After the major iteration count is exhausted, the channel performs a number of operations — for example, final source and destination address calculations — and optionally generates an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field. **NOTE** When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. **NOTE** If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

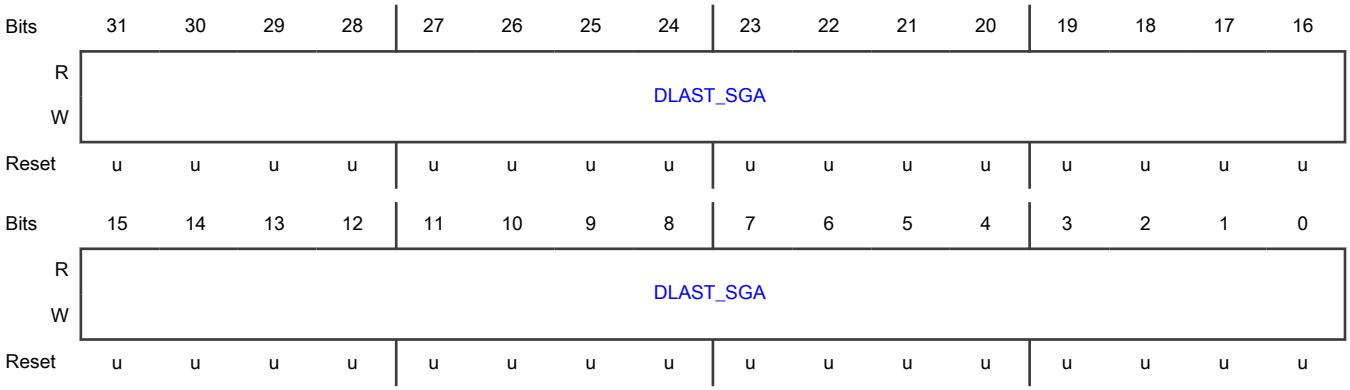
Diagram



Fields

Field	Function
31-0 DLAST_SGA	Last Destination Address Adjustment / Scatter Gather Address Adjustment of the last destination address or the memory address for the next transfer control descriptor to be loaded into this channel (scatter/gather). If (TCDn_CSR[ESG] = 0) then: • Adjustment value is added to the destination address at the completion of the major iteration count. This value can apply to restore the destination address to the initial value or adjust the address to reference the next data structure. • This field uses two's complement notation for the final destination address adjustment. Otherwise: • This address points to the beginning of a 0-modulo 32-byte region containing the next transfer control descriptor to be loaded into this channel. This channel reload is performed as the major iteration count completes. The scatter/gather address must be 0-modulo 32-byte, or else a configuration error is reported.

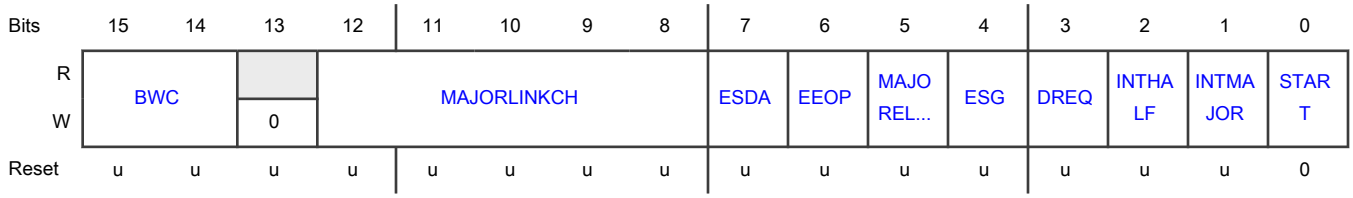
Diagram



Fields

Field	Function
15-14 BWC	Bandwidth Control Throttles the amount of bus bandwidth consumed by the eDMA. Generally, as the eDMA processes the minor loop, it continuously generates read/write sequences until the minor count is exhausted. This field forces eDMA to stall after the completion of each read/write access, to control the bus request bandwidth seen by the system bus interconnect. **NOTE** If the source and destination sizes are equal, this field is ignored between the first and second transfers and after the last write of each minor loop. This behavior is a side effect of reducing start-up latency. 00b - No eDMA engine stalls 01b - Enable eDMA master high-priority elevation (HPE) mode. No eDMA engine stalls. 10b - eDMA engine stalls for 4 cycles after each R/W 11b - eDMA engine stalls for 8 cycles after each R/W
13 —	Reserved
12-8 MAJORLINKCH	Major Loop Link Channel Number If (MAJORELINK = 0) then: • No channel-to-channel linking, or chaining, is performed after the major loop counter is exhausted. Otherwise: • After the major loop counter is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by setting that channel's TCDn_CSR[START] field to 1.
7 ESDA	Enable Store Destination Address As the channel completes the major loop by either the current iteration counter (CITER) decrementing to 0, or by receiving an enabled end-of-packet signal, this field enables writing the destination address (DADDR) to the address stored in the SLAST_SDA field. The value written to system memory is the last DADDR value prior to the DLAST_SGA offset being applied, or overwritten by an enabled scatter/gather operation. When the SDA bit is 1, SLAST_SDA contains the write pointer instead of the final source address offset. Because this is a pointer and not a final offset, a last source address offset of zero is applied to SADDR instead of the SLAST_SGA value. 0b - Ability to store destination address to system memory disabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Ability to store destination address to system memory enabled
6 EEOP	Enable End-Of-Packet Processing When enabled by the EEOP field, an end-of-packet hardware input signal directs eDMA to discontinue executing the active channel, and to treat the shutdown as the major-loop-completed event. If the EEOP field is 1, the end-of-packet signal from supported peripherals is accepted. If the EEOP field is 0, the end-of-packet input is ignored. With an end-of-packet retirement, the current TCD destination address (or ESDA-saved destination address), minus the software-saved initial address (DADDR), reflects the total amount of data transferred. 0b - End-of-packet operation disabled 1b - End-of-packet hardware input signal enabled
5 MAJORELINK	Enable Link When Major Loop Complete As the channel completes the major loop, this flag enables linking to another channel defined by MAJORLINKCH. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] field of the specified channel. **NOTE** To support the dynamic linking coherency model, this field is forced to 0 if written when TCDn_CSR[DONE] is 1. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
4 ESG	Enable Scatter/Gather Processing As the channel completes the major loop, this flag enables scatter/gather processing in the current channel. If enabled, the eDMA engine uses TCDn_DLAST_SGA as a memory pointer to a 0-modulo 32-bit address containing a 32-byte data structure, which is loaded as the transfer control descriptor into local memory. **NOTE** To support the dynamic scatter/gather coherency model, this field is forced to 0 if written when TCDn_CSR[DONE] is 1. 0b - Current channel's TCD is normal format 1b - Current channel's TCD specifies scatter/gather format.
3 DREQ	Disable Request If this flag is 1, the eDMA hardware automatically clears the corresponding ERQ bit when the current major iteration count reaches 0. 0b - No operation. Channel's ERQ field not affected 1b - Clear the ERQ field to 0 upon major loop completion, thus disabling hardware service requests. Channel's ERQ field cleared to 0 when major loop complete
2	Enable Interrupt If Major Counter Half-complete

Table continues on the next page...

Table continued from the previous page...

Field	Function
INTHALF	If this flag is 1, the channel generates an interrupt request by setting the appropriate field in the INT register to 1 when the current major iteration count reaches the halfway point. Specifically, the comparison performed by the eDMA engine is (CITER = (BITER/2)). This halfway point interrupt request is provided to support double-buffered, also known as ping-pong, schemes, or other types of data movement where the processor needs an early indication of the transfer's progress. **NOTE** If BITER = 1, do not use INTHALF; use INTMAJOR instead. 0b - Halfway point interrupt disabled 1b - Halfway point interrupt enabled
1 INTMAJOR	Enable Interrupt If Major count complete If this flag is 1, the channel generates an interrupt request by setting the appropriate field in the INT register to 1 when the current major iteration count (CITER) reaches 0. 0b - End-of-major loop interrupt disabled 1b - End-of-major loop interrupt enabled
0 START	Channel Start If this flag is 1, the channel is requesting service. The eDMA hardware automatically clears this flag to 0 after the channel begins execution. 0b - Channel not explicitly started 1b - Channel explicitly started via a software-initiated service request

14.7 Glossary

TCD Transfer control descriptor

Chapter 15
Interrupt Monitor (INTM)

15.1 Overview

The INTM module provides a mechanism to monitor the latency of the responses on interrupt requests to ensure that the processing of these critical interrupts executes within the expected time frame, increasing the reliability of the device.

15.1.1 Block diagram

The following block diagram shows the major registers involved in monitoring the interrupt sources. INTM_IRQSEL provides selection of the source, the INTM_MM enables the monitor, INTM_ACK captures the event when the interrupt is acknowledged, INTM_LATENCY can be programmed to trigger a monitor error when a threshold value is exceeded, INTM_STATUS is available to read the monitor error over periperhal bus.

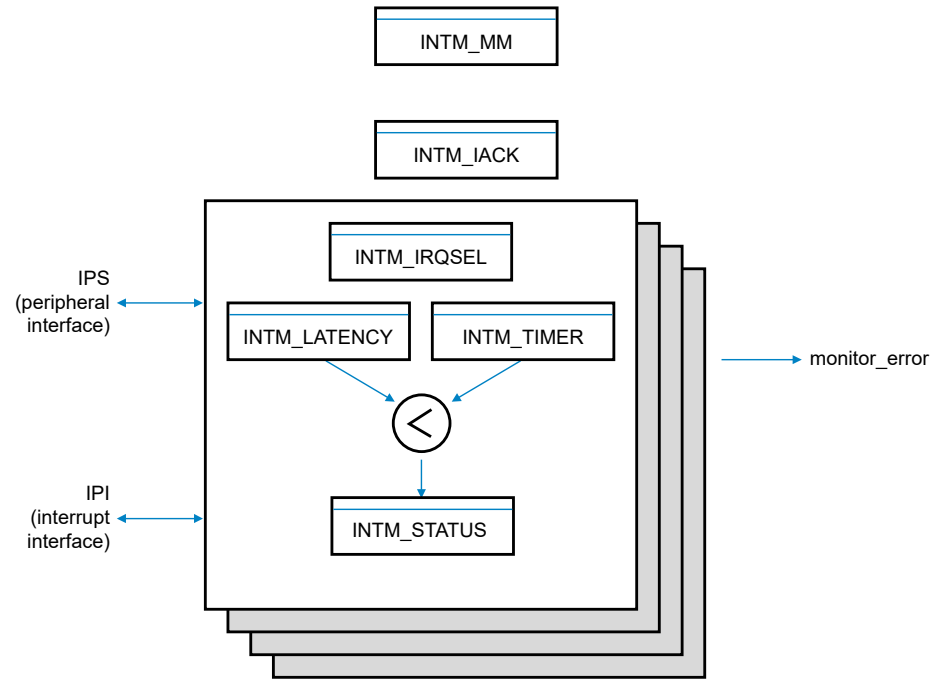

Figure 36. INTM block diagram

15.1.2 Features

INTM supports the following features:

- Up to 4 programmable interrupt monitors
- Programmable interrupt source per monitor
- Programmable 24-bit maximum latency counter per monitor
- Timer expired status bit per monitor
- One interrupt acknowledge for all monitors

15.2 Functional description

To monitor a subset of interrupt sources:

1. Program INTM_IRQSEL with a value corresponding to the interrupt source number to be monitored.
   - Only defined interrupt sources can be monitored.
2. Program the INTM_LATENCYa registers to the maximum expected latency time for each monitored interrupt source.
3. When ready, enable INTM_MM to monitor the registers.
4. During the interrupt service routine, write the IRQ of the ISR to the INTM_IACK register.
5. If the exceeds INTM_LATENCYa, then an error indication is sent to the Fault Collection Control Unit (FCCU). This information can also be seen by reading the INTM_STATUSa register.

To clear an error condition, clear the corresponding INTM_TIMERa which interrupt source exceeded the programmed latency value. When the source is not known its recommended to clear all INTM_TIMERa.

15.3 INTM register descriptions

INTM provides a way to set a maximum timer count for the interrupt latency from interrupt request to interrupt acknowledge. The purpose of this function is to provide a mechanism to monitor the latency of interrupt sources to ensure that these critical interrupts execute within the expected time frame, increasing the reliability of the device. The hardware for this function is isolated in its own hierarchy to decrease the risk of fault interference.

An error indication is sent to the Fault Collection Control Unit (FCCU) if the interrupt processing latency exceeds the programmed threshold of the expected latency. The error indication can be read from the Monitor status register.

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-1 —	Reserved
0 MM	Monitor Mode This field controls whether the INTM monitors the latency of an interrupt response. 0b - disabled 1b - enabled

15.3.3 Interrupt Acknowledge (INTM_IACK)

Offset

Register	Offset
INTM_IACK	4h

Function

This register is written by the interrupt service routine when it acknowledges the interrupt processing. This write operation must provide the number of the processed interrupt, which is compared with the interrupt request number in each INTM_IRQSELa register and stops the corresponding INTM_TIMERa when it found a match.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved

Fields

Field	Function
31-10 —	Reserved
9-0 IRQ	This field is used to specify the interrupt request number to stop INTM_TIMERa.

15.3.4 Interrupt Request Select a (INTM_IRQSEL0 - INTM_IRQSEL3)

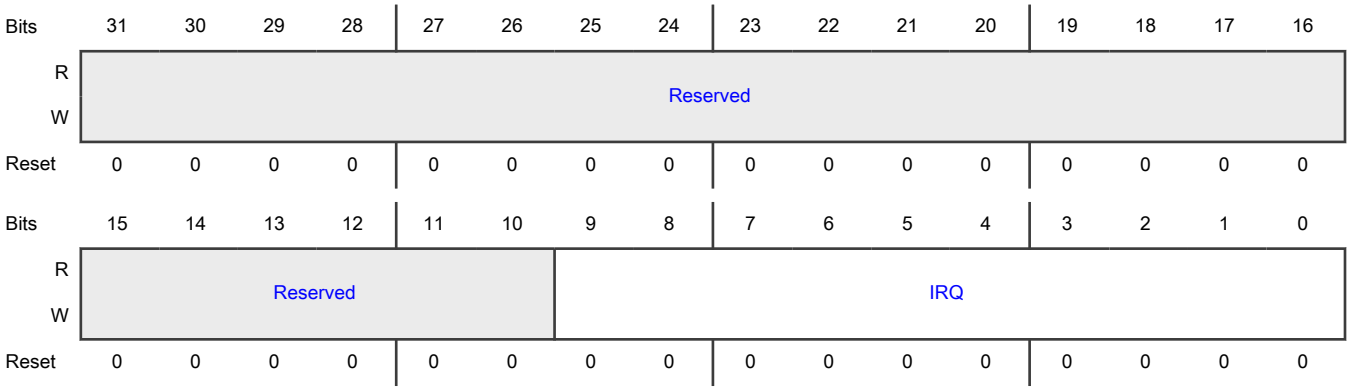
Offset

Register	Offset
INTM_IRQSEL0	8h
INTM_IRQSEL1	18h
INTM_IRQSEL2	28h
INTM_IRQSEL3	38h

Function

These registers are used to indicate which interrupt request is to be monitored or checked. The mnemonic is of the form INTM_IRQSELa, where ‘a’ is the monitor instance.

Diagram



Fields

Field	Function
31-10 —	Reserved
9-0 IRQ	This field helps you select the interrupt request number to monitor.

15.3.5 INTM_LATENCYa (INTM_LATENCY0 - INTM_LATENCY3)

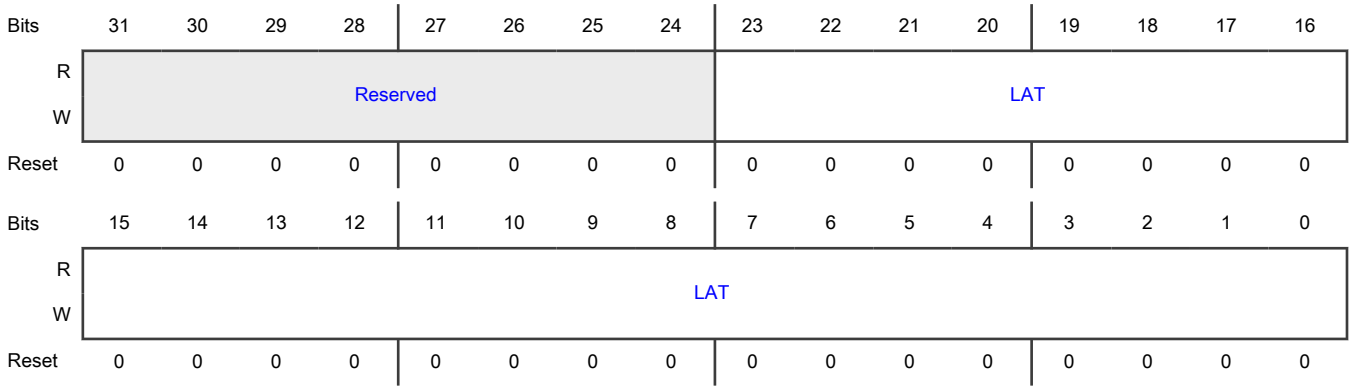
Offset

Register	Offset
INTM_LATENCY0	Ch
INTM_LATENCY1	1Ch
INTM_LATENCY2	2Ch
INTM_LATENCY3	3Ch

Function

These registers are used to indicate the maximum time before an error signal is asserted for a detected interrupt request to interrupt acknowledge. The mnemonic is of the form INTM_LATENCYa, where ‘a’ is the monitor instance.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-0 LAT	This field helps you select the maximum number of INTM clock cycles allowed for the monitored interrupt request. Maximum programmed value should not exceed 0xFF_FFFD to allow for proper timer error capture.

15.3.6 Timer a (INTM_TIMER0 - INTM_TIMER3)

Offset

Register	Offset
INTM_TIMER0	10h
INTM_TIMER1	20h
INTM_TIMER2	30h
INTM_TIMER3	40h

Function

These registers are used to count the number of INTM clock cycles for a detected interrupt request to an acknowledged interrupt processing. If the INTM_LATENCYa register is non-zero, the monitor error is not asserted, and if there is a zero to one transition on the monitored interrupt request, the INTM_TIMERa register is reset to one. As long as the INTM_LATENCYa register is non-zero and the monitor error is not asserted and the timer is enabled, the timer increments.

Following are the conditions for the timer being enabled:

- INTM_MM=1 and there was a zero-to-one transition on the monitored interrupt source

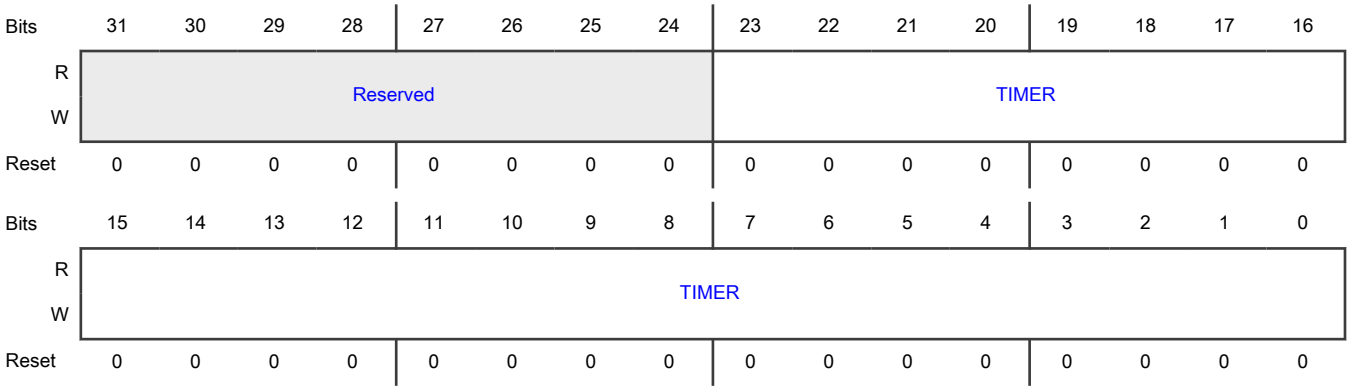
Following are the conditions for disabling the INTM_TIMERa:

- Reset
- INTM_MM=1 and monitor error

- INTM_MM=1 and monitored interrupt request is not asserted
- Interrupt acknowledge for corresponding interrupt request
- Once the timer is enabled, setting INTM_MM=0 will not disable it

The mnemonic is of the form INTM_TIMERa, where ‘a’ is the monitor instance.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-0 TIMER	This field is used to count the number of INTM clock cycles up to 24 bits of resolution.

15.3.7 Status a (INTM_STATUS0 - INTM_STATUS3)

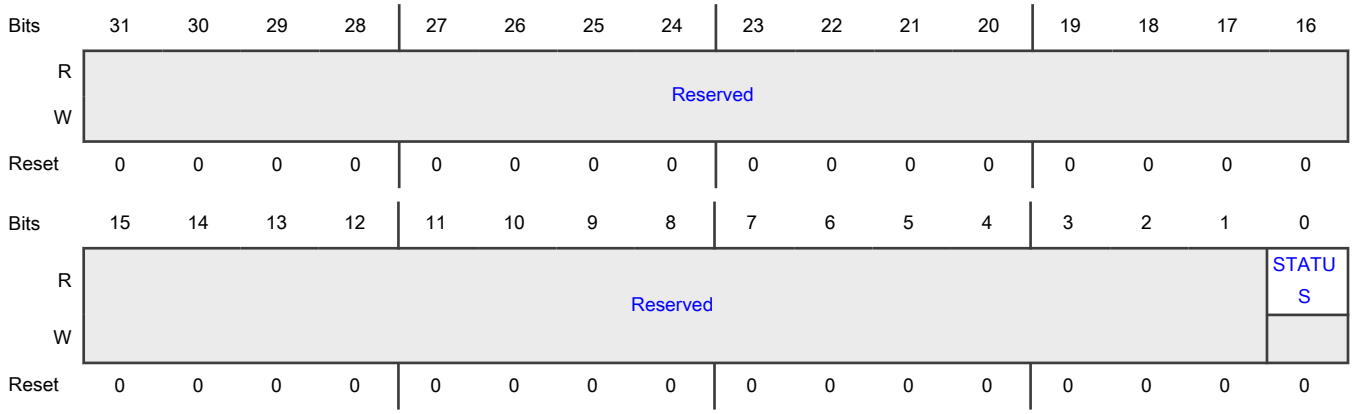
Offset

Register	Offset
INTM_STATUS0	14h
INTM_STATUS1	24h
INTM_STATUS2	34h
INTM_STATUS3	44h

Function

These registers define the monitor status. They indicate whether the INTM_TIMERa value has exceeded the INTM_LATENCYa value. The monitor status can be cleared by clearing the corresponding INTM_TIMERa register. The mnemonic is of the form INTM_STATUSa, where ‘a’ is the monitor instance.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 STATUS	Monitor status This field indicates whether INTM_TIMER value has exceeded the INTM_LATENCY value. 0b - INTM_TIMER value has not exceeded the INTM_LATENCY value. 1b - INTM_TIMER value has exceeded the INTM_LATENCY value.

Chapter 16
Semaphores2 (SEMA42)

16.1 Chip-specific SEMA42 information

16.1.1 SEMA42 instance and configuration

This chip has up to one instance of SEMA42. See the following table for availability of SEMA42 instance across MWCT2xxxS product series.

Table 50. SEMA42 instance

Instance	MWCT2D17S/MWCT2D16S	MWCT2014S/ MWCT2015S/MWCT2016S
SEMA42[1]	Yes	No

1. Load- and store-exclusive instructions are supported at the core level, but on multi-core devices the SEMA42 must be used.

See "Chip-specific XRDC information" for the domain ID of each master on the MWCT2xxxS product series. The following table shows the number of domains per chip:

Table 51. Number of domains

Chip	Number of domains
MWCT2014S/MWCT2015S/MWCT2016S	Not available
MWCT2D16S	3
MWCT2D17S	3

16.2 Introduction

SEMA42 is a memory-mapped module that provides robust hardware support needed in multi-core systems for implementing semaphores and provides a simple mechanism to achieve "lock and unlock" operations via a single - write access. The hardware semaphore module provides hardware-enforced gates as well as other useful system functions related to the gating mechanisms.

16.2.1 Multi-core programming: software gates

Multi-processor systems require a function that can be used to safely and easily provide a locking mechanism for system software to control access to shared data structures, shared hardware resources, and so on. The software uses the gating mechanisms to serialize (and synchronize) accesses to shared data and/or resources to prevent race conditions and preserve memory coherency between different processes and domains.

Consider the following description of a typical use-case: Domain X enters a section of code where shared data values are to be updated. The domain must first acquire a semaphore. Think of this as the locking (or closing) of a software gate. After the gate locks, a properly-architected software system does not allow other processes (or domains) to execute the same code segment or modify the shared data structure protected by the gate. In other words, the system locks out other processes/domains. Many software implementations include a spin-wait loop within the lock function until the gate locks. After domain X obtains the lock, domain X continues execution and updates the data values protected by the particular lock. After domain X completes the updates, it unlocks (or opens) the software gate, allowing other processes/domains access to the updated data values.

A correctly-implemented system solution must follow these important rules:

- A gate variable must protect all writes to shared data values or shared hardware resources.
- After a domain locks a gate, the system must block other processes/domains from accessing the shared data or resources. Software conventions enforce this.

- The domain that locks a particular gate is the only domain that can open (unlock) that gate.

Information in the hardware gate identifying the locking domain can be extremely useful for system-level debugging.

16.2.2 Features

SEMA42 implements hardware-enforced semaphores as an IPS-mapped slave peripheral device. The feature set includes:

- Support for 16 hardware-enforced gates in a multi-domain configuration that supports up to 15 domains. In this chapter, dm*X* represents domain *X*.
  - Gates appear as a 16-entry byte-size array with read and write accesses.
    - Domains lock gates by writing "domainID_number+1" to the appropriate gate and must read back the gate value to verify that the lock operation succeeded.
    - After the gate locks, the locking domain unlocks the gate by writing zeroes.
  - Each hardware gate appears as a 16-state, 4-bit state machine.
    - 16-state implementation

      If gate = 0h, then state = unlocked

      if gate = 1h, then state = locked by domain (master) 0

      if gate = 2h, then state = locked by domain (master) 1

      …

      if gate = Fh, then state = locked by domain (master) 14
    - SEMA42 uses the logical domain number and the specified data patterns as reference attributes to validate all write operation.
    - After a gate locks, the locking domain must unlock the gate by writing zeroes.
  - Support for secure reset mechanisms to clear the contents of individual gates, as well as a clear-all capability
- Memory-mapped slave peripheral that offers programming-model accesses

The following figure shows a simplified SEMA42 block diagram. In the diagram, the register blocks named gate0, gate1,…, gate (n-2) and gate (n-1) include the finite state machines implementing the semaphore gates.

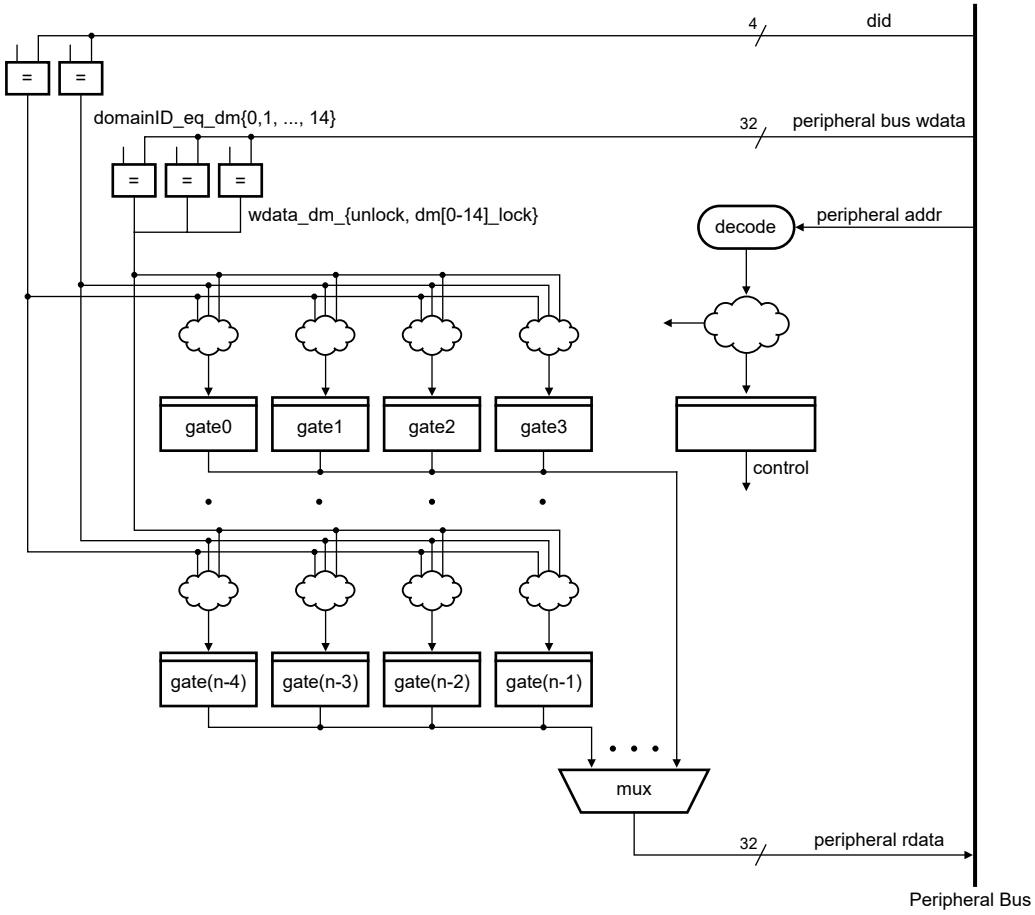

Figure 37. SEMA42 block diagram

16.3 Functional description

This section describes more about the SEMA42 functional operation and specific details of the state machines of the GATE*n* registers.

As described previously, each of the GATE*n* registers implements a 4-bit, 16-state machine. The following figure shows a simplified diagram of the state transitions for each gate.

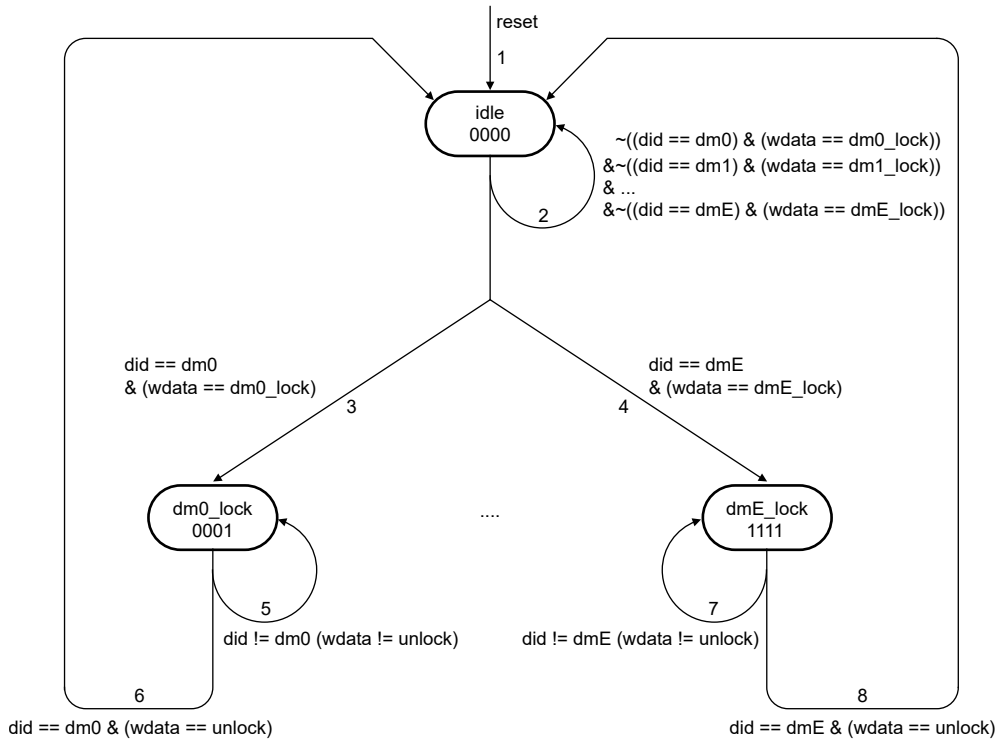

Figure 38. GATE*n* state machine

In the figure above, "did" is the domain identifier and "dm" is the domain number. The domain number identifies core domain *X* (dm*X*). Thus, for example, "dmE" represents domain 14 (E in hexadecimal). The platform passes the domain number to SEMA42.

The following table defines the GATE*n* state transitions.

Table 52. GATE*n* state transitions

Current state	Next state	Transition	Description
–	idle	1	Any reset, whether a system reset or a software-initiated gate reset, unconditionally forces the gate into the idle state.
idle	idle	2	Unless a write of the appropriate lock value from the corresponding domain occurs, the gate remains in the idle state.
idle	dm0_lock	3	When domain 0h initiates a write of the dm0_lock data value, the gate transitions into the dm0_lock state.
idle	dmE_lock	4	When domain Eh initiates a write of the dmE_lock value, the gate transitions into the dmE_lock state.
dm0_lock	dm0_lock	5	When in this state, the gate remains here if any attempted write is not from domain 0h with the unlock data value.
dm0_lock	idle	6	The gate returns to the idle (unlocked) state after a write from domain 0h with the unlock data value occurs.

Table continues on the next page...

Table 52. GATE*n* state transitions (continued)

Current state	Next state	Transition	Description
dmE_lock	dmE_lock	7	When in this state, the gate remains here if any attempted write is not from domain Eh with the unlock data value.
dmE_lock	idle	8	The gate returns to the idle (unlocked) state after a write from domain Eh with the unlock data value occurs.

SEMA42 uses these gate data values:

- The lock data value is (domain number) + 1.
- The unlock data value is 00h.

16.4 Memory map/register definition

You can access these registers only in Supervisor mode. User accesses terminate with an error.

16.4.1 SEMA42 register descriptions

16.4.1.1 SEMA42 memory map

SEMA42 base address: 4046_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h - Fh	Gate Register (GATE0 - GATE15) [1]	8	RW	00h
42h	Reset Gate Read (RSTGT_R)	16	RO	0000h
42h	Reset Gate Write (RSTGT_W)	16	WO	See description

1. In this array, the index and offset values of the registers do not increment in direct alignment. For details, see the register description.

16.4.1.2 Gate Register (GATE0 - GATE15)

Offset

For n = 0 to 15:

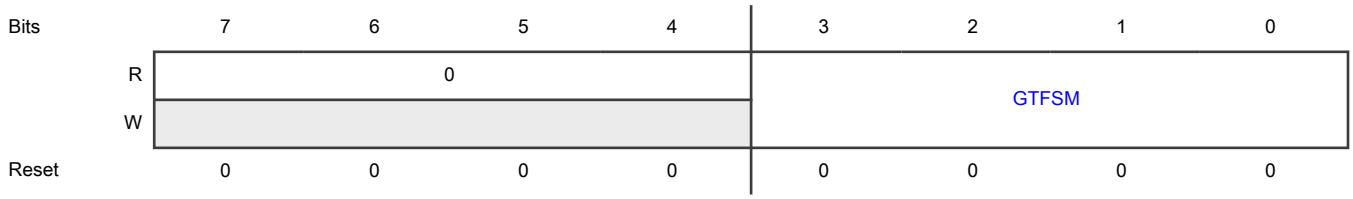
Register	Offset
GATEn	0h + (n + 3 - 2 × (n mod 4))

Function

SEMA42 implements each semaphore gate in a 4-bit finite state machine, right-justified in a byte data structure. The hardware uses the logical domain-identifier number in conjunction with the data patterns to validate all attempted write operations. Only domain masters can modify the gate registers. After a gate locks, only the locking domain must open (unlock) the gate.

You can read multiple gate values in a single access. However, you can update only a single gate at a time, via a write operation. If you attempt to write a byte-wide value that is neither the unlock value (00h) nor the appropriate lock value (domainID_number + 1), SEMA42 considers this as "no operation" and does not change any gate state. Attempts to write multiple gates in a single-aligned access with a size larger than 8 bits (byte) generate an error termination and do not allow any gate state changes.

Diagram



Fields

Field	Function
7-4 —	Reserved
3-0 GTFSM	Gate finite state machine The state of the gate reflects the last domain that locked it. This can be useful during system debug. The hardware gate has a 16-state implementation, defined as: 0000b - The gate is unlocked (free). 0001b - Domain 0 locked the gate. 0010b - Domain 1 locked the gate. 0011b - Domain 2 locked the gate. 0100b - Domain 3 locked the gate. 0101b - Domain 4 locked the gate. 0110b - Domain 5 locked the gate. 0111b - Domain 6 locked the gate. 1000b - Domain 7 locked the gate. 1001b - Domain 8 locked the gate. 1010b - Domain 9 locked the gate. 1011b - Domain 10 locked the gate. 1100b - Domain 11 locked the gate. 1101b - Domain 12 locked the gate. 1110b - Domain 13 locked the gate. 1111b - Domain 14 locked the gate.

16.4.1.3 Reset Gate Read (RSTGT_R)

Offset

Register	Offset
RSTGT_R	42h

Function

This section and Reset Gate Write (RSTGT_W) describe the same register. This section describes the general operation of the register and also shows how the register fields appear when you read the register. Reset Gate Write (RSTGT_W) shows how the register fields appear when you write to the register.

The intent of the hardware gate implementation is to specify a protocol where the locking domain must unlock the gate. However, some systems may require a reset function to re-initialize the state of any gate(s) without requiring a system-level reset. To support this special gate reset requirement, SEMA42 implements a secure reset mechanism that allows you to initialize a hardware gate (or all the gates) by following a specific dual-write access pattern. The secure-gate reset:

- Uses a technique similar to that required for the servicing of a software watchdog timer
- Requires two consecutive writes with pre-defined data patterns from the same domain

You must do this to force the clearing of the specified gate(s). The required access pattern as follows:

1. A domain performs a 16-bit write to the RSTGT memory location. The most significant byte (RSTGT_W[RSTGDP]) must be E2h. The value of least significant byte is irrelevant for this reference and can be anything.
2. The same domain then performs a second 16-bit write to the RSTGT location. For this write, the upper byte (RSTGT_W[RSTGDP]) is the logical complement of the first data pattern (1Dh) and the lower byte (RSTGT_W[RSTGTN]) specifies the gate(s) to be reset. This gate field can specify a single gate or all gates to be cleared. If the same domain writes incorrect data on the second access or another domain performs the second write access, SEMA42 aborts the special gate reset sequence and does not assert an error signal.
3. Reads of the RSTGT location return information on the 2-bit reset state machine (RSTGT_R[RSTGSM]) that implements these functions:
   - The domain performing the reset (RSTGT_R[RSTGMS])
   - The last-cleared gate number(s) (RSTGT_R[RSTGTN])

   Reads of the RSTGT register do not affect the secure-reset finite state machine in any manner.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0		RSTGSM		RSTGMS				RSTGTN							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
15-14	ROZ

Table continues on the next page...

Table continued from the previous page...

Field	Function
ROZ	This field always returns the value 0 when you read it.
13-12 RSTGSM	Reset gate finite state machine Reads of the RSTGT register return the encoded state machine value. RSTGSM = 10b is valid for only a single machine cycle, so a read can never return this value. SEMA42 maintains the reset state machine in a 2-bit, 3-state implementation, defined as follows: 00b - Idle, waiting for the first data pattern write. 01b - Waiting for the second data pattern write 10b - The 2-write sequence has completed. Generate the specified gate reset(s). After the reset is performed, this machine returns to the idle (waiting for first data pattern write) state. 11b - This state encoding is never used and therefore reserved.
11-8 RSTGMS	Reset gate domain This field records the logical number of the domain performing the gate reset function. The logical number is the domain number. This domain number is determined by the XRDC's Master Domain Assignment Controller (XRDC_MDAC). To succeed, this function requires that the same domain initiate the two consecutive writes to this register. SEMA42 updates the field each time a write to this register occurs.
7-0 RSTGTN	Reset gate number This field specifies the specific hardware gate to be reset. The second write updates this field. If RSTGTN < 64, SEMA42 resets the single gate defined by RSTGTN. Otherwise, SEMA42 resets all the gates.

16.4.1.4 Reset Gate Write (RSTGT_W)

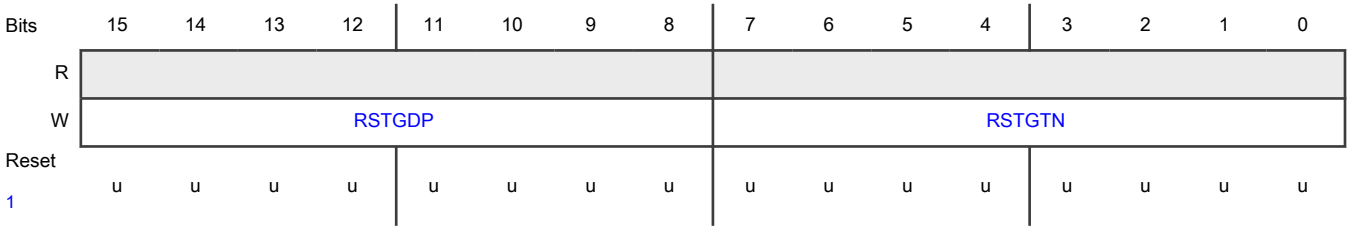
Offset

Register	Offset
RSTGT_W	42h

Function

This section describes how the RSTGT fields appear when the register is written. See Reset Gate Read (RSTGT_R) for the description of the register's overall operation and how the register fields appear when you read the register.

Diagram



1. Reset value is not applicable for writes.

Fields

Field	Function
15-8 RSTGDP	Reset gate data pattern You access this field with the specified data patterns on the two consecutive writes to enable the gate-reset mechanism. For the first write, RSTGDP must be E2h. For the second write, RSTGDP must be 1Dh.
7-0 RSTGTN	Reset gate number This field specifies the specific hardware gate to be reset. The second write updates this field. If RSTGTN < 64, SEMA42 resets the single gate defined by RSTGTN. Otherwise, SEMA42 resets all the gates.

16.5 Glossary

IPS Protocol used for peripheral accesses to the programming model

Chapter 17
Crossbar Integrity Checker (XBIC)

17.1 Chip-specific XBIC information

17.1.1 XBIC instances and configuration

This chip has up to seven instances of XBIC. The following tables describes the instances and their configuration.

Table 53. XBIC instances

Instance	MWCT2D17S/MWCT2D16S	MWCT2016S
XBIC_0	Yes	Yes
XBIC_1	Yes	No
XBIC_2	Yes	No
XBIC_3	Yes	No

17.1.2 Target master IDs

See "Chip-specific XRDC information" for master IDs.

17.2 Overview

XBIC verifies the integrity of crossbar transfers.

17.3 Features

XBIC includes the following features:

- Verification of attribute information for crossbar transfers [1],[2]
  - EDC detects single- and double-bit errors
- Verification of feedback information for each data phase during crossbar transfers
- Error injection for testing
  - Programmable master and slave port specifiers
  - Programmable 8-bit toggle vector to insert error in master EDC value
  - Address, EDC syndrome, master, and slave port information are captured when error is detected
- Crossbar transfer attribute integrity check programmable on a per-slave-port basis
- Feedback integrity check programmable on a per-master-port basis

17.4 Block diagram

The chip routes crossbar transfer attribute information for all mapped master and slave ports to XBIC, which calculates and checks the EDC value of the attribute information, as shown in the following diagram.

[1] See Table 54 for a list of crossbar attribute signals verified.
[2] The chip verifies read and write data separately, via the end-to-end ECC architecture.

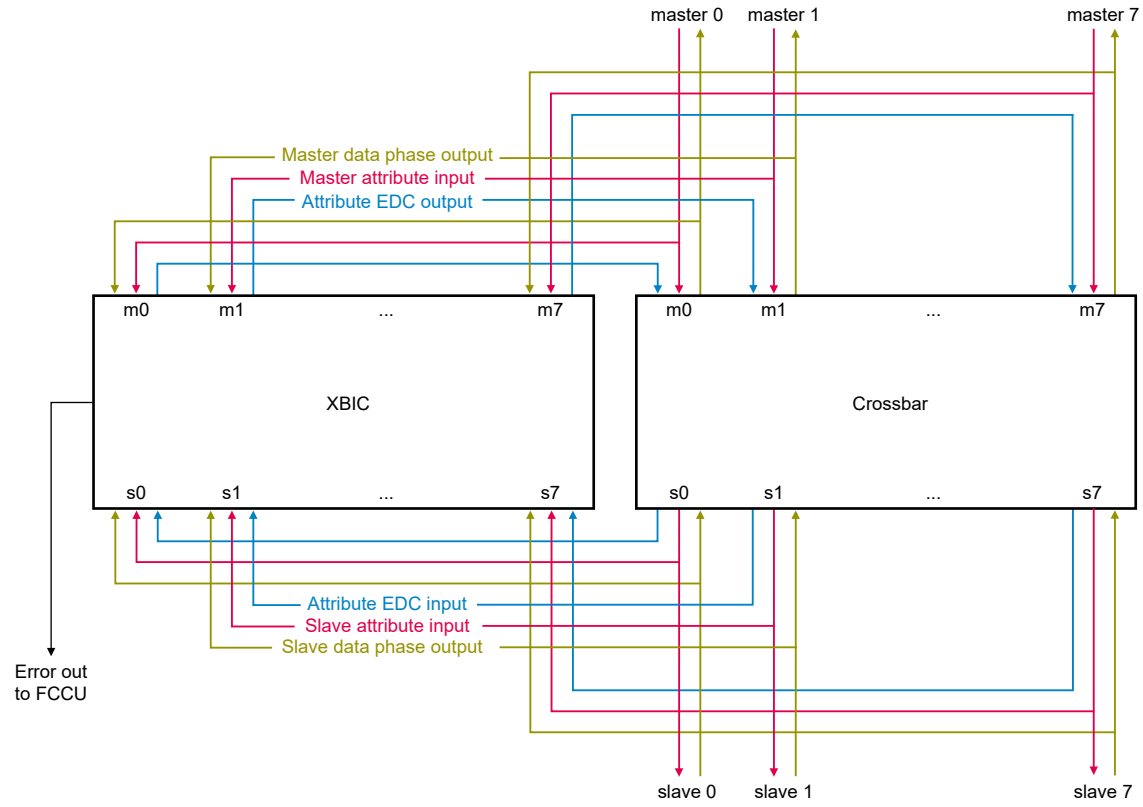


Figure 39. XBIC system block diagram

The above figure illustrates one of many possible XBIC and crossbar configurations. See the Chip-specific XBIC information section for actual port mappings.

17.5 Signal description

XBIC has no external interface signals.

17.6 Functional description

XBIC verifies the integrity of the crossbar interface on an individual port basis according to the configuration specified via the MCR register. When XBIC detects an error, it reports relevant information and sends an error signal to the FCCU module, but does not generate a bus error. XBIC integrity checking is independent of end-to-end ECC, which monitors the integrity of the transfer address and data.

During the address phase of a transfer, XBIC verifies the crossbar attribute information using an 8-bit EDC, which detects any single-bit or double-bit errors. When XBIC detects an error (an attribute integrity error), due to either hardware fault or error injection, it reports information related to the error in ESR and EAR.

During the data phase of a data transfer, XBIC verifies the integrity of response signals from slave to master as they pass through the crossbar. When XBIC detects an error in the response signals (a feedback integrity error), it reports the XBIC slave and master ports in ESR[DPSE0] - ESR[DPSE7] and ESR[DPME0] - ESR[DPME7], respectively.

During the data phase, XBIC sends an alarm to the FCCU module if a master port attempts back-to-back accesses in which:

1. The first access terminates normally.
2. The second attempts access to an address space not mapped to any slave on the crossbar.

The resultant 'absent slave error' causes the crossbar to generate a bus error response to the requesting master. XBIC detects the bus error response as a difference because the bus error did not originate from the slave port.

You can program XBIC to inject EDC errors for testing purposes. Error injection targets a single slave port and a single master port, as specified by the configuration settings in the EIR register. When XBIC inserts an error, it changes the EDC syndrome, causing the XBIC to assert an error indication to the FCCU module. Otherwise, transfers are unaffected by error injection. This enables verification of the check logic without compromising the integrity of the data transfer. After you enable error injection function by writing 1 to EIR[EIE], XBIC induces errors on all subsequent targeted transactions until you write a 0 to the field. After the FCCU error indication asserts, it remains asserted even after you write 0 to EIR[EIE]. The error indication deasserts after FCCU specifically clears the existing error. After FCCU clears the XBIC error, additional error injection testing can continue.

To trace a fault reported by the XBIC to the FCCU:

1. Note the error reported by the FCCU. For example, "NCF[46]".
2. Locate the source module and error description in the attached fault mapping spreadsheet. For example:
   - Channel number: NCF[46]
   - Source module: AXBS_1 integrity checker
   - Description: Instruction crossbar error indication to FCCU if syndrome calculated using EDC on the data is not zero
3. Refer to the Chip-specific XBIC information section for the source XBIC module to determine the specific XBIC module instance—"XBIC_1", for example.
4. Determine the type of error (attribute integrity error or feedback integrity error) and the XBIC port(s) involved by reading the information reported in the ESR register of the reported XBIC instance.
5. For attribute integrity check errors, read the XBIC EAR register for the target address of the requested transfer.
6. Refer to the Chip-specific XBIC information section and possibly the Chip-specific AXBS information section for port mapping of XBIC ports to AXBS ports.

Decode a single-bit error syndrome value reported in ESR[SYN] by finding the value in the following table. Any syndrome value not included in the table indicates a multi-bit error.

Table 54. Hexadecimal attribute single-bit error syndromes

17.7 XBIC register descriptions

The XBIC programming model consists of four 32-bit registers. Software can access this model only in supervisor mode using 32-bit (word) accesses. Each of the following generates a transaction error back to the requesting master. Such errors could cause core exceptions apart from other problems.

- Access size other than 32-bit
- Access to an undefined (reserved) address
- Unsupported access type—an attempted write to a read-only register, for example
- Access in user mode

17.7.1 XBIC memory map

XBIC_AXBS base address: 4020_4000h

XBIC_AXBS_PERI base address: 4020_8000h

XBIC_AXBS_TCM base address: 4040_0000h

XBIC_AXBS_eDMA base address: 4040_4000h

Offset	Register	Width (In bits)	Access	Reset value
0h	XBIC Module Control (MCR)	32	RW	FFFF_0000h
4h	XBIC Error Injection (EIR)	32	RW	0000_0000h
8h	XBIC Error Status (ESR)	32	RO	0000_0000h
Ch	XBIC Error Address (EAR)	32	RO	0000_0000h

17.7.2 XBIC Module Control (MCR)

Offset

Register	Offset
MCR	0h

Function

Use this register to turn attribute integrity checking and feedback integrity checking on or off on a per-port basis.

- Turn on attribute integrity checking on one or more XBIC slave ports by ensuring that the associated SE*n* field(s) have a value of 1. For example, setting field SE*0* enables attribute integrity checking for slave port 0. The default (reset) behavior is for attribute integrity checking to be performed for all slave ports. XBIC performs EDC-based checks on all transfer requests targeting the selected slave port(s). The signals verified are transfer attribute signals going from master to slave. When XBIC detects an attribute integrity error, it reports relevant information in the ESR and EAR registers.
- Turn on feedback integrity checking on one or more XBIC master ports by ensuring that the associated ME*n* field(s) have a value of 1. For example, setting field ME*0* to 1 enables feedback integrity checking for master port 0. The default (reset) behavior is for feedback integrity checking to be performed for all master ports. XBIC checks slave-to-master feedback signals for transfer requests originating from the selected XBIC master port(s). If any feedback signal value is different at the master and slave ports during the data phase, XBIC reports the relevant master and slave ports in the ESR register.

Each field in this register references a specific master or slave port using XBIC port numbering. Referring to Figure 39, "slave port 0" refers to XBIC port "s0" in the figure, "slave port 1" refers to port "s1", and so on. Similarly, "master port 0" refers to XBIC port "m0", "master port 1" refers to port "m1", and so on. See the "Chip-specific XBIC information" section in this document for the mapping of XBIC instances to AXBS instances and XBIC ports to AXBS ports. See the "Chip-specific AXBS information" section in this document for the device component(s) mapped to each port of an AXBS instance.

17.7.3 XBIC Error Injection (EIR)

Offset

Register	Offset
EIR	4h

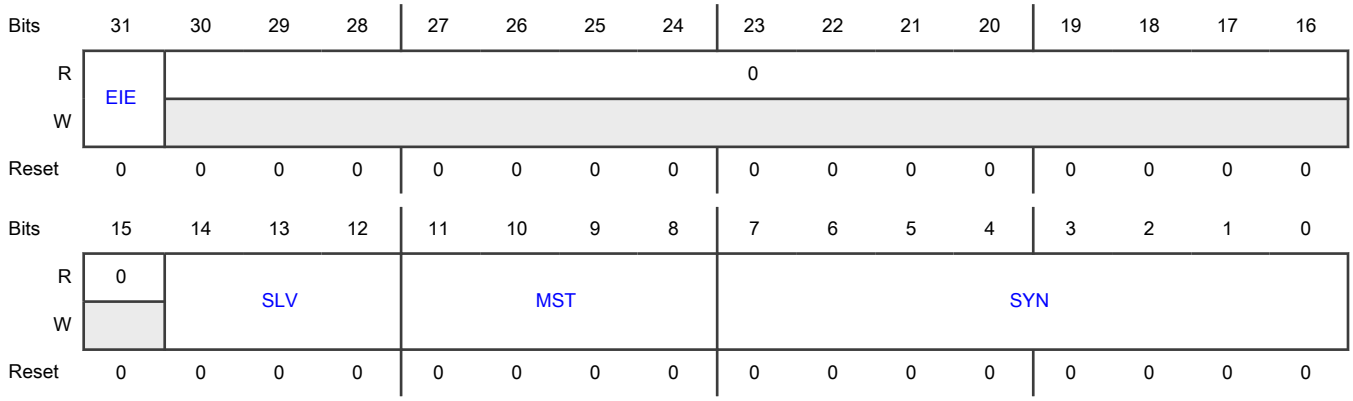
Function

Use this register to configure the XBIC error injection function and turn it on or off. When enabled, the XBIC error injection function inserts an attribute integrity error when the targeted master requests a transaction of the targeted slave port. The inserted error changes the calculated EDC syndrome value, causing XBIC to:

- Capture transfer information in the ESR and EAR registers
- Assert an error signal to the FCCU module

Otherwise, XBIC error injection does not affect transfers.

Diagram



Fields

Field	Function
31 EIE	Error Injection Enable 0b - Error injection disabled 1b - Error injection enabled
30-15 —	Reserved
14-12 SLV	Target Slave Port Specifies the target slave port for error injection—other slave ports are unaffected. Specify the target slave port by its XBIC slave port number (0–7). See the "Chip-specific XBIC information" section in this document for the mapping of XBIC instances to AXBS instances and XBIC ports to AXBS ports. See the "Chip-specific AXBS information" section in this document for the device component(s) mapped to each port of an AXBS instance.
11-8 MST	Target Master ID Specifies the target master port for error injection—transfers with other masters are unaffected. Specify the target master port using the logical master ID number of the target bus master. See the "Chip-specific XBIC information" section in this document for the master IDs and their corresponding components.
7-0 SYN	Syndrome XBIC performs an exclusive OR operation on the value in this field and the calculated syndrome, to generate an error with the specified syndrome. A value of zero does not generate an error. See Table 54 for a list of transfer attribute single-bit error syndromes, noting that the values given in the table are hexadecimal.

17.7.4 XBIC Error Status (ESR)

Offset

Register	Offset
ESR	8h

Function

In this register, XBIC reports information about the most recent transfer with an error detected. If XBIC detects an attribute integrity check error, it reports:

- The slave port identifier (SLV)
- The master port identifier (MST)
- The error syndrome (SYN)

If XBIC detects a mismatch among feedback signals during the data phase:

- The DPSE0 - DPSE7 field with a value of 1 indicates the XBIC slave port. In the DPSE0-DPSE7 field descriptions, the slave port number refers to the XBIC slave port number. Referring to Figure 39, "slave port 0" refers to XBIC port "s0" in the figure, "slave port 1" refers to port "s1", and so on. See the "Chip-specific XBIC information" section in this document for the mapping of XBIC instances to AXBS instances and XBIC ports to AXBS ports. See the "Chip-specific AXBS information" section in this document for the device component(s) mapped to each port of an AXBS instance.
- The DPME0 - DPME7 field with a value of 1 indicates the XBIC master port. In the DPME0-DPME7 field descriptions, the master port number refers to the XBIC master port number. Referring to Figure 39, "master port 0" refers to XBIC port "m0" in the figure, "master port 1" refers to port "m1", and so on. See the "Chip-specific XBIC information" section in this document for the mapping of XBIC instances to AXBS instances and XBIC ports to AXBS ports. See the "Chip-specific AXBS information" section in this document for the device component(s) mapped to each port of an AXBS instance.

XBIC sets this register to all 0s only on reset.

18.1.2 MRC configuration

Table 56. MRC configuration

Submodule instance	Region format	Number of region descriptors	Slaves protected (port number)	Applicability
XRDC_MRC0	Auto	16[1] or 8	PFLASH_0 (0) PFLASH_1 (1) PFLASH_2 (2)[1] PFLASH_3 (3) PFLASH_WR (3)	MWCT2015S, MWCT2016S, MWCT2D16S, MWCT2D17S
XRDC_MRC1	Auto	16[1] or 8	PRAM0_0 (0) PRAM1_0[1] (2)	MWCT2015S, MWCT2016S,

Table continues on the next page...

Table 56. MRC configuration (continued)

Submodule instance	Region format	Number of region descriptors	Slaves protected (port number)	Applicability
			TCM backdoor (1)	MWCT2D16S, MWCT2D17S
XRDC_MRC2	Auto	4	QuadSPI (0)	MWCT2D16S, MWCT2D17S

1. Applicable to MWCT2D16S and MWCT2D17S

18.1.3 PAC configuration

Table 57. PAC configuration

Module name	Slaves protected	Applicability
XRDC_PAC0	AIPS_0	MWCT2015S, MWCT2016S, MWCT2D16S, MWCT2D17S
XRDC_PAC1	AIPS_1	MWCT2015S, MWCT2016S, MWCT2D16S, MWCT2D17S
XRDC_PAC2	AIPS_2	MWCT2D16S, MWCT2D17S

NOTE

For PDAC registers assignment to peripherals, see the memory map file attached to this document.

18.1.4 Domain Error Word registers (DERR_W*x*_0-18) mapping

The mapping of the domain error capture registers is as follows:

Table 58. Domain Error Word registers mapping

Register	Corresponding MRC/PAC	Available in chips
DERR_W*x*_0	MRC0	MWCT2015S, MWCT2016S, MWCT2D16S, MWCT2D17S
DERR_W*x*_1	MRC1	MWCT2015S, MWCT2016S, MWCT2D16S, MWCT2D17S
DERR_W*x*_2	MRC2	MWCT2D16S, MWCT2D17S
DERR_W*x*_16	PAC0	MWCT2015S, MWCT2016S, MWCT2D16S, MWCT2D17S
DERR_W*x*_17	PAC1	MWCT2015S, MWCT2016S, MWCT2D16S, MWCT2D17S
DERR_W*x*_18	PAC2	MWCT2D16S, MWCT2D17S

Where *x*: 0, 1, 2, 3.

If the above registers are accessed in chips wherein they are not present, a bus error gets reported.

18.1.5 Exceptions and violations

A write attempt by a noncore bus master outside the defined ranges leads to an exception in case the XRDC region is defined to prevent noncore master access. The chip generates a bus error if you violate XRDC policies.

18.1.6 Configuration using SBAF

SBAF must protect access to its own resources. Hence, XRDC is configured during initialization. SBAF provides the mechanism for you to configure XRDC during boot. You must program the configuration data in the application flash memory region.

18.1.6.1 Default configuration of MDAC when HSE_B firmware feature is disabled

Table 59. MDAC registers default value

MDAC register	Value	Domain number assigned
HSE_B CPU (MDAC3)	C000_0002h	0

All the other MDAC domain numbers are 0 and SBAF does not lock them.

18.1.6.2 Default configuration of MRC registers when HSE_B firmware usage feature flag is disabled

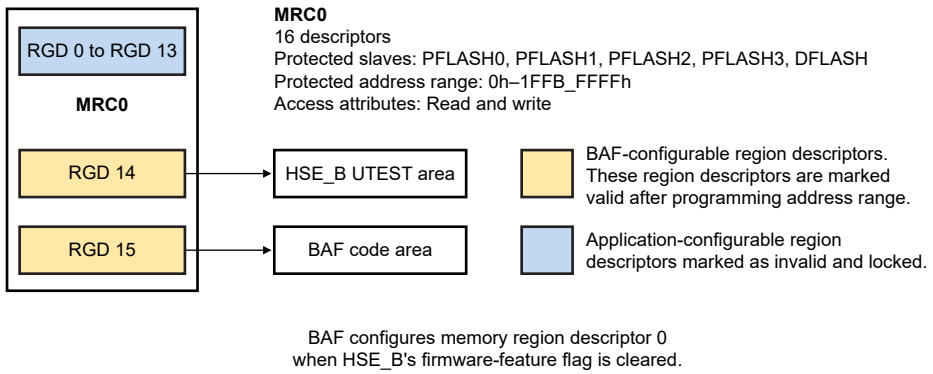

Figure 40. Default configuration of MRC registers when HSE_B firmware usage feature flag is disabled

Table 60. Default configuration of MRC registers when HSE_B firmware usage feature flag is disabled

MRC number	Region descriptor number	Region address range (in hex)	Name	Remarks	SBAF's configuration
0	14	1B00_0200 - 1B00_06FF	HSE_B UTEST area	UTEST area that is accessible by HSE_B core only. Start address is 1B00_0200h and 1B00_06FFh for others LC	W0 = start address = 1B00_0200h W1 = end address = 1B00_06FFh W2 = {SE = 0, SNUM = 0, D3ACP = 7h [all permission]}
1	15	007F_4000 - 007F_FFFF	SBAF code area	Code area for SBAF and HSE_B firmware	W0 = start address= 007F_4000h W1 = end address= 007F_FFFFh W2 = {SE = 0, SNUM = 0, D2ACP =7h [all permission], D1ACP = 0h [no permission], D0ACP = 0h [no permission]}

18.1.6.3 PDAC default configuration

SBAF configures and lock the following peripherals for its exclusive use. Read and write access to these peripheral are not provided to application domains.

Table 61. PDAC default configuration

Peripheral	Peripheral PDAC number	Remarks
Flash memory controller alternate	155	HSE_B uses the alternate interface exclusively.

Table continues on the next page...

Table 61. PDAC default configuration (continued)

Peripheral	Peripheral PDAC number	Remarks
Flash memory alternate	188	HSE_B uses the alternate interface exclusively.
HSE_GPR	231	All cores have all permissions.

18.1.7 Configuration when HSE_B firmware-feature flag is cleared

When the HSE_B firmware-feature flag is cleared, SBAF:

- Does not permit XRDC configuration.
- Locks the aforementioned configurations.

18.2 Introduction

18.2.1 Overview

XRDC manages access control between masters (cores and noncore masters) and targets (memories and peripherals) by placing them in virtual groups called domains.

Conceptually, a domain is one or more masters and memories and peripherals, that are isolated from others. It may help to look at a domain as a permissions group within a computing environment. All masters in a domain have the same access to chip resources such as memory and peripherals. See Introduction to domains for more information on domains.

The protection provided by XRDC access control is in addition to the local memory protection unit contained within each core.

18.2.2 Features

- Enables you to partition chip resources (master and target) into access-controlled domain .
  - Each domain has a unique DID .
  - The DID is an attribute of every system bus transaction.
- Provides a four-level hierarchical access control scheme for defining an ACP for each target in a domain. See Access control model for more information.
  - Memory region descriptors define access policies for address ranges within memories.
  - Peripheral access control registers define access policies for individual peripherals.
- Supports optional hardware semaphores to dynamically modify access rights for target resources.

18.2.3 Block diagram

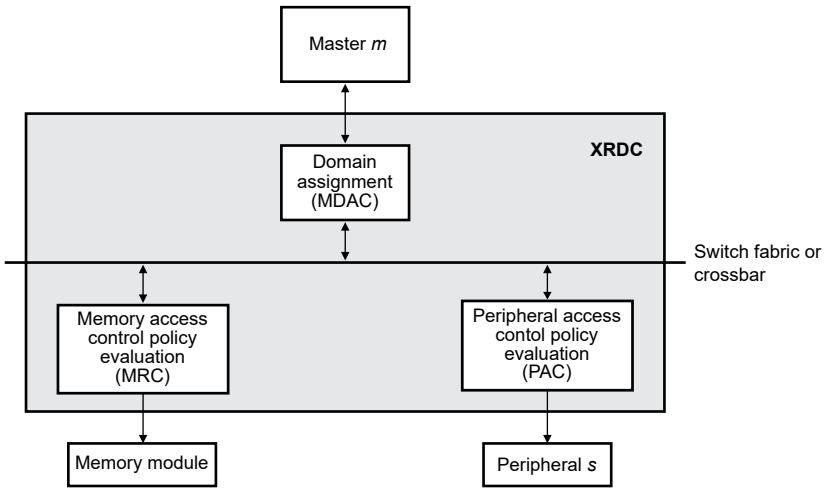

Figure 41. Block diagram

18.2.4 Block descriptions

Block	Description
Domain assignment	A process that adds information to transactions, including: • DID • Privileged attribute • Secure attribute Domain assignment is performed by the MDAC submodule. See: • Domain assignment • Master domain assignment controller (MDAC)
Master	A core or noncore (for example, DMA) module that can initiate transactions with memory or peripheral resources.
Memory	A block of flash memory, RAM, or other memory.
Memory access control policy evaluation	A process that determines whether the domain associated with a transaction has access rights to a memory location. The process is performed by the MRC submodule. See: • Memory region ACP evaluation • Memory region controller (MRC)
Peripheral	A nonmemory resource module within the chip—an ADC, timer module, or communications module, for example.
Peripheral access control policy evaluation	A process that determines whether the domain associated with a transaction has access rights to a peripheral. The process is performed by the PAC submodule.

Table continues on the next page...

Table continued from the previous page...

Block	Description
	See Peripheral access controller (PAC).
Crossbar	The chip's module and I/O interconnect infrastructure.

18.2.5 Indexes used in this chapter

Table 62. Indexes used in this chapter

Index	Description
c	Memory controller number. For example, MRC*c*.
d	Domain number. For example, PDAC_W0_6[D*d*ACP].
m	Master number. For example, PID*m*.
r	Memory region number. For example, RGD_W0_*r*.
s	PDAC slot number. For example, PDAC_W0_*s*[D0ACP].
w	Word number. In a group of registers consisting of consecutive 32-bit registers, *w* is the 0-indexed register number. For example, MRGD_W*w*_0.

18.3 Modes of operation

XRDC does not support any special modes of operation.

18.4 External signal description

XRDC does not have any external signals.

18.5 Functional description

18.5.1 Introduction to domains

A domain typically consists of one or more master, along with the memories and peripherals those masters are allowed to access. Because it is access-controlled, a domain acts as an independent computing environment.

Domains enable applications to coexist on the same silicon with a firewall between them, enforcing absolute interference protection.

Generally, you create each domain to meet a specific need. Examples of XRDC domain usage include:

- Isolation of real-time from non-real-time applications to ensure resource availability
- Isolation of safety-critical code from non-safety-critical code
- Isolation of third-party untrusted applications from trusted software
- Isolation of memory regions to ensure data security or to prevent accidental overwrites
- Limiting write access for a specific area of system memory to a single DMA module instance
- Limiting read access for a specific area of system memory to a specific processor core

You can assign a core to multiple domains but only one of those domains can be active at a given time.

Within each XRDC instance, each domain has a unique identifier, known as its DID. If an XRDC instance has 16 DIDs, that means the instance has 16 available domains.

You control which masters can access a peripheral by configuring the domain ACP for each peripheral. Similarly, you control which masters can access a memory region by configuring the ACP for each memory region.

18.5.2 Submodules

XRDC implements its functionality through its hardware submodules:

- Master domain assignment controller (MDAC)
- Memory region controller (MRC)
- Peripheral access controller (PAC)

18.5.2.1 Master domain assignment controller (MDAC)

The MDAC submodule performs domain assignment logic. XRDC contains an MDAC submodule for each XRDC-protected master. Each MDAC assigns a DID to every transaction from its associated master. You configure the domain assignment activity for each MDAC through a set of registers, in one of two formats:

- DFMT0 core domain assignment registers
- DFMT1 noncore domain assignment registers

To understand the role of domains in XRDC protection, see Introduction to domains.

For a full explanation of the domain assignment process, see Domain assignment.

18.5.2.2 Memory region controller (MRC)

The MRC submodule performs memory region access control. Each XRDC instance contains the number of MRCs indicated in HWCFG0[NMRC]. Each MRC is associated with one or more memories (see the chip-specific XRDC information for details). The MRC controls memory access using memory region descriptors. MRCFG*c*[NMRGD] indicates the number of region descriptors available for MRC *c*.

Each memory region descriptor defines a memory address range and a configurable access control policy for each domain using a set of four or five 32-bit registers (see Memory ACP evaluation registers).

Memory region descriptors also support including an optional hardware semaphore in the ACP evaluation for memory regions shared by multiple domains (see Hardware semaphores and dynamic access rights).

For a full explanation of the memory region ACP evaluation process, see Memory region ACP evaluation.

18.5.2.3 Peripheral access controller (PAC)

The PAC submodule provides domain access control for all peripherals connected to a single peripheral bus. Each XRDC contains the number of PACs indicated in HWCFG0[NPAC]. Each PAC supports up to 128 peripheral slots (see Finding the PDAC slot number for a peripheral). You configure the ACP for each peripheral using a set of PDAC_W*w*_*s* registers (see Peripheral ACP evaluation registers).

Peripheral access control also enable a hardware semaphore to be included in the access control policy evaluation for peripherals shared by multiple domains. See Hardware semaphores and dynamic access rights for more details.

For a full explanation of the peripheral ACP evaluation process, see Peripheral ACP evaluation process.

18.5.3 Transaction protection

During application execution, high-level chip modules such as cores or DMA, Ethernet, Zipwire, or FlexRay, known as masters, initiate transaction requests to memory and peripheral resources. XRDC adds protection capabilities to ensure the requesting master accesses only the resources that it is authorized to access. These capabilities support security and safety requirements.

XRDC provides this protection by adding two steps to the unprotected transaction flow, as shown in XRDC transaction flow.

XRDC transaction processing differs depending on:

- The type of master making the request (see Transaction request sources).
- The type of target receiving the request (see Transaction targets).

18.5.4 XRDC transaction flow

Table 63. XRDC transaction flow

Step	Operation	Performed by	Description
1	Transaction request	Master	A master requests a read or write transaction targeting memory or a peripheral.
2	Domain assignment	XRDC	XRDC MDAC submodule intercepts the request and performs domain assignment, which adds this metadata to the transaction: • DID • Privileged attribute • Secure attribute
3	Interconnect	Chip	The chip transmits the domain-assigned transaction request across the interconnect (crossbar).
4	ACP evaluation	XRDC	XRDC MRC or PAC submodule intercepts the transaction request and evaluates it against the target's ACP to determine whether the requesting master has sufficient access rights to the target. If it does, the transaction continues. Otherwise, XRDC generates an access violation error and the transaction terminates.
5	Transaction response	Target resource	If the previous step does not generate an access violation error, the target resource processes the transaction request and transmits data (for read transactions) and transaction status information (for all transactions) back across the interconnect to the requesting master. XRDC is not involved in the flow of information from the target resource back to the requesting master.

18.5.5 Domain assignment

18.5.5.1 Overview

Domain assignment associates a DID with each transaction request from a master. To determine the DID for a transaction, XRDC evaluates the domain-specific configuration data in the set of MDAC registers (MDA_W*n*_*m*_DFMT0 or MDA_W*n*_*m*_DFMT1) associated with the requesting master. The exact process depends on the source of the request (see Transaction request sources).

The number of MDAC registers can vary for each master. See the chip-specific information. MDACFG*m*[NMDAR] indicates the number of MDA registers, where *m* is the master number. You need *m* to locate the registers relevant for domain assignment. See the chip-specific XRDC information for more on master numbers. See:

- Register settings for DFMT0 direct domain assignment transactions
- Register settings for DFMT0 PID-based transactions
-

Domain assignment also assigns the secure and privileged attributes to the transaction.

18.5.5.2 PID-based domain assignment

To provide more flexibility in routing core tasks to chip resources in different access-controlled domains, XRDC supports the use of a PID. If the core master contains a built-in PID register, indicated by HWCFG2[PIDP*m*] = 1 , XRDC reflects the core PID value in PID*m*[PID], and bit 5 of that field indicates the secure attribute for the transaction request. Otherwise, an application can mimic PID-based domain assignment by writing a value to that field.

18.5.5.3 Transaction request sources

The domain assignment process for an XRDC-protected transaction request depends on the source of the request.

Table 64. Transaction request sources

Request source	Topic	Brief description
Core master	DFMT0 direct domain assignment example	Direct domain assignment using a DFMT0 master domain assignment register.
Core master	DFMT0 PID-based domain assignment example	PID-based domain assignment using a DFMT0 master domain assignment register.

18.5.5.4 DFMT0 core domain assignment registers

Table 65. DFMT0 core domain assignment registers

Register	Index
MDACFG*m*	*m* = master number. See the chip-specific XRDC information for the available list of masters with their IDs.
MDA_W*w*_*m*_DFMT0[1]	*m* = master number. *w* = word (see MDA register structure). MDACFG*m*[NMDAR] indicates the number of MDA registers (words) per master.
PID*m*	*m* = master number.

1. See MDA register structure.

18.5.5.5 DFMT1 noncore domain assignment registers

Table 66. DFMT1 noncore domain assignment registers

Register	Index
MDACFG*m*	*m* = master number. See the chip-specific XRDC information for the available list of masters and their IDs.
MDA_W*w*_*m*_DFMT1[1]	*m* = master number. *w* = word. MDACFG*m*[NMDAR] indicates the number of MDA registers (words) per master.

1. See MDA register structure.

18.5.5.6 MDA register structure

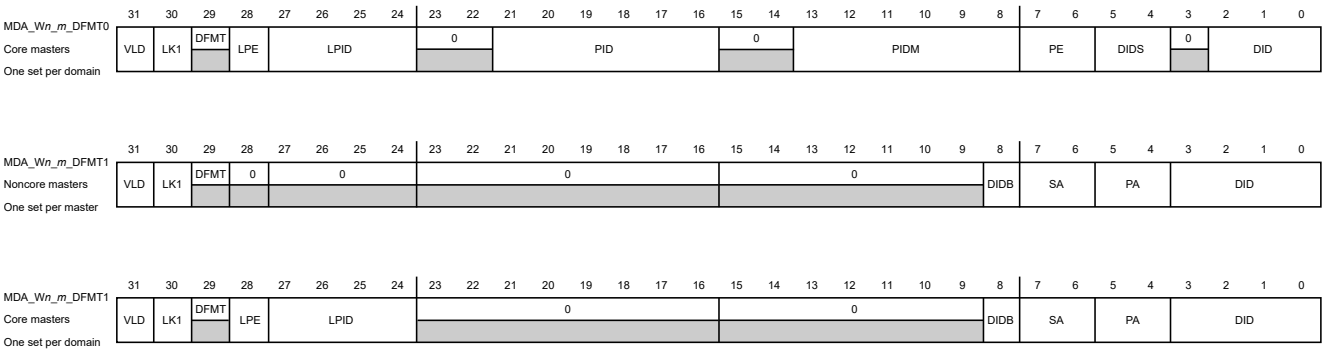

Figure 42. MDA register structure

18.5.6 ACP evaluation

18.5.6.1 Overview

When XRDC is not enabled, all peripherals and memories allow unrestricted access. XRDC allows you to limit that access to requests from a particular domain or domains with an application-specified ACP. XRDC intercepts the transaction request and evaluates it against the target's ACP to determine whether the requesting master has sufficient access rights to the target, based on the:

- Domain ID assignment (DID)
- Privileged attribute
- Secured attribute

XRDC obtains the target resource's domain ACP from the associated Domain Access Control Policy (D*d*ACP) field (see Domain ACP specification) in the appropriate register set:

- Peripheral ACP evaluation registers
- Memory ACP evaluation registers

If ACP evaluation determines that the transaction request has sufficient access rights to the target resource, XRDC allows the transaction to continue. Otherwise, it terminates the request with an error and captures the address and attribute information in the appropriate error registers.

The exact process depends on the target of the request (see Transaction targets).

XRDC optionally supports the inclusion of a hardware semaphore to dynamically alter the ACP of a memory region or peripheral (see Hardware semaphores and dynamic access rights).

18.5.6.2 Transaction targets

The ACP evaluation for an XRDC-protected transaction request depends on the target of the request.

Table 67. Transaction targets

Request target	Topic	Brief description
Peripheral	Peripheral ACP evaluation example	Process for a transaction request to a target peripheral that is within a protected domain, with ACP evaluation configured by PDAC_W*w*_*s*.

Table continues on the next page...

Table 67. Transaction targets (continued)

Request target	Topic	Brief description
Memory	Memory ACP evaluation example	Process for a transaction request to a target memory region that is within a protected domain, with ACP evaluation configured by MRGD_W*w_r*.

18.5.6.3 Peripheral ACP evaluation registers

Table 68. Peripheral ACP evaluation registers

Register	Index	Brief description
PDAC_W0_*s*[1]	*s* = peripheral slot	Specifies the ACP for an XRDC-protected peripheral, and an optional hardware semaphore.
PDAC_W1_*s*[1]	*s* = peripheral slot	Enables the set of PDAC registers for the associated peripheral and locks the set. Typically, you configure the peripheral by writing to the PDAC registers and then limiting their respective domains from making updates to the D*d*ACP fields or by locking the set for all updates.

1. See PDAC register structure.

18.5.6.4 PDAC register structure

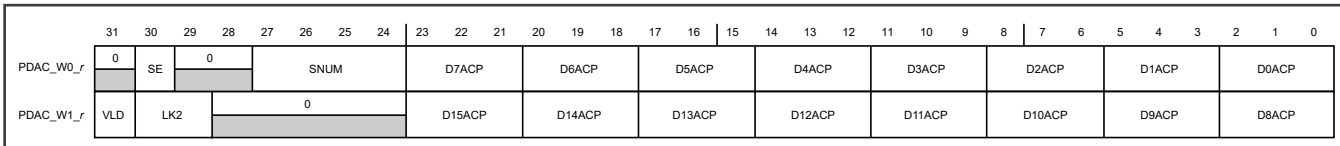

Figure 43. PDAC register structure

18.5.6.5 Memory ACP evaluation registers

When XRDC is enabled (CR[GVLD] = 1), you cannot access any XRDC-protected memory unless you configure at least one set of memory region descriptors (see MRGD_W*w_r*) that includes the targeted memory.

Table 69. Memory ACP evaluation registers

Register	Index	Brief description
MRCFG*c*	*c* = memory controller instance	Indicates the number of memory regions per memory controller (NMRGD). Each memory region is configured by a set of memory region descriptor registers (MRGD_W*w_r*) described below.
MRGD_W0_*r*[1]	*r* = memory region	Specifies starting address for the memory region.
MRGD_W1_*r*[1]	*r* = memory region	Specifies ending address for the memory region.
MRGD_W2_*r*[1]	*r* = memory region	Specifies the ACP for each supported domain, and an optional hardware semaphore.
MRGD_W3_*r*[1]	*r* = memory region	Enables the set of MRGD registers for the associated region and locks the set. Typically, you define the memory region by writing to the MRGD registers and then limiting their respective domains from updating the D*d*ACP fields or by locking the set for all updates.

1. See MRGD register structure.

18.5.6.6 MRGD register structure

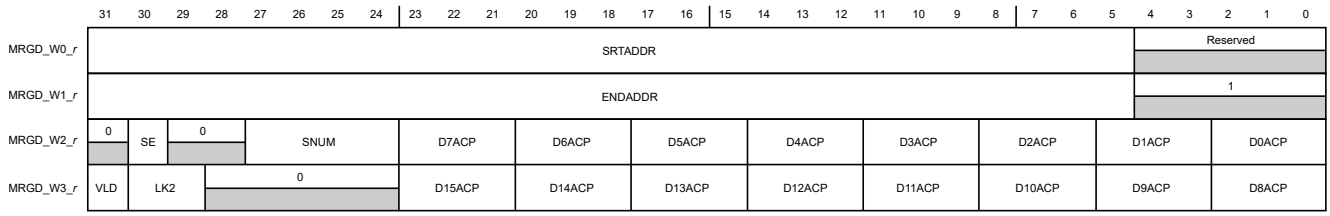

Figure 44. MRGD register structure

18.5.6.7 Access control model

XRDC supports a four-level hierarchical access control model. This model combines the traditional privileged (also known as supervisor) and user access levels with an additional signal for the secure attribute of each memory reference, as shown in Access control model levels.

Each level has different access control policies that specify the read and write accessibility for a target. XRDC combines the privileged and secure attributes with the DID assigned to each system bus transaction to form the hardware basis for the access control mechanism. You specify the ACP for target resources using the D*d*ACP fields (see Domain ACP specification) found in the configuration registers shown in Peripheral ACP evaluation registers and Memory ACP evaluation registers.

You can dynamically control access to shared memory regions and target peripherals with the optional inclusion of a hardware semaphore (see Hardware semaphores and dynamic access rights). If you enable this semaphore for a given address space or peripheral, XRDC allows writes to the target resource only if the requesting domain owns the semaphore.

For cores that support only the three-state access control model (Secure Privileged, Secure User, Nonsecure User), XRDC forces the nonsecure output signal from the MDAC submodule to 0 in privileged mode. This change enables precise state transitions between user and privileged modes. Specifically, the MDAC logic for master *m* generates the nonsecure attribute output signal as a function of the Three-State Model (PID*m*[TSM]) and PID Present (HWCFG2[PIDP*m*]) fields, as shown in Generation of secure attribute).

18.5.6.7.1 Access control model levels

Table 70. Access control model levels

Secure	Nonsecure	Privileged (supervisor)	Not privileged (user)	Level
Yes	Not applicable	Yes	Not applicable	Most restricted
Yes	Not applicable	Not applicable	Yes	More restricted
Not applicable	Yes	Yes	Not applicable	Less restricted
Not applicable	Yes	Not applicable	Yes	Least restricted

18.5.6.7.2 Generation of secure attribute

This table shows how XRDC generates the secure attribute for a transaction.

Table 71. Generation of secure attribute

Access levels [1]	PID*m*[TSM] (b)	PID present [2]	Secure attribute determined by
4	0	No	Master secure attribute

Table continues on the next page...

Table 71. Generation of secure attribute (continued)

Access levels [1]	PID*m*[TSM] (b)	PID present [2]	Secure attribute determined by
4	0	Yes	Master secure attribute && ~master privileged attribute
3	1	No	PID*m*[5] && ~master privileged attribute
3	1	Yes	Local secure attribute && ~master privileged attribute

1. XRDC assumes a core master supports the four-level access model. If a core supports only the three-state access control model, you must write 1 to PID*m*[TSM] before loading any nonsecure value into the PID.
2. Indicated in HWCFG2–3[PIDP*m*].

18.5.6.8 Domain ACP specification

Table 72. Domain ACP specification

D*d*ACP	Allowable accesses			
	Secure Privileged	Secure User	Nonsecure Privileged	Nonsecure User
111b	R, W	R, W	R, W	R, W
110b	R, W	R, W	R, W	None
101b	R, W	R, W	R	R
100b	R, W	R, W	R	None
011b	R, W	R, W	None	None
010b	R, W	None	None	None
001b	R	R	None	None
000b	None	None	None	None

18.5.6.9 Memory region ACP evaluation

During ACP evaluation of a memory transaction request, if the target memory location falls within the address range specified by any XRDC memory region descriptor, then XRDC identifies the request as a memory region hit. For each memory region hit, XRDC compares the DID, privileged attribute, and secured attribute of the transaction to the associated domain ACP (MRGD_W{2,3}_*r*[D*d*ACP]) in the memory region descriptor. See ACP evaluation for additional details on this function.

The following conditions cause XRDC to report an access error:

- The target memory location does not fall within any defined memory regions; in other words, the transaction request is not a hit.
- The transaction request does not have the appropriate access permissions for the region, which triggers a domain violation.
- The transaction request hits multiple (overlapping) regions, and all of those regions signal access violations.

Unimplemented domain identifiers default to no access privileges, and therefore the access type of a D*d*ACP field for an unimplemented domain is read-as-zero/writes-ignored (RAZ/WI).

18.5.6.10 Hardware semaphores and dynamic access rights

XRDC memory region descriptors and peripheral access control support an optional hardware semaphore in their access evaluations. This hardware semaphore allows hardware enforcement of dynamic access rights, based on the state of the semaphore for shared memory regions or shared peripherals.

If enabled, the state of the semaphore dynamically modifies the access control policies so that only the domain owning it has write access to the resource. The write permissions for all other domains are revoked based on the semaphore state. If no domain owns the semaphore, the PAC and MRC submodules evaluate DdACP normally.

If you enable a hardware semaphore (by writing 1 to MRGD_W2_*r*[SE] or PDAC_W0_*r*[SE]) then, before the normal DdACP evaluation, XRDC checks the state of the hardware semaphore specified in MRGD_W2_*r*[SNUM] or PDAC_W0_*r*[SNUM].

On a write transaction, if the semaphore is not idle (the semaphore state is non-zero) and the requesting domain does not own the semaphore, the memory or peripheral access terminates with an error. In other words, writes into a semaphore-enabled address space or peripheral are allowed only if the semaphore is idle or the requesting domain owns the semaphore.

18.5.7 XRDC transaction examples

To see the complete transaction process for an XRDC-protected transaction request from a master to target:

1. Follow one of these examples of domain assignment:
   - DFMT0 direct domain assignment example
   - DFMT0 PID-based domain assignment example
   -
2. Then follow one of these examples of ACP evaluation:
   - Peripheral ACP evaluation example
   - Memory ACP evaluation example

18.5.7.1 DFMT0 direct domain assignment example

This configuration assigns a specific domain to all incoming transactions.

- A core master has master number = 6.
- The core has one MDAC register (MDACFG6[NMDAR] = 1), configured as shown in Register settings for DFMT0 direct domain assignment transactions.

MDAC_W*w*_*m*_DFMT0 registers do not include fields for secure and privileged attributes. Those attributes are part of the transaction data from core masters and are forwarded with the transaction after domain assignment.

18.5.7.1.1 Register settings for DFMT0 direct domain assignment transactions

Table 73. Register settings for DFMT0 direct domain assignment transactions

Field	MDA_W0_6_DFMT0	Comments
VLD	1	Enables this register for use in domain assignment.
LK1	1	Locks the settings in this register until the next module reset.
DFMT	0	Indicates that this is a DFMT0 register.
PID	00_0000b	Not used because PE = 00b.
PIDM	00_0000b	Not used because PE = 00b.
PE	00b	Disables PID-based filtering.

Table continues on the next page...

Table 73. Register settings for DFMT0 direct domain assignment transactions (continued)

Field	MDA_W0_6_DFMT0	Comments
DIDS	00b	All incoming transactions are to be assigned to the domain specified by the DID field.
DID	01b	Because PE = 00b and DIDS = 00b, all incoming transactions are to be assigned DID value 01b.

18.5.7.1.2 DFMT0 direct domain assignment process

The application configures XRDC as it boots. After application boot completes, a core issues a read request to a target peripheral.

1. XRDC intercepts the request and performs domain assignment using the configuration in MDA_W0_6_DFMT0. In this example, XRDC assigns DID = 01b to all incoming transactions.
2. The transaction proceeds with DID = 01b and the privileged and secure attributes provided by the core.

18.5.7.2 DFMT0 PID-based domain assignment example

This example configuration demonstrates PID-based domain assignment:

- A core master with master number = 4 processes both safety-critical tasks and routine tasks, using two domains:
  - Domain 0 is reserved for safety-critical tasks (PID = 0–15).
  - Domain 1 is reserved for routine tasks (PID > 15).
- The core has eight MDAC registers (MDACFG4[NMDAR] = 8), configured as follows (see Register settings for DFMT0 PID-based transactions):
  - MDA_W0_4_DFMT0 assigns safety-critical tasks (PID = 0–15) to domain 0.
  - MDA_W1_4_DFMT0 assigns routine tasks (PID = 16–31) to domain 1.
  - MDA_W2_4_DFMT0 assigns routine tasks (PID = 32–63) to domain 1.
  - MDA_W3_4_DFMT0 through MDA_W7_4_DFMT0 are not used.

MDAC_W*w_m*_DFMT0 registers do not include fields for secure and privileged attributes. Those attributes are part of the transaction data from core masters and are forwarded with the transaction after domain assignment.

18.5.7.2.1 Register settings for DFMT0 PID-based transactions

Table 74. Register settings for PID-based transactions

Field	Registers				
	MDA_W0_4_DFMT0	MDA_W1_4_DFMT0	MDA_W2_4_DFMT0	MDA_W[3–7]_4_DFMT0	Comments
VLD	1	1	1	0	Enables this register for use when assigning domains.
LK1	1	1	1	1	Locks the settings in each register until the next device reset.
DFMT	0	0	0	0	Indicates that these registers apply to domain assignment for core masters.
PID	00_0000b	01_0000b	10_0000b	—	Constant match value to be used for PID-based filtering.

Table continues on the next page...

Table 74. Register settings for PID-based transactions (continued)

Field	Registers				
	MDA_W0_4_DFMT0	MDA_W1_4_DFMT0	MDA_W2_4_DFMT0	MDA_W[3–7]_4_DFMT0	Comments
PIDM	00_1111b	10_1111b	01_1111b	—	Each 0 bit causes the corresponding PID bit to be considered in domain assignment.
PE	10b	10b	10b	—	Specifies the type of pattern matching used for PID evaluation.
DIDS	00b	00b	00b	—	Assign all incoming transactions with PIDs that pass the filtering criteria to the domain specified by the DID field.
DID	00b	01b	01b	—	This DID value is assigned to incoming transactions with PIDs that pass the filtering criteria.

18.5.7.2.2 DFMT0 PID-based domain assignment process

The application configures XRDC as it boots. After booting completes, a core issues a read request to a target peripheral. The task making the request has PID = 6, indicating that it is a safety-critical task.

1. XRDC intercepts the request and performs domain assignment using each enabled MDA_W*n*_4_DFMT0 register, regardless of whether it has already found a match. In this example, XRDC performs the domain assignments as shown in DFMT0 PID-based domain assignment evaluation.
2. After XRDC completes all domain assignment evaluations, it logically ORs the assigned DIDs to determine the final DID assigned to the transaction. In this example, only one evaluation results in a DID assignment, so there is no OR operation.
3. The transaction proceeds with DID 00b and the privilege and secure attributes provided by the core.

18.5.7.2.3 DFMT0 PID-based domain assignment evaluation

Table 75. DFMT0 PID-based domain assignment evaluation

Register	Evaluation steps	Boolean math	Result
MDA_W0_4_DFMT0	1. Bitwise AND of PID with inverted PIDM.	00_0000b & 11_0000b	00_0000b
	2. Bitwise AND of transaction PID (PID4[PID]) with inverted PIDM.	000110b & 11_0000b	00_0000b
	3. Compare the results of steps 1 and 2.	00_0000b == 000000b	True: Assign DID 0
MDA_W1_4_DFMT0	1. Bitwise AND of PID with inverted PIDM.	01_0000b & 01_0000b	01_0000b
	2. Bitwise AND of transaction PID (PID4[PID]) with inverted PIDM.	00_0110b & 01_0000b	00_0000b
	3. Compare the results of steps 1 and 2.	01_0000b == 00_0000b	False: No DID assignment
MDA_W2_4_DFMT0	1. Bitwise AND of PID with inverted PIDM.	10_0000b & 10_0000b	10_0000b
	2. Bitwise AND of transaction PID (PID4[PID]) with inverted PIDM.	00_0110b & 10_0000b	00_0000b
	3. Compare the results of steps 1 and 2.	10_0000b == 00_0000b	False: No DID assignment

18.5.7.3 Peripheral ACP evaluation example

This example configuration demonstrates ACP evaluation for a target peripheral.

- The core master must have highly available, exclusive access to the ADC0 peripheral for safety-critical tasks in domain 0.
- The core master supports 8 domains (HWCFG0[NDID] = 111b).
- ADC occupies PDAC slot 40 in the chip, as defined in the memory map file attached to this document (see Finding the PDAC slot number for a peripheral).
- Given 8 domains and PDAC slot 40, the PDAC registers associated with ADC0 are PDAC_W0_40 and PDAC_W1_40.

The following sections describe the register configurations for this example.

18.5.7.3.1 Finding the PDAC slot number for a peripheral

This topic shows how to find the PDAC slot number for a peripheral, but it is a generic example. Memory map file organization and appearance can vary.

To find the PDAC slot number for a peripheral:

1. Open the memory map file attached to this document and view the peripherals page.
2. Locate the peripheral in the "Instance" column.
3. The PDAC slot number for the peripheral is at the intersection of the "PDAC slot number" column and the peripheral row.

In this figure, for peripheral ADC_0, the PDAC slot number is 40. Therefore, the PDAC registers for ADC0 are PDAC_W*w*_40.

	A	B	D	E	I	J
1	Instance	Description	Start address	End address	PDAC slot number	AIPS instance
8	LCU_0	Logic Control Unit 0	0x40098000	0x4009BFFF	38	AIPS_0
9	LCU_1	Logic Control Unit 1	0x4009C000	0x4009FFFF	39	AIPS_0
10	ADC_0	Analog-to-digital converter 0	0x400A0000	0x400A3FFF	40	AIPS_0
11	ADC_1	Analog-to-digital converter 1	0x400A4000	0x400A7FFF	41	AIPS_0
12	ADC_2	Analog-to-digital converter 2	0x400A8000	0x400ABFFF	42	AIPS_0

Figure 45. Finding the PDAC slot number for a peripheral

18.5.7.3.2 Register settings for peripheral ACP evaluation

This table shows the PDAC_W*w*_40 settings for a safety-critical task assigned to domain 0.

Table 76. Register settings for peripheral ACP evaluation

Register	Field	Value (b)	Comments
PDAC_W0_40	SE	0	The hardware semaphore (see the SEMA42 chapter) is disabled.
	SNUM	(don't care)	The hardware semaphore is not used in this example.
	D7ACP	000	Domain 7 has no access to the peripheral.
	D6ACP	000	Domain 6 has no access to the peripheral.
	D5ACP	000	Domain 5 has no access to the peripheral.
	D4ACP	000	Domain 4 has no access to the peripheral.

Table continues on the next page...

Table 76. Register settings for peripheral ACP evaluation (continued)

Register	Field	Value (b)	Comments
	D3ACP	000	Domain 3 has no access to the peripheral.
	D2ACP	000	Domain 2 has no access to the peripheral.
	D1ACP	000	Domain 1 has no access to the peripheral.
	D0ACP	010	Only privileged, secure transactions from domain 0 have access.
PDAC_W1_40	VLD	1	Use this register set in domain ACP evaluations.
	LK2	11	Lock the settings in this register until the next device reset.

18.5.7.3.3 Peripheral ACP evaluation process

XRDC performs the following process for ACP evaluation:

1. When the application is running, the core issues a read request to a target peripheral. The task making the request has PID = 0, indicating that it is a safety-critical task. The transaction request is privileged and secured.
2. Between the chip interconnect and ADC0, XRDC intercepts the request and compares its DID, privileged attribute, and secured attribute to the configuration in PDAC_W0_40 and PDAC_W1_40.
3. Because the ADC0 D0ACP field is 010b for privileged, secured access, XRDC grants access to the transaction.
4. The transaction proceeds normally without any further intervention from XRDC.

18.5.7.4 Memory ACP evaluation example

This example configuration demonstrates ACP evaluation for a target memory. Following are the desired features:

- The core master must have highly available, exclusive access to the memory region for safety-critical tasks in domain 0.
- The target memory is the address range 1B00_0000h–1B00_1FFFh, protected by memory controller 0 (MRC0).
- Access to the entire memory range will be controlled by the memory region descriptor defined by MRGD_W*w*_0.
- The requested transaction is secure privileged.

With the configuration settings shown in Register settings for memory ACP evaluation, XRDC grants access and the transaction proceeds normally. There is no further XRDC intervention.

18.5.7.4.1 Register settings for memory ACP evaluation

Table 77. Register settings for memory ACP evaluation

Register	Field	Value	Comments
MRGD_W0_0	SRTADDR	1B00_0000h	Starting address of the memory region.
MRGD_W1_0	ENDADDR	1B00_1FFFh	Ending address of the memory region.
MRGD_W2_0	SE	0	The hardware semaphore (see the SEMA42 chapter) is disabled.
	SNUM	(don't care)	The hardware semaphore is not used in this example.
	D7ACP	000b	Domain 7 has no access to the peripheral.
	D6ACP	000b	Domain 6 has no access to the peripheral.
	D5ACP	000b	Domain 5 has no access to the peripheral.
	D4ACP	000b	Domain 4 has no access to the peripheral.

Table continues on the next page...

Table 77. Register settings for memory ACP evaluation (continued)

Register	Field	Value	Comments
	D3ACP	000b	Domain 3 has no access to the peripheral.
	D2ACP	000b	Domain 2 has no access to the peripheral.
	D1ACP	000b	Domain 1 has no access to the peripheral.
	D0ACP	010b	Only privileged, secure transactions from domain 0 have access.
MRGD_W3_0	VLD	1	Use this register set in domain ACP evaluations.
	LK2	11b	Lock the settings in this register until the next device reset.

18.5.7.4.2 Memory ACP evaluation process

In this example, XRDC performs the following process for ACP evaluation:

1. When the application is running, the core issues a read request to address 1B00_0100h. The transaction request is secure privileged.
2. Between the chip interconnect and the memory, XRDC intercepts the request and compares its DID, memory location of the address, privileged attribute, and secured attribute to the configuration in MRGD_W0_0, MRGD_W1_0, MRGD_W2_0 and MRGD_W3_0.
3. Because the address 1B00_0100h is in the memory range 1B00_0000h–1B00_1FFFh and its D0ACP field is 010b for privileged, secured access, XRDC grants access to the transaction.
4. The transaction proceeds normally without any no further intervention from XRDC.

18.6 Initialization information

Out of reset, XRDC is disabled (CR[GVLD] = 0), which allows secure privileged startup code to configure the entire programming model.

18.6.1 Initialization procedure

1. Read the hardware configuration registers to obtain the implemented XRDC hardware capabilities for the chip:
   - HWCFG0
   - HWCFG1
   - HWCFG2
   - MDACFG*m* (one for each supported bus master—number indicated in HWCFG0[NMSTR])
   - MRCFG*c* (one for each supported memory controller—number indicated in HWCFG0[NMRC])
2. Use the information retrieved in step 1 and the desired domain architecture to configure:
   - Domain assignments (MDA_W*w_m*_DFMT0 and MDA_W*w_m*_DFMT1)
   - Memory region descriptors (MRGD_W*w_n*)
   - Peripheral access control (PDAC_W*w_s*)

   Ensure that you enable the necessary registers and register sets using the appropriate VLD fields. Also, you can limit access to these registers or lock them after you configure them, by using the appropriate LK1 fields.
3. Enable XRDC (write 1 to CR[GVLD]).

XRDC is now fully operational.

18.6.2 Minimize access errors

When you configure and enable XRDC, it begins generating DIDs for transaction requests and evaluating access rights at the target memory and peripheral resources. Because of the distributed design hierarchy and the pipelined nature of the hardware system bus fabric, it can take multiple cycles for a generated DID to propagate. Until that happens, XRDC uses the master's default DID. Depending on the programmed ACPs, the default DID might generate an access error response.

If XRDC generates incorrect error responses, you can use the following approaches to minimize or eliminate these extraneous access errors:

- Minimize the amount of system bus traffic when XRDC is enabled (CR[GVLD] = 1).
- Ensure that all target memory addresses provide sufficient access rights for any default DIDs and for the newly programmed DIDs. After XRDC is fully operational, as confirmed by a read of HWCFG1, you can remove the permissions for the default DIDs.
- Try to have the bus master that programs and configures XRDC use the same DID, that is, its default DID, for both initialization and configuration, besides normal system operation. You do this when you define the DID assignments for the system.

18.7 Application information

18.7.1 Master domain assignments

The typical use case for master domain assignments is to include one or more core bus masters in a single domain, possibly combined with other noncore bus master modules such as DMA. This configuration may be static or may be changed dynamically to select between a small number of domains. HWCFG0[NDID] indicates the maximum number of supported domains. XRDC also supports the optional use of PIDs to create multiple classes of cores, each in different domains.

For example, you can group critical tasks—safety-critical, performance-critical, and so on—into one domain and all other tasks into a second domain. Typically, you assign the DID at initialization, but you can also reconfigure domain assignment while the application is running.

A core bus master typically has multiple MDA_W*w_m*_DFMT0 registers associated with it.

A noncore bus master typically has a single MDA_W*w_m*_DFMT1 register associated with it.

The master domain assignment, memory region descriptor, and peripheral domain access control registers have lock fields that enable you to limit access to, or to lock, the registers. These actions protect the configuration.

18.7.2 Memory region descriptor management

There are two important concepts to consider for managing the memory region descriptors.

Each MRC*c* configuration is chip-specific. See the chip-specific XRDC information for the number of implemented memory region descriptors (MRGD_W*w_n*) in a given MRC*c* instance, and the specific port numbers associated with the target memories being monitored.

Second, as detailed in Memory region ACP evaluation, after you enable the XRDC, a memory reference must hit one or more of the configured regions. Otherwise, the transaction results in an access violation. Two other conditions also result in access errors:

- The access hits a single region descriptor and that region signals a domain violation.
- The access hits multiple (overlapping) regions and all regions signal violations.

The second condition reflects that XRDC gives priority to permission granting over access denying for overlapping regions. This approach provides more flexibility to system software in memory region descriptor assignments.

18.7.3 Domain error capture management

18.7.3.1 Domain error capture registers

When an MRC or PAC detects a domain access violation, XRDC captures information about the transaction in the following registers:

Table 78. Domain error capture registers

Register[field]	Index	Information
DERRLOC*d*[MRCINST]	*d* = DID	Domain error location for MRC instances, with asserted bits indicating which MRC instance numbers are reporting an error
DERRLOC*d*[PACINST]	*d* = DID	Domain error location for PAC instances, with asserted bits indicating which PAC instance numbers are reporting an error
DERR_W0_*i*	*i* = instance number	Transaction target address
DERR_W1_*i*	*i* = instance number	Additional information about the transaction
DERR_W3_*i*	*i* = instance number	Reset and rearm domain error capture for the instance

18.7.3.2 Handling domain access violation errors

When an MRC or PAC instance detects a domain access violation, it reports the error by asserting the associated bit in DERRLOCd[MRCINST] or [PACINST], and XRDC asserts the error interrupt output. To retrieve information about the error, the error handler must:

1. Read each DERRLOC*d* register until it finds a non-zero MRCINST or PACINST value.

   The index of the DERRLOC*d* register is the DID for the domain in which the error occured.

2. Configure the domain assignment for the master executing the exception handler (MDA_Ww_m_DFMTf[DID]) to assign the DID that corresponds to the DERRLOC*d* register index.
3. Read HWCFG1[DID] to be sure the error handler is now operating in the correct domain. In other words, make sure HWCFG1[DID] equals the value written to MDA_Ww_m_DFMTf[DID].
4. Find the number of an MRC or PAC instance reporting an error by parsing DERRLOC*d*[MRCINST] and DERRLOC*d*[PACINST] for an asserted bit.

   There may be multiple access violations, across multiple MRC or PAC instances, pending for a given domain. To quickly find the lowest numbered instance reporting an access violation, execute a "find first one bit" instruction (alternatively known as "count leading zeroes") on the MRCINST and PACINST fields.

5. Retrieve the error address (DERR_W0_*i*[EADDR]).
6. Retrieve the error information (DERR_W1_*i*).

   More than one error may have occurred in the MRC or PAC instance, as indicated by the error status (DERR_W1_*i*[EST] = 11b). If more than one error has occurred in the instance, XRDC captures data only for the first error.

7. Use the error address and information to handle the error (whatever that may require).
8. Reset the DERR_W*w_i* registers and rearm error capture (write 1b to DERR_W3_*i*[RECR]).

   Rearming error capture deasserts the instance bit in DERRLOC*d*.

9. Repeat steps 1 and 8 for each asserted bit in PACINST and MRCINST until there are no more asserted bits.

Domain error retrieval illustrates an example error retrieval.

18.7.3.3 Domain error retrieval

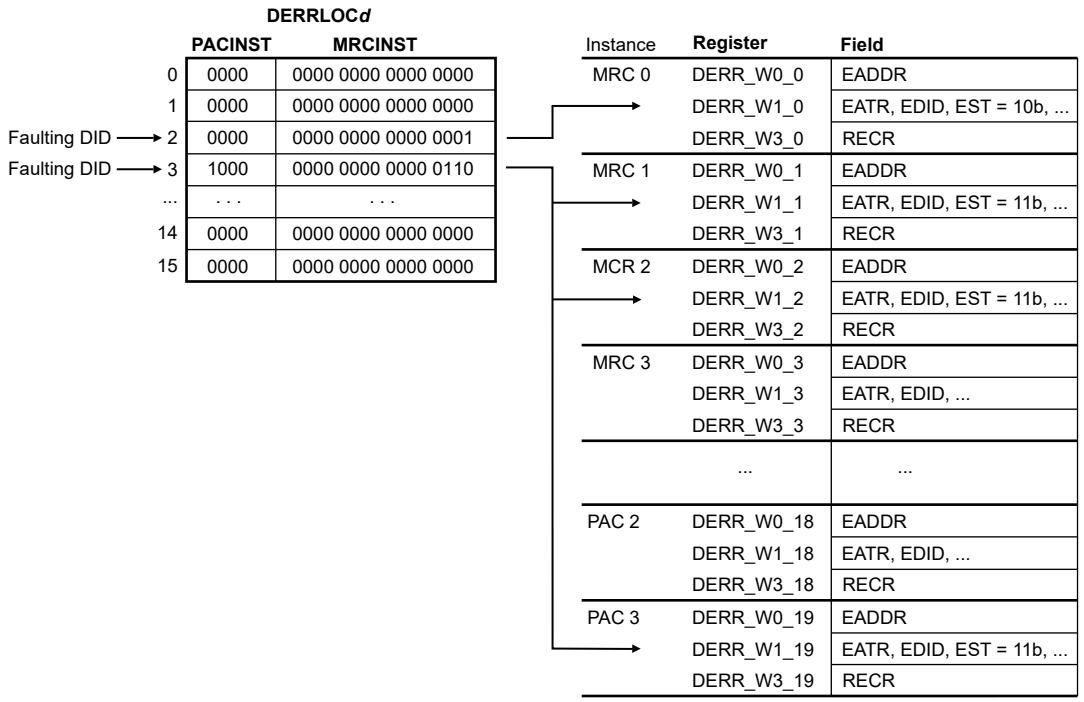

Figure 46. Domain error retrieval

18.8 Memory map and register definitions

18.8.1 Register organization

XRDC registers are partitioned into these groups:

- Basic hardware control and configuration
- Domain errors (including location and details)
- Master domain assignments
- Peripheral domain access controls
- Memory region descriptors

18.8.2 Register access guidelines

The following guidelines apply to XRDC register access:

- You can access the XRDC registers only in secure, privileged access mode.
- Unless stated otherwise, the registers support 8-, 16-, and 32-bit reads, and 32-bit writes.
- Unless stated otherwise, XRDC terminates the following access attempts with an error:
  - Accesses in a different access mode
  - Unsupported write data size
  - Writes to read-only resources
  - Writes to reserved address spaces

- Accesses to these memory map holes return an error:
  - Any access to a register that does not exist
  - Holes in the 0–F0h and DERR to PID register space
  - For MDAC, gaps in the master domain assignment (MDA_W*w*_*m*_DFMT*n*) registers
  - For MRCs, any gap in the MRGD_W*w*_*r* registers (for example, if there are four memory region descriptors, attempted access to a fifth descriptor fails)
- Accesses to these memory map holes do not return a bus error:
  - MRCs: Memory region descriptors occupy only four words but have an additional four words of address available: words 4–7
  - PDAC: Registers associated with unimplemented PDAC slots
- Read accesses to these memory map holes do not return a bus error:
  - Offset F8h and FCh
  - Offset 100–13Fh
  - Offset 140–14Fh
  - Offset 200–23Ch

18.8.3.2 Control (CR)

Offset

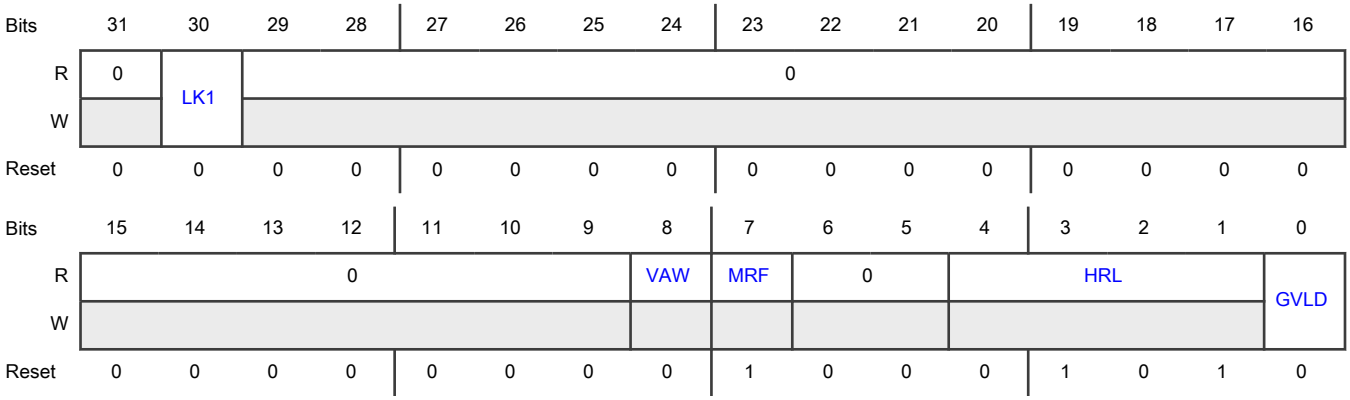
Register	Offset
CR	0h

Function

Provides XRDC status and enables XRDC operation.

Access: Secure privileged read/write

Diagram



Fields

Field	Function
31 —	Reserved
30 LK1	Lock Prohibits writes to this register. • If unlocked, this register accepts any secure privileged write. • If locked, you cannot write to this register and it remains read-only until after the next reset. **NOTE** This field behaves differently for read and write operations. When reading 0b - Unlocked 1b - Locks When writing

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No effect 1b - Locks
29-9 —	Reserved
8 VAW	Virtualization Aware Indicates whether domain assignments support the optional inclusion of a logical partition identifier, which is also known as an operating system number or ARM virtual machine identifier (VMID). 0b - Not virtualization-aware 1b - Virtualization-aware
7 MRF	Memory Region Format Indicates the format of memory region descriptors. 0b - Reserved 1b - SMPU family format
6-5 —	Reserved
4-1 HRL	Hardware Revision Level Indicates the XRDC hardware revision level, which is associated with a set of functional characteristics of the module.
0 GVLD	Global Valid (XRDC Global Enable/Disable) Enables XRDC. When XRDC is disabled, all bus masters can access all targets. 0b - Disables 1b - Enables

18.8.3.3 Hardware Configuration 0 (HWCFG0)

Offset

Register	Offset
HWCFG0	F0h

Function

Indicates XRDC configuration details, including:

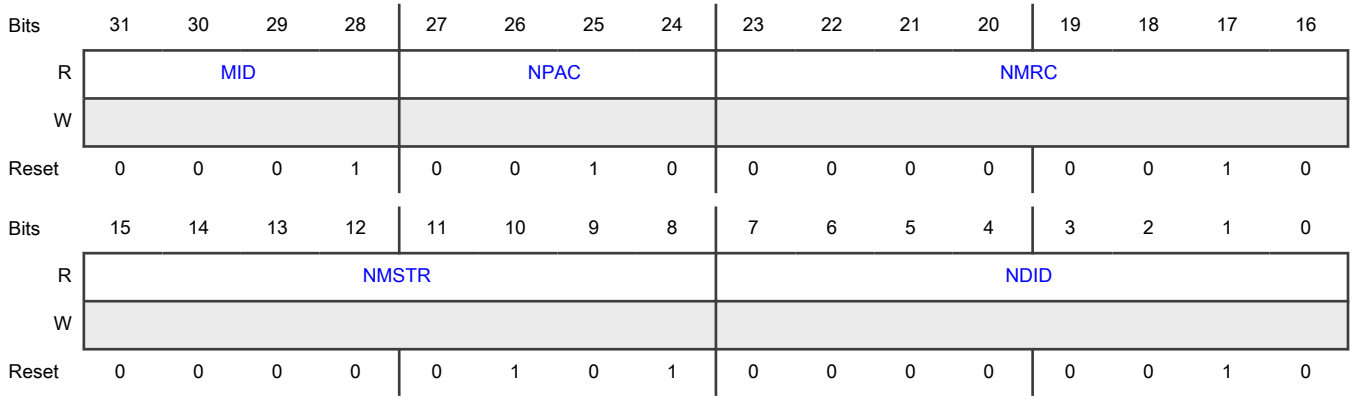
- XRDC module ID
- Number of implemented domains

- Number of bus masters
- Number of MRCs
- Number of PACs

Attempting to write to this register causes an error.

Access: Secure privileged read

Diagram



Fields

Field	Function
31-28 MID	Module ID
27-24 NPAC	Number Of PACs Indicates the number of PACs minus 1. In other words, the actual number of PACs is NPAC + 1.
23-16 NMRC	Number of MRCs Indicates the number of MRCs minus 1. In other words, the actual number of MRCs is NMRC + 1.
15-8 NMSTR	Number Of Bus Masters Indicates the number of bus masters minus 1. In other words, the actual number of bus masters is NMSTR + 1.
7-0 NDID	Number Of DIDs Indicates the number of domains (DIDs) minus 1. In other words, the actual number of DIDs is NDID + 1.

18.8.3.4 Hardware Configuration 1 (HWCFG1)

Offset

Register	Offset
HWCFG1	F4h

Function

Indicates the DID of the bus master making the current transaction request. See Domain error capture management for information about typical usage.

Attempting to write to this register causes an error.

Access: Secure privileged read

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

1. The reset value is determined by the current configuration of the accessing master.

Fields

Field	Function
31-4 —	Reserved
3-0 DID	Domain Identifier Indicates the DID of the requesting bus master.

18.8.3.5 Hardware Configuration 2 (HWCFG2)

Offset

Register	Offset
HWCFG2	F8h

Function

For masters 0–31, indicates whether a given master has a built-in PID register as part of its programming model. If not, you must use the corresponding PID*m* register to mimic the functionality of a built-in PID register.

Each bit corresponds to the same numbered master. For example, if PIDP18 is 1, bus master 18 has its own PID register. If PIDP18 is 0, then master 18 does not have its own PID register and you must use PID18.

Attempting to write to this register causes an error.

Access: Secure privileged read

Diagram

18.8.3.6 Master Domain Assignment Configuration (MDACFG0 - MDACFG5)

Offset

Register	Offset
MDACFG0	100h
MDACFG1	101h
MDACFG2	102h
MDACFG3	103h
MDACFG4	104h
MDACFG5	105h

Function

Indicates the number of implemented master domain assignment registers (MDA_W*w*_*m*_DFMT0 or MDA_W*w*_*m*_DFMT1) for master *m*, where *m* ranges from 0 to 63. You can read these registers using 8-, 16-, or 32-bit accesses.

If NMDAR is 0, the associated master does not exist.

Attempting to write to this register causes an error.

Access: Secure privileged read

Diagram

Bits	7	6	5	4	3	2	1	0
R	NCM	0			NMDAR			
W								
Reset	See Register reset values.							

Register reset values

Register	Reset value
MDACFG0	01h
MDACFG1–MDACFG2	81h
MDACFG3–MDACFG4	01h
MDACFG5	81h

Fields

Field	Function
7 NCM	Noncore Master If NMDAR is greater than zero, indicates whether master *m* uses MDA_W*w*_*m*_DFMT0 or MDA_W*w*_*m*_DFMT1 to configure domain assignment. This field is 0 for a non-existent master. 0b - Core master or master does not exist 1b - Noncore master
6-4 —	Reserved
3-0 NMDAR	Number Of Master Domain Assignment Registers Indicates the number of master domain assignment registers (MDA_W*w*_*m*_DFMT0 or MDA_W*w*_*m*_DFMT1) associated with master *m*. 0000b - Master does not exist 0001b-1000b - Number of registers All other values are reserved.

18.8.3.7 Memory Region Configuration (MRCFG0 - MRCFG2)

Offset

Register	Offset
MRCFG0	140h
MRCFG1	141h
MRCFG2	142h

Function

Indicates the number of memory region descriptors (*r*) for MRC*c*, from 4 to 16 in increments of four, with 0 indicating a non-existent MRC. These registers are organized as byte-sized data arrays and can be read using 8-, 16-, or 32-bit accesses.

Attempting to write to this register causes an error.

Access: Secure Privileged Read

Diagram

Bits	7	6	5	4	3	2	1	0

18.8.3.8 Domain Error Location (DERRLOC0 - DERRLOC2)

Offset

Register	Offset
DERRLOC0	200h
DERRLOC1	204h
DERRLOC2	208h

Function

Indicates the MRC or PAC instance in domain *d* where an access violation has occurred. Each bit corresponds to the like-numbered instance. For more information, see Domain error capture management.

Attempting to write to this register causes an error.

Access: Secure privileged read

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0												PACINST

R	MRCINST															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-20 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
19-16 PACINST	PAC Instance Indicates the presence of a detected access violation for domain *d* in a PAC instance. Each bit corresponds to the instance index for the DERR_W*w*_*i* registers: bit 16 of the register corresponds to the DERR_W*w*_*16* registers, which show error informatioon for PAC 0, and so on. Multiple bits can be 1 at any time, indicating access violations have been detected across multiple PACs. For each bit in this field: 0b - No access violation error or the PAC instance is not physically present 1b - Access violation detected
15-0 MRCINST	MRC Instance Indicates the presence of a detected access violation for domain *d* in an MRC instance. Each bit corresponds to the like-numbered MRC instance: bit 0 (bit 0 of the register) corresponds to MRC instance 0, and so on. Multiple bits can be 1 at any time, indicating access violations have been detected across multiple MRCs. For each bit in this field: 0b - No access violation error or the MRC instance is not physically present 1b - Access violation detected

18.8.3.9 Domain Error Word 0 (DERR_W0_0 - DERR_W0_18)

Offset

Register	Offset
DERR_W0_0	400h
DERR_W0_1	410h
DERR_W0_2	420h
DERR_W0_16	500h
DERR_W0_17	510h
DERR_W0_18	520h

Function

Indicates the address of an access violation detected by an MRC or a PAC, indexed by the MRC or PAC instance (*i*) that detected the violation, as indicated in DERRLOC*d*. This register is part of a 16-byte set:

- DERR_W0_*i*: Word 0, the first 4 bytes
- DERR_W1_*i*: Word 1, the second 4 bytes
- Word 2, 4 reserved bytes
- DERR_W3_*i*: Word 3, the fourth 4 bytes

The first 16 sets (*i* from 0 to 15) are associated with MRCs and the rest (starting with *i* = 16) are associated with PACs. For more information, see Domain error capture management.

The access violation exception handler for each domain has visibility only into the captured error information for that domain.

When XRDC detects an access violation, it captures the error information and disables subsequent updates to the error capture registers until you write to DERR_W3_*i*.

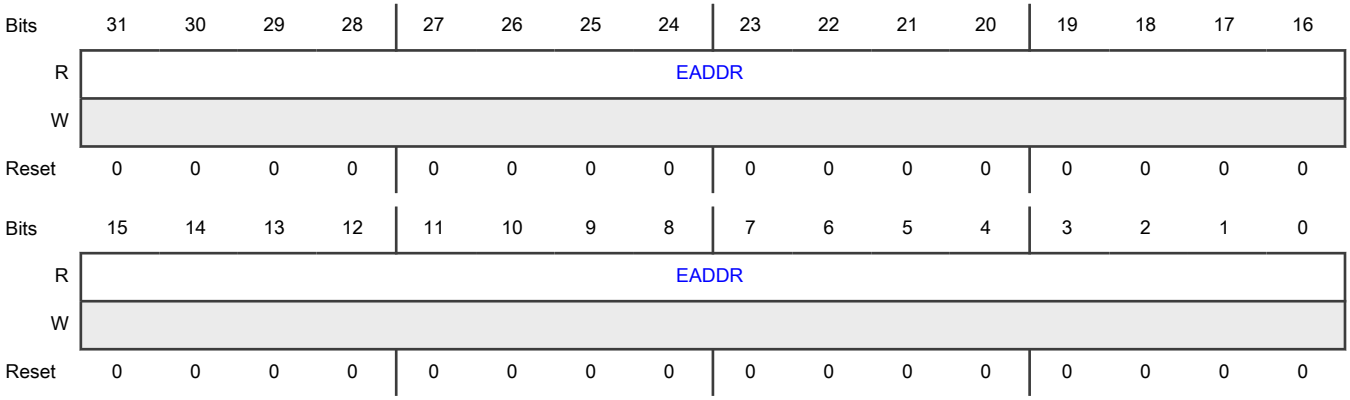
NOTE

If masters with the same DID cause simultaneous error accesses, the error capture registers record only the error of the lowest target index.

Attempting to write to this register causes an error. Attempting to read the error registers for a non-existent MRC or PAC instance causes an error.

Access: Secure privileged read

Diagram



Fields

Field	Function
31-0 EADDR	Error Address Indicates the target address of the first transaction that causes an access violation after reset or after rearming error capture.

18.8.3.10 Domain Error Word 1 (DERR_W1_0 - DERR_W1_18)

Offset

Register	Offset
DERR_W1_0	404h
DERR_W1_1	414h
DERR_W1_2	424h
DERR_W1_16	504h

Table continues on the next page...

Table continued from the previous page...

Register	Offset
DERR_W1_17	514h
DERR_W1_18	524h

Function

Indicates the attributes of an access violation detected by an MRC or a PAC, indexed by the MRC or PAC instance (*i*) that detected the access violation, as indicated in DERRLOC*d*. For more information, see DERR_W0_*i* and Domain error capture management.

NOTE

If masters with the same DID cause simultaneous error accesses, the error capture registers record only the error of the lowest target index.

Attempting to write to this register causes an error. Attempting to read the error registers for a non-existent MRC or PAC instance causes an error.

Access: Secure privileged read

R	0				ERW	EATR			0				EDID			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-30 EST	Error State Indicates the state of access violations for this domain in this instance of the MRC or PAC. After the first access violation to occur after reset or rearming of error capture, XRDC records subsequent errors as an overrun condition without any data captured. 00b-01b - No access violations detected 10b - A single access violation has been detected 11b - Multiple access violations have been detected
29-27 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
26-24 EPORT	Error Port Identifies the encoded port number of the MRC that detected the access violation. See the chip-specific configuration details for the MRC port connections. For access violations detected by a PAC, this field is zero.
23-12 —	Reserved
11 ERW	Error Read Or Write Indicates whether the captured access violation occurred on a read or write access. 0b - Read access 1b - Write access
10-8 EATR	Error Attributes Indicates attributes of the access violation. 000b - Secure user mode, instruction fetch access 001b - Secure user mode, data access 010b - Secure privileged mode, instruction fetch access 011b - Secure privileged mode, data access 100b - Nonsecure user mode, instruction fetch access 101b - Nonsecure user mode, data access 110b - Nonsecure privileged mode, instruction fetch access 111b - Nonsecure privileged mode, data access
7-4 —	Reserved
3-0 EDID	Error Domain Identifier Indicates the DID of the access violation.

18.8.3.11 Domain Error Word 3 (DERR_W3_0 - DERR_W3_18)

Offset

Register	Offset
DERR_W3_0	40Ch
DERR_W3_1	41Ch
DERR_W3_2	42Ch

Table continues on the next page...

Table continued from the previous page...

Register	Offset
DERR_W3_16	50Ch
DERR_W3_17	51Ch
DERR_W3_18	52Ch

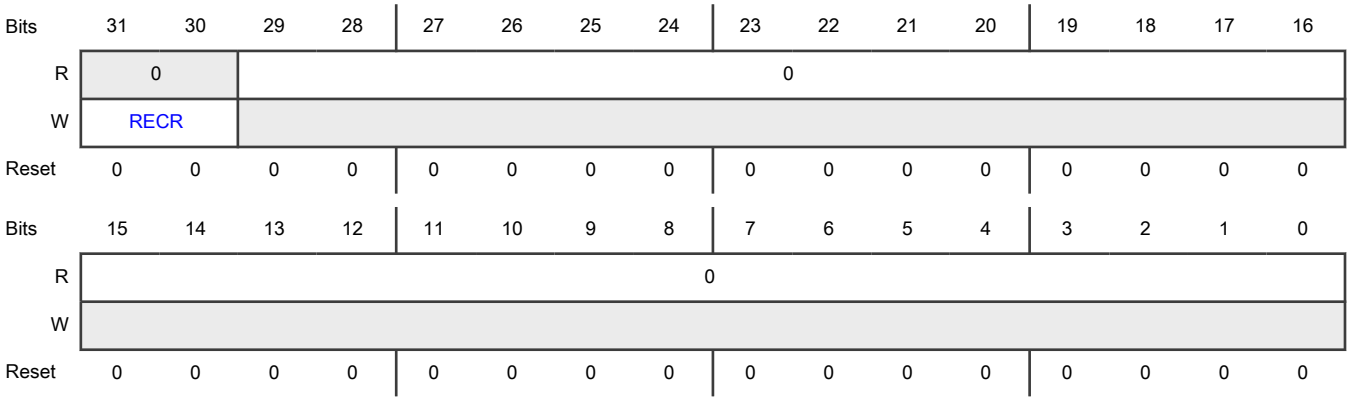
Function

Rearms instance error capture, resets the error capture registers (DERR_W0_*d*, DERR_W1_*d*), and deasserts the instance bit in DERRLOC*d*. After reading the access violation error information, an error handler must write 1 to RECR.

This register returns 0000h when read. Attempted reads of an MRC or PAC instance that is not physically present cause an error.

For more information, see Domain error capture management.

Diagram



Fields

Field	Function
31-30 RECR	Rearm Error Capture Registers Resets and rearms the domain error capture registers for this instance, including deasserting the instance bit in DERRLOC*d*. 00b,10b,11b - No effect 01b - Rearms error capture, resets error capture registers, and deasserts instance bit in DERRLOCd
29-0 —	Reserved

18.8.3.12 Process Identifier (PID0 - PID4)

Offset

Register	Offset
PID0	700h
PID3	70Ch
PID4	710h

Function

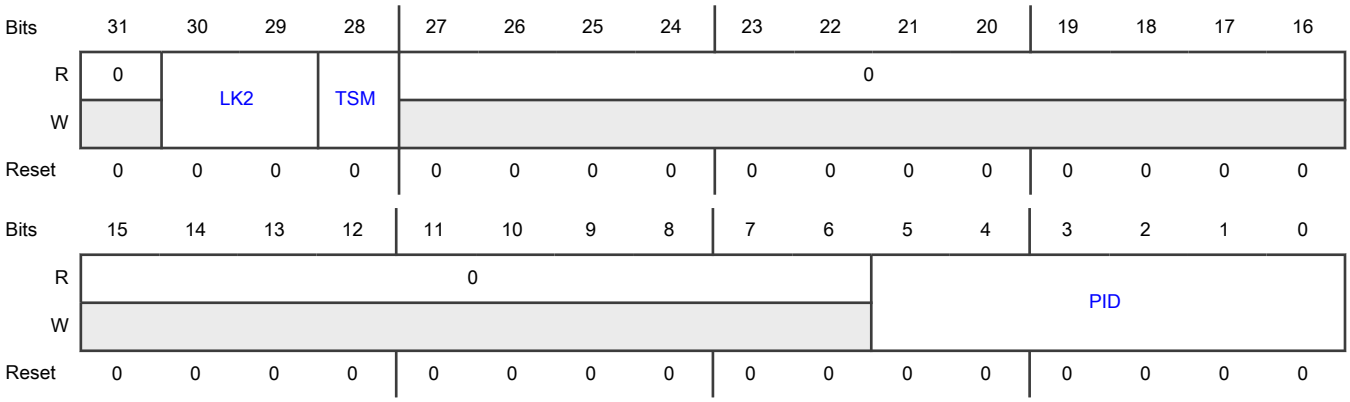
Specifies the PID for the associated core master *m*.

Some cores contain a built-in PID register. If the core has a built-in PID register, XRDC populates the PID field with the value from the core PID register. If the core does not have the built-in register, the XRDC PID register allows applications to mimic PID operation for that core by writing the desired PID to the associated register.

HWCFG2 provides a bitmap of the implemented PID*m* registers. Noncore masters do not have an associated PID register.

For information about PID-based operation, see PID-based domain assignment.

Diagram



Fields

Field	Function
31 —	Reserved
30-29 LK2	Lock Limits or prohibits writes to this register. When you assert a bit in this field, it remains asserted until the next module reset. If the core master has a built-in PID register, as indicated in HWCFG2, then a secure privileged read returns 0 for this field.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	00b,01b - Any secure privileged write 10b - Secure privileged writes from master only 11b - Locks
28 TSM	Three-State Model Specifies that the core master supports only the three-state access control model. If you write 1 to this field, it remains asserted until the next reset. For cores that support only the three-state access control model, you must assert this field before loading any nonsecure value into the PID. See Generation of secure attribute.
27-6 —	Reserved
5-0 PID	Process Identifier Specifies the transaction PID for the corresponding core master. If the core has a built-in PID register, then a secure privileged read returns the core's PID register value. Bit 5 specifies the secure attribute (0 = secure, 1 = nonsecure) for the transaction.

18.8.3.13 Master Domain Assignment (MDA_W0_0_DFMT0 - MDA_W0_4_DFMT0)

Offset

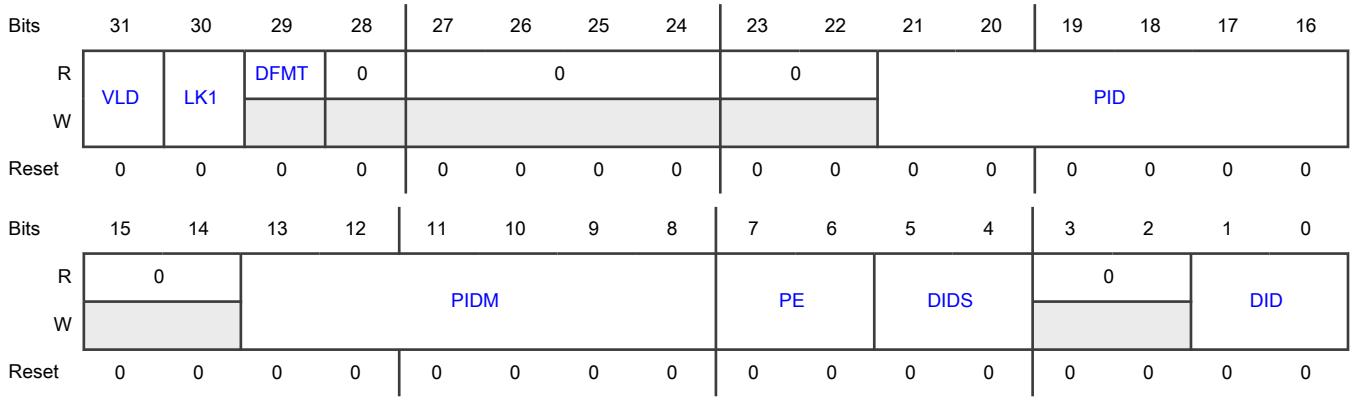
Register	Offset
MDA_W0_0_DFMT0	800h
MDA_W0_3_DFMT0	860h
MDA_W0_4_DFMT0	880h

Function

Specifies the information used by the MDAC to assign a core bus master to a specific domain (DID). For more information, see Master domain assignment controller (MDAC).

Access: Secure privileged read/write

Diagram



Fields

Field	Function
31 VLD	Valid Specifies whether this domain assignment is valid. In other words, if VLD and CR[GVLD] are both asserted, XRDC uses the configuration in this register in the domain assignment process. This field has no effect unless XRDC is enabled (CR[GVLD] = 1). 0b - Invalid 1b - Valid
30 LK1	Lock Prohibits writes to this register. • If unlocked, this register accepts any secure privileged write. • If locked, you cannot write to this register and it remains read-only until after the next reset. **NOTE** This field behaves differently for read and write operations. When reading 0b - Unlocked 1b - Locks When writing 0b - No effect 1b - Locks
29 DFMT	Domain Format Indicates the domain assignment format. 0b - Core bus master domain assignment (DFMT0)
28	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
27-24 —	Reserved
23-22 —	Reserved
21-16 PID	Process Identifier Specifies the PID to be combined with the PIDM field and included in the domain assignment process. This field applies only if PID is enabled (PE = 1).
15-14 —	Reserved
13-8 PIDM	Process Identifier Mask Specifies a mask applied to the PID to support including multiple PIDs in the domain hit determination. For each bit asserted in PIDM, the corresponding bit of the PID is ignored in the comparison. This field applies only if PID is enabled (PE = 1).
7-6 PE	Process Identifier Enable Enables the optional inclusion of PID, qualified by PIDM, in the domain hit evaluation. This inclusion supports the definition of inclusive or exclusive sets of masked PID values. 00b-01b - No PID is included 10b - Partial domain hit = (PID & ~PIDM) == (PIDm[PID] & ~PIDM) 11b - Partial domain hit = ~((PID & ~PIDM) == (PIDm[PID] & ~PIDM))
5-4 DIDS	DID Select Selects the source of the DID. 00b - Use the DID field of this register 01b - Use the input DID 10b - Concatenate bits 3–2 of this register with the least significant 2 bits of the input DID (DID_in[1:0]) 11b - Reserved
3-2 —	Reserved
1-0 DID	Domain Identifier Specifies the DID. DIDS controls whether and how this value is used.

18.8.3.14 Master Domain Assignment (MDA_W0_1_DFMT1 - MDA_W0_5_DFMT1)

Offset

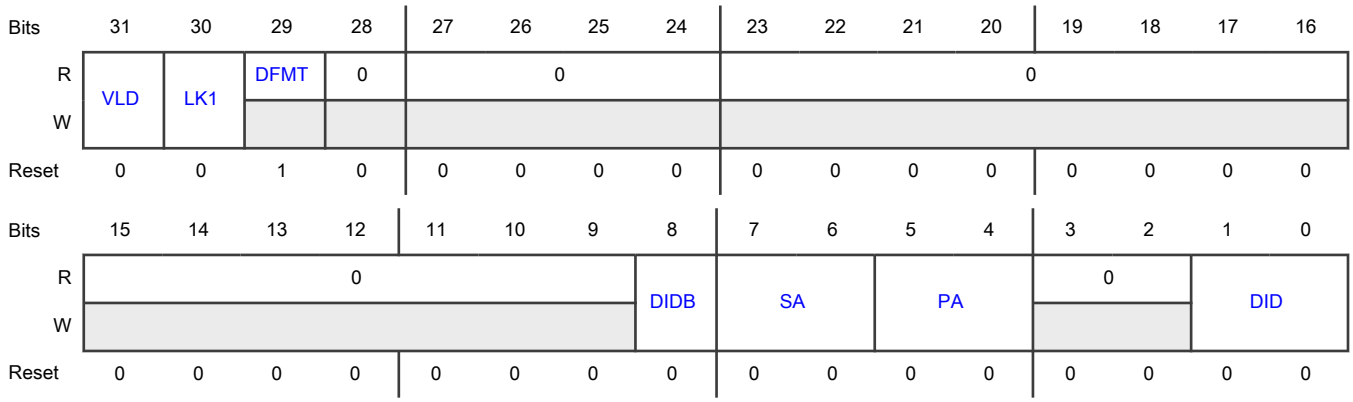
Register	Offset
MDA_W0_1_DFMT1	820h
MDA_W0_2_DFMT1	840h
MDA_W0_5_DFMT1	8A0h

Function

Specifies the information used by the MDAC to assign a bus master to a specific domain (DID). For more information, see Master domain assignment controller (MDAC).

Access: Secure privileged read/write

Diagram



Fields

Field	Function
31 VLD	Valid Specifies whether this domain assignment is valid. In other words, if VLD and CR[GVLD] are both asserted, XRDC uses the configuration in this register in the domain assignment process. This field has no effect unless XRDC is enabled (CR[GVLD] = 1). 0b - Invalid 1b - Valid
30 LK1	Lock Prohibits writes to this register. • If unlocked, this register accepts any secure privileged write. • If locked, you cannot write to this register and it remains read-only until after the next reset.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for read and write operations. When reading 0b - Unlocked 1b - Locks When writing 0b - No effect 1b - Locks
29 DFMT	Domain Format Indicates the domain assignment format. 1b - Bus master domain assignment (DFMT1)
28 —	Reserved
27-24 —	Reserved
23-9 —	Reserved
8 DIDB	DID Bypass Enables bypassing of an input DID as the domain identifier for this master. This capability allows noncore masters (for example, a DMA) to appear as a core. After this field is set to 1, it remains at that value until the next reset. 0b - Bypass DID input. Use DID 1b - Use DID input
7-6 SA	Secure Attribute Specifies the secure attribute. **NOTE** If SA = 1X or VLD = 0, use the secure attribute input from the master. 00b - Force to secure 01b - Force to nonsecure 1xb - Use secure attribute from the master
5-4	Privileged Attribute

Table continues on the next page...

Table continued from the previous page...

Field	Function
PA	Specifies the privileged (supervisor/user) attribute. **NOTE** If PA = 1X or VLD = 0, use the secure attribute input from the master. 00b - Force to user 01b - Force to privileged 1xb - Use privileged attribute from the master
3-2 —	Reserved
1-0 DID	Domain Identifier Specifies the DID.

Function

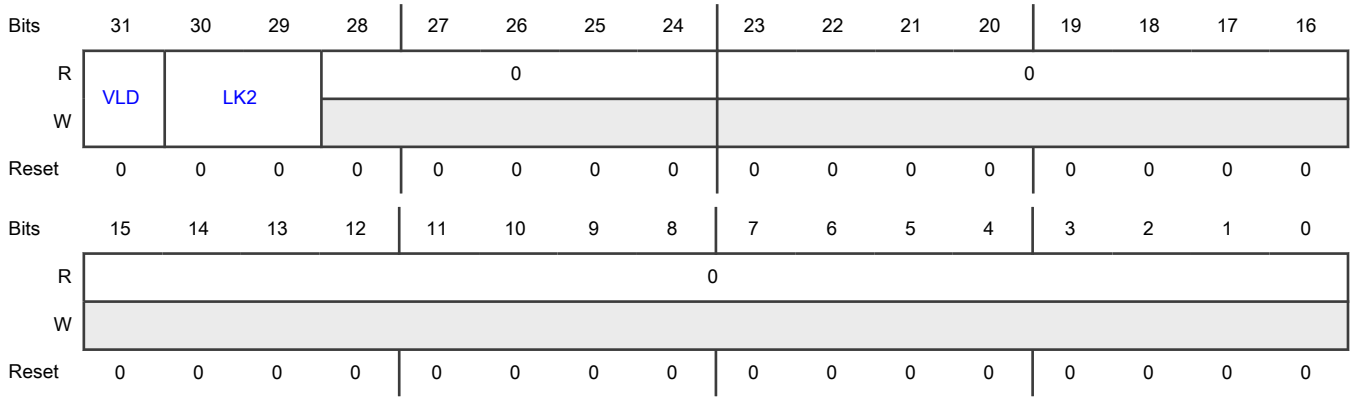
In conjunction with PDAC_W0_*s*, specifies the ACP configuration for peripheral slot *s*.

Access: Secure privileged read/write

Diagram



Fields

Field	Function
31 VLD	Valid Specifies whether this domain assignment is valid. In other words, if VLD and CR[GVLD] are both asserted, XRDC uses the configuration in this pair of registers. If either CR[GVLD] or this field is 0, all accesses to the peripheral are allowed. To support a coherent register state, any write to PDAC_W0_*s* forces this field to zero. This field has no effect unless XRDC is enabled (CR[GVLD] = 1). 0b - Invalid 1b - Valid
30-29 LK2	Lock Limits or prohibits writes to the set of PDAC words (PDAC_W0_*s* and PDAC_W1_*s*) for this peripheral slot. When you assert a bit in this field, it remains asserted until the next module reset. 00b-01b - Both words can be written to 10b - Domain d can update only its associated DdACP field—all other fields are read-only 11b - Locks (both words are read-only)
28-24 —	Reserved
23-0 —	Reserved

18.8.3.17 Memory Region Descriptor Word 0 (MRGD_W0_0 - MRGD_W0_35)

Offset

Registers in this array exist only for the following combinations of index values.

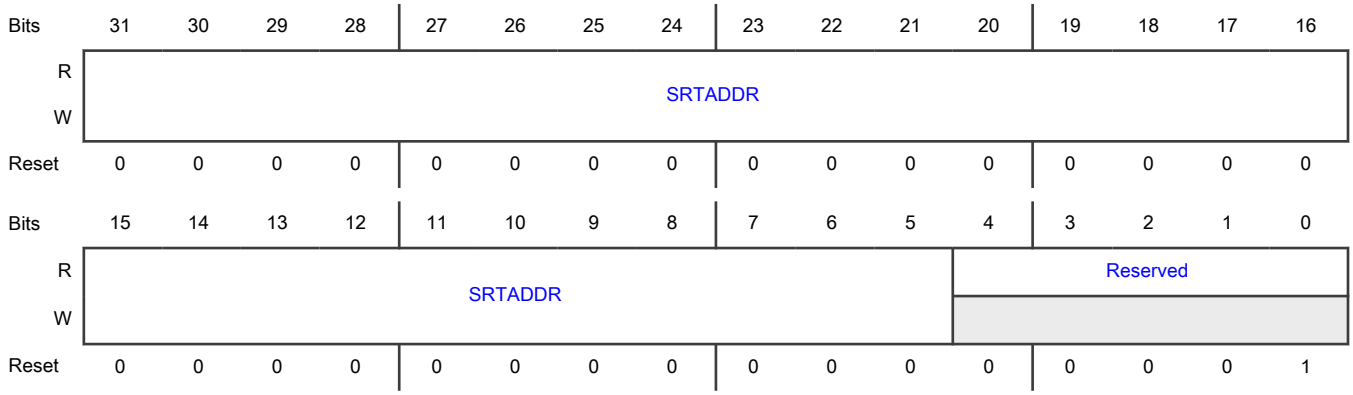
Index *n*	Index *m*
0–1	0–15
2	0–3

Register	Offset
MRGD_W0_(n * 16 + m)	2000h + (n × 200h) + (m × 20h)

Function

Specifies the starting address of memory region *r*.

Diagram



Fields

Field	Function
31-5 SRTADDR	Start Address Specifies the most significant bits of the 0-modulo 32-byte start address of the memory region. The minimum region size is 32 bytes.
4-0 —	Reserved

18.8.3.18 Memory Region Descriptor Word 1 (MRGD_W1_0 - MRGD_W1_35)

Offset

Registers in this array exist only for the following combinations of index values.

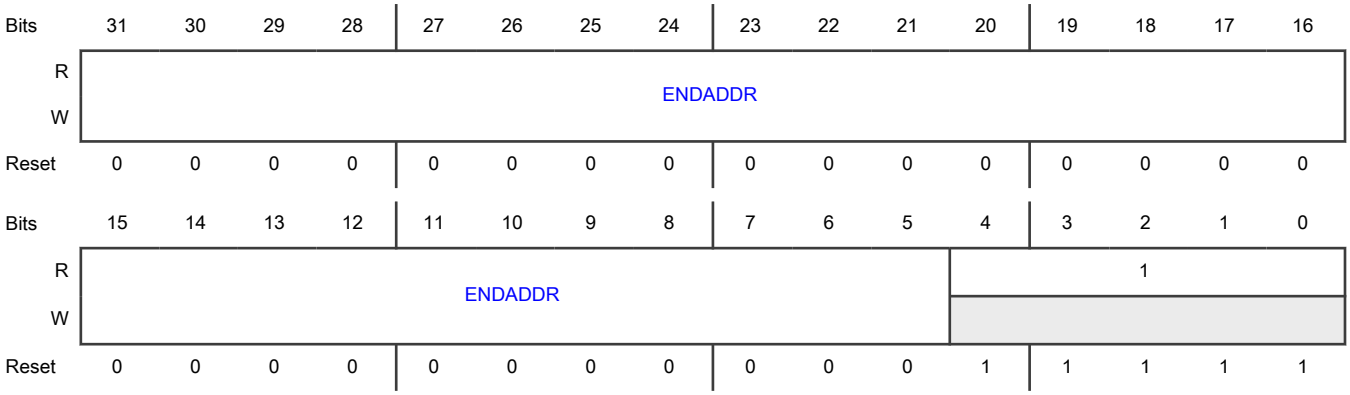
Index *n*	Index *m*
0–1	0–15
2	0–3

Register	Offset
MRGD_W1_(n * 16 + m)	2004h + (n × 200h) + (m × 20h)

Function

Specifies the ending address of memory region *r*.

Diagram



Fields

Field	Function
31-5 ENDADDR	End Address Specifies the most significant bits of the 31-modulo 32-byte end address of memory region *r*.
4-0 —	Reserved

18.8.3.19 Memory Region Descriptor Word 2 (MRGD_W2_0 - MRGD_W2_35)

Offset

Registers in this array exist only for the following combinations of index values.

Index *n*	Index *m*
0–1	0–15
2	0–3

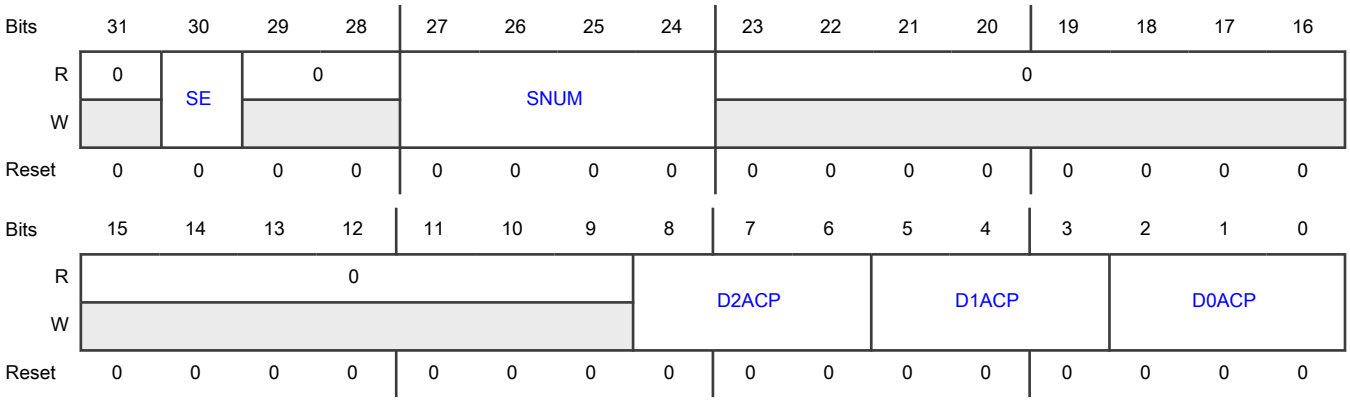
Register	Offset
MRGD_W2_(n * 16 + m)	2008h + (n × 200h) + (m × 20h)

Function

Specifies the ACP for the associated domain. The encodings specify read and write access capabilities based on the four operating states. This field applies only for a supported DID; if the DID is not implemented, the field is read-only zero (no access rights).

For field values, see Domain ACP specification.

Diagram



Fields

Field	Function
31 —	Reserved
30 SE	Semaphore Enable Enables the inclusion of the semaphore specified in SNUM in the D*d*ACP evaluation. 0b - Disables 1b - Enables
29-28 —	Reserved
27-24 SNUM	Semaphore Number Specifies the hardware semaphore to include in the D*d*ACP access evaluation. This field applies only if you enable semaphore (write 1 to SE).
23-9 —	Reserved
8-6: D2ACP 5-3: D1ACP 2-0: D0ACP	Domain Access Control Policy Specifies the ACP for the associated domain. This field applies only for a supported DID; if the DID is not implemented, the field is read-only zero (no access rights). For field values, see Domain ACP specification.

18.8.3.20 Memory Region Descriptor Word 3 (MRGD_W3_0 - MRGD_W3_35)

Offset

Registers in this array exist only for the following combinations of index values.

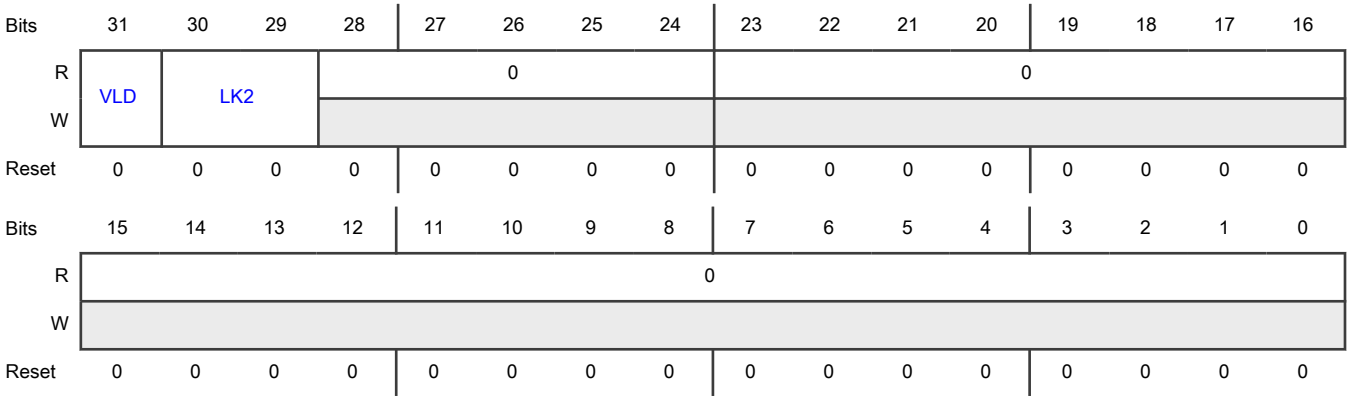
Index *n*	Index *m*
0–1	0–15
2	0–3

Register	Offset
MRGD_W3_(n * 16 + m)	200Ch + (n × 200h) + (m × 20h)

Function

Specifies whether this memory region descriptor is enabled and limits or prohibits writes to it.

Diagram



Fields

Field	Function
31 VLD	Valid Specifies whether this domain assignment is valid. In other words, if VLD and CR[GVLD] are both asserted, XRDC uses the configuration in this set of registers. If either CR[GVLD] or this field is 0, all accesses to the memory region are allowed. To support a coherent register state, a write to any of the MRGD W0–W2 registers forces this field to zero. This field has no effect unless XRDC is enabled (CR[GVLD] = 1). 0b - Invalid 1b - Valid
30-29	Lock Limits or prohibits writes to the set of MRGD words (MRGD_W*w_n*) for this memory region.

Table continues on the next page...

Table continued from the previous page...

Field	Function
LK2	When you assert a bit in this field, it remains asserted until the next module reset. 00b - All words in the set can be written to 01b - Reserved 10b - Domain d can update only its associated DdACP field; all other fields are read-only 11b - Locks (all words are read-only)
28-24 —	Reserved
23-0 —	Reserved

18.9 Glossary

ACP access control policy. The access limitations specified for memory and peripheral resources.

DID domain identifier. A numeric value that identifies a specific domain.

domain An access-controlled virtual group of on-chip masters (cores and noncore masters) and targets (memories and peripherals) that comprise an isolated computing environment. All masters in a domain have the same access to chip resources within that domain.

See Introduction to domains for more information.

LPID logical partition identifier. Also called an operating system ID or VMID, the LPID identifies a virtual master (either core or noncore) that runs on a hypervisor.

master A processor core or non-processor module, such as DMA or a communications channel, that can initiate transactions with memory and peripheral resources.

MDAC Master Domain Assignment Controller. Manages resource assignments and DIDs.

MGR Manager. Manages accesses through the XRDC programming model.

MRC Memory Region Controller. Controls access to memories based on memory region descriptors.

PAC Peripheral Access Controller (also sometimes called PDAC). Controls access to peripherals.

PDAC See PAC.

PID process identifier. A numeric value provided by some core processors to identify the currently active process.

SDAC Deprecated. See MRC.

target A peripheral or memory resource that one or more masters can access. This term replaces "slave."

transaction A read or write request made by a master to a target peripheral or memory.

VMID virtual machine identifier. See LPID.

Chapter 19
Memory and Memory Interfaces

19.1 Introduction

This chapter discusses the configuration of memories and memory interfaces, such as flash memory, flash memory controller, and SRAM.

19.2 Flash memory controller and flash memory modules

For information on this, see the following chapters:

- Flash Memory Controller (PFLASH)
- Embedded Flash Memory

19.4 SRAM access

In case a master accesses an SRAM with multi-bit ECC errors, the chip may respond as follows:

- Map all such faults to FCCU. The recommended reaction for the fault is to generate the functional reset.
- Map such faults to ERM. If the ERM interrupt is enabled, ERM generates an interrupt.

19.5 Memories

The following table provides information on the types of memories, with their associated configurations, available in MWCT2xxxS family.

Table 80. Memory configuration

Memory	Size	Configuration (words × bits)	ECC or parity	ECC or parity width	Diagnostic information or error report	Applicability
SRAM0	160 KB	32 KB with STANDBY mode retention (4096 × (64 + 8))	ECC (SECDED)	8	ERM	MWCT2D17S

19.6 Recommendations for ARM memories

As per ARM M-7 Safety manual, following considerations must be ensured for proper operation of ARM memories:

- ITCM and DTCM must be properly initialized with correct ECC before any read operation to avoid any code runaway or software malfunction or core lockup.

NOTE

ITCM must be initialized with 64-bit writes whereas DTCM can be initialized with 32-bit writes also.

- To safely disable TCM:
  1. Clear ITCMCR[EN] or DTCMCR[EN] as required. See ARM Cortex-M7 Devices Generic User Guide for details on ITCMCR and DTCMCR register.
  2. Execute DSB instruction
  3. Execute ISB instruction

NOTE

Care must be taken if disabling the ITCM while executing from it. In this case, software must ensure that the switch-off code is stored in the L2 code memory region from where execution continues when the ITCM is disabled.

- To safely disable the I-cache:
  1. Clear CCR[IC]. See ARM Cortex-M7 Devices Generic User Guide for details on CCR register.
  2. Execute DSB instruction
  3. Execute ISB instruction
- To safely disable the D-cache:
  1. Clean and invalidate non-WT locations in D-cache
  2. Clear CCR[DC]
  3. Execute DSB instruction

See Table 81 for details on memory ECC initialization.

19.7 Memory ECC initialization summary

The table below summarizes memory ECC initialization.

Table 81. Memory ECC initialization summary

Memory	Write access size	Masters

Table continues on the next page...

Table 81. Memory ECC initialization summary (continued)

		CM7_ n	CM7_ m	eDMA
SRAM	64-bits only	System	System	System
CM7_n ITCM	64-bits only	Direct or Backdoor	Backdoor	Not possible
CM7_n DTCM	32-bits or 64-bits	Direct or Backdoor	Backdoor	Backdoor
CM7_m ITCM	64-bits only	Backdoor	Direct or Backdoor	Not possible
CM7_m DTCM	32-bits or 64-bits	Backdoor	Direct or Backdoor	Backdoor

19.8 Glossary

DTCM	Data tightly coupled memory
ECC	Error code correction
ETF	Embedded trace FIFO
ETMD	Embedded trace macrocell-data
ETMI	Embedded trace macrocell-instruction
ITCM	Instruction tightly coupled memory
MTB	Macrocell trace buffer
PKC	Public key cryptography
RXPARSER	Receive parser memory
SECDED	Single error correction double error detection
SRAM	Static random access memory
TSN	Time sensitive network

Chapter 20
Embedded Flash Memory (c40asf)

20.1 Chip-specific c40asf flash memory information

20.1.1 Flash memory configuration and register settings

Table 82 shows flash memory blocks and their associated configuration.

Table 82. Flash block configuration

Block or address number	Block name	Start address (hex)	End address (hex)	Size	Applicability
0	Code flash memory 0	0040_0000	0047_FFFF	512 KB	MWCT2014S, MWCT2015S
		0040_0000	004F_FFFF	1 MB	MWCT2D17S, MWCT2D16S, MWCT2016S
1	Code flash memory 1	0048_0000	004F_FFFF	512 KB	MWCT2015S
		0050_000	005F_FFFF	1 MB	MWCT2D17S, MWCT2D16S, MWCT2016S
2	Code flash memory 2	0060_0000	006F_FFFF	1 MB	MWCT2D17S
3	Code flash memory 3	0070_0000	007F_FFFF	1 MB	MWCT2D17S
4[1]	Data flash memory	1000_0000	1001_FFFF	128 KB	MWCT2D17S
2[1]				128 KB	MWCT2D16S, MWCT2016S
		1000_0000	1000_FFFF	64 KB	MWCT2015S, MWCT2016S
0 [2]	UTest NVM	1B00_0000	1B00_1FFF	8 KB	MWCT2015S, MWCT2016S, MWCT2D16S, MWCT2D17S, MWCT2014S

1. Sector operation should be used for data flash during high voltage operation.
2. The address region number is the same as block number for all the blocks except this one. Address region is called UTest NVM address region in this case.

No application cores except HSE_B can access the address regions shown in Table 83.

Table 83. Secure flash memory configuration

Description	MWCT2015S		MWCT2016S		MWCT2D17S		Size
	Start address	End address	Start address	End address	Start address	End address	
Secure BAF code (SBAF_CODE)	004F_4000h	004F_FFFFh	005F_4000h	005F_FFFFh	007F_4000h	007F_FFFFh	48 KB

NOTE

For HSE memory configuration, see *'Memory map when HSE firmware usage feature flag is enabled'* section in *'Boot Overview'* chapter.

The flash memory can perform multiple reads in parallel (between different blocks), using the single-, dual-, or quad-read feature. It also includes an internal UTest mode that can generate single- and double-bit ECC errors.

The code flash memory lets you access data paths as per the following table:

Chip	No. of data paths that can be accessed simulataneously
MWCT2D17S	3
MWCT2016S	2

You can configure the flash memory sectors as erase- or write-protected by using the flash memory's sector and super-sector locking features.

Data flash and/or Code flash memory blocks can be altered by a code executing from different flash block or SRAM.

Data flash memory is the same as code flash memory—supporting program, erase, and read operations.

After the completion of the program or erase operations, the MCR and MCRS registers notify you as soon as the code flash memory code can be executed. At the end of reset recovery, MCRS[DONE] transitions from 0 to 1.

NOTE

MCRS[RWE] might become 1 during the program or erase operation because of speculative accesses by Cortex-M7 core(s). If there are memory regions where no speculative accesses must be initiated, Arm recommends to configure the on-core MPU to set those regions with these attributes:

- Device or strongly-ordered
- Execute never

NOTE

- ADR[A3] and ADR[A4] field are reserved for MWCT2016S, as code flash memory size in 2 MB for MWCT2016S.
- For MWCT2016S, reset value of FLASH_SSPELOCK and FLASH_XSSPELOCK register is 0x0FFF_FFFF.

20.1.2 MCRE register reset value

The reset value of the MCRE register depends on the chip-specific flash memory configuration. This table provides the flash memory configuration of the chip and the associated register reset values.

Table 84. MCRE register reset value

MCRE fields	Reset value
n1M (bit position 23:21)	100b – Four 1 MB blocks
	010b – Two 1 MB blocks
n2M (bit position 31:29)	100b – Four 2 MB blocks
n512K (bit position 15:14)	00b – Zero 512 KB blocks
	01b – One 512 KB block
	10b – Two 512 KB blocks
n256K (bit position 7:6)[1]	01b – One 256 KB blocks
MCRE register reset value	MWCT2014S - 0000_8040h
	MWCT2015S - 0000_4040h

Table continues on the next page...

Table 84. MCRE register reset value (continued)

MCRE fields	Reset value
	MWCT2D17S - 0080_0040h
	MWCT2x16S - 0040_0040h

1. For block size less than equal to 256 KB

20.1.3 Debugger considerations while Flash Program/Erase

While flash programming is done via debugger, special considerations should be taken care off. See "Debug Subsystem" chapter for details.

20.2 Introduction

The primary function of the embedded flash memory serves as an electrically programmable and erasable non-volatile memory (NVM) that may be used for instruction or data storage.

20.2.1 Overview

The embedded flash memory is designed for use in embedded MCU and SoC applications. It supports a total memory size up to 8.5 MB of NVM in main space and 8 KB of UTest NVM space per module. Multiple flash modules may be instantiated within an SoC to achieve higher density. The embedded flash memory is addressable by page (256 bits) for read operation and double-word(s) and page and quad page for program operations. Flash memory reads always return 256 bits, although read page buffering may be performed by the PFC. The flash memory is able to do multiple reads in parallel (between different blocks), utilizing the quad read feature.

For details on the embedded flash memory architecture and features, see Functional description.

The following figure shows the top-level diagram and functional organization of the flash memory unit.

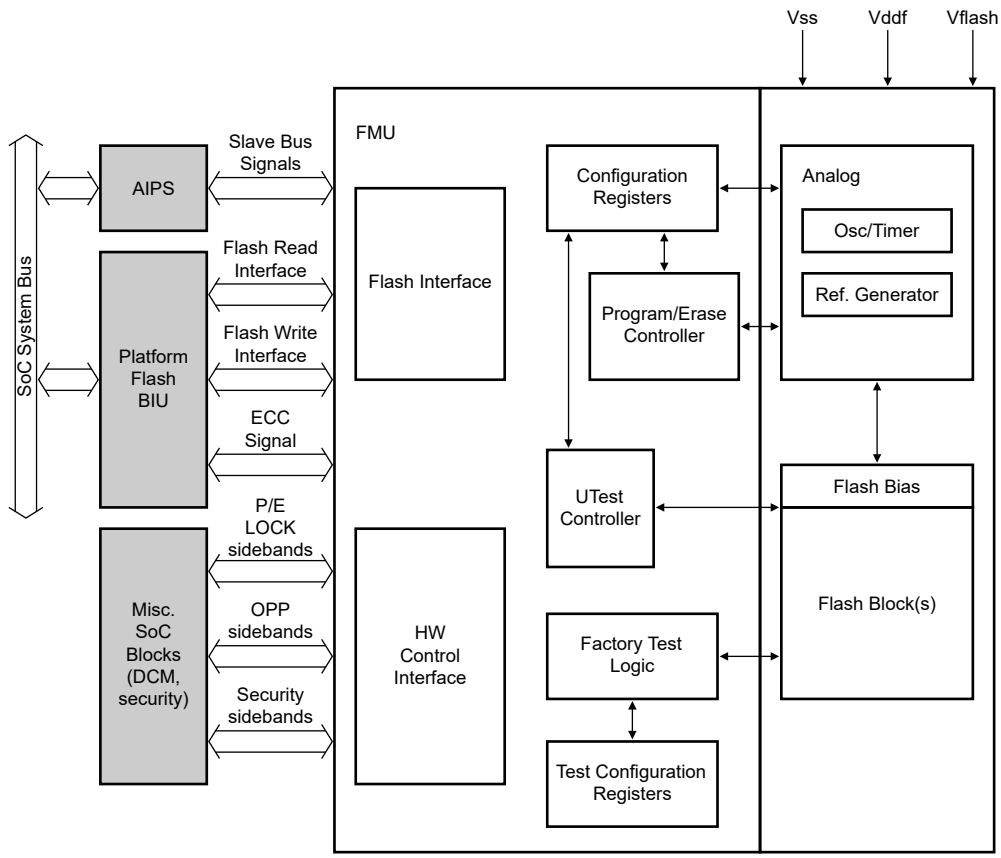

Figure 47. Block diagram

20.2.2 Features

The embedded flash memory includes these distinct features:

- Test information stored in a dedicated non-volatile sector (referred to as the UTest sector)
- OTP space made available in the UTest sector
- Read page size of 256 bits (8 words)
- ECC with single bit correction, double bit detection (all 1s valid) with 64-bit granularity
- Quad page programming (256-bit granularity)
- Hardware programmable sector and super sector program or erase restriction control
- Erasing of selected sector or block erase
- Independent programming of the UTest NVM sector
- Embedded hardware program and erase algorithms
- Support for reading while writing when the accesses are to different blocks
- UTest mode (user-accessible test modes) including array integrity and margin read
- Triple-voted flops for safety-critical flash memory functions (for example, internal trimming, redundancy, mode control, and others)

20.2.3 Modes of operation

Following is a brief description of the embedded flash memory operating modes.

- User mode is the default operating mode of the embedded flash memory. In this mode, it is possible to read and write registers (including register-based interlock writes), read the memory array, program the memory array, and erase the memory array. In this mode program and erase operations are initiated by doing register writes. Program and erase operations are controlled by an internal state machine.
- Low-Power mode turns off all DC current sources within the embedded flash memory and enables VFLASH and VDDF to be power gated. The embedded flash memory is not accessible for read, write, program, or erase when in Low-Power mode. This mode results in the lowest current draw that embedded flash memory can achieve.
- UTest mode is a tiered test mode strategy in which a portion of the factory test modes are made available. This mode is protected but accessible.

20.3 UTest NVM sector

The UTest NVM sector may be enabled by PEADR[PEASAD] during interlock writes. When the UTest NVM space is enabled, all program and erase operations are mapped to the UTest NVM sector. User-mode programming of the UTest NVM sector is enabled only when PEADR[PEASAD] is high.

The UTest NVM sector is an OTP sector (assuming Test mode disable seal is written) . Therefore, performing an erase operation is not permitted.

The UTest NVM sector supports RWW, and is grouped with the sectors in partition 0.

The UTest NVM sector may be locked against program by using hardware program and erase protection input to the flash module (MCRS[TSPELOCK]).

The UTest NVM sector contains specified data that is needed for embedded flash memory or SoC features.

Programming of the UTest NVM space has restrictions that are similar to those of the main space in terms of how ECC is calculated. Only one program operation is allowed per 64-bit ECC segment.

20.4 Test mode disable seal

The UTest NVM sector includes a mechanism to disable factory entry into Test mode selectable by block. Extreme care must be taken when using this feature, because blocks that are selected to be protected in this method will not have possible failures analyzed by factory failure analysts. Once sealed, the UTest sector becomes OTP (erase locked, and OPP enabled). The UTest sector is not accessible in Test Mode.

Protection of this sort prevents all high voltage operations to the flash memory executed by the internal state-machine, as well as reads through this state machine, and reads through the array integrity state machine when using Test mode interfaces.

UTest operations, margin read and array integrity, are also protected by preventing MISR updates on blocks selected for protection, although reads are still performed, and single bit corrections and double bit detections will be logged. Protection through other interfaces is provided by normal User mode protection mechanisms and is device-specific.

The method to disable factory entry into Test mode is to first program the Test mode disable seal location to be 5A4B_3C2Dh. After the next reset is asserted, Test mode is disabled.

It is possible to create a password to enable factory entry into Test mode. This can be programmed into the Test mode disable override passcode. The passcode may not be 0000_0000h, FFFF_FFFFh, or 5555_5555h. These are all invalid passcodes and will not be accepted to override. If it is desired, by the customer, that override never be possible, one of the three invalid passcodes must be put into the Test mode disable override passcode location. Passcode may be entered to authenticate entry, if enabled, by performing a 32-bit register write to register address 90h.

Even if the Test mode disable seal password is written, the UTest NVM sector is always protected and the UTest operations, margin read and array integrity, are always protected.

Only blocks selected in the Test mode disable block select field are controlled by the Test mode disable feature. Therefore, it is possible for customers to selectively pick blocks that have this type of protection and will not be eligible for factory failure

analysis. Bits programmed to 0 in the Test mode disable block select field(s) designate blocks that are controlled by the Test mode disable feature.

In order to let two opportunities to select blocks for the Test mode disable, two regions are available, Test mode disable bock select - 1 and Test mode disable block select - 2. If either Test mode disable block select - 1 or Test mode disable block select - 2 has a 0 programmed, that block will be protected. The bits of these two regions are logically ANDed to define the blocks that are effectively selected for the Test mode disable feature. The bock select field is organized as shown in the next table:

Table 85. Test mode disable block select

Block	Bits used to select blocks
Block 0 disable	Data[0]
Block 1 disable	Data[8]
Block 2 disable	Data[16]
Block 3 disable	Data[24]
Block 4 disable	Data[32]
Block 5 disable	Data[40]

20.5 Functional description

The embedded flash memory module consists of blocks with the following options:

- 2 MB blocks (0, 1, 2, 3 or 4 blocks allowed per module)
- 1 MB blocks (0, 1, 2, 3 or 4 blocks allowed per module)
- 512 KB blocks (0, 1, 2 or 4 blocks allowed per module)
- 256 KB blocks (0, 1, 2 or 4 blocks allowed per module)
- A total of six blocks are allowed per module

Read while Write is allowed within a module, and is determined based on block boundaries. Read while Write partitions are used to determine locations for valid read-while-write (RWW) operations. While the embedded flash memory performs a write (program or erase) to a given partition, it can simultaneously perform a read from any other partition. For program and erase operations, only the address specified by an interlock write determines the partition being written (sector or super sector locking does not determine the RWW partitions being written).

The main address space is also divided into sectors and super sectors to implement independent erase and program protection. The UTest NVM space also exists as a sector and has independent program protection. The UTest NVM sector is included to support systems that require non-volatile memory (NVM) for security or to store system initialization information.

A number of MCR bits are protected against write when another field, or set of fields, is in a specific state. These write locks are covered on a bit-by-bit basis in Module Configuration Register. The write locks do not consider the effects of trying to write two or more bits simultaneously. This module does not allow fields to be written simultaneously that put the device into an illegal state. This is implemented through a priority mechanism among the fields, and the next table shows this mechanism.

Table 86. MCR field set and clear priority levels

Priority level	MCR field(s)
1	ERS
2	PGM
3	EHV

If two or more MCR fields are written simultaneously, only the field with the lowest priority number is accepted for modification. For example, writing 1 to ERS and PGM simultaneously results in 1 being written only to ERS.

Each read of the embedded flash memory retrieves a page, or eight consecutive words (256 bits), of information. The address for each word retrieved within a page differs from the other addresses in the page only by address bits [4:2]. The flash memory page read architecture easily supports both cache and burst mode at the PFC BIU level for high-speed read applications.

The embedded flash memory supports fault tolerance through error correction code (ECC) and error detection. ECC implemented within the embedded flash memory corrects single bit failures and detects double bit failures.

Program and erase of the embedded flash memory requires multiple system clock cycles to complete. Program and erase may be aborted.

The embedded flash memory may operate in various modes as described in the following sections.

20.5.1 User mode

In User mode, the embedded flash memory may be read and written (register writes and interlock writes), programmed or erased. The following sub-sections define all actions that may be performed in User mode.

20.5.1.1 Read and write

The default state of the embedded flash memory is read. The main and UTest NVM address spaces can be read only in the read state. The flash registers are always available for read, except when the embedded flash memory is in Low-Power mode. The module enters the read state on reset, and remains in the read state under two sets of conditions:

- The read state is active when the embedded flash memory is enabled (User mode read).
- The read state is active when MCR[PGM] or MCR[ERS] are 1 and a high voltage operation is ongoing (RWW).

NOTE

Reads done to the partition(s) being operated on (either erased or programmed) result in MCRS[RWE] becoming 1.

In embedded flash memory, flash core reads return 256 bits (1 page). Register reads return 32 bits of data.

NOTE

Flash core reads are performed through the PFC BIU. In many cases, the BIU does read page buffering to allow sequential reads to be done with higher performance. This could provide a data coherency issue that must be handled with software. Data coherency may be an issue after a program or erase operation, as well as UTest NVM sector operations.

In user mode, registers may be written (including interlock writes using registers).

Register reads to unmapped register address space return all 0s.

Register writes to unmapped register address space have no effect.

Interlock writes that are attempted during a high voltage operation (MCR[EHV] = 1 or MCRS[DONE] =0) result in the interlock write being ignored, and address and data will not be updated.

20.5.1.2 Program

A flash memory program sequence operates on any page within the flash core. Within a page, up to eight words may be altered in a single program operation. Also, up to four pages can be altered in a single program operation. Whenever the array is programmed, the ECC bits also get programmed.

ECC is handled on a 64-bit boundary. Thus, if only one word in any given 64-bit ECC segment is programmed, the adjoining word in that segment should not be programmed, because ECC calculation is already complete for that 64-bit segment. Attempts to program the adjoining word may likely result in an operation failure. It is recommended that all programming operations ranger from 64 bits to 1024 bits, and be 64-bit aligned. The programming operation should completely fill selected ECC segments within the page. Only one program is allowed per 64-bit ECC segment between erases.

Caution

In rare cases, over-programming of a 64-bit ECC segment may be done (EEPROM emulation in data flash region). In this case, approved EEPROM emulation drivers must be used, and they must limit the number of over-program operations to three times (four total programs between erases).

Programming changes the value stored in an array bit from logic 1 to logic 0 only. Programming cannot change a stored logic 0 to a logic 1.

NOTE

If a logic 0 is attempted to be over-programmed by a logic 1, the resulting operation fails (MCRS[PEG] = 0), and the 0s that are interlocked are merged (ORed) with the 0s that are already present in the 64-bit ECC segment, unless the block is designated as an over-orogram protected block.

Addresses in locked sectors cannot be programmed. Values may be programmed in any or all of eight words, within a page, with a single program sequence. Up to four pages can be programmed at once on a quad-page boundary. The program operation consists of the following sequence of events:

1. Write the address to be programmed using logical address registers located in the PFC. The result of this write will also be reflected physically in the PEADR register.

   NOTE

   PEADR writes are initiated by writes that first occur in the PFC. Please see the platform flash memory controller chapter for more information. PEADR reads are allowed, and represent the flash memory physical address.

   NOTE

   Ensure the sector that contains the address to be programmed is unlocked. Sector and super sector lock status is latched at this step and does not change until the next program or erase sequence is started.

2. Data to be programmed must be written in the appropriate DATAX register (where X is 0 to 31). All unwritten data words default to FFFF_FFFFh.
3. Change the value in MCR[PGM] from a 0 to a 1.
4. Write a 1 to MCR[EHV] to start the internal program sequence or skip to step 8 to terminate.
5. Wait until MCRS[DONE] becomes 1.

   NOTE

   Since MCRS[DONE] clears with MCR[EHV] being set, it may not be possible for software to read MCRS[DONE] as 0 between step 4 and step 5, depending on the operation selected.

6. Confirm MCRS[PEG] = 1.
7. Write 0 to MCR[EHV].
8. Write 0 to MCR[PGM] to terminate the program sequence.

Program may be initiated with the writing of the PEADR register (enabled with a write done in the PFC block). The PEADR write to initiate the program sequence determines the quad-page address to be programmed. Data must also be written to the DATA register(s). This first write is referred to as an interlock write. Unwritten locations default to a data value of FFFF_FFFFh.

An interlock write must be performed before writing 1 to MCR[PGM], and MCR[PGM] must be set before writing 1 to MCR[EHV] during a program sequence. A program sequence may be terminated by writing 0 to MCR[PGM] prior to writing 1 to MCR[EHV].

While MCR[EHV] is 1 and MCRS[DONE] is 0, MCR[EHV] may be cleared, resulting in a program abort. A program abort forces the embedded flash memory to step 8 of the program sequence. An aborted program results in PEG becoming 0, indicating a failed operation. The data space being operated on before the abort contains indeterminate data.

Caution

Aborting a program operation leaves the FC addresses being programmed in an indeterminate data state. This may be recovered by executing an erase on the affected block.

20.5.1.2.1 Program hardware locking

Hardware locking which affects the program and erase operations is available for UTest sector and all array blocks.

20.5.1.2.2 Over-program protection enable

One-time programming can be enabled. If over-program protection is enabled, any double word that has already been programmed cannot be programmed again. The over-program protection enable does not affect the erase operation. Attempts to over-program result in MCRS[PEG] becoming 0. If any double word within a quad-page has an over-program protection violation, MCRS[PEG] becomes 0, and no double words are programmed.

One-time programming can be enabled for the UTest NVM sector.

20.5.1.3 Erase

An erase changes the value stored in all bits of the selected sector or block to logic 1, and operates on a sector or a block in the main address space. The erase sequence is fully automated within the flash memory. Locked sectors cannot be erased. The erase sequence consists of the following events:

1. Write to the sector or block address to be erased using logical address registers located in the PFC. The result of this write is reflected physically in the PEADR register. One, and only one, DATA register must also be written. This is referred to as an erase interlock write.

   NOTE

   PEADR writes are initiated by writes that first occur in the PFC. Please see the platform memory flash controller chapter for more information. PEADR reads are allowed, and represent the flash memory physical address.

   NOTE

   The selected block or sector must be unlocked prior to initiating an erase with the appropriate sector or super sector lock registers. Sector and super sector lock status is latched at this step and does not change until the next program or erase sequence starts. If a block is selected for erase, all the sectors and super sectors must be unlocked within that block.

2. Change the value in MCR[ERS] from a 0 to a 1, and at the same time select the size of erase using MCR[ESS].
3. Write a 1 to MCR[EHV] to start the internal erase sequence or skip to step 6 to terminate.
4. Wait until MCRS[DONE] becomes 1.

   NOTE

   Since MCRS[DONE] clears with MCR[EHV] being set, it may not be possible for software to read MCRS[DONE] as 0 between step 3 and step 4, depending on the operation selected.

5. Confirm MCRS[PEG] = 1.
6. Write 0 to MCR[EHV].
7. Write 0 to MCR[ERS] to terminate the erase, and if set MCR[ESS] should also be cleared (else the field auto clears).

Erase may be initiated with the writing of the PEADR register (enabled with a write done in the Platform Flash Controller block). The PEADR write to initiate the erase sequence determines the sector or block to be erased. One write must also occur to a DATA register. Data word written during an erase sequence interlock write is ignored. This write is referred to as an erase interlock write.

An erase interlock write must occur before writing 1 to MCR[ERS] (and optionally MCR[ESS]), and MCR[ERS] must be set before writing 1 to MCR[EHV] during an erase sequence. The erase sequence may be terminated by writing 0 to MCR[ERS] prior to writing 1 to MCR[EHV].

While MCR[EHV] is 1 and MCRS[DONE] is 0, MCR[EHV] may be cleared, resulting in an erase abort. An erase abort forces the embedded flash memory to step 7 of the erase sequence. An aborted erase results in PEG becoming 0, indicating a failed operation. The sector or block being operated on before the abort contain indeterminate data.

20.5.1.3.1 Erase hardware locking

Hardware locking which affects the erase and program operations is available for UTest sector and all array blocks. For details, see Program hardware locking.

20.5.1.4 Express program

A mechanism is made available to provide an express method to program up to 1024 bits of flash memory. When activated, all ongoing program and erase operations through the register interface are automatically aborted (MCR[EHV] becomes 0 automatically) and the express interface is given priority. When using the express interface, sequence requirements are ignored, although a XPEADR write is required to start the express program sequence.

The flash express program mechanism is provides a quicker way to get information programmed into a block of flash memory when an application needs an immediate diary access, or a crash log access.

Addresses in locked sectors cannot be express programmed.

The express program operation consists of the following sequence of events:

1. Write the address to be programmed using the logical address register located in the PFC. The result of this write will also be reflected physically in the XPEADR register.

   NOTE

   XPEADR writes are initiated by writes that first occur to the PFC. Please see the platform flash controller chapter for more information. XPEADR reads are allowed, and represent the flash memory physical address.

   NOTE

   Ensure the sector that contains the address to be programmed is unlocked. Sector and super sector lock status is latched at this step and does not change until the next program, erase or express program is started.

   NOTE

   If XMCR[XPGM] interrupts a program or erase setup after MCR[EHV] is written to 1, the MCR and MCRS registers indicate if the operation was automatically aborted (MCR[EHV] = 0, MCRS[PEG] = 0, MCR[PGM] =1 or MCR[ERS] = 1), or if the operation was successful (MCR[EHV] = 1, MCRS[PEG] = 1, MCR[PGM] =1 or MCR[ERS] = 1). If express program interrupts a program or erase setup prior to MCR[EHV] being written to a 1, the MCR and PEADR registers will be preserved to show the state of the setup upon interruption. If fields MCR[PGM] = 1 or MCR[ERS] = 1 at interruption, the user must terminate the event by writing 0 to these fields. However, if MCR[PGM] or MR[ERS] were not 1 at interruption, PEADR is preserved and does not need to be rewritten, but the PDATA registers are required to be rewritten for the interrupted operation. After the PDATA write(s) are repeated to finish the interlock write, the remainder of the program and erase sequence can be done to restart the interrupted operation (including doing a terminate after PGM or ERS are written to 1, if desired).

   NOTE

   Before starting the express program, ensure that UTest operations (array integrity or user margin read) are not ongoing (or about to be started). UT0[UTE] must be low before requesting the express program, and remain low during express program operations. Hardware locks are in place to ensure this occurs.

2. Wait until XMCR[XDOK] goes high.
3. Write the DATA registers with the data desired to be programmed. Up to 1024b (128B) may be programmed with express program. Only DATA registers that are written will receive program pulses.
4. Change the value in XMCR[XPGM] from a 0 to a 1.
5. Write a 1 to XMCR[XEHV] to start the internal express program sequence.

6. Wait until XMCR[XDONE] becomes 1.
7. Confirm XMCR[XPEG] = 1.
8. Write 0 to XMCR[XEHV].
9. Write 0 to XMCR[XPGM] to terminate the express program sequence.

20.5.2 Low-Power mode

In Low-Power mode, the embedded flash memory is put into a state where VDDF power gating and VFLASH power gating is allowed. It is the lowest current mode for the flash memory. No reads from or writes to the embedded flash memory are possible when in this mode. Most power dissipation is due to leakage in this mode.

Prior to entering Low-Power mode, it is required that all program, erase, and UTest operations be stopped.

When in Low-Power mode, register access is prevented. Flash core accesses are also prevented until power mode is exited. Flash core reads and writes may occur after power mode is exited.

The embedded flash memory returns to a post-reset state in all cases.

20.5.3 Program and erase watchdog timer

The embedded flash memory contains an internal watchdog timer that is used to prevent denial of service issues and events.

The watchdog timer is active during two periods of a program and erase event: program/erase setup and program/erase cleanup. If it is desired that program and erase operations also be checked with a watchdog timer, a system resource may be used for this purpose.

Program/erase setup always starts at the time of the PEADR write. An express program setup starts with a write to XPEADR and XMCR[XDOK] = 1. In the event of an Express program interrupt of main or alternate interface setup, the timer starts at the time when the express program operation completes (write of XMCR[XPGM] = 0). The watchdog stops when either MCR[EHV] is set to start the operation, or when the operation is terminated. Termination can occur when MCR[PGM] or MCR[ERS] are written to 0 (prior to MCR[EHV] being written to 1), or MCRS[PES] written to 0. If the express program interrupts the program/erase setup, this also stops the timer on that interface, and express program maintains priority. The above statements also apply to the alternate interface.

NOTE

If PEADR writes occur while UT0[UTE] is 1, the watchdog feature does not activate for setup. Watchdog timer is not active during UTest operations.

Program/erase cleanup always starts at the time of MCRS[DONE] = 1 on completion or an abort. In the event of an express program auto-abort of main or alternate interface, the cleanup starts at the time of MCRS[DONE] becoming 1 and the express program operation completed (XMCR[XPGM] written to 0). The watchdog stops when MCR[PGM] or MCR[ERS] are written to 0 at the end of the operation. If express program interrupts the program/erase cleanup, the timer on that interface also stops. The above statements also apply to the alternate interface.

Watchdog timers exist for each interface (main, alternate and express).

If a watchdog timeout occurs, the watchdog interrupt will be reflected in MCRS[WDI], AMCRS[AWDI] or XMCR[XWDI]. Interrupts can be enabled on the main and alternate interfaces using MCR[WDIE] or AMCR[AWDIE]. When a watchdog timeout occurs and an interrupt register asserts, the PEID restrictions on that interface are released. At that point, any master can complete the operation, and PEID locking is no longer enforced. If the watchdog timeout occurs, the EHV bit on that interface (MCR[EHV], AMCR[AEHV], and XMCR[XEHV]) are locked for writing to a 1. In this instance, any master can take the interface to a program and erase terminate. This enables accepted MCRS[WDI], AMCRS[AWDI] or XMCR[XWDI] to become 0, and the operation may restart with a new interlock write.

NOTE

If the watchdog timeout occurs before PGM becomes 1 (on any interface), or ERS becomes 1 (on any interface), the sequence must be taken to the point that the PGM or ERS bit for that interface is written and then the field for that interface can be cleared to create the terminate event and to clear the watchdog interrupt.

By default, the watchdog is enabled. Through the alternate MCR, the watchdog may be disabled (AMCR[WDD]), and the watchdog timeouts maybe adjusted (AMCR[WDT]) for all timeouts and all interfaces.

20.5.4 UTest mode

UTest mode enables customers to do specific tests that check the integrity of the embedded flash memory.

NOTE

When entering UTest mode, a best practice is to ensure all error flags and address error reporting in ADR are cleared to their reset value to ensure robust software and procedure execution.

NOTE

UTest mode diagnostic features ECC Logic Check, EDC after ECC Logic Check, Address Encode Logic Check, and Read Reference and Voltage Check, require serialization of flash reads starting with mode setup and ending with mode exit. This may be accomplished by executing diagnostic code from system RAM (with single reads to flash tagged address) as well as ensuring any flash reads outside of this diagnostic code are idle (single core).

20.5.4.1 Array integrity self check

Array integrity is checked using a predefined address sequence (based on UT0[AIS]), and this operation is executed on selected blocks.

The data to be read is customer-specific user code programmed into the flash memory and the correct MISR signature is calculated based on that code.

Any random or nonrandom code is valid. After the operation completes, the results of the reads can be checked by reading the MISR value, to determine if an incorrect read or ECC detection was noted. Array integrity MISR value is calculated after ECC detection and correction. Array integrity requires that the read wait states control registers in the CTL register be set to match the system frequency being used.

The array integrity self check consists of the following steps:

1. Enable UTest mode.
2. Select the block to receive the array integrity check by performing an interlock write to that block. Write logical address register in the PFC (which will be reflected in the PEADR register) and 1 DATA register (PDATA is ignored). The block selected for array integrity check does not need to be unlocked.

   NOTE

   Blocks protected with the Test mode disable seal are still read as part of the array integrity sequence. The resulting read on sealed blocks is not captured in the MISR, but single bit correction, double bit detection and breakpoints are still honored.

   NOTE

   It is not possible to perform array integrity operations on the UTest NVM sector.

3. If desired, write 1 to UT0[AIS] for sequential addressing only.

   NOTE

   For normal integrity checks of the flash memory, sequential addressing is recommended. If it is required to more thoroughly check the read path (in a diagnostic mode), AIS shall remain 0 to examine more read transitions. This sequence takes more time.

4. Seed the MISR registers (UM0 - UM9) with desired values.
5. If breakpoints are desired, write 1 to UT0[AIBPE], and ensure that MCRS[EER] and MCRS[SBC] are 0. If it is desired to break on a single bit correction, ensure that UT0[SBCE] = 1.
6. Write 1 to UT0[AIE].

a. If desired, the array integrity operation may be aborted before UT0[AID] goes high. This may be done by writing 0 to UT0[AIE] and then continuing to the next step. Note that in the event of an aborted array integrity check, MISRs contain a signature for the portion of the operation that was completed prior to the abort and are not deterministic. Before performing another array integrity operation, the UM0, UM1, UM2, UM3, UM4, UM5, UM6, UM7, UM8, and UM9 registers may need to be initialized to the desired seed value by doing register writes.

b. If desired, the array integrity operation may be suspended before UT0[AID] goes high. This may be done by writing 1 to UT0[AISUS] to request an array integrity suspend. After UT0[AISUS] becomes 1, the user should wait for UT0[AID] to become 1, which indicates that the flash memory has entered the suspend state, and normal reads to the flash memory may be done. After UT0[AID] becomes 1, UT0[AISUS] may be written to 0 to resume the array integrity sequence.

NOTE

User mode array reads requested during the array integrity test are ignored to ensure that the array integrity operation is not corrupted. The memory array does not respond to array read requests during this time. User mode array reads may be executed if suspended or at a breakpoint.

7. Wait until UT0[AID] becomes 1.
8. If breakpoints are enabled, check if UT0[NAIBP] = 1. If the value of this field is 1, MCRS[EER], MCRS[SBC], and ADDR may be checked to determine the cause of the break and the address of the break. Prior to resuming the operation, write 1 to clear MCRS[SBC] or MCRS[EER]. Then, the operation may be resumed by writing 0 to UT0[NAIBP]. Continue to wait until UT0[AID] becomes 1. If breakpoints are not enabled, or if UT0[NAIBP] = 0 when UT0[AID] becomes 1, the operation is complete. Continue to the next step.
9. Read values in MISRs (UM0 - UM9) to ensure correct signature.

NOTE

Array integrity reads may be done to unselected (or non-present) locations. Reads done to these locations do not update the MISRs, MCRS[EER] and MCRS[SBC].

10. Write 0 to UT0[AIE].

20.5.4.2 User margin read

User margin read may be done using the array integrity interface, and has all the associated features of the array integrity interface (MISR and breakpoints).

User margin reads are done at a read margin level, checking for erased bits or programmed bits encroaching on the nominal read level.

User margin read requires that the Read Wait States control registers in the CTL register be written to match the system frequency being used. Margin ECC corrections and detections are noted during the user margin read test. Margin read MISR value is calculated after ECC detection and correction.

The data to be read is customer-specific user code programmed into the flash memory.

Any random or non-random code is valid. After the operation completes, the margin read results can be checked by reading MCRS[EER] and the MCRS[SBC] to determine if zero, one, or two bits are being detected by the margin read, as well as checking the MISR signature.

The use model for margin read is in the event of a user-detected single bit correction (through user reads), a margin read may be done to check for a possible second bit falling within the selected margin levels.

The user margin read consists of the following steps:

1. Enable UTest mode.
2. Select the block to receive the array integrity check by performing an interlock write to that block. Write logical address register in the PFC (which will be reflected in the PEADR register) and 1 DATA register (PDATA is ignored). The block selected for user margin read check does not need to be unlocked.

NOTE

Blocks protected with the Test mode disable seal are still read as part of the margin read sequence. The resulting read on sealed blocks is not captured in the MISR, but single bit correction, double bit detection and breakpoints are still honored.

NOTE

It is not possible to perform margin read operations on the UTest NVM sector.

3. Write 1 to UT0[AIS] for sequential addressing only.

NOTE

For margin read checks of the flash memory, sequential addressing is recommended. Writing 0 to UT0[AIS] is possible for margin reads, but using the sequence takes more time, and is not recommended.

4. Seed the MISR registers (UM0 - UM9) with desired values.
5. Ensure that MCRS[EER] and MCRS[SBC] are 0.
6. To enable single bit correction reporting during margin read, write UT0[SBCE] = 1.
7. Write 1 to UT0[MRE].
8. Write UT0[MRV] to the desired value depending on if it is desired to do one's margin or zero's margin.
9. Write 1 to UT0[AIE].

NOTE

User mode array reads requested during the margin read test are ignored to ensure that the margin read operation is not corrupted. The memory array does not respond to array read requests during this time. User mode array reads may be executed if suspended or at a breakpoint.

NOTE

During margin read operations, with UT0[AID] = 0, it is not recommended to attempt write operations to MCRS[SBC] and MCRS[EER]. It is recommended that these fields only be written during suspend, breakpoints or at the completion of the margin read operation.

10. Wait until UT0[AID] becomes 1.
11. If breakpoints are enabled or a suspend was requested during margin read, the operation may be at a breakpoint or a suspend state. See Array integrity self check for more information.
12. Read values in the MISRs (UM0 - UM9) to ensure correct signature.

NOTE

Margin reads may be done to unselected (or non-present) locations. Reads done to these locations do not update the MISRs, MCRS[EER] and MCRS[SBC].

13. Write 0 to UT0[AIE].

20.5.4.3 ECC logic check

ECC logic can be checked by providing data to be read in UD0[EDATA], UD1[EDATA] and/or UD2[EDATAC]. Array reads can then be performed, ensuring expected results.

The ECC logic check consists of the following steps:

1. Enable UTest mode.
2. Write 1 to UT0[EIE].
3. Write to UD0[EDATA], UD1[EDATA] and/or UD2[EDATAC] to provide data and check bit values to be read. Single bit detections or double bit corrections can be simulated by properly selecting data and check bit combinations.

4. Write the page address to receive data provided in step 3 into ADR.
5. Write to UD2[ED3], UD2[ED2], UD2[ED1] and/or UD2[ED0] to select the double words on the page to receive the check.
6. Reads can now be done through the BIU using an array read request. In the event of a BIU read requested from an address that matches the address in ADR, expected data and corrections or detections are observed based on data written into UD0[EDATA], UD1[EDATA] and/or UD2[EDATAC]. MCRS[EER] and MCRS[SBC] can be checked to evaluate the status of reads done.

NOTE

In the event of an ECC error or single bit correction, during the ECC logic check (UT0[EIE] = 1), ADR is not loaded, and the address tagged to receive the ECC logic check values is preserved.

7. Once completed, write UT0[EIE] to 0.

20.5.4.4 EDC after ECC logic check

EDC after ECC logic can be checked by providing data to be read in UD3[EDDATA], UD4[EDDATA] and/or UD5[EDDATAC]. Array reads can then be performed, ensuring expected results.

The EDC after ECC logic check consists of the following steps:

1. Enable UTest mode.
2. Write 1 to UT0[EDIE].
3. Write to UD3[EDDATA], UD4[EDDATA] and/or UD5[EDDATAC] to provide data and check bit values to be read.
4. Write the page address to receive data provided in step 3 into ADR.
5. Write to UD2[EDD3], UD2[EDD2], UD2[EDD1] and/or UD2[EDD0] to select the double words on the page to receive the check.
6. Reads can now be done through the BIU using an array read request. In the event of a BIU read requested from an address that matches the address in ADR, expected EDC after ECC errors are observed based on data written into UD3[EDDATA], UD4[EDDATA] and/or UD5[EDDATAC]. MCRS[EEE] can be checked to evaluate the status of reads done.
7. Once completed, write UT0[EDIE] to 0.

20.5.4.5 Address encode logic check

Address encode logic can be checked by inverting the address encode information from the memory array in UA0[AEI] and UA1[AEI]. Array reads can then be performed, ensuring expected results.

The Address encode check consists of the following steps:

1. Enable UTest mode.
2. Write 1 to UT0[AEIE].
3. Write to UA0[AEI] and/or UA1[AEI] to provide address bit(s) to be inverted.
4. Write the page address to receive inverted addresses provided in step 3 into ADR.
5. Reads can now be done through the BIU using an array read request. In the event of a BIU read requested from an address that matches the address in ADR, expected address encode errors are observed based on address invert values written into UA0[AEI] and/or UA1[AEI]. MCRS[AEE] can be checked to evaluate the status of reads done.
6. Once completed, write UT0[AEIE] to 0.

20.5.4.6 Read reference and voltage check

Read reference and voltage detection logic can be checked by writing 1 to UT0[RRIE]. Array reads can be then be performed, ensuring expected results.

The read reference and voltage check consists of the following steps:

1. Enable UTest mode.
2. Write 1 to UT0[RRIE].
3. Write the page address to receive a read reference error MCRS[RRE] and a read voltage error MCRS[RVE] into ADR.
4. Reads can now be done through the BIU using an array read request. In the event of a BIU read requested from an address that matches the address in ADR, expected read reference and read voltage errors are observed based on ADR registers. MCRS[RRE] and MCRS[RVE] can be checked to evaluate the status of reads done.
5. Once completed, write UT0[RRIE] to 0.

20.5.5 Data flash memory requirements for EEPROM emulation

The embedded flash memory may be used to emulate an EEPROM utilizing software drivers, strategic over-programming of double words in the flash memory and following the below requirement and best practices in EEPROM software drivers.

It is required that the EEPROM emulation driver must build in fault tolerance allowing for the ability to “skip” records. In the case of an unsuccessful program, the ability to retry programming in the next available record location is required (record retirement). In the case of an unsuccessful sector erase, the ability to retire a sector is required (sector retirement).

In addition, following are best practices for the EEPROM emulation software driver to be considered:

- Choose a record scheme which allows for grouping of EEPROM data contents that are updated at one time such that unchanged data is not needlessly copied while minimizing record qualifier and status overhead. A variable length record scheme may be used to allow for grouping of data that is written together and limiting total record overhead.
- Copy only the valid records during a sector change and re-constitution of EEPROM data set to avoid needless copying of data within flash memory. This avoids rebuilding the entire data set.
- Only redundantly storing critical data which cannot be recovered in two sectors if attempting to protect against record or sector failures.
- Load level total program/erase cycles applied to flash memory locations allocated for EEPROM emulation by using a round-robin sector scheme.

When combining round-robin with sector retirement requirement, three or more sectors must be allocated for EEPROM emulation inclusive of extra spare sector(s).

For details, see NXP application notes published on this topic.

20.6 Initialization information

A reset is the highest priority operation for the embedded flash memory and terminates all other operations.

The embedded flash memory uses reset to initialize register and status fields to their default reset values. If the embedded flash memory is executing a program or erase operation (MCR[PGM] = 1 or MCR[ERS] = 1) and a reset is issued, the operation aborts and the embedded flash memory disables the high voltage logic without causing any damage to the high voltage circuits. Reset aborts all operations and forces the embedded flash memory into User mode, ready to receive accesses.

After reset is requested, MCRS[DONE] becomes 0, and remains low during reset and reset recovery.

At the end of reset recovery, MCRS[DONE] transitions from 0 to 1.

After a reset completes, register reads may be performed.

NOTE

Registers that require updating from UTest NVM information, or other inputs, may not read updated values until MCRS[DONE] becomes 1.

During reset recovery, register writes are not allowed until MCRS[DONE] becomes 1 to indicate reset recovery is complete.

Caution

Resetting during a program or erase operation leaves the FC blocks being programmed or erased in an indeterminate data state. This may be recovered by executing an erase on the affected blocks.

20.7 Memory map and register description

20.7.1 c40asf flash memory register descriptions

The embedded flash memory map consists of a flash memory array (which includes main array space and UTest NVM space) and a region of registers associated with the programming model that enable flash memory array operation and modification.

The address space consists of up to 6 blocks (with restrictions), and blocks can be 2 MB, 1 MB, 512 KB or 256KB in size.

20.7.1.1 c40asf_flash memory map

Fields

Field	Function
31-24 —	Reserved
23-16 PEID	Program and Erase Master/Domain ID This field shows the ID of the master that has started the Program or Erase sequence (as well as Array Integrity and User Margin Reads). The ID is latched when the sequence has started (writing of the PEADR register). Upon completion of an operation (Program (MCR[PGM] written to 0 and MCRS[PES] equals 0), Erase (MCR[ERS] written to 0 and MCRS[PES] equals 0), Array Integrity (UT0[AIE] written to 0), User Margin Read(UT0[AIE] written to 0)), or Program and Erase Sequence clear (MCRS[PES] cleared to 0) the PEID field will return to an all ones state. See the chip-specific information for a list of Master IDs.
15 PECIE	Program/Erase Complete Interrupt Enable PECIE provides a mechanism to trigger an interrupt request upon the assertion of the DONE status due to a high voltage event (program or erase) finishing (normal, abort). If PECIE is written while not in a high voltage event, the interrupt will not immediately trigger, but will trigger after the next high voltage event is completed. Writing (and reading) of this bit will be restricted to the master that updated the PEADR register as captured in the PEID register at the start of the Program or Erase sequence. **NOTE** See the chip-specific information for interrupt details 0b - Interrupt request not generated when MCRS[DONE] is 1 1b - Interrupt request generated when MCRS[DONE] is 1
14-13 —	Reserved
12 WDIE	Watch Dog Interrupt Enable WDIE provides a mechanism to trigger an interrupt request upon the assertion of the WDI bit on the main interface. If WDIE is asserted, when WDI asserts, an interrupt from the flash will trigger to the system. The interrupt from the flash will mirror exactly the WDI bit. WDIE does not affect the register bit WDI. Writing (and reading) of this bit will be restricted to the master that updated the PEADR register as captured in the PEID register at the start of the Program or Erase sequence. **NOTE** See the chip-specific information for interrupt details 0b - Watchdog interrupt not enabled 1b - Watchdog interrupt enabled
11-9 —	Reserved
8 PGM	Program

Table continues on the next page...

Table continued from the previous page...

Field	Function
	PGM is used as part of the setup for a program operation. A 0 to 1 transition of PGM after program interlock write(s) is part of the program sequence. A 1 to 0 transition of PGM ends the program sequence. PGM can be set while in user mode read (ERS is low and UTE is low), and after the interlock write is completed. PES must also be low to enable PGM to be set. PGM can be cleared only when EHV is low and DONE is high. PGM is cleared on reset. Writing (and reading) of this bit will be restricted to the master that updated the PEADR register as captured in the PEID register at the start of the Program or Erase sequence. 0b - Flash memory not executing a program sequence 1b - Flash memory executing a program sequence
7-6 —	Reserved
5 ESS	Erase Size Select ESS is used to qualify the embedded flash memory erase operation for either sector erase or block erase. If ESS is selected for block erase, only the main array of that block will be erased. **NOTE** Block erase is for Factory use only, under controlled conditions. See Appendix A (Electrical Specifications) for more information on environmental condition requirements, and cycle limit. **NOTE** If interlock write occurs to UTest sector, ESS will be locked from setting to a 1. Block Erase of UTest sector is not supported, only sector erase is allowed. Erase of UTest space is not allowed if sealed, although ERS can be set and a PEG error will occur in response to the HV request. ESS can only be written to a 1 at the same time that ERS is written to a 1. If ESS is set, ESS will auto clear with ERS clearing (independent of the value written to ESS). ESS can not be cleared by writing a zero. ESS is cleared on reset. Writing (and reading) of this bit will be restricted to the master that updated the PEADR register as captured in the PEID register at the start of the Program or Erase sequence. 0b - Flash memory erase is on a sector 1b - Flash memory erase is on a block
4 ERS	Erase ERS is used as part of the setup for an erase operation. A 0 to 1 transition of ERS after an erase interlock write is part of the erase sequence. A 1 to 0 transition of ERS ends the erase sequence. ERS can only be set in user mode read (PGM is low and UTE is low), and after the interlock write is completed. PES must also be low to enable ERS to be set. ERS can be cleared only when EHV is low and DONE is high. ERS is cleared on reset. Writing (and reading) of this bit will be restricted to the master that updated the PEADR register as captured in the PEID register at the start of the Program or Erase sequence. 0b - Flash memory not executing an erase sequence

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Flash memory executing an erase sequence
3-1 —	Reserved
0 EHV	Enable High Voltage The EHV bit enables the embedded flash memory for a high voltage program/erase operation. EHV is cleared on reset. EHV must be set after the PGM or ERS bit is set in a program or erase sequence. Writing (and reading) of this bit will be restricted to the master that updated the PEADR register as captured in the PEID register at the start of the Program or Erase sequence. EHV may be set, initiating a program/erase under one of the following conditions: • Erase (ERS = 1, PEP = 0, PES = 0, WDI = 0) • Program (PGM = 1, PEP = 0, PES = 0, WDI = 0) Clearing EHV while DONE is low will abort the current program/erase high voltage operation. An abort causes the value of PEG to be cleared, indicating a failed program/erase; address locations being operated on by the aborted operation contain indeterminate data after an abort. EHV may not be written to a 1 after an abort is requested (EHV being cleared) and before DONE transitions high. EHV may not be written to a 1 after it is cleared as part of a program or erase cleanup, until after the next PEADR write. **NOTE** Aborting a high voltage operation leaves addresses in an indeterminate data state. This may be recovered by executing an erase on the affected sectors. 0b - Flash memory is not enabled to perform a high voltage operation. 1b - Flash memory is enabled to perform a high voltage operation.

20.7.1.3 Module Configuration Status (MCRS)

Offset

Register	Offset
MCRS	4h

Diagram

Fields

Field	Function
31 EER	ECC Event Error This bit provides information on previous reads (either user initiated reads or internally initiated reset reads).If a double bit detection occurred, the EER bit is set to a '1'. This bit must then be cleared, or a reset must occur before it returns to a 0 state. This bit may not be set by software. In the event of a single bit detection and correction, this bit is not set. If EER is not set, or remains 0, this indicates that all previous reads (from the last reset, or clearing of EER) are correct. Since this bit is an error flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0b - Reads occurring normally 1b - ECC error occurred during a previous read
30 SBC	Single Bit Correction SBC provides information on previous reads, if the SBCE is set. If a single bit correction occurred, the SBC bit is set to a 1. This bit must then be cleared, or a reset must occur before this bit returns to a 0 state. If SBC is not set, or remains 0, this indicates that all previous reads (from the last reset, or clearing of SBC) did not require a correction. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0b - Reads occurring without corrections 1b - Single bit correction occurred during a previous read
29 AEE	Address Encode Error AEE provides information on previous reads monitoring the address encode feature. On every read request to the flash, the incoming address is compared to an encoded address (row, column, and block) coming back from the memory array using the read data sense amplifier timing. If these two values do not match (zero selected, multiple selected, wrong selected), or the timing is incorrect, an address encode error will be recorded. If an address encode mismatch is detected, this bit is set to indicate that previous reads requested may have been corrupted. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0b - Reads are occurring without address encode mismatches 1b - Previous read may be corrupted based on address encode mismatch

Table continues on the next page...

Table continued from the previous page...

Field	Function
28 EEE	EDC after ECC Error EEE provides information on previous reads monitoring the EDC after ECC feature. On every read request to the flash, ECC is recalculated serially, and if there is a mismatch between the ECC calculations (taking into account corrections or detections) a late error will be reported. If an EDC after ECC mismatch is detected, this bit is set to indicate that previous reads requested may have been corrupted. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0b - Reads are occurring without EDC after ECC mismatches 1b - Previous read may be corrupted based on ECC calculation errors
27-26 —	Reserved
25 RVE	Read Voltage Error RVE provides information on previous reads monitoring the read voltage. If the read voltage is detected to be out of range, this bit is set to indicate that previous reads requested may have been corrupted. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0b - Reads are occurring without voltage issues 1b - A previous read may have been corrupted due to read voltage being out of range
24 RRE	Read Reference Error RRE provides information on previous reads monitoring the read reference. If the read reference is detected to be out of range, this bit is set to indicate that previous reads requested may have been corrupted. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0b - Reads occur without reference issues 1b - Previous read may be corrupted because of read reference being out of range
23-21 —	Reserved
20 RWE	Read-While-Write Event Error This bit provides information on previous read-while-write (RWW) reads. If an RWW error occurs, this bit is set to 1. The bit must then be cleared, or a reset must occur before it returns to a 0 state. If RWE is not set, or remains 0, this indicates that all previous RWW reads (from the last reset, or clearing of RWE) are correct. Since this bit is an error flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0b - Reads occur normally 1b - RWW error occurred during a previous read
19-18 —	Reserved
17	Program and Erase Protection Error

Table continues on the next page...

Table continued from the previous page...

Field	Function
PEP	PEP provides information about program and erase operations with respect to protection errors. A protection error occurs if a program is attempted to a locked sector or super sector, or if an erase is selected to a locked sector or super sector. This is evaluated prior to the operation beginning, and if an error is detected, high voltage operations (either a Program or Erase) will not be attempted for this request. **NOTE** If a location has both OTP and Lock protection, the response from the NVM will be PEP=1 only. If PEP is asserted, it must be cleared prior to attempting another high voltage operation. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0b - Program and erase protection errors do not exist 1b - Previous program or erase protection error encountered
16 PES	Program and Erase Sequence Error PES provides information about program and erase operations with respect to sequence errors. A sequence error occurs when the program or erase sequence is not followed exactly. If an “out-of-order” event is detected, PES will assert, and the remainder of the sequence will not be accepted. PES monitoring begins when the PEADR register is written and ends when EHV is set to start the operation. PES monitoring only applies to Program and Erase (Sector and Block). It does not apply to Express Program, or UTest operations. Following is a complete list of sequence error conditions: • Any specific DATA register written twice. • More than one DATA register write for ERS operations. • Attempts to write PGM or ERS register out of sequence. • Attempts to write PGM after ERS, or ERS after PGM. • Attempts to write DATA registers after PGM or ERS are written. • Attempts to write EHV out of sequence. Writes to the MCR that are protected by the MCR Priority Levels (i.e. simultaneous PGM, ERS and EHV writes) will not result in a PES condition. Attempts to write MCR or DATA registers by a master that does not match the PEID, will not result in a PES condition. Those reads and writes will be blocked, and the master in control of the interface may continue with its' sequence. Clearing of PES (due to a sequence error) has the same effect as the clearing of PGM or ERS after a program or erase operation. PEADR and DATA registers are cleared, PEID is cleared, and the operation must be re-started from the beginning. If PGM or ERS are already set, they must be cleared before PES is cleared. PES can only be cleared once the PGM or ERS bit for the sequence in progress is cleared. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0b - Program and erase sequence errors do not exist 1b - Previous program or erase sequence encountered an error
15 DONE	State Machine Status

Table continues on the next page...

Table continued from the previous page...

Field	Function
	DONE indicates whether the embedded flash memory is performing a high voltage operation. DONE is set to a 1 on termination of the embedded flash memory reset. DONE is read only. DONE is set to a 1 at the end of program and erase high voltage sequences. **NOTE** This field transitions from a 0 to 1 during reset and remains at 1 after reset. 0b - Performing a high voltage operation 1b - Not executing a high voltage operation
14 PEG	Program/Erase Good The value of PEG is updated automatically during the program and erase high voltage operations. Aborting a program/erase high voltage operation causes PEG to be cleared, indicating the sequence failed. PEG is set to a 1 when the embedded flash memory is reset. PEG is read only. The value of PEG is valid only when PGM = 1 or ERS = 1 and after DONE transitions from 0 to 1 due to an abort or the completion of a program/erase operation. PEG is valid until PGM/ERS makes a 1 to 0 transition or EHV makes a 0 to 1 transition. **NOTE** 1. If program or erase operations are attempted on sector(s) that are locked, the response from embedded flash memory is PEG = 1, indicating that the operation was successful, and the contents of the sector(s) are properly protected from the program or erase operation. PEG = 1 is also true if an abort occurs during an HV request to a locked sector. 2. If a program or erase operation is attempted to a location marked as OTP, the response from the embedded flash memory is PEG = 0, indicating that the operation was not allowed. The value interlocked is not programmed, since desired double word was already programmed with a previous program operation. Erase is prevented on OTP locations. 0b - Program or erase operation failed 1b - Program or erase operation successful
13 —	Reserved
12 WDI	Watch Dog Interrupt WDI is a status register to indicate that the Watchdog Timer for Program or Erase had expired. WDI is status only, and will be automatically cleared once the operation that caused the watchdog timeout is terminated or clean up from the operation is completed (clearing of PGM (with PES low), ERS (with PES low) or PES bit). 0b - Normal Operation, Watchdog Timer has not expired. 1b - Program Watchdog Timer has expired.
11-10 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
9 EPEG	ECC Enabled Program/Erase Good EPEG is a qualifier to PEG to indicate if a passing program or erase required ECC Enabled verifies to pass. In the event of a failed operation (PEG=0), EPEG will always remain 0. The value of EPEG is updated automatically during the program and erase high voltage operations. EPEG is set to a 0 when the embedded flash memory is reset. EPEG is read only. The value of EPEG is valid only when PGM = 1 or ERS = 1 and after DONE transitions from 0 to 1 due to an abort or the completion of a program/erase operation. EPEG is valid until PGM/ERS makes a 1 to 0 transition or EHV makes a 0 to 1 transition. 0b - Program or erase operation did not require ECC Enabled verifies. 1b - Program or erase operation required ECC Enabled verifies to pass.
8 TSPELOCK	UTest NVM Program and Erase Lock TSPELOCK reflects the status of the hardware program and erase protection input to the flash module. The TSPELOCK register is latched on the PEADR[PEASAD] write (UTest Sector Interlock), is not writable, and is status only. During high voltage events, the status is locked. When not interlocked this bit will read 1. The default value of the TSPELOCK bits is program and erase protected. 0b - Corresponding sector not locked, and may be programmed or erased 1b - Corresponding sector protected from the program and erase sequences
7-1 —	Reserved
0 RE	Reset Error This bit provides information on previous resets. Checks are done within the flash and if a coherency issue or ECC error is detected during the reset reads used for trimming on the flash, this status flag will assert. This bit is status only, and is not writable. 0b - Reset occurred without errors 1b - Reset error encountered

20.7.1.4 Extended Module Configuration (MCRE)

Offset

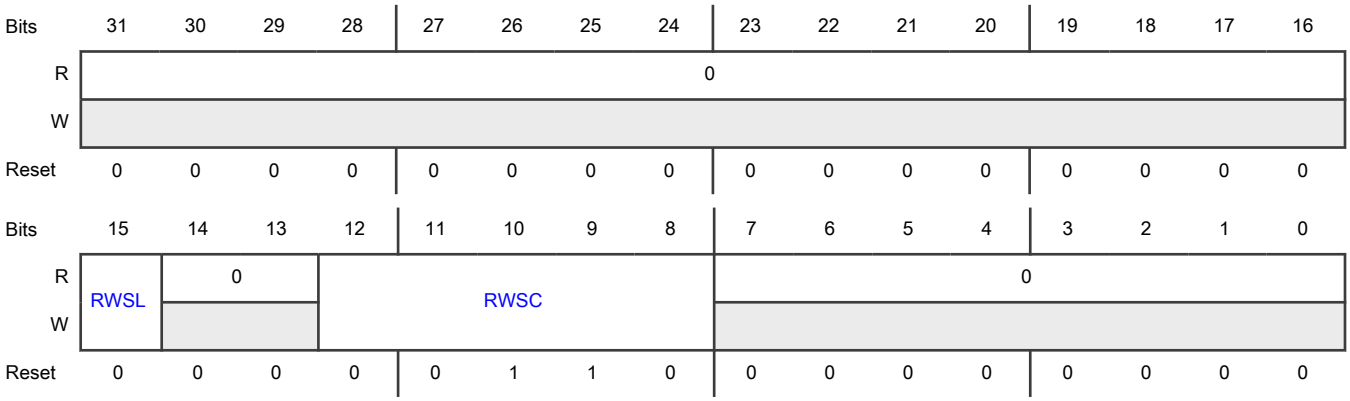
Offset

Register	Offset
CTL	Ch

Diagram



Fields

Field	Function
31-16 —	Reserved
15 RWSL	Read Wait State Lock Read Wait State Lock. The RWSL bit locks the read wait state control register (RWSC). If RWSL is set, then the RWSC field can not be written. RWSL is not clearable by a register write, it is only cleared upon reset.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Once RWSL is written to a 1, it will remain a 1 until the next reset and RWSC will be locked from writing. RWSC and RWSL are allowed to be written simultaneously. RWSL does not affect readability of RWSC. 0b - RWSC not locked and available for writing 1b - RWSC locked and unavailable for writing
14-13 —	Reserved
12-8 RWSC	Wait State Control This field controls the number of wait states to be added to the best-case flash array access time for reads. RWSC is only writable when RWSL is a 0. The best case flash array access time for reads is one cycle. This field must be set to a value corresponding to the operation frequency of the Flash and the actual read access time of the Flash to the flash boundary. Total read latency will be SoC dependant based on the how the cores are coupled within the platform. The frequency information, and total latency details are documented in the SoC specification. Higher operating frequencies require non-zero settings for this field for proper flash operation. **NOTE** • Updates to this configuration field that control reads must take place only when the flash memory is idle. Changing configuration settings while flash memory access is in progress can lead to non-deterministic behavior. • Values of RWSC[4:0] not listed here are reserved. **NOTE** 0_0000b - Reserved 0_0001b - One additional wait state is added. 0_0010b - Two additional wait states are added. 0_0011b - Three additional wait states are added. 0_0100b - Four additional wait states are added. 0_0101b - Five additional wait states are added. 0_0110b - Six additional wait states are added. 0_0111b - Seven additional wait states are added. 0_1000b - Eight additional wait states are added. 0_1001b - Reserved 1_1111b - Reserved
7-0 —	Reserved

20.7.1.6 Address (ADR)

Offset

Register	Offset
ADR	10h

Function

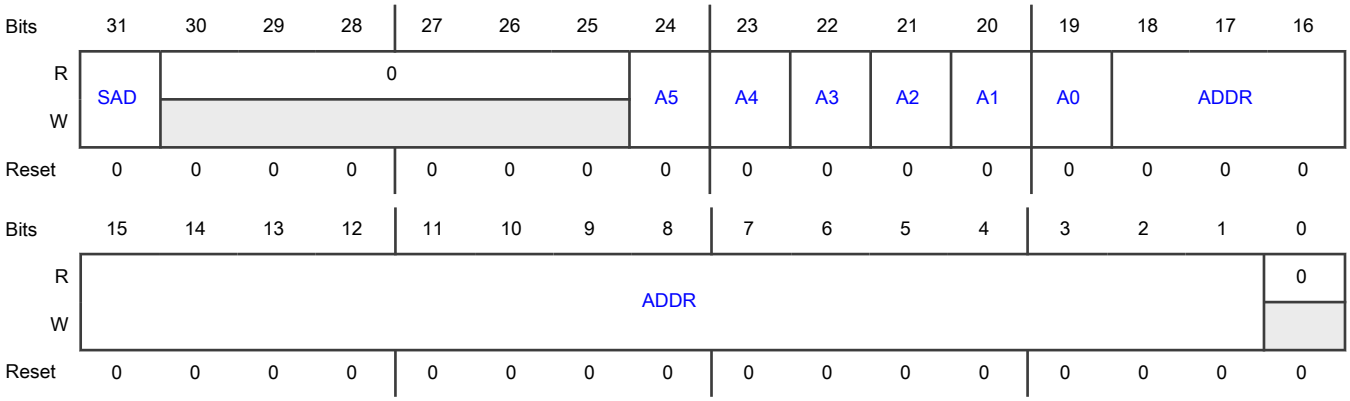
The Address register (ADR) provides the first failing address in the event of a failure (ECC or PGM/Erase state machine), as well as single bit correction information. The address register is also writable for UTest Mode operations. The address is identified using a combination of bits that identify the memory region and offset address.

NOTE

- The address given is an offset from the base address of the address space.
- The block numbering scheme that corresponds to the offset address is based on the flash memory's *internal* addressing scheme, which may be different than the chip's system addressing scheme.

Understanding the mapping between the flash address, which is specified relative to the flash module's internal addressing scheme, and the location within the chip's system memory map requires a clear understanding of the flash memory layout. See the chip-specific information for a detailed explanation of the chip's flash memory layout and how to map system addresses to the flash module's internal addressing.

Diagram



Fields

Field	Function
31 SAD	UTest NVM Address Qualifies the address captured during an ECC event error, single bit correction, or state machine operation. See the description of the ADDR field for more information. This field is not writeable if UTE = 1, and is ignored if it's in UTest mode. 0b - Address captured or to be accessed is from the main array space 1b - Address captured or to be accessed is from the UTest NVM array space

Table continues on the next page...

Table continued from the previous page...

Field	Function
30-25 —	Reserved Reserved; reset to 0
24 A5	Address Region 5 Qualifies the address field (ADDR) to region 5 If the value of this field is 1, the ADDR field maps to region 5. See the description of the ADDR field for more information. If the region is not present, this field is locked to 0. 0b - Address captured or to be accessed is not from region 5 1b - Address captured or to be accessed is from region 5
23 A4	Address Region 4 Qualifies the address field (ADDR) to region 4 If the value of this field is 1, the ADDR field maps to region 4. See the description of the ADDR field for more information. If the region is not present, this field is locked to 0. 0b - Address captured or to be accessed is not from region 4 1b - Address captured or to be accessed is from region 4
22 A3	Address Region 3 Qualifies the address field (ADDR) to region 3 If the value of this field is 1, the ADDR field maps to region 3. See the description for the ADDR field for more information. If the region is not present, this field is locked to 0. 0b - Address captured or to be accessed is not from region 3 1b - Address captured or to be accessed is from region 3
21 A2	Address Region 2 Qualifies the address field (ADDR) to region 2 If the value of this field is 1, the ADDR field maps to region 2. See the description of the ADDR field for more information. If the region is not present, this field is locked to 0. 0b - Address captured or to be accessed is not from region 2 1b - Address captured or to be accessed is from region 2
20 A1	Address Region 1 Qualifies the address field (ADDR) to the region If the value of this field is 1, the ADDR field maps to region 1. See the description for the ADDR field for more information. If the region is not present, this field is locked to 0. 0b - Address captured or to be accessed is not from region 1 1b - Address captured or to be accessed is from region 1
19	Address Region 0

Table continues on the next page...

Table continued from the previous page...

Field	Function
A0	Qualifies the ADDR field to region 0. If A0 = 1, then the ADDR field maps to that region. If the region is not present, this field is locked to 0. For details, see the field description for ADDR. 0b - Address captured or to be accessed is not from region 0 1b - Address captured or to be accessed is from region 0
18-1 ADDR	Address The ADR register provides the first failing address in the event of ECC event error (EER set), single bit correction (SBC set), as well as providing the address of a failure that may have occurred in a state machine operation (PEG cleared). ECC event errors take priority over single bit corrections, which take priority over state machine errors. This is especially valuable in the event of an RWW operation, where the read senses an ECC error or single bit correction, and the state machine fails simultaneously. The failing address for ECC event error is held until EER is cleared. The failing address for single bit correction is held until an ECC event error, or until SBC is cleared. State machine address is held until an ECC event error or single bit correction event occurs, or until the next state machine event (PEG cleared) occurs. This address is always a double word address that selects 64 bits. The ADR register is writable, and can be used in the UTest ECC Logic Test, UTest EDC after ECC Logic Test, and UTest Address Encode Logic Test. If any of these tests are enabled (UT0[EIE] = 1, UT0[EDIE] = 1, or UT0[AEIE] = 1) then the ADR register will not update for ECC event error, single bit correction or state machine errors. If MCRS[EER] or MCRS[SBC] are set, the ADR register is locked from writing. MCRS[PEG] does not affect the writeability of the ADR register. ADDR[18:1] is an offset from a base address of 0h for each block region. The A0, A1, A2, A3, A4, and A5 bits qualify the block size region the ADDR field.
0 —	Reserved Reserved; reset to 0

20.7.1.7 Program and Erase Address (PEADR)

Offset

Register	Offset
PEADR	14h

Function

The Program and Erase Address register (PEADR) is used to provide the address to be programmed or the location of the sector or block to be erased. The program and erase address register is read only in user mode (user mode writes occur with writes done to the Platform Flash Controller). The address is identified using a combination of bits that identify the memory region and offset address.

NOTE

- The address provided is an offset from the base address of the address space.
- The block numbering scheme that corresponds to the offset address is based on the flash memory's *internal* addressing scheme, which may be different from the chip's system addressing scheme.

Understanding the mapping between the flash address, which is specified relative to the flash module's internal addressing scheme, and the location within the chip's system memory map requires a clear understanding of the flash memory layout. See the chip-specific information for a detailed explanation of the chip's flash memory layout and how to map system addresses to the flash module's internal addressing.

21 PEA2	Program and Erase Address Region 2 Qualifies the address field (PEADDR) to the region. If PEA2 = 1, the PEADDR field maps to region 2. See the description of the PEADDR field for more information. If region 2 is not present, this field is locked to 0. 0b - Address accessed is not from region 2 1b - Address accessed is from region 2
20 PEA1	Program and Erase Address Region 1 Qualifies the address field (PEADDR) to the region. If PEA1 = 1, the PEADDR field maps to region 1. See the description of the PEADDR field for more information. If region 1 is not present, this field is locked to 0. 0b - Address accessed is not from region 1 1b - Address accessed is from region 1
19 PEA0	Program and Erase Address Region 0 Qualifies the address field (PEADDR) to the region. If PEA0 = 1, the PEADDR field maps to region 0. See the description of the PEADDR field for more information. If region 0 is not present, this field is locked to 0. 0b - Address accessed is not from region 0 1b - Address accessed is from region 0
18-5 PEADDR	Program and Erase Address The PEADDR register provides offset address location to be programmed or the sector to be erased in the case of sector erase. This address is always a quad page address that selects 1024 bits.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	The PEADDR register is read only in user mode and represents the flash physical address status. PEADDR may be updated once (and only once) per Program or Erase event. PEADDR writes initiate a Program, Erase, Array Integrity or User Margin Read request. Once PEADDR is updated, it will be locked for the full program and erase operation, until MCR[PGM] or MCR[ERS] is cleared at the end of the operation (as long as MCRS[PES] is zero). If MCRS[PES] is set, PEADR is locked until this bit is also cleared. **NOTE** If Express Program has been initiated (XPEADR written), the PEADR is locked from writing until Express Program is completed (XPGM written to 0). Upon completion of an operation (Program (MCR[PGM] written to 0 and MCRS[PES] equals 0), Erase (MCR[ERS] written to 0 and MCRS[PES] equals 0), Array Integrity (UT0[AIE] written to 0), User Margin Read(UT0[AIE] written to 0)), or Program and Erase Sequence clear (MCRS[PES] written to 0) the PEADR registers will return to an all zeros state. When MCR[EHV] or UT0[AIE] are set, PEADDR bits will not be writeable. Once PEADDR is updated, it will have read restrictions based on the PEID master that did the original write in the Platform Flash Controller. PEADDR[18:5] is an offset from a base address of 0h for each block region. The PEA0, PEA1, PEA2, PEA3, PEA4 and PEA5 qualify the block size region the PEADDR field.
4-0 —	Reserved Reserved; reset to 0

20.7.1.8 Sector Program and Erase Hardware Lock (SPELOCK)

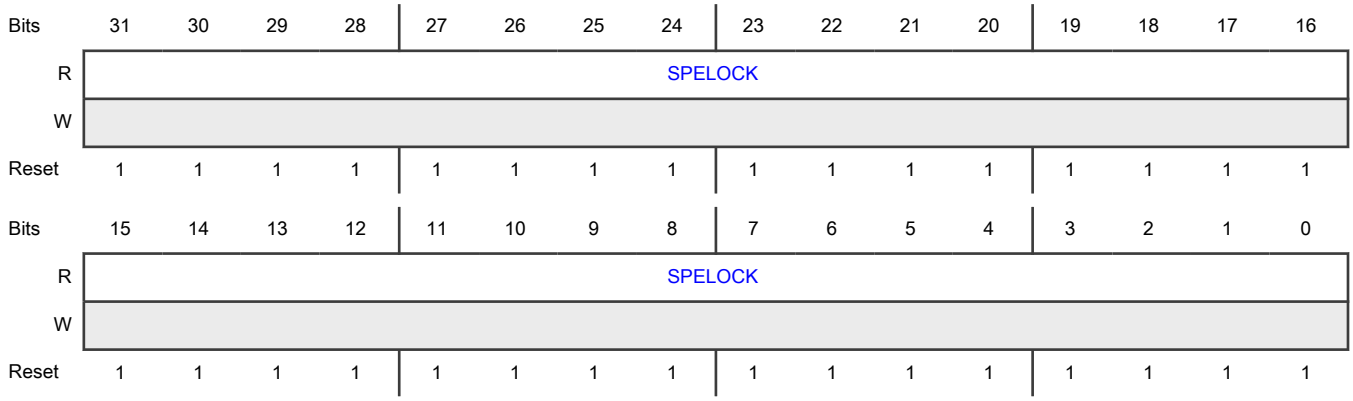
Offset

Register	Offset
SPELOCK	50h

Function

The Sector Program and Erase Lock register provides a means to protect sectors from being programed and erased on the main interface. The last 256 KB of all blocks have sector lock protection capability. The rest of the block (if applicable) is protected with super sector protection capability. This register shows the status of the pelock hardware input for the block that is interlocked. For more information on hardware program and erase protection see Program hardware locking and Erase hardware locking .

Diagram



Fields

Field	Function
31-0 SPELOCK	Sector Program and Erase Lock [31:0] SPELOCK reflects the status of the hardware program and erase protection input to the flash module for the block interlocked on the main interface. The SPELOCK register is latched on the PEADR write, is not writable, and is status only. SPELOCK will return back to all ones at the same time that PEADR is cleared. When not interlocked this register will read all ones. During high voltage events, the status is locked. The default value of the SPELOCK bits is program and erase protected. In the event that sectors are not present (due to configuration or total memory size), the SPELOCK bits default to locked, and will remain 1. 0 - The corresponding sector is not locked, and may be programed or erased. 1 - The corresponding sector is protected from program or erase.

20.7.1.9 Super Sector Program and Erase Hardware Lock (SSPELOCK)

Offset

Register	Offset
SSPELOCK	54h

Function

The Program and Erase Lock register provides a means to protect super sectors from being programed and erased on the main interface. Super Sector protection is available on block space greater than 256 KB. For 256 KB blocks, this register is not applicable. For 512 KB blocks, the first half of the block is protected with super sector granularity. For 1 MB blocks, the first 768 KB is protected with super sector granularity. For 2 MB blocks, the first 1792 KB is protected with super sector granularity. This register shows the status of the pelock hardware input for the block interlocked. For more information on hardware program and erase protection see Program hardware locking and Erase hardware locking .

31 UTE	UTest Enable This status bit indicates when U-Test is enabled. All bits in UT0, UM0, UM1, UM2, UM3, UM4, UM5, UM6, UM7, UM8, UM9, UD0, UD1, UD2, UD3, UD4, UD5, UA0 and UA1 registers are locked when this bit is 0. This bit is not writeable to a 1, but may be cleared. The reset value is 0. The method to set this bit is to provide a password, and if the password matches, the UTE bit is set to reflect a status of enabled, and is enabled until it is cleared by a register write. The UTE password (set UTE=1) and UTE clearing to 0 will only be accepted if Program or Erase are not in progress (PEADR write through clearing of PGM/ERS/PES), Alternate Program or Erase are not in progress (APEADR write through clearing of APGM/AERS/APES), AI/MR Operation are not in progress (PEADR write through clearing of AIE), and an Express Program operation is not in progress (XPEADR write through the clearing of XPGM). UTE can only be cleared if AID = 1, MRE, AIE, EIE, EDIE, AEIE, and RRIE are all equal to 0. While successfully clearing UTE, writes to set AIE, MRE, EIE, EDIE, AEIE or RRIE will be ignored. For UTE, the password F9F9_9999h must be written to the UT0 register, and this must be a 32bit write. 0b - U-Test mode is not enabled. 1b - U-Test mode is enabled.
30 SBCE	Single Bit Correction Enable SBCE enables single bit correction results to be observed in SBC. ECC corrections that occur when SBCE is cleared will not be logged. 0b - Disabled 1b - Enabled
29-16 —	Reserved Reserved; reset to 0
15 RRIE	Read Reference Input Enable RRIE enables the force of an error on the read reference detection circuit. This is useful in the Read Reference Error check. If this bit is set, the read reference error register MCRS[RRE] will set when an address match is achieved to the ADR register. RRIE is not simultaneously writable to a 1 as UTE is being successfully cleared to a 0. 0b - Read reference input disabled 1b - Read reference input enabled
14 AEIE	Address Encode Invert Enable AEIE enables the input register AEI to invert the address encode value received from the array, and force a mismatch in the address encode comparison. This is useful in the Address Encode logic check. If this bit is set, address encode information from the memory array will be inverted based on values in the AEI register when an address match is achieved to the ADR register. AEIE is not simultaneously writable to a 1 as UTE is being successfully cleared to a 0. 0b - Address encode invert is disabled 1b - Address encode values are inverted based on UA0[AEI]
13	EDC after ECC Data Input Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
EDIE	EDIE enables the input registers EDDATA and EDDATAC to be the source of data to the EDC after ECC comparator or EDC after ECC encoder. This is useful in the EDC after ECC logic check. If this bit is set, data read via a BIU read request will be from the EDDATA and EDDATAC registers when an address match is achieved to the ADR register. EDIE is not simultaneously writable to a 1 as UTE is being successfully cleared to a 0. 0b - EDC after ECC data input is disabled 1b - Data read is from UD3[EDDATA] and UD5[EDDATAC]
12 EIE	ECC Data Input Enable EIE enables the input registers EDATA and EDATAC to be the source of data to the ECC logic (instead of from the memory array). This is useful in the ECC logic check. If this bit is set, data read via a BIU read request will be from the EDATA and EDATAC registers when an address match is achieved to the ADR register. EIE is not simultaneously writable to a 1 as UTE is being successfully cleared to a 0. 0b - ECC data input is disabled 1b - Data read is from UD0[EDATA] and UD2[EDATAC]
11-10 —	Reserved
9 NAIBP	Next Array Integrity Break Point If AIBPE is set, NAIBP will be set once a single bit correction (if enabled) or double bit detection is noted during the Array Integrity test. NAIBP is not writable to 1, but may be cleared to 0. Clearing NAIBP to 0, will enable the Array Integrity operation to be re-started after a breakpoint is encountered. NAIPB may only be cleared to 0 if both EER = 0 and SBC = 0. If the Array Integrity operation completes without encountering another correction or detection, AID will be set with NAIBP remaining 0. 0b - Array integrity state machine is not currently at a breakpoint 1b - Array integrity state machine is at a breakpoint
8 AIBPE	Array Integrity Break Point Enable To enable breakpoints during an array integrity test, AIBPE may be set. See NAIBP description for more information about array integrity breakpoints. 0b - Array integrity breakpoints disabled 1b - Array integrity breakpoints enabled during array integrity checks
7 —	Reserved Reserved; reset to 0
6 AISUS	Array Integrity Suspend AISUS enables a suspend of an Array Integrity Operation. Array Integrity may be suspend by setting AISUS, and resumed by clearing AISUS. AISUS is writeable to a 1 only when AID is low. AISUS is clearable to a 0 only when AID is high. Attempting to write AISUS and AIE on the same clock cycle will result in only AIE getting written.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Array integrity sequence not suspended. 1b - Array integrity sequence is suspended.
5 MRE	Margin Read Enable MRE combined with MRV enables user margin reads to be done. Normal user reads are not affected by MRE, although user reads while the margin read operation is ongoing are not supported. MRE is not writable if AID is low, or if AISUS is high, or if NAIBP is high. MRE is not simultaneously writable to a 1 as UTE is being successfully cleared to a 0. 0b - Margin reads are not enabled. 1b - Margin reads are enabled.
4 MRV	Margin Read Value MRV selects the margin level that is being checked. Margin can be checked to an erased level (MRV=1) or to a programmed level (MRV=0). In order for this value to be valid, MRE must also be set. MRV is not writable if AID is low, or if AISUS is high, or if NAIBP is high. 0b - Zero's margin reads are requested. 1b - One's margin reads are requested.
3 —	Reserved
2 AIS	Array Integrity Sequence AIS determines the address sequence to be used during array integrity checks. The default sequence (AIS = 0) is meant to replicate sequences that normal user code follows, and thoroughly checks the read propagation paths. This sequence is proprietary. The alternative sequence (AIS = 1) is logically sequential. It should be noted that the time to run a sequential sequence is shorter than the time to run the proprietary sequence. AIS is not writeable if AIE is high. 0b - Array integrity sequence is proprietary sequence 1b - Array integrity sequence is sequential
1 AIE	Array Integrity Enable AIE set to one starts the array integrity check done on all selected blocks. The address sequence is determined by AIS, and the MISR (UM0 through UM9) can be checked after the operation is complete, to determine if a correct signature has been obtained. Once an array integrity operation is requested (AIE=1), it may be terminated by clearing AIE if the operation has finished (AID = 1) or aborted by clearing AIE if the operation is ongoing (AID = 0). AIE is locked from writing unless an interlock write occurred (PEADR write and DATA write). AIE is not simultaneously writable to a 1 as UTE is being successfully cleared to a 0. 0b - Array integrity checks not enabled 1b - Array integrity checks enabled
0	Array Integrity Done

Table continues on the next page...

Table continued from the previous page...

Field	Function
AID	AID is cleared upon an array integrity check being enabled (to signify the operation is ongoing). Once completed, AID is set to indicate that the array integrity check is complete. At this time the MISR (UMR registers) can be checked. AID may also assert if breakpoints are enabled (AIBPE is set), an abort is requested or a suspend is requested. AID cannot be written, and is status only. 0b - Array integrity check ongoing 1b - Array integrity check complete

20.7.1.14 UMISRn (UM0 - UM8)

Offset

For a = 0 to 8:

Register	Offset
UMa	98h + (a × 4h)

Function

Provides a means to evaluate array integrity. UM9 to UM0 are a set of multiple-input signature registers (MISRs) that hold the 289-bit MISR value as shown in the next table.

Table 87. MISR mapping

UM register	MISR bits
UM0	MISR[31:0]
UM1	MISR[63:32]
UM2	MISR[95:64]
UM3	MISR[127:96]
UM4	MISR[159:128]
UM5	MISR[191:160]

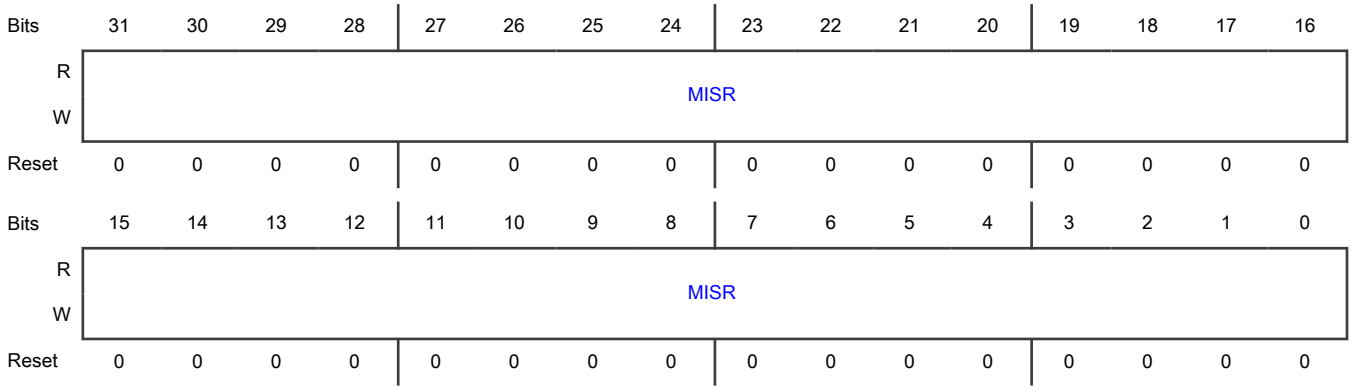
UM7	MISR[255:224]
UM8	MISR[287:256]
UM9	MISR[288]

Diagram



Fields

Field	Function
31-0 MISR	MISR[31:0] The MISR registers accumulate a signature from an array integrity event. The MISR captures all data fields, as well as ECC fields, and the ECC error signal. Data (read and ECC) captured in the MISR is after the ECC logic, and represents corrected data (if required). The MISR can be seeded to any value by writing the MISR registers. **NOTE** Writing the MISR register during an array integrity operation (including suspend or breakpoint) although possible, is not recommended. A write of the MISR registers at this point may alter the final signature in an unpredictable way. Writing the MISR registers prior to an Array Integrity operation (to seed the MISR) is allowed. The MISR register provides a means to calculate a MISR during array integrity operations. The MISR can be represented by the following polynomial: $x^{289} + x^{7} + x^{6} + x^{5} + x^{4} + x^{2} + 1$ The MISR is calculated by taking the previous MISR value and then "exclusive ORing" the new data. In addition the most significant bit (in this case it is MISR[288]), is then "exclusive ORed" into input of MISR[7], MISR[6], MISR[5], MISR[4], MISR[2] and MISR[0]. The result of the "exclusive OR" is shifted left on each read. The MISR register is used in array integrity operations. If during address sequencing, reads extend into an invalid address location (in other words, greater than the maximum address for a given array size) then reads are still executed to the array, but the results from the array read are not deterministic. In this instance, the MISR registers are not recalculated, and the previous value is retained. Once the AIE register is cleared, the MISR register will return to an all 0's state.

20.7.1.15 UMISR9 (UM9)

20.7.1.22 UTest Address 0 (UA0)

Offset

Register	Offset
UA0	E8h

Function

Provides a means to enable address to be inverted during UTest procedures.

NOTE

- UTest Address 0 (UA0) and UTest Address 1 (UA1) combine to represent a 52-bit wide field, which matches the width of the address internally to the flash memory that is used for the address encode comparison.
- Writing 1 to any one of the fields in UA0 or UA1 leads to flagging an AEE error when causing the error injection.
- When the value of a field within the range of bits 18:3 is 1, the corresponding address signal to the flash memory controller or BIU is inverted.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	AEI

R W	AEI															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 AEI	Address Encode Invert [31:0] Enables checks of address encode logic by allowing address bits to be inverted into the address encode compare logic, forcing a miscompare. Performing array reads on the page selected in ADR allows the address encode invert(s) to be active.

Table continues on the next page...

Field	Function
	Additionally, in the event of an address encode error during normal user mode operation, the page address provided to the PFC is inverted when an address encode error is encountered. AEI[18:3], which reflects the page address, can be used with the Address Encode Logic Check to control this inversion feature (aligning with ADR). Any bit in AEI[18:3] written to a 1 also enables the inversion of the corresponding signal of that address, allowing checks to be performed on the comparison logic that exists in the PFC. **NOTE** Multiple bits in AEI[18:3] may be written to a 1, which causes these bits to miscompare on the address encode comparison logic, as well as causing multiple bits to have their inversion enabled as part of the address provided to the BIU.

20.7.1.23 UTest Address 1 (UA1)

Offset

Register	Offset
UA1	ECh

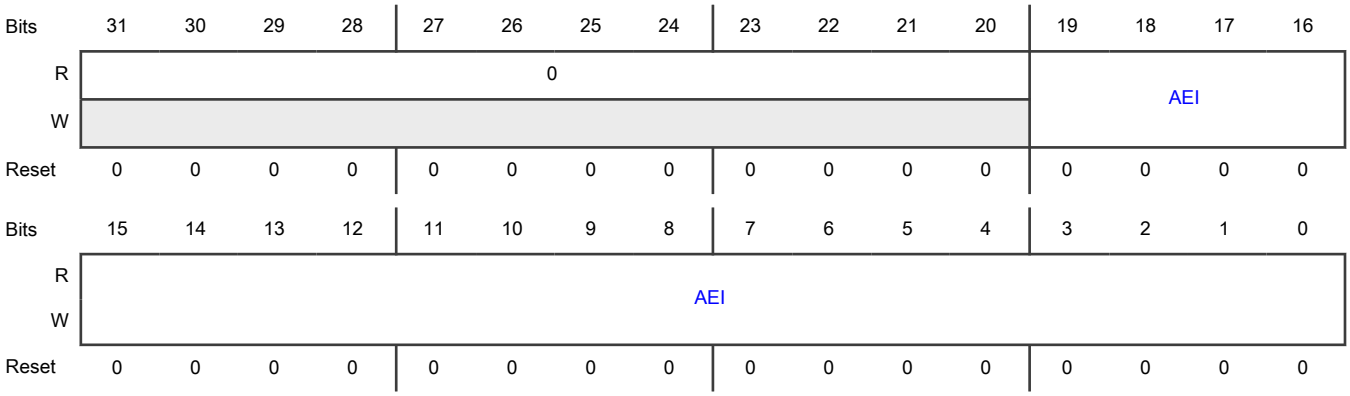
Function

Provides a means to enable address to be inverted during UTest procedures.

NOTE

- UTest Address 0 (UA0) and UTest Address 1 (UA1) combine to represent a 52-bit wide field, which matches the width of the address internally to the flash that is used for the address encode comparison.
- Writing 1 to any one of the fields in UA0 or UA1 leads to flagging an AEE error when causing the error injection.

Diagram



Fields

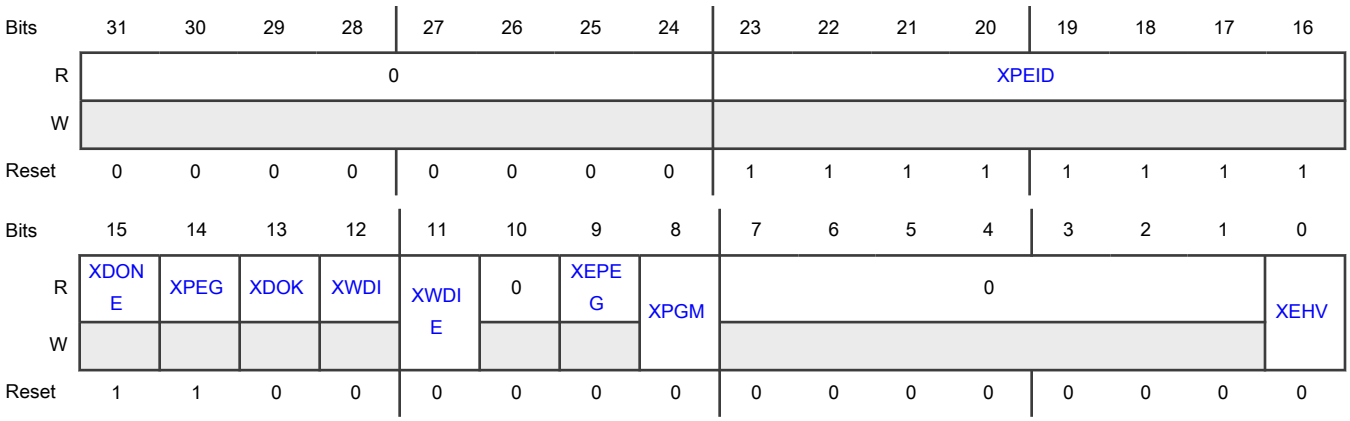
Field	Function
31-20 —	Reserved
19-0 AEI	Address Encode Invert [51:32] Enables checks of address encode logic by allowing address bits to be inverted into the address encode compare logic, forcing a miscompare. Performing array reads on the page selected in ADR allows the address encode invert(s) to be active.

20.7.1.24 Express Module Configuration (XMCR)

Offset

Register	Offset
XMCR	F0h

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16 XPEID	Express Program Master/Domain ID This field shows the ID of the master that has started the express program sequence. The ID is latched when the sequence has started (writing of the XPEADR register). It is set back to the reset value (set to all '1') when the operation is completed. See the chip-specific information for a list of Master IDs.
15	Express State Machine Status

Table continues on the next page...

Table continued from the previous page...

Field	Function
XDONE	XDONE indicates whether the embedded flash memory is performing an express program operation. XDONE is set to a 1 on completion of the express program operation. 0b - Executing an express program operation 1b - Not executing an express program operation
14 XPEG	Express Program Good The XPEG field indicates the completion status of the last flash memory express program operation. The value of XPEG is updated automatically after the program operations. XPEG will be 0 if the program operation failed. See MCRS[PEG] for more information, as the features of that bit apply to XPEG as well. 0b - Program operation failed 1b - Program operation successful
13 XDOK	Express Data OK This field is a status signal from the flash to indicate that it is OK to load Data into the DATA registers. It will assert in response to a XPEADR load (once ongoing operations are aborted, if required). XDOK will clear once the Express Program operation is complete (XPGM written to 0). 0b - Flash memory not ready to accept writes to the DATA registers 1b - Writes to DATA registers allowed
12 XWDI	Express Watch Dog Interrupt XWDI is a status register to indicate that the Watchdog Timer for Express Program had expired. XWDI is status only, and will be automatically cleared once the operation that caused the watchdog timeout is terminated or clean up from the operation is completed (clearing of XPGM bit). 0b - Normal Operation, Watchdog Timer has not expired. 1b - Express Program Watchdog Timer has expired.
11 XWDIE	Express Watch Dog Interrupt Enable XWDIE provides a mechanism to trigger an interrupt request upon the assertion of the XWDI bit on the express interface. If XWDIE is asserted, when XWDI asserts an interrupt from the flash will trigger to the system. The interrupt from the flash will mirror exactly the XWDI bit. XWDIE does not affect the register bit XWDI. Writing (and reading) of this bit will be restricted to the master that updated the XPEADR register as captured in the XPEID register at the start of the Express Program sequence. 0b - Express watchdog interrupt disabled 1b - Express watchdog interrupt enabled
10 —	Reserved
9 XEPEG	Express ECC Enabled Program Good XEPEG is a qualifier to XPEG to indicate if a passing program required ECC Enabled verifies to pass. In the event of a failed operation (XPEG=0), XEPEG will always remain 0. The value of XEPEG is updated

Table continues on the next page...

Table continued from the previous page...

Field	Function
	automatically after the program operations. See MCRS[EPEG] for more information, as the features of that bit apply to XEPEG as well. 0b - Program operation did not require ECC-enabled verifies 1b - Program operation required ECC-enabled verifies to pass
8 XPGM	Express Program XPGM is used as part of the setup for an express program operation. A 0 to 1 transition of XPGM after program interlock write(s) is part of the setup for an express program sequence. A 1 to 0 transition of XPGM ends the express program sequence. XPGM can be set at any time if UT0[UTE] is low, and after the interlock write is completed (XPEADR written, XDOK asserted, and DATAn register(s) written). XPGM may be cleared when XEHV is low. Writing (and reading) of this bit will be restricted to the master that updated the XPEADR register as captured in the XPEID register at the start of the Program sequence. 0b - Flash memory not executing an express program sequence 1b - Flash memory executing an express program sequence
7-1 —	Reserved
0 XEHV	Express Enable High Voltage The XEHV field enables the embedded flash memory for a high voltage program/erase operation. XEHV is cleared on reset. XEHV must be set after DATA writes to start an express program operation and XPGM is set. This field may be set when XPGM = 1, XDOK = 1, and XWDI = 0. XEHV may not be written to a 1 after it is cleared as part of an express program cleanup, until after the next XPEADR write. Express Program operations may not be aborted. XEHV may only be cleared once XDONE is set to 1. Writing (and reading) of this bit will be restricted to the master that updated the XPEADR register as captured in the XPEID register at the start of the Program sequence. 0b - Flash memory is not enabled to perform an express high voltage operation. 1b - Flash memory is enabled to perform an express high voltage operation.

20.7.1.25 Express Program Address (XPEADR)

Offset

Register	Offset
XPEADR	F4h

Function

The Express Program Address register (XPEADR) is used to provide the address to be programmed. The express program address register is read only in user mode (user mode writes occur with writes done to the Platform Flash Controller). The address is identified using a combination of bits that identify the memory region and offset address.

NOTE

- The address given is an offset from the base address of the address space.
- The block numbering scheme that corresponds to the offset address is based on the flash memory's *internal* addressing scheme, which may be different than the chip's system addressing scheme.

Understanding the mapping between the flash address, which is specified relative to the flash module's internal addressing scheme, and the location within the chip's system memory map requires a clear understanding of the flash memory layout. See the chip-specific information for a detailed explanation of the chip's flash memory layout and how to map system addresses to the flash module's internal addressing.

See the description of the XPEADDR field for more information. If this region is not present, the field is locked to 0. 0b - Address accessed is not from region 4 1b - Address accessed is from region 4
22 XPEA3	Express Program Address Region 3 Qualifies the address field (XPEADDR) to the region.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If XPEA3 = 1, the XPEADDR field maps to that region. See the description of the XPEADDR field for more information. If this region is not present, the field is locked to 0. 0b - Address accessed is not from region 3 1b - Address accessed is from region 3
21 XPEA2	Express Program Address Region 2 Qualifies the address field (XPEADDR) to the region. If XPEA2 = 1, the XPEADDR field maps to that region. See the description of the XPEADDR field for more information. If this region is not present, the field is locked to 0. 0b - Address accessed is not from region 2 1b - Address accessed is from region 2
20 XPEA1	Express Program Address Region 1 Qualifies the address field (XPEADDR) to the region. If XPEA1 = 1, the XPEADDR field maps to that region. See the description of the XPEADDR field for more information. If this region is not present, the field is locked to 0. 0b - Address accessed is not from region 1 1b - Address accessed is from region 1
19 XPEA0	Express Program Address Region 0 Qualifies the address field (XPEADDR) to the region. If XPEA0 = 1, the PEADDR field maps to that region. See the description of the XPEADDR field for more information. If this region is not present, the field is locked to 0. 0b - Address accessed is not from region 0 1b - Address accessed is from region 0
18-5 XPEADDR	Express Program Address The XPEADDR register provides offset address location to be programmed. This address is always a quad page address that selects 1024 bits. The XPEADDR register is read only in user mode and represents the flash physical address status. XPEADDR may be updated once (and only once) per Express Program event. XPEADDR writes initiate an Express Program request. XPEADDR may be updated four times between reset events. Upon completing the fourth Express Program request (clearing of XPGM register), the XPEADDR register will return to all zeros, and remain locked from future XPEADDR updates and thus future Express Program requests will be ignored until the next reset. Once XPEADDR is updated, it will be locked for the full express program operation, until XMCR[XPGM] is cleared at the end of the operation. Writing of XPEADDR has the effect of blocking other registers used for program and erase to be written (PEADR/MCR registers as well as APEADR/APDATA/AMCR registers) until the express program operation is completed.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Upon completion of an Express Program operation (XMCR[XPGM] written to 0) the XPEADR registers will return to an all zeros state. When UT0[UTE] is set or XMCR[XEHV] is set, XPEADDR bits will not be writeable. Once XPEADDR is updated, it will have read restrictions based on the PEID master that did the original write in the Platform Flash Controller. XPEADDR[18:5] is an offset from a base address of 0h for each block region. The XPEA0, XPEA1, XPEA2, XPEA3, XPEA4 and XPEA5 qualify the block size region the XPEADDR field.
4-0 —	Reserved Reserved; reset to 0

20.7.1.26 Program Data (DATA0 - DATA31)

Offset

For a = 0 to 31:

Register	Offset
DATAa	100h + (a × 4h)

Function

Enables data to be provided for program (or express program). This set of 32 data registers enables 1024 bits of data to be programmed.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-0	Program Data

Table continues on the next page...

Field	Function
PDATA	PDATA registers will reset to all ones. PDATA is not writable before PEADR is written or updated to start a program, express program, erase or UTest operation, and will read a value of all ones. Once PEADR is written, all PDATA registers will be made available for writing. Writing (and reading) of the PDATA registers will be restricted to the master that updated the PEADR register as captured in the PEID register. **NOTE** PDATA restrictions related to PEID will be disabled if UT0[UTE] is set. **NOTE** For Express Program a similar behavior exists on the PDATA registers. Once XPEADR is written, and XDOK comes back as a 1, all PDATA registers will switch to all 1's (program safe state) and be made available for writing (and reading) to the master's ID that matches XPEID captured during the XPEADR update. In the event of an interrupted operation, XPEID permissions will override PEID permissions until the express program operation is completed (XPGM written to a 0). Upon completion of an operation (Program (MCR[PGM] written to 0 and MCRS[PES] equals 0), Erase (MCR[ERS] written to 0 and MCRS[PES] equals 0), Express Program (XMCR[XPGM] written to 0), Array Integrity (UT0[AIE] written to 0), User Margin Read(UT0[AIE] written to 0)) or Program and Erase Sequence clear (MCRS[PES] written to 0) the PDATA registers will return to an all ones state. When UT0[AIE] is set, PDATA bits will not be writeable. When MCRS[PES] is set, PDATA bits will not be writeable except when an express program request occurs and XMCR[XDOK] is set. Also, when MCR[PGM] or MCR[ERS] are set, PDATA bits will not be writeable except when an express program request occurs and XMCR[XDOK] is set. When an express program operation is in process, PDATA bits will not be writeable once XMCR[XEHV] is set until XMCR[XPGM] is cleared. Only PDATA Bits that are written will receive program or express program pulses.

20.8 Glossary

Abort Premature end of a mode, sequence, state or operation. An abort may leave the embedded flash memory in a state in which it contains indeterminate or corrupted data.

BIU Bus interface unit(Contains all system-level customization required to make the embedded flash memory part of an SoC)

Block Subdivision of the Flash Module containing NVM memory bits. Block sizes range from 256KB to 2MB. Each block is made up of 8KB sectors.

Double word Two words, or 64 bits.

ECC Error correction code(Internally used to correct single bit errors, or detect double errors within a 64-bit double word.)

ECC segment 64 bit double word, representing the size of data used to calculate ECC information.

EDC Error detection code

FC Flash memory core

FMU	Flash Management Unit - Logic that enables program, erase, read, and other flash functions.
Interlock Write	A write to the PEADR register followed by a write to any DATA register performed while initiating a program, erase, array integrity, or user margin read sequence. Interlock in cleared once the operation is finished by clearing the appropriate control bit, causing PEADR register to clear.
MCU	Microcontroller unit
Module	Flash memory instance that contains flash block(s), FMU, and required analog support structures.
NVM	Nonvolatile memory
OTP	One time programmable
PFC	Platform flash memory controller(Contains all system-level customization required to make the embedded flash memory part of an SoC)
Page	8 words of data (256 bits). When doing reads to the embedded flash memory, this is the width of data read. Up to 4 pages can be programmed at a time.
Partition	Subdivision of the Flash Module. Used for read-while-write operation, where addresses in the partition being written may not be read. Partitions is always equal to 1 block, and contains multiple sectors.
RWW	Read-while-write (operation)
Sector	Subdivision of the Flash Block that is independently erasable. Sector Size is always 8 KB.
Super sector	Subdivision of the flash block that includes a group of sectors. Super Sector Size is always 64 KB, and consists of 8 sectors.
SoC	System-on-chip
UTest NVM sector	8 KB sector outside the main address space
Word	32 bits

Chapter 21
Flash Memory Controller (PFLASH)

21.1 Chip-specific PFLASH information

21.1.1 Flash memory architecture

The flash memory on the chip consists of a flash memory controller and a flash memory array module. The flash memory controller provides flash–memory configuration and control functions and manages the interface between the flash memory array and the chip's crossbar switch.

This chip implements upto four 64-bit AHB buses.

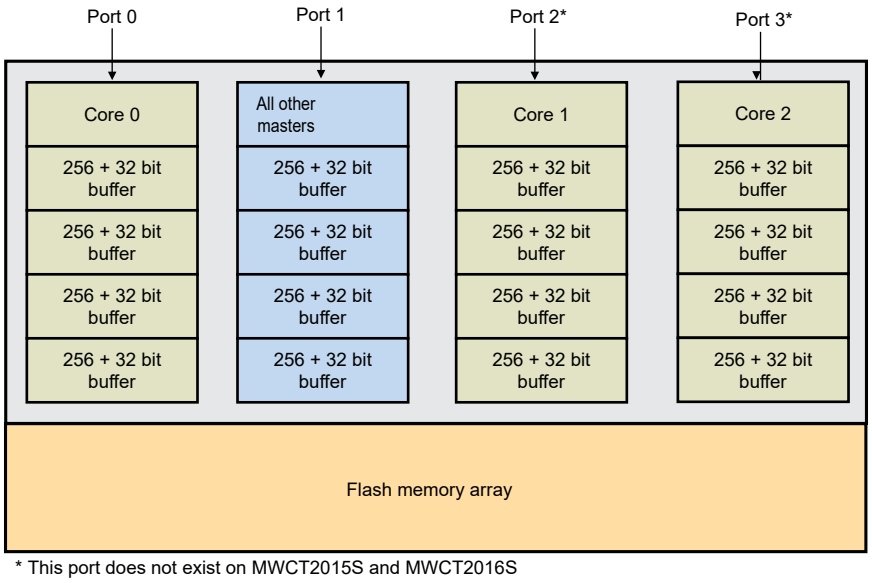

Figure 48. Flash memory architecture

21.1.2 Flash memory controller

The flash memory controller:

- Acts as an interface between the system bus and flash memory array.
- Is a triple-ported controller with a dedicated line buffering per port and per master ID. This enables you to use the line buffers more efficiently because various masters have dedicated buffers that are not compromised when other masters perform read operations.

Also, by having separate ports, you can have separate connections for each CPU instruction bus and a single port for all data accesses as shown in Figure 48.

In general, the flash memory controller registers affect the global flash memory behavior (for example, read buffering and access control).

NOTE

In MWCT2016S:

- PFLASH block 3 and block 4 are not present, so both the sector and super sector registers are not available.
- For PFLASH block 2, the super sector registers are not available.

21.1.3 Platform flash configuration registers (PFCR*n*)

The table below defines the PFCR*n* fields that the chip uses.

Table 88. Platform flash configuration registers (PFCR*n*)

Master	Buffer enable field	Prefetch enable field
Cortex–M7_0	P0_CBFEN, P0_DBFEN	P0_CPFEN, P0_DPFEN
eDMA + HSE_B + EMAC[1] + GMAC_1	P1_CBFEN, P1_DBFEN	P1_CPFEN, P1_DPFEN
Cortex–M7_1	P2_CBFEN, P2_DBFEN	P2_CPFEN, P2_DPFEN
Cortex–M7_2	P3_CBFEN, P3_DBFEN	P3_CPFEN, P3_DPFEN

1. MWCT2015S and MWCT2016S do not support EMAC.

21.1.4 Platform flash access protection register (PFAPR)

This table defines the PFAPR[M*n*AP] fields that the chip uses. This chip does not use the other master access protection fields, but those fields are readable and writable.

Table 89. Platform flash access protection register (PFAPR)

Master number	Master name	Access protection field
0	Cortex–M7_0 AHBM	M0AP
1	eDMA	M1AP
2	HSE_B	M2AP
3	EMAC	M3AP
4	Cortex–M7_1 AHBM	M4AP
5	Cortex–M7_2 AHBM	M5AP
6	uSDHC/ GMAC_1	M6AP
7	Cortex–M7_3 AHBM	M7AP

21.2 Introduction

PFLASH acts as an interface between the system bus (AHB-Lite 2.v6) and flash memory array.

PFLASH supports three 64-bit AHB buses and a 256-bit read data interface from each flash memory array. The slave port assignments and buffer organization are organized to offer maximum performance of code execution in a multicore architecture. The buffer mechanism serves to deliver flash memory read data with zero-wait state response on lines that reside in cache. AHB requests that miss the prefetch cache generate the needed flash memory array access and are forwarded to the AHB upon completion. Each cache entry is 256 bits, matching the flash memory array page size and providing 512 bytes of high-speed local storage.

21.3 Features

- Three 64-bit AHB interface ports (p0, p1, p2) allowing simultaneous access to dedicated prefetch mini-cache per slave port
- 256-bit read data bus and 64-bit write data bus
- Configurable read buffering and line prefetching support via a mini-cache, plus a prefetch controller for each AHB port to provide single-cycle buffer hit read response
- Configurable access control based on read/write and AHB master ID attributes

- Support for reporting single-bit and multi-bit flash memory ECC events on a 64-bit doubleword boundary

21.4 Block diagrams

The following figure provides a block diagram showing PFLASH and the attached flash memory array.

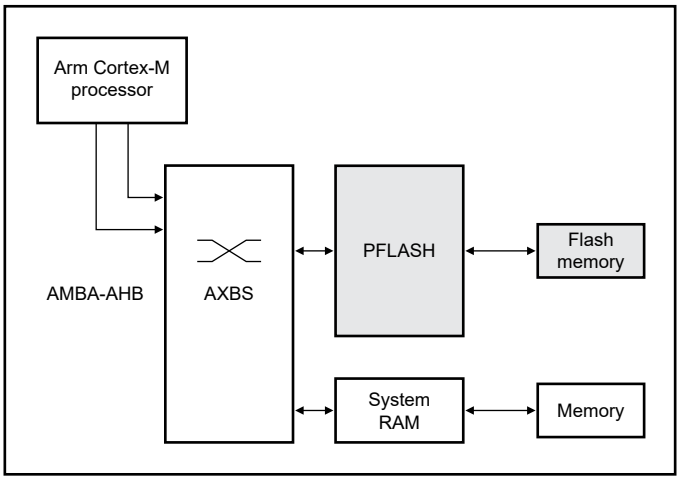

Figure 49. Platform-centric simple block diagram with PFLASH

21.5 Functional description

As shown in Figure 49, PFLASH interfaces between:

- The AHB system bus ports
- The flash memory array

For accesses targeting flash memory, the PFLASH generates as inputs to the flash memory array:

- Read and write enables
- Block selects
- Array address
- Write size
- Write data

PFLASH captures read data from the flash memory array and drives it onto the AHB system bus. Up to four pages of data (256-bit page size) may be buffered in each prefetch buffer for AHB Port0, Port1, and Port2. Lines may be prefetched in advance of being requested, allowing single-cycle (zero AHB wait-states) read data responses on buffer hits.

Access protections may be applied on a per-master basis for both reads and writes to support security and privilege mechanisms.

21.5.1 Read transactions

On an incoming AHB read request, a mini-cache lookup and access privilege evaluation are performed during the AHB address phase. If a buffer hit occurs, the requested data is retrieved from the previously loaded prefetch buffer entry and returned on the system bus with a zero wait-state response. If a buffer miss occurs, a flash memory access is initiated.

Read accesses are terminated under control of the appropriate wait state settings. Access timing can be varied to account for the operating conditions of the chip (for example, frequency, voltage, temperature, and so on) by appropriately setting the read wait state field in flash memory.

21.5.2 Write transactions

An interlock write on a program or erase sequence is initiated by first writing to Platform Flash Memory Program Erase Address Logical (PFCPGM_PEADR_L), Platform Flash Memory Express Program Erase Address Logical (PFCPGM_XPEADR_L)(see the Flash Memory chapter for write sequence details).

21.5.3 Access protections

21.5.3.1 PFAPR

PFLASH provides programmable, configurable access protections for read cycles on a per-master basis in PFAPR[M*n*AP]. This field restricts read access on a per-master basis. This functionality is described in Platform Flash Memory Access Protection (PFAPR). Detection of a protection violation based on PFAPR settings results in an error response from PFLASH on the AHB transfer.

21.5.4 Error termination

PFLASH can invoke a system bus error termination in the following scenarios:

- Access privilege violation (see Access protections for details)
- Attempted access by an AHB master to a reserved region in the flash memory map
- Multi-bit ECC error detection on AHB read, and PFCR4[DMEEE] = 0 (for data flash memory, it is further qualified by PFCR4[DERR_SUP] = 0)

21.5.5 Line read buffers and prefetch operation

The PFLASH AHB ports of the each contain a mini-cache. PFLASH uses the buffers for both prefetch and normal demand fetches. Also, the buffers are shared for code and data fetches, and can be controlled independently for code and data from control registers.

Prefetch triggering is controllable on a per-port basis. A PFLASH read access may trigger a prefetch to the next sequential line of array data on the cycle following the request. The access address is incremented by 32 bytes, and a subsequent flash memory access is initiated. A flash memory array prefetch is initiated if the data is not already resident in a line read buffer. Prefetched data is always loaded into the least-recently-used buffer.

For Port0, Port1, and Port2 there are four line buffer entries in their respective prefetch mini-caches that follow a fully associative, least-recently-used replacement policy.

For prefetching to occur, you must set the following configuration fields, where *n* corresponds to the port number and *m* corresponds to *C* (code) or *D* (data):

PFCRn[Pn_mBFEN] = 1 and PFCRn[Pn_mPFEN] = 1

21.5.6 Array integrity considerations

During an array integrity sequence, the flash memory array ignores any incoming read requests. When a flash memory array integrity check is in progress, PFLASH terminates all flash memory access requests with an error. More specifically, it aborts the incoming flash memory access requests and terminates the system bus transfer with an error.

21.5.7 Safety considerations

21.5.7.1 Flash memory address generation check

Functional safety coverage of the address path and control within PFLASH rely on a feedback path between PFLASH and flash memory. Remember that on a requested access to flash memory, PFLASH must decode the system AHB bus signals to generate the corresponding flash memory interface signals to invoke a flash memory lookup. In addition to providing the requested read data, the flash memory also provides output sidebands reflecting the encoded address and block selects used to perform the actual row lookup.

PFLASH uses this sideband information to verify the expected transaction. If a mismatch is detected, indicating a failure in the address generation or control logic within PFLASH or the transmission path between PFLASH and the flash memory array, then the event is forwarded to the chip fault collection module and the corresponding buffer is invalidated.

21.5.8 ECC error handling on data flash block

When PFCR4[DERR_SUP] is enabled, ECC errors on data flash blocks are handled specially.

If there is a noncorrectable error detection, a fixed, illegal opcode value is returned to the requesting master along with the associated ECC checkbits as determined by the requesting address.

For noncorrectable error detection, PFLASH returns a value of 1555_1555h to the requesting master.

This is mainly used for EEPROM emulation applications.

21.5.9 Read cycles—buffer miss

On an incoming AHB read request, a mini-cache lookup and access privilege evaluation are performed during the AHB address phase. If a buffer miss occurs, a flash memory access is initiated.

If the flash memory access was the direct result of an AHB transaction, the corresponding page buffer is loaded and marked as the most-recently-used. If the flash memory access was the result of a speculative prefetch to the next sequential line, it is loaded into the least-recently-used buffer. The status of this buffer is not changed to most-recently-used until a subsequent buffer hit occurs as a result of an AHB read request.

21.5.10 Read cycles—buffer hit

PFLASH allows single-cycle read responses to the AHB when the requested read access was previously loaded into one of the page buffers. In these cases of a buffer hit, read data is returned on the system bus with a zero wait-state response.

21.5.11 Flash memory error response operation

The flash memory array may signal an error response to terminate a requested access because of improper sequencing during program/erase operations and improper sequencing during array integrity testing. When an error response is received, PFLASH does not update or validate a page read buffer. An error response may be signaled on a read or interlock write operation. For more information on the specifics related to signaling of flash memory errors, including flash memory ECC events, array integrity testing, and read-while-write events, see the flash memory chapter.

21.6 PFLASH register descriptions

PFLASH provides an IPS programming model mapped to a standard 16 KB on-platform peripheral slot. The programming model consists of flash memory access configuration.

You can reference the programming model only by using a 32-bit (word) access. References that are attempted using different access sizes, or to undefined (reserved) addresses, or in User mode generate an IPS error termination. PFLASH allows access to the programming model by all system bus masters.

Write to read only registers don't generate error termination.

You can only access the programming model in Supervisor mode, except *PEADR* registers which can be accessed in Supervisor or User mode.

Attempted updates to the programming model when PFLASH is in the middle of an operation results in non-deterministic behavior. You must architect software to avoid this scenario. The recommended flow for multicore devices is:

1. Start only one core.
2. Execute initialization code until it is complete.
3. Start the remaining cores.

If you need to reconfigure the flash memory, code execution must be temporarily moved to system RAM.

21.6.1 PFLASH memory map

4 P2_CPFEN	Port2 Code Prefetch Enable Enables or disables code prefetching initiated by a read access on Port2. Prefetching can only be enabled if the buffers are enabled by writing 1 to CBFEN. Hardware reset returns this field to 0. 0b - Disable 1b - Enable
3-2 —	Reserved
1 P2_DBFEN	Port2 PFLASH Line Read Data Buffers Enable Enables or disables line read data buffer hits. It is also used to invalidate the buffers. If this field is 0, the line read buffers are disabled from satisfying read requests, and all buffer valid bits are set to 0. If this field is enabled, the line read buffers are enabled to satisfy read requests on hits. Buffer valid bits may be set when the buffers are successfully filled. 0b - Disable 1b - Enable
0 P2_CBFEN	Port2 PFLASH Line Read Code Buffers Enable Enables or disables line read code buffer hits. It is also used to invalidate the buffers.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If disabled, the line read buffers are disabled from satisfying read requests, and all buffer valid bits are set to 0. If enabled, the line read buffers are enabled to satisfy read requests on hits. Buffer valid bits may be set when the buffers are successfully filled. 0b - Disable 1b - Enable

21.6.5 Platform Flash Memory Configuration 4 (PFCR4)

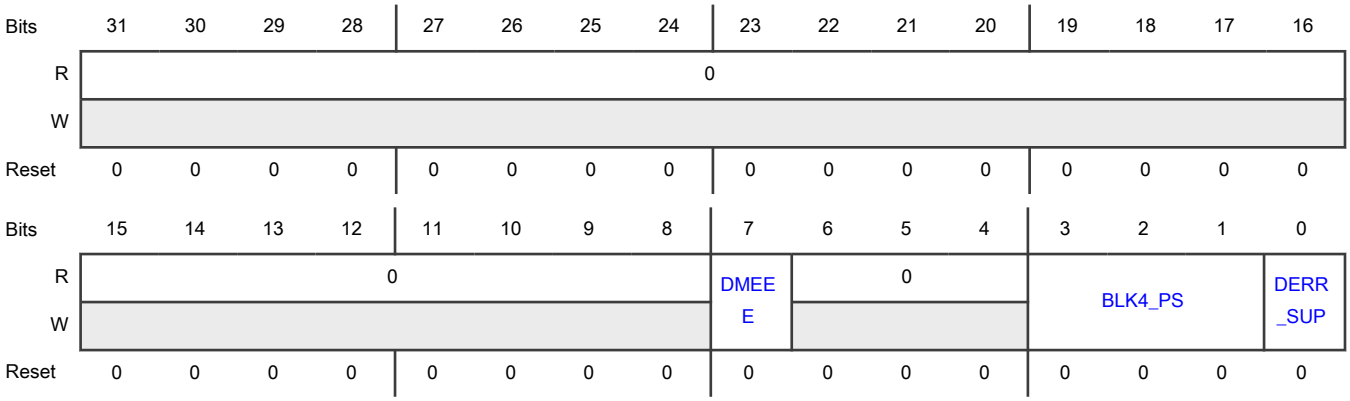
Offset

Register	Offset
PFCR4	10h

Function

Specifies operation of the flash memory controller buffer.

Diagram



Fields

Field	Function
31-8 —	Reserved
7 DMEEE	Disable Multi-Bit ECC Error Exception Enables or disables system bus error response on multi-bit ECC error. Hardware reset returns this field to 0. 0b - Error response sent on system bus for multi-bit ECC error 1b - Error response not sent on system bus for multi-bit ECC error

Table continues on the next page...

Table continued from the previous page...

Field	Function
6-4 —	Reserved
3-1 BLK4_PS	Block 4 Pipe Select Selects the active pipe for flash memory block 4 access. PFLASH has four independent command pipes to issue four parallel read commands to different flash memory blocks. Reads from flash memory block 0–3 are always done through command pipe 0–3, respectively. However, the access to block 4 is not fixed and can be through any of the command pipes. You must only change this field when there is no ongoing block 4 access. A special round-robin arbitration scheme snoops the availability of a command pipe during block 4 access. If any of the command pipes are idle during the first read request to block 4, the ownership of that command pipe gets shared between block 4 and the respective block. If none of the command pipes are idle during a block 4 read request, block 4 gets associated with each of the command pipes in round-robin fashion. When a command pipe acquires ownership of block 4, it keeps that ownership until all the commands to block 4 from all the masters are served. 000b - Block 4 access is always through pipe0 001b - Block 4 access is always through pipe1 010b - Block 4 access is always through pipe2 011b - Block 4 access is always through pipe3 1xxb - Block 4 access can be through any of the command pipes, based on which command pipe is available for block 4 access
0 DERR_SUP	Data Error Suppression See the Embedded Flash Memory configuration information or system memory map for which flash memory blocks are affected by this field. 0b - Reports ECC events on data flash memory accesses 1b - Single-bit and multi-bit ECC events on data flash memory accesses are suppressed

21.6.6 Platform Flash Memory Access Protection (PFAPR)

Offset

Register	Offset
PFAPR	14h

Function

Controls read accesses to the flash memory array.

See the chip-specific PFLASH information for details about the actual masters available on the chip.

21.6.7 Platform Flash Memory Program Erase Address Logical (PFCPGM_PEADR_L)

Offset

Register	Offset
PFCPGM_PEADR_L	300h

Function

Provides the flash memory address to be programmed, or the location of the sector or block to be erased through main flash memory (pgm/erase) queue. Write access to this register is domain-ID aware.

The respective bus master must have program/erase permission to the flash memory address written to this register. Otherwise a transfer error results. For further information on flash memory address restrictions see the XRDC chapter.

A write to this register is managed via three-cycle access. Before updating the register, you must ensure that no ongoing high-voltage operation is executing through the flash memory main queue.

Unauthorized flash memory address writes result in a transfer error.

Writes to this register during an ongoing high-voltage operation (initiated through the flash memory main queue) or during express program operation are ignored.

Chapter 22
RAM Controller (PRAMC)

22.1 Chip-specific PRAMC information

22.1.1 PRAMC instances and configuration

This chip supports up to three instances of PRAMC.

Table 90. PRAMC instances and configuration

Instance	SRAM array	Applicability
PRAMC_0	SRAM 0	MWCT2015S, MWCT2016S, MWCT2D16S, MWCT2D17S
PRAMC_1	SRAM 1	MWCT2D16S, MWCT2D17S

See chapter'Memory and Memory Interfaces' for details on SRAM size.

22.1.2 RAM initialization

After chip power-on reset, you must initialize RAM to a known value using a 64-bit master before 32-bit masters can read or write to RAM. If you do not initialize RAM this way, any attempt to execute a 32-bit read or write access terminates with an uncorrectable ECC error event on this chip.

22.1.3 SRAM0 behavior while XRDC is configured to block access to SRAM0

While XRDC is configured to restrict access to SRAM0, the below behaviors should be considered:

1. In case if XRDC is configured to restrict access to SRAM0 and a read transaction to SRAM0 is performed: To ensure faster SRAM0 accesses, the access is routed to SRAM0 and blocked by PRAMC if XRDC is configured to block access. In such a case, if an error is present on the SRAM0 data, (that is error on data or error injected by EIM), the same is latched by ERM as well. This data is not used by application core since PRAMC gives a bus error in this case.
2. In case if XRDC is configured to restrict access to SRAM0 and a 32-bit write access is performed: Since SRAM is 64-bit wide, so a 32-bit write transaction is performed as a read-modify-write. In the read cycle, again as described in previous scenario, the PRAMC will initiate an error response. In this case also, if there is any error on SRAM0 data bus (i.e., error or error injected via EIM), the same is captured in ERM as well.

22.2 Introduction

The RAM controller is an interface between the system bus (AHB-Lite 2.v6) and the integrated system RAM. It converts the protocols between the system bus and the dedicated RAM array interface.

The RAM controller supports one 64-bit AHB interface and a 64-bit RAM array interface. The AHB port provides a connection to the platform crossbar for direct RAM access from the various crossbar masters. Shown below in Figure 50 is a simplified block diagram depicting the position of the RAM controller within a typical platform architecture.

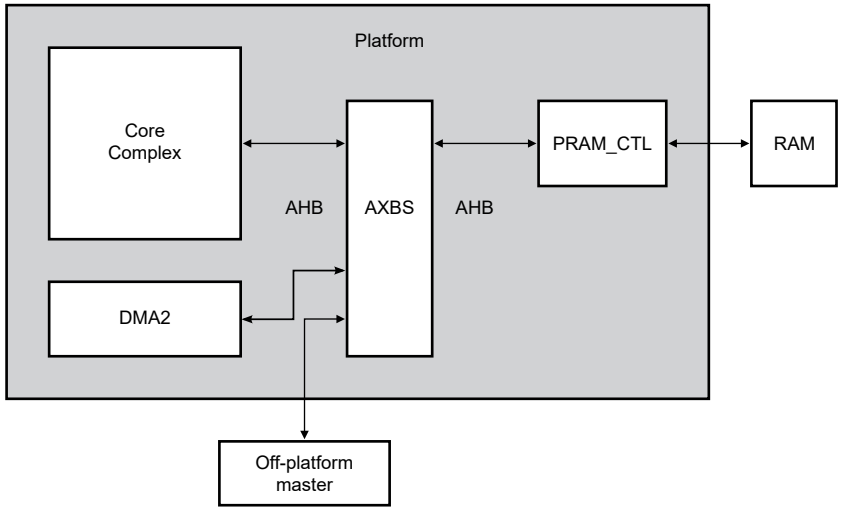

Figure 50. Simplified platform block diagram

The following list summarizes the key features of the RAM controller:

- System bus supports 64-bit data
- Array interface supports a 64-bit data + 8-bit ECC interface
- Late-write support via 64-bit data + 8-bit ECC storage buffer supports single-cycle write accesses
- Configurable read access timing (zero or one wait state programmable) allowing use in large range of frequency targets
- Read-modify-write operation supports array write size smaller than a doubleword
- Hardware EDC after ECC feature to check the ECC logic.

The address path of the RAM controller contains a MUX that chooses among the addresses presented on the system bus for a read request—either the address from the temporary holding register or the address from the late-write buffer. The temporary holding register contains the address presented during the AHB address phase of the write request. The request is delayed when being presented to the RAM by one cycle. This step makes it possible to simultaneously present the address and associated write data, which is not valid until the AHB data phase. The late-write buffer holds write requests that are delayed to facilitate single-cycle response on the system bus.

The read data path contains a MUX that chooses the source of the read data to be presented on the system bus on a read request. When a read request matches the contents of the late-write buffer, a RAM access is not required, and the late-write buffer contents are transferred to the read data bus. Otherwise, the read data is a result of a RAM access.

The write data path contains the MUX that chooses the source of the write data, as well as the control logic for generating read-modify-write operations on writes less than 64 bits in size. A write operation can be performed to empty the contents of the late-write buffer. In the case of back-to-back writes, the write may be forced to bypass the late-write buffer and instead be stored directly in RAM.

22.3 Functional description

This section describes the functions of the RAM controller.

22.3.1 Read and write operations

The RAM controller processes read and write requests to on-chip RAM and provides a register interface for access to performance tuning functions.

NOTE

The RAM controller register interface is accessible only in supervisor mode. Accesses in user mode return a transfer error.

22.3.1.1 Reads

Read transfers, of any size, can be configured to complete with a zero or one additional wait state response on the system bus.

22.3.1.2 Optional read wait state

The RAM controller can be optionally programmed to register RAM read data prior to returning it on the system bus. Setting the PRCRx[FT_DIS] field inserts a register in the read data path for use when operating the controller at high frequencies. The state of PRCRx[FT_DIS] field has no effect on writes.

A random, initial access takes two clock cycles (2T) to complete if PRCRx[FT_DIS]=0, and a WRAP4 burst will have an access time of 2-2-2-2. A random, initial access takes three clock cycles (3T) to complete if PRCRx[FT_DIS]=1, and a WRAP4 burst has an access time of 3-2-2-2.

NOTE

The number of cycles taken for a RAM access can vary ±1 clock cycle depending on the RAM speed relative to the PRAMC controller clock frequency. If system RAM is running at the same frequency as the PRAMC controller, a random initial access takes two clock cycles. If system RAM is running at a slower frequency, a random initial access may take 3 clock cycles. Subsequent burst beats take either one or two cycles depending on RAM speed relative to the PRAMC controller clock frequency.

22.3.2 Writes

This section discusses various write operations of the RAM controller.

22.3.2.1 64-bit writes

Aligned 64-bit writes execute in a single AHB data phase cycle, resulting in zero wait states on back-to-back writes of these sizes. If, during the data phase of a write, a read is requested on the AHB, the write is registered in the late-write buffer, enabling the read to take place without a wait state. The valid buffered or late-write data is stored on the next available array address phase.

Back-to-back 64-bit writes execute slightly differently. The first write bypasses the late-write buffer—the write data is stored directly to the array in the same cycle in which it is valid on the AHB.

22.3.2.2 Less than 64-bit writes

Writes of size less than 64 bits incur a read-modify-write action as a consequence of the ECC coding scheme's 64-bit granularity. In the case of a read-modify-write action, the RAM controller performs SEC/DED on the read data. The write data is merged into the appropriate byte lanes along with the potentially corrected read data. A new codeword is generated based on the newly formed doubleword. This doubleword and its associated checkbits are subsequently written to RAM. Figure 51 provides details on the read-modify-write data path.

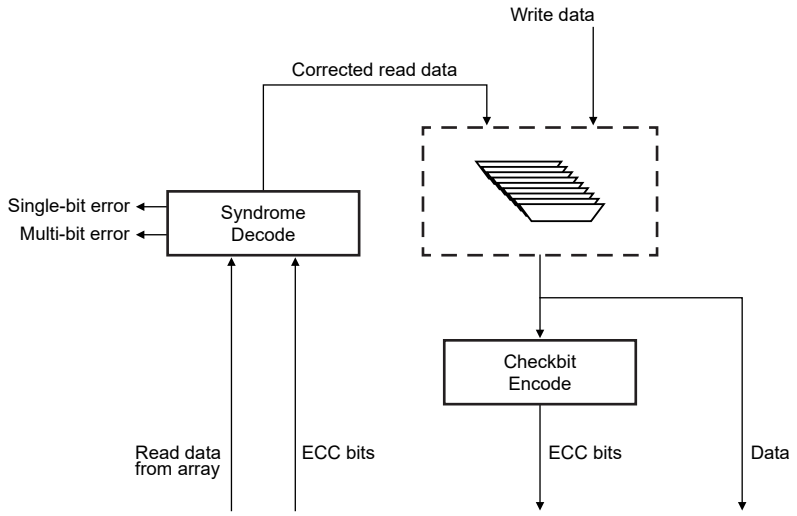

Figure 51. Read-modify-write data path

On a read-modify-write operation, the array read data is registered after it is decoded and before it is merged with the AHB write data. Therefore, writes of size less than 64 bits require the insertion of one wait state before the data phase can be completed.

22.3.2.3 Unaligned writes

The RAM controller is compliant with the AMBA-AHB2.v6 Extensions specification with regard to byte strobes. The size of the transfer is sufficient to cover all bytes being written, and covers more bytes in the case of an unaligned transfer. The address of the transfer is rounded down to the nearest boundary of the size of the transaction.

NOTE

Unaligned writes always generate read-modify-write operations in the RAM controller in order to preserve the validity of the ECC codeword.

22.4 Initialization/application information

Each memory address must be written to a known value before it is read, to initialize the ECC. This includes reads generated from the read-modify-write operation that occurs when a write transfer of less than 64 bits or an unaligned write is requested. Without first writing an address to a known value, a read from the address will most likely generate an uncorrectable ECC event.

22.5 PRAMC register descriptions

The RAM controller module provides an IPS programming model mapped to a standard on-platform peripheral slot.

NOTE

1. The programming model can only be referenced using a 32-bit (word) access. Attempted references using different access sizes or to undefined (reserved) addresses generate an IPS error termination.
2. Attempted updates to the PRAMC programming model while a PRAMC operation is in progress will result in non-deterministic behavior. Software must be architected to avoid this scenario by ensuring that PRAMC configuration changes are made only during system boot or when only one master is enabled. In multi-core devices, update the PRAMC configuration only when one core is active and no other masters, for example, DMA or communications modules, are enabled. Move any instruction execution or memory references outside the system RAM while updating the PRAMC configuration, for example, to the core local memory space.

22.5.1 PRAMC memory map

PRAMC_0 base address: 4026_4000h

PRAMC_1 base address: 4046_4000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Platform RAM Configuration register 1 (PRCR1)	32	RW	0000_0100h

22.5.2 Platform RAM Configuration register 1 (PRCR1)

Offset

Register	Offset
PRCR1	0h

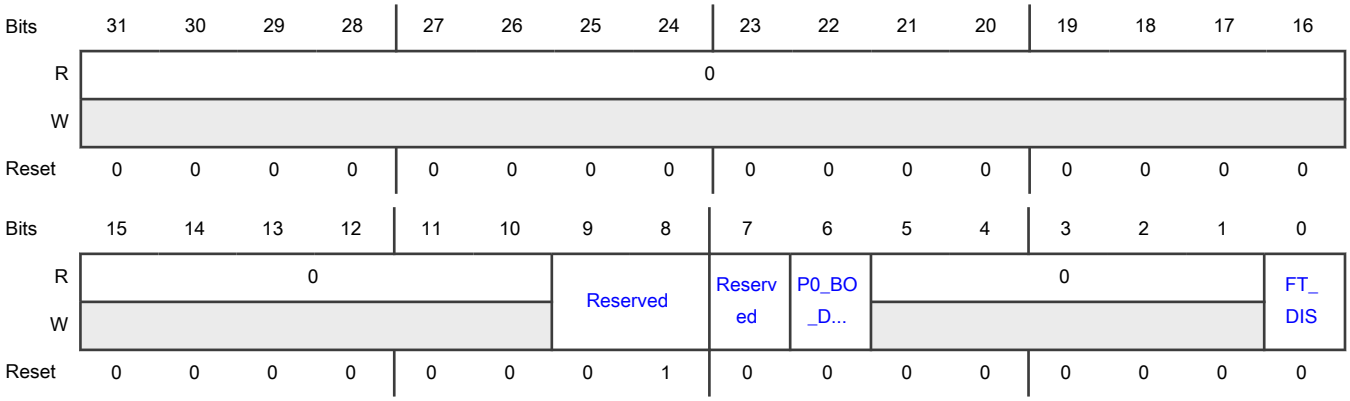
Function

The Platform RAM Configuration register 1 (PRCR1) is used to specify operation of the RAM controller.

NOTE

This register is accessible only in supervisor mode. Accesses in user mode return a transfer error.

Diagram



Fields

Field	Function
31-10 —	Reserved
9-8 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
7 —	Reserved
6 P0_BO_DIS	Port p0 read burst optimization disable. **NOTE** The number of cycles taken for a RAM access can vary ± 1 clock cycle depending on the RAM speed relative to the PRAMC controller clock frequency. If system RAM is running at the same frequency as the PRAMC controller, a random initial access takes 2 clock cycles. If system RAM is running at a slower frequency, a random initial access may take 3 clock cycles. Subsequent burst beats take either 1 or 2 cycles depending on RAM speed relative to the PRAMC controller clock frequency. 0b - 64-bit WRP4 read bursts are optimized such that the controller returns a 2-1-1-1 response when PRCR1[FT_DIS]=1 1b - 64-bit WRP4 read bursts are not optimized; the controller returns a 2-2-2-2 response when PRCR1[FT_DIS]=1
5-1 —	Reserved
0 FT_DIS	Flow-through disabled This field defines the AHB response on reads. The state of this field has no impact on the response latency on writes. This bit is cleared by hardware reset. **NOTE** Do not change the FT_DIS bit value while accessing system RAM. Relocate code programming the FT_DIS bit to another memory area, for example, local core memory. 0b - RAM read data is passed directly to the system bus, incurring no additional latency 1b - RAM read data is registered prior to returning on the system bus, incurring one extra cycle of latency

Chapter 23
Clocking

23.1 Introduction

This chapter describes the clocking architecture and includes the following information:

- System clock specifics
- Clock sources
- Clock architecture
- Clock control registers
- Clock monitoring
- Clock gating
- Module clocking

This chapter discusses the clocks generated on the chip. Peripheral-specific protocol clocks are described in the corresponding peripheral chapters.

23.2 Features

- Multiple clock sources supported for clock generation:
  - Fast internal RC oscillator (FIRC)
  - Slow internal RC oscillator (SIRC)
  - Fast external crystal oscillator (FXOSC)
  - Slow external crystal oscillator (SXOSC)

    NOTE

    SXOSC is not available in 100-MAX QFP and 48-pin LQFP packages. For details, see 'MWCT2xxxS chip's feature comparison' table in Introduction chapter.

  - Phase-locked loop (PLL)
- Frequency-modulated PLL output clock to reduce electromagnetic emissions
- Precise clocks for timers and communication functions
- Glitchless clock switching Clock Generation module (MC_CGM) clock selectors
- System clock progressive clock frequency switching (PCFS)
- Clock monitoring units (CMU_FC, CMU_FM) to check clock integrity
- Core and peripheral clock gating using the Mode Entry module's (MC_ME) partition process configuration registers

23.3 Clocking overview

The MWCT2xxxS clocking architecture consists of multiple:

- Clock sources
- Monitors
- Multiplexers
- Dividers

The blocks in the above bullet list provide the required clocking domains for the different functional blocks.

The sections in the following list show the clocking configuration of the chip:

- Clock source generation: PLL, FXOSC, FIRC, SIRC, and SXOSC
- MC_CGM mux 0 clocks: MC_CGM mux 0 generated clocks (not including EMAC clock signals)
- Clockout overview: CLKOUT_STANDBY and CLKOUT_RUN
- Other clocks
- EMAC clocking: Ethernet utilized clocking

The figures shown in MWCT2D17S and MWCT2D16S clock system diagram, MWCT2016S clock system diagram, and MWCT2015S clock system diagram show the overall clock tree for the different chip variants of the MWCT2xxxS family, which are a combination of the sections mentioned in the bullet list above.

23.3.1 Clock source generation

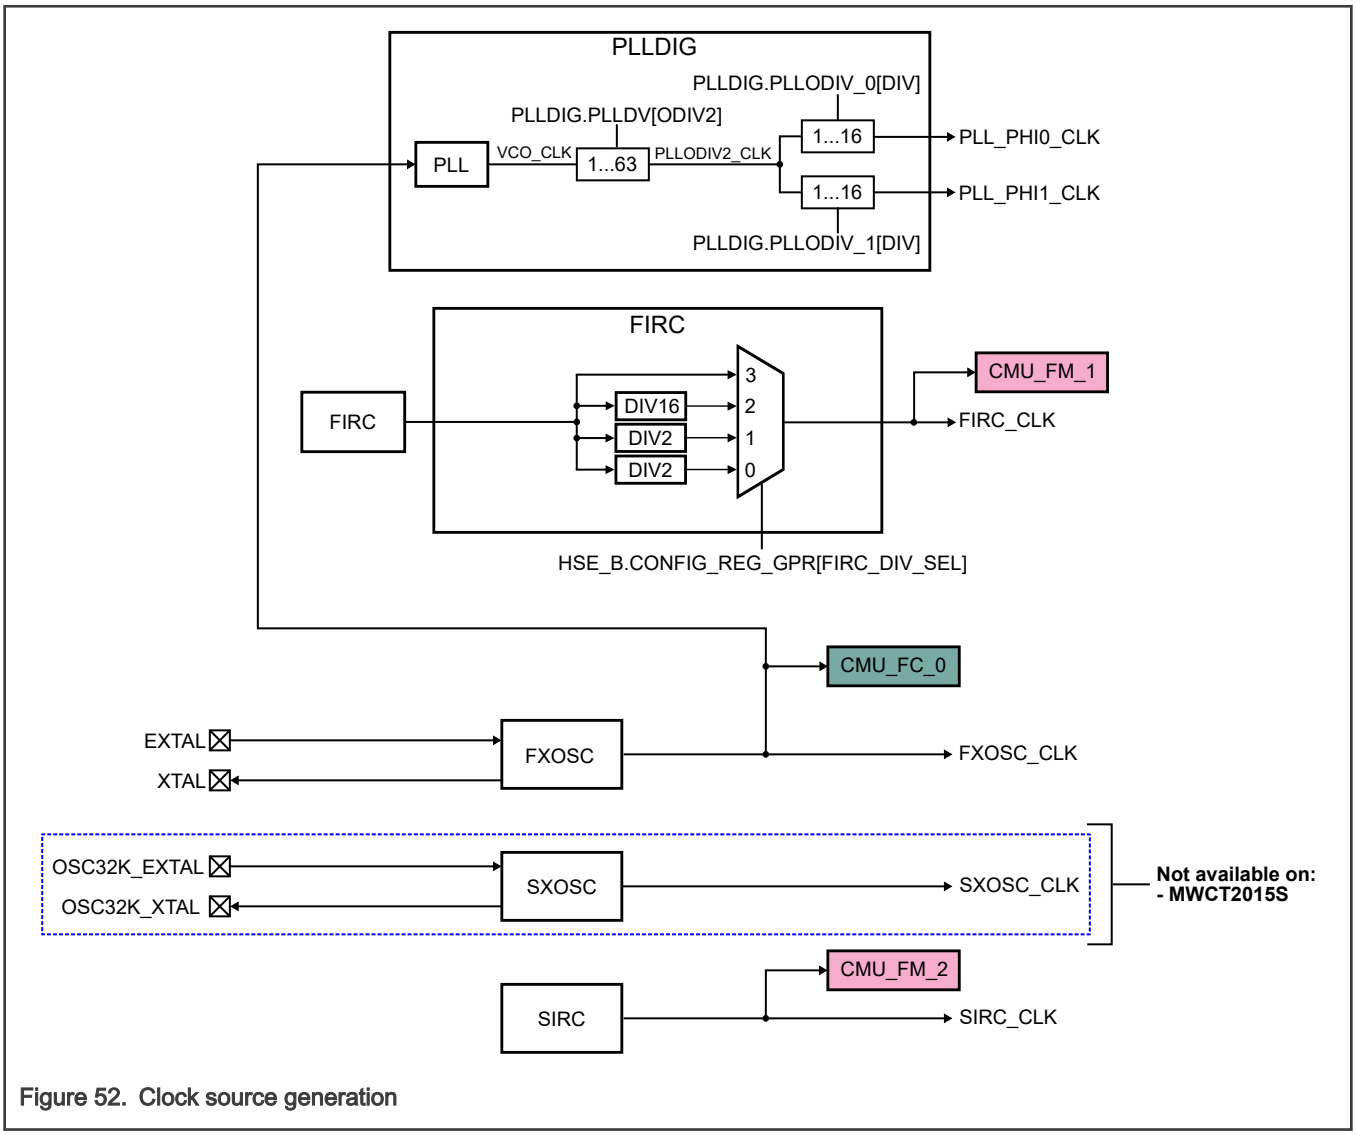

Figure 52. Clock source generation

23.3.2 MC_CGM mux 0 clocks

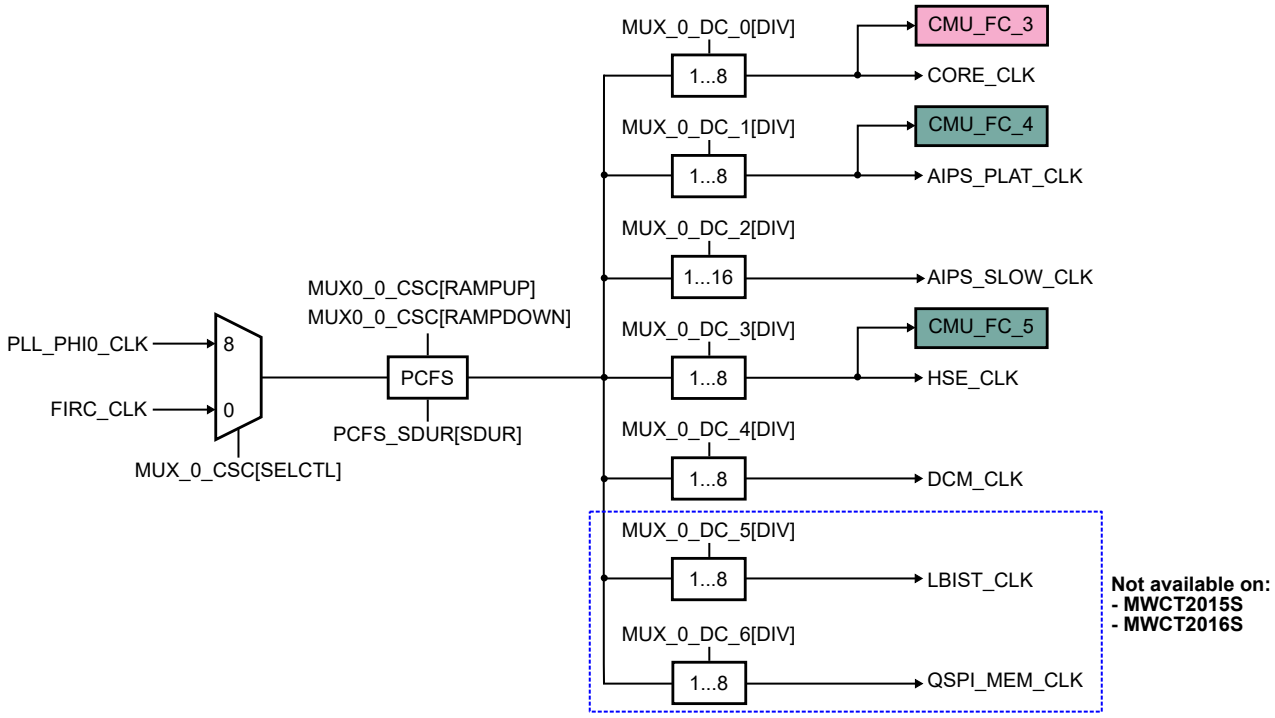

Figure 53. MC_CGM mux 0 clocks

NOTE

The clock frequency relationship between TCK and HSE_CLK clocks for HSE_B must be a minimum ratio of 1:1.5. For example, if HSE_CLK equals 80 MHz, then TCK must be less than or equal to 53 MHz (80 MHz ÷ 1.5).

23.3.3 Clockout overview

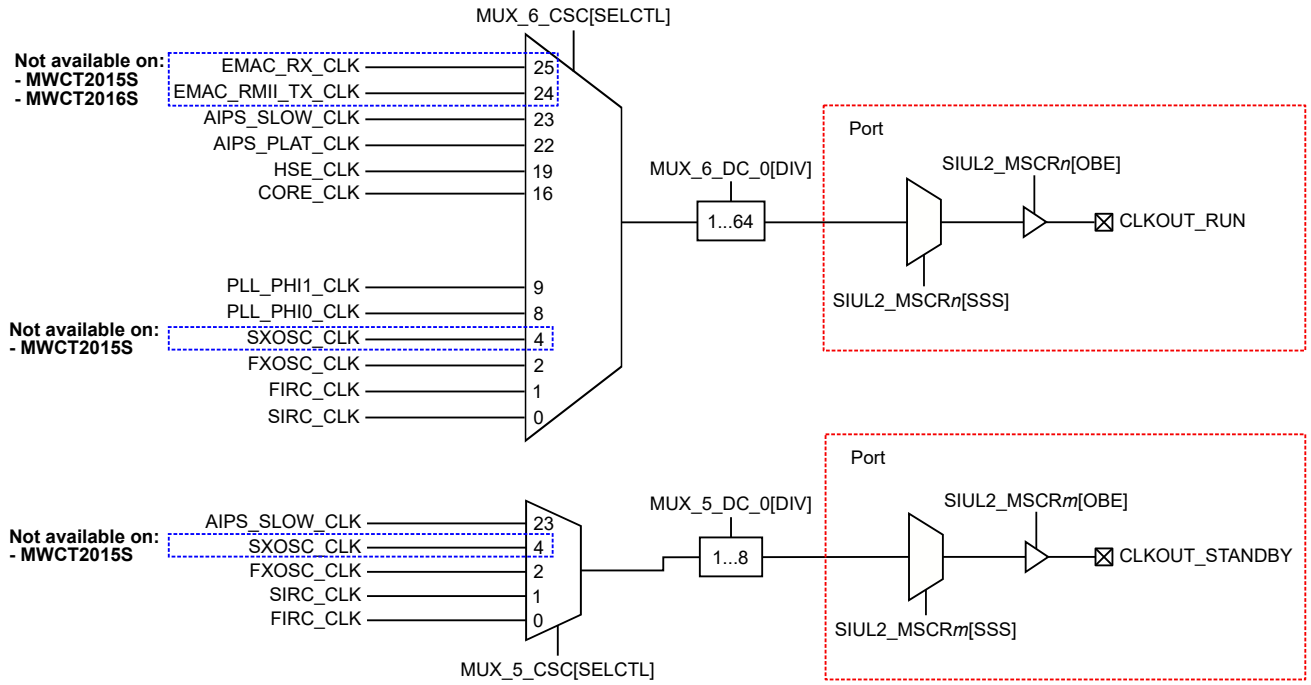

Figure 54. Clockout overview

NOTE

CLKOUT_RUN is not available during Standby mode.

23.3.3.1 SIUL2 options for CLKOUT_RUN

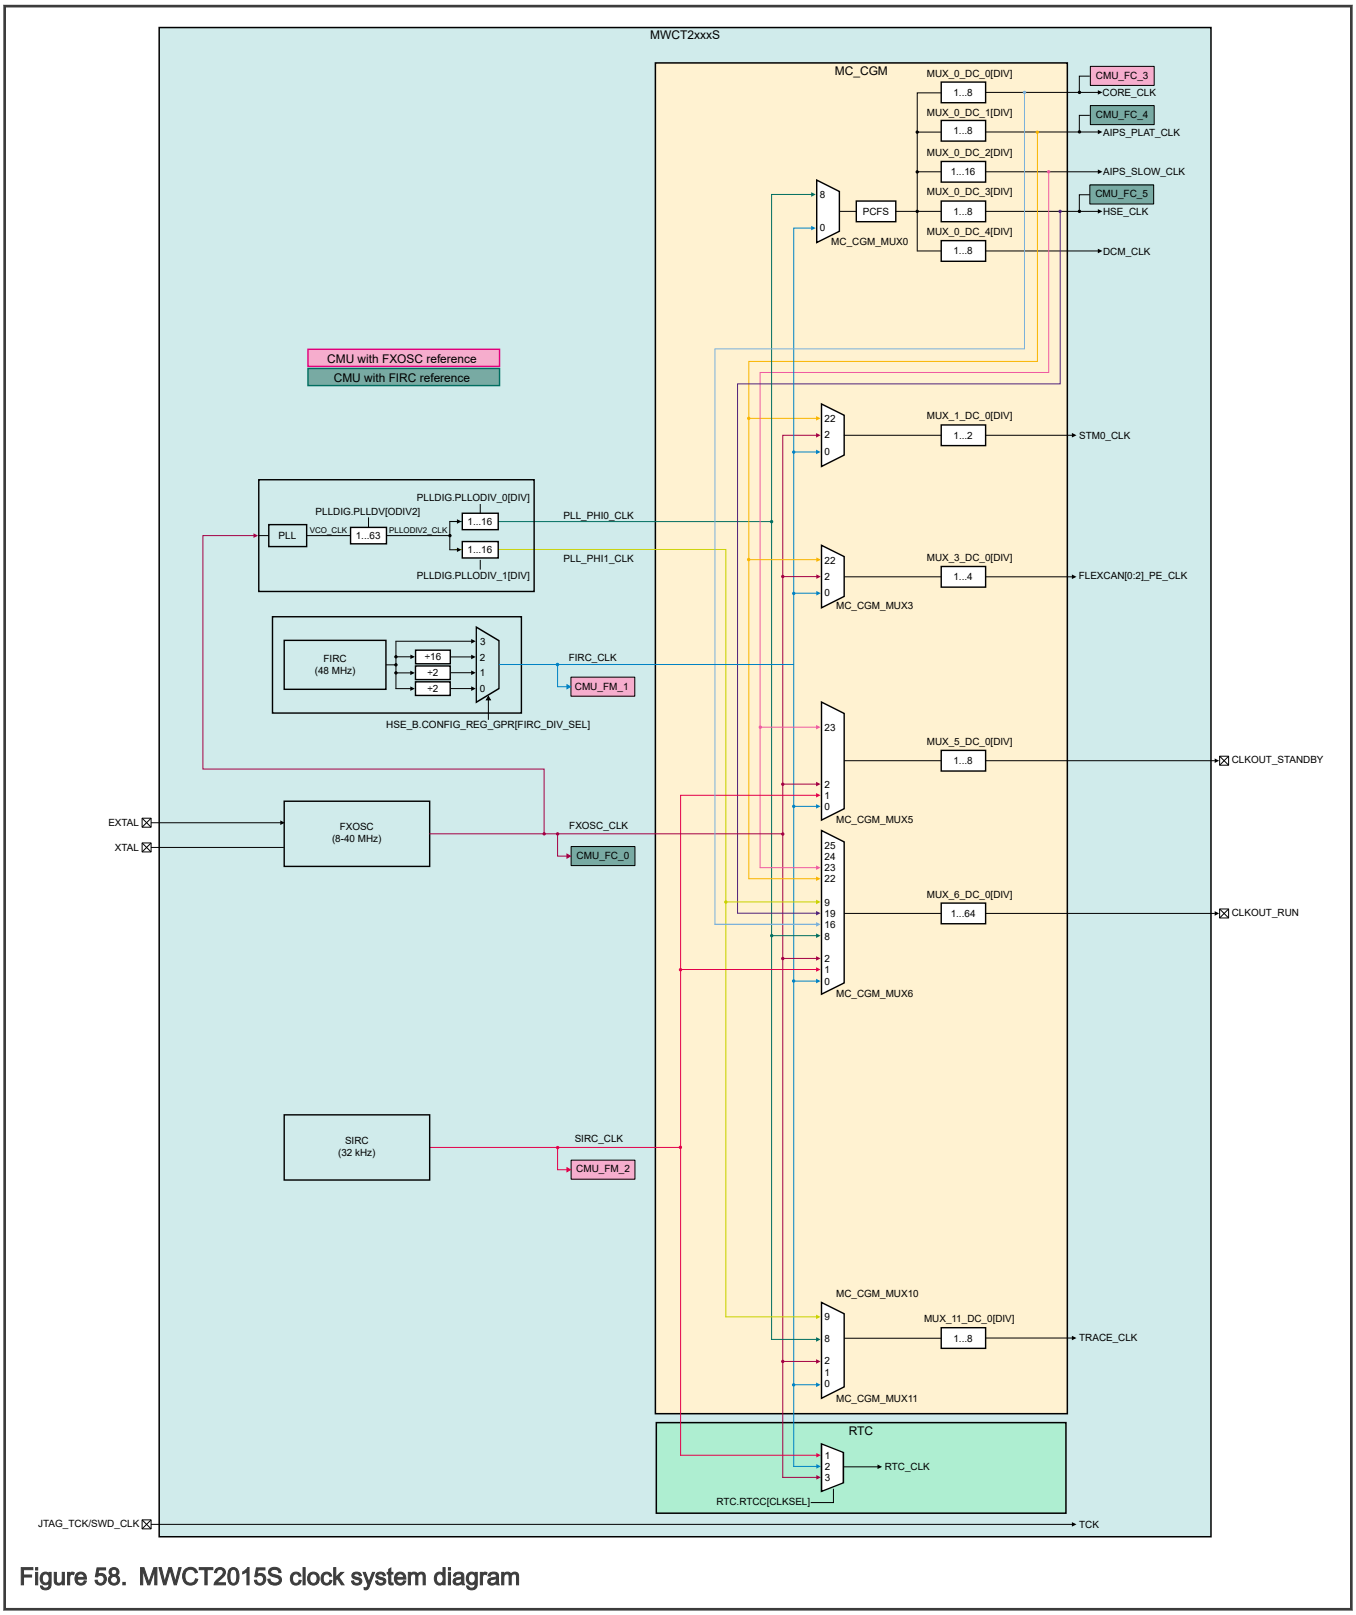

Figure 58. MWCT2015S clock system diagram

23.4 Clock sources

23.4.1 Introduction

The chip contains the following clock sourcing modules:

- FIRC
  - FIRC_CLK is the default system clock source.
- SIRC
- PLL
- FXOSC
- SXOSC (not available on the MWCT2015S)

The following list shows some of the clock system features:

- All clock sources support software configurability for enabling or disabling. [34]
- All clock sources, except SXOSC_CLK, are initialized to their default state on functional reset.
- The SXOSC_CLK supports RTC applications across functional reset and is reset on destructive reset.

Only SIRC_CLK and FIRC_CLK are enabled out of reset and are enabled on any functional reset. The other clock sources are disabled on reset.

23.4.1.1 Chip clock sources

Table 93. Chip clock sources

Clock source	Divider	Default state	Reset	Uses
FIRC_CLK (48 MHz)	1, 2, 16	On	POR (enabled on functional and destructive reset) POR assertion - FIRC_CLK disabled asynchronously POR deassertion - FIRC_CLK enabled	• Boot clock • Default system clock source • Safe clock for safety modules FCCU and FOSU • SIUL2 filter clock • MC_RGM clock source
PLL_PHI*n*_CLK (640-1280 MHz)	1...16	Off	Functional (disabled on functional reset)	• Optional system clock source • Communication modules (FlexCAN, EMAC, QuadSPI, and so on)
FXOSC_CLK (8-40 MHz)	—	Off	Functional (disabled on functional reset)	• Reference clock source for PLL • Communication modules (FlexCAN, EMAC, QuadSPI, and so on)
SXOSC_CLK (32.768 KHz)	—	Off	Destructive (disabled on destructive reset)	• RTC source for operation across functional reset (SXOSC_CLK is not available on the MWCT2015S)

Table continues on the next page...

[3] FIRC_CLK and SIRC_CLK cannot be disabled during Run mode.

Table 93. Chip clock sources (continued)

Clock source	Divider	Default state	Reset	Uses
SIRC_CLK (32 KHz)	—	On	POR (enabled on functional reset)	• Safe clock along with FIRC_CLK • SWT clock source • POR_WDG source clock

23.4.2 Chip input clocks

Table 94. Chip input clocks

Pin	Description
XTAL	FXOSC crystal pins
EXTAL	
OSC32K_XTAL	SXOSC crystal pins (not available on the MWCT2015S)
OSC32K_EXTAL	
EMAC_MII_RMII_TX_CLK	EMAC transmitter clock/EMAC RMII clock (not available on the MWCT2015S or MWCT2016S)
EMAC_MII_RX_CLK	EMAC receiver clock (not available on the MWCT2015S or MWCT2016S)
JTAG_TCLK/SWD_CLK	JTAG/SWD clock
SAI*n*_MCLK	SAI_*n* clock in slave mode (not available on the MWCT2015S or MWCT2016S)
SAI*n*_BCLK	SAI_*n* bit clock in slave mode (not available on the MWCT2015S or MWCT2016S)
LPSPI*n*_SCK	LPSPI*n* serial clock in slave mode
LPI2C*n*_SCL	LPI2C_*n* clock
LPI2C*n*_SCLS	LPI2C_*n* secondary clock

23.4.3 Chip output clocks

Table 95. Chip output clocks

Pin	Description
CLKOUT_RUN	Available during Run mode, unavailable during Standby mode
CLKOUT_STANDBY	Available during both Run and Standby modes
LPSPI*n*_SCK	LPSPI*n* serial clock in master mode
LPI2C*n*_SCL	LPI2C_*n* clock
LPI2C*n*_SCLS	LPI2C_*n* secondary clock
EMAC_MII_RMII_MDC	EMAC clock for control data transfer to PHY (not available on MWCT2015S or MWCT2016S)
EMAC_MII_RMII_TX_CLK	EMAC transmit clock (not available on MWCT2015S or MWCT2016S)

Table continues on the next page...

Table 95. Chip output clocks (continued)

Pin	Description
TRACE_ETM_CLKOUT	ETM trace clock (not available on MWCT2015S, MWCT2016S, or MWCT2D16S)
SAI*n*_BCLK	SAI_*n* bit clock in master mode (not available on MWCT2015S or MWCT2016S)
QuadSPI_SCKFA	QuadSPI serial clock for serial flash device A (fast) (not available on MWCT2015S or MWCT2016S)

23.4.4 Fast internal RC oscillator (FIRC)

The chip has an FIRC with the following features:

- Acts as the system clock source on power-up and after any reset event.
  - Important to detect FIRC_CLK failure and recovery
- Acts as the chip's safe clock for safety-relevant applications.
- Is always enabled in Run mode and can be optionally enabled in Standby mode.
- Used as clock source for the following:
  - MC_RGM
  - FCCU and FOSU
  - SIUL2 filters

23.4.4.1 FIRC failure detection

The FIRC_CLK is the safe clock source used as the FCCU and FOSU clock source. The chip supports FIRC_CLK failure detection and recovery by the mechanisms described in the following cases:

- Case 1 - FIRC_CLK not used as system clock and goes out of range:
  - CMU_FM_1 continuously measures the FIRC_CLK clock frequency using FXOSC_CLK as the reference. On each metering window completion, CMU_FM_1 asserts an interrupt (if configured, CMU_FM_1.IER[FMCIE] is 1). You store a configured reference clock count CMU_FM_1.RCCR[REF_CNT] (for example, number of FXOSC_CLK cycles in metering window). Your software checks the FIRC_CLK clock counts by reading CMU_FM_1.SR[MET_CNT].
  - In the event FIRC_CLK goes out of range, the software detects the frequency variation after the subsequent metering window by checking CMU_FM_1.SR[MET_CNT] and takes necessary action by either of the recommended options:
    - SBC-driven power cycle: The SBC receives indication from the chip (through GPIO toggle, QuadSPI communication, and so on). The SBC initiates a power cycle sequence.
    - Software-driven functional reset: The chip executes a functional reset as configured by your software.
- Case 2 - FIRC_CLK not used as system clock and fails (becomes stuck):
  - CMU_FM_1 continuously measures the FIRC_CLK frequency with FXOSC_CLK as the reference. Application software must check FIRC_CLK after a defined time limit by reading CMU_FM_1.SR[MET_CNT] and CMU_FM_1.SR[FMTO].
  - If there is an FIRC_CLK failure, the CMU_FM_1 writes a 1 to the timeout status flag CMU_FM_1.SR[FMTO].
  - When CMU_FM_1.SR[FMTO] is 1, application software takes necessary action by an SBC-driven power cycle wherein the chip provides an indication to the SBC (through GPIO toggle, QuadSPI communication, and so on). The SBC then initiates a power cycle sequence.
- Case 3 - FIRC_CLK used as system clock and goes out of range or fails (becomes stuck):
  - CMU_FC_3, CMU_FC_4, and CMU_FC_5 continuously monitor the system clock nodes with FXOSC_CLK as reference for FLL or FHH events.

- In the event of FIRC_CLK failure (when FIRC_CLK acts as the system clock source), these CMUs report the FLL event, acting as a destructive reset source.
- The system then undergoes the reset sequence, during which the FIRC_CLK is reinitialized.
- The MC_RGM.DES fields indicate the source of the reset event.
- In addition, CMU_FM_1 monitors FIRC_CLK. If the software is not able to service the CMU_FM_1 interrupt before POR_WDG timeout, POR_WDG treats this as a critical FIRC_CLK failure and initiates a POR_WDG recovery. Therefore, you must ensure that, if enabled, the CMU_FM_1 interrupt must be serviced within the POR_WDG timeout duration.

23.4.4.2 FIRC_CLK behavior in Standby mode

FIRC_CLK can be optionally enabled in Standby mode by configuring FIRC.STDBY_ENABLE[STDBY_EN].

When the PMC acknowledges the Standby mode entry, the FIRC_CLK switches from the On state to the Standby mode configuration selected by the FIRC.STDBY_ENABLE[STDBY_EN] configuration. On wakeup from Standby mode, the FIRC_CLK configuration switches from the Standby mode configured state to the On state.

The FIRC at 3 MHz is meant to be used with the Low Power Run Mode only. If the chip needs to enter Standby mode, then the FIRC must be configured to 48 MHz with the FIRC_DIV_SEL as '0b11' during the Standby Mode. After exiting the Standby mode, the FIRC can be changed to 3 MHz if desired.

NOTE

When the trims are being applied, the FIRC will appear as momentarily disabled as shown in Reset timing diagram in the Reset overview chapter.

23.4.5 SIRC

The chip has a SIRC having the following features:

- Is always enabled in Run mode and can be optionally enabled in Standby mode. Having the SIRC always enabled improves system robustness by ensuring that a clock is always available for various SWTs when reducing the chip power consumption in Standby mode.
- Used as clock source for the following:
  - SWT
  - POR_WDG

23.4.5.1 SIRC failure detection

Like the FIRC_CLK, the SIRC_CLK is a safe clock for the design. The SIRC_CLK is used as clock source for SWTs and POR_WDG and therefore it is important to detect SIRC failure and ensure its recovery. The chip supports SIRC_CLK failure detection and recovery by the mechanism described below.

- Case 1 - SIRC_CLK goes out of range:
  - CMU_FM_2 continuously measures the SIRC_CLK clock frequency with FXOSC_CLK as reference. On each metering window completion, the CMU_FM_2 raises an interrupt. The software checks the SIRC clock counts by CMU_FM_2.SR[MET_CNT] with respect to the reference clock counts CMU_FM_2.RCCR[REF_CNT].
  - In the event of clock going out of range, the software detects the frequency variation after the subsequent metering window by checking CMU_FM_2.SR[MET_CNT] and takes necessary action by either of the recommended options:
    1. SBC-driven power cycle. The chip gives an indication to the SBC (through GPIO toggle, QuadSPI communication, and so on.). The SBC then initiates a power cycle sequence.
    2. SW-driven functional reset. The chip executes a functional reset by software.
- Case 2 - SIRC_CLK fails (becomes stuck):

— CMU_FM_2 continuously measures the SIRC clock frequency with FXOSC_CLK as reference. Software needs to check this reference after a predefined time by checking CMU_FM_2.SR[MET_CNT] and CMU_FM_2.SR[FMTO].

— In the event of SIRC_CLK clock failure, the CMU_FM_2 writes 1 to the timeout status flag field in its status register, namely, CMU_FM_2.SR[FMTO].

— When CMU_FM_2.SR[FMTO] is 1, the software takes necessary action by either of the recommended options:

1. SBC-driven power cycle: The chip gives an indication to the SBC (through GPIO toggle, QuadSPI communication, and so on). The SBC then initiates a power cycle sequence.
2. Software-driven functional reset: User software executes a functional reset.

23.4.5.2 SIRC behavior in Standby mode

SIRC can optionally be enabled in Standby mode by configuring SIRC.MISCELLANEOUS_IN[STANDBY_ENABLE].

When PMC acknowledges the Standby mode entry, the SIRC switches from the On state to the standby configuration selected by SIRC.MISCELLANEOUS_IN[STANDBY_ENABLE] configuration. On wake-up from Standby mode, the SIRC configuration switches back from the standby-configured state to the On state.

NOTE

When the trims are being applied, the SIRC will appear as momentarily disabled similar to FIRC, as shown in section Reset timing diagram.

23.4.6 FXOSC

The chip supports an 8–40 MHz fast crystal oscillator which has following features:

- Acts as the reference for PLL.
- Supports crystal input mode and bypass mode if using an external oscillator.
- Acts as a clock source for communication modules:
  - FlexCAN
  - QuadSPI[35]
  - EMAC (EMAC_CLK_TS)[35]

23.4.7 SXOSC

The chip supports a slow crystal oscillator (SXOSC) which has the following features (not available on the MWCT2015S):

- Supports crystal input mode.
- Acts as a clock source for RTC. As SXOSC is not affected by functional reset, it supports RTC operation across functional reset. SXOSC is only reset on destructive reset.

23.4.8 PLL

The chip contains up to two PLL to provide precision clock source with the following features:

- Optional system clock source (in high performance applications)
- System clock source in safety applications
- Can be used as clock source for communication modules, when configured as system clock source:
  - FlexCAN (in SYNC mode operation)
  - EMAC (not available on MWCT2015S or MWCT2016S)

[4] Not present in MWCT2015S & MWCT2016S.

  - QuadSPI (not available on MWCT2015S or MWCT2016S)
  - LPSPI
  - LPI2C
  - FlexIO
  - LPUART
- Supports frequency modulation
- Contains lock status monitoring logic which supports loss-of-lock indication

In case of a loss of lock after lock has been acquired, the Second PLL will generate a loss of lock flag. At Power-Up, the Second PLL shall be disabled. It will be up to the application software to enable it when needed. The default reaction of loss of lock flag from the Second PLL will be an interrupt. The reaction of a loss of lock from the Second PLL will be optionally configured as a functional reset, controlled by GPR.

The Second PLL supports a clock output frequency of up to 250MHz (nominal), for the FXOSC input frequencies.

NOTE

See PLL Digital Interface (PLLDIG) for PLL configuration details. See the *MWCT2xxxS Data Sheet* for PLL limitations.

23.4.8.1 PLL configurations

The PLL output predivider frequency depends on the PLLDIG.PLLDV[RDIV] and PLLDIG.PLLDV[MFI] configurations. The PLL VCO clock can be divided further by configuring PLLDIG.PLLODIV_0[DIV] for PLL_PHI0_CLK and PLLDIG_PLLODIV_1[DIV] for PLL_PHI1_CLK (see the PLL Digital Interface (PLLDIG) chapter for configuration details).

23.4.8.1.1 PLL configuration sequence

Before enabling the PLL, you must enable FXOSC_CLK and wait until it is stable. FXOSC.STAT[OSC_STAT] must be monitored to determine the FXOSC_CLK status.

To disable the PLL, the software must disable PLL first and only then disable FXOSC (if required).

23.4.9 Chip clock outputs

The chip supports two CLKOUT_*x* pins for allowing viewing of some internal clocks as follows:

- CLKOUT_STANDBY
  - Used for showing clocks available in Run and Standby modes.
- CLKOUT_RUN
  - Used for showing only Run mode clocks.

See the Clockout overview section and the Clock Generation Module (MC_CGM) chapter for details on available clocks and configuration.

NOTE

The CLKOUT_STANDBY registers are latched when the chip enters Standby mode and are reset in Standby mode sequence. Therefore, the CLKOUT_STANDBY signal needs to be reconfigured on Standby mode exit.

NOTE

CLKOUT_STANDBY is available on two pads GPIO[12] and GPIO[138] but CLKOUT across functional reset and standby is supported only on GPIO[12] and OBE(output buffer enable) is controlled by DCM GPR bit. Please refer to DCMRWP1[3] bit for detail.

23.5 MC_CGM

The MC_CGM controls the clock functionality of the chip. See the Clock Generation Module (MC_CGM) chapter for details on MC_CGM clocking controls.

23.5.1 MC_CGM clock multiplexer types

In this chip, CLKOUT_RUN, CLKOUT_STANDBY, and TRACE_CLK multiplexers are software-controlled multiplexers. The rest are hardware-controlled multiplexers (see the Clock Generation Module (MC_CGM) chapter for details on software and hardware multiplexers).

23.5.2 MC_CGM clock multiplexers for MWCT2015S and MWCT2016S

Table 96. MC_CGM clock multiplexers for MWCT2015S and MWCT2016S

	Select Status		MUX_11_CSS		
	Divider 0 Control	—	MUX_11_DC_0		TRACE_CLK

1. The default clock selected for all clock mux selectors is FIRC_CLK (out of reset).
2. FLEXCAN[4:5]_PE_CLK are not available on the MWCT2D16S.

23.5.4 MC_CGM clock sources mapping

Table 98. MC_CGM clock sources mapping

Clock selector index [1]	MC_CGM clock source	Clock source
0	clk_src_0	FIRC_CLK
1	clk_src_1	SIRC_CLK

Table continues on the next page...

Table 98. MC_CGM clock sources mapping (continued)

Clock selector index [1]	MC_CGM clock source	Clock source
2	clk_src_2	FXOSC_CLK
3	Reserved	Reserved
4	clk_src_4	SXOSC_CLK [2]
5–7	Reserved	Reserved
8	clk_src_8	PLL_PHI0_CLK
9	clk_src_9	PLL_PHI1_CLK
10–14	Reserved	Reserved
15	Reserved	Reserved
16	clk_src_16	CORE_CLK
17–18	Reserved	Reserved
19	clk_src_19	HSE_CLK
20–21	Reserved	Reserved
22	clk_src_22	AIPS_PLAT_CLK
23	clk_src_23	AIPS_SLOW_CLK
24	clk_src_24	EMAC_RMII_TX_CLK [3]
25	clk_src_25	EMAC_RX_CLK [3]
26–49	Reserved	Reserved
50	clk_src_50	CLKOUT_RUN

1. All clock selector indexes not shown are reserved.
2. SXOSC_CLK is not available on the MWCT2015S.
3. EMAC_RMII_TX_CLK and EMAC_RX_CLK are not available on the MWCT2015S or MWCT2016S.

23.6 Peripheral clocking

The module clocking diagrams for the peripherals are shown in the following subsections (see Peripheral clock gating for peripheral clock gating possibilities).

23.6.1 Module clocking

The following sections show how the chip modules use MODULE_CLK and REG_INTF_CLK to control their functionality.

23.6.1.1 Communication modules

Figure 59 shows the REG_INTF_CLK and MODULE_CLK connections, and Table 99 shows the REG_INTF_CLK and MODULE_CLK signals used by these modules. Any module diagram that does not explicitly show a REG_INTF_CLK uses the same source for REG_INTF_CLK as used by MODULE_CLK.

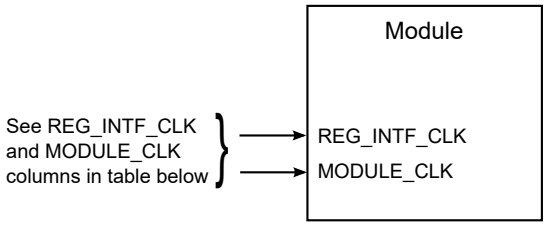

Figure 59. Communication module clocks

Table 99. Communication module clocking

Module	MODULE_CLK	REG_INTF_CLK
LPSPI	See LPSPI*n* clocking.	
LPI^{2}C	See LPI2C_*n* clocking.	
FlexIO	See FlexIO clocking.	
FlexCAN	See FlexCAN_*n* clocking.	
SAI	See SAI_*n* clocking.	
EMAC	See EMAC clocking.	
LPUART_[0,8]	AIPS_PLAT_CLK	AIPS_PLAT_CLK
LPUART_[1:7,9:15]	AIPS_SLOW_CLK	AIPS_SLOW_CLK
QuadSPI	See QuadSPI clocking.	

23.6.1.1.1 FlexCAN_*n* clocking

The figure below shows the FlexCAN_*n* clocking.

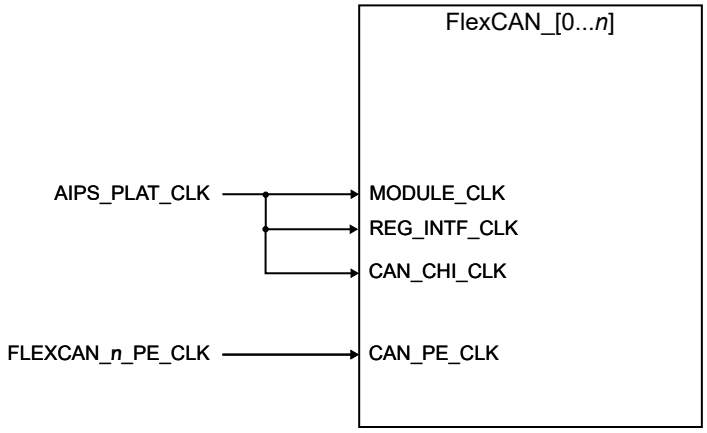

Figure 60. FlexCAN_*n* clocking

FlexCAN has the following unique clocks:

- CAN_CHI_CLK—FlexCAN controller host interface clock
- CAN_PE_CLK—FlexCAN protocol engine clock

FlexCAN supports up to an 8 Mbps data rate using a 40 MHz CAN_PE_CLK. With a 16 MHz crystal source, 3.2 Mbps is achievable for baud rate calculations (see the section Protocol timing in the "CAN (FlexCAN)" chapter for details).

For MWCT2016S, the maximum data rate supported in FlexCAN_0 instance is 5.7 Mbps.

NOTE

- See Feature comparison for details on this module's availability on your chip variant.
- For MC_CGM input sources for different variants, see clocking diagram in 'Clocking Overview' section in 'Clocking' chapter

23.6.1.1.1.1 FlexCAN timestamp implementation

The following figure shows the FlexCAN timestamping implementation. The related table shows the timestamp sources and corresponding clock nodes.

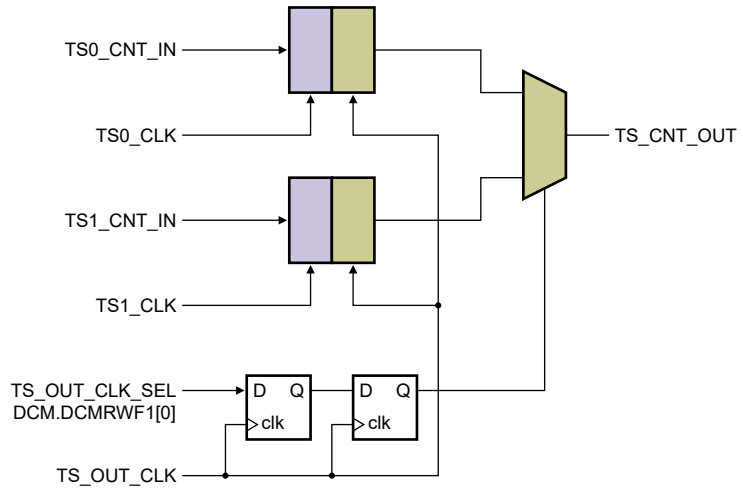

Figure 61. FlexCAN timestamping

Table 100. Timestamp sources and clock nodes

Timestamp	Module	TS clock domain
TS0_CLK	EMAC	TS0_CLK—EMAC_TS_CLK
TS1_CLK	STM0	TS1_CLK—AIPS_PLAT_CLK
TS_OUT_CLK	FlexCAN_*n*	TS_OUT_CLK—EMAC_TS_CLK

NOTE

The timestamp clock (TS_OUT_CLK, EMAC_TS_CLK for MWCT2xxxS) must be greater than or equal to FLEXCAN_*n*_PE_CLK. When using STM0 as the timestamp source, the FlexCAN timestamp clock (TS_OUT_CLK, EMAC_TS_CLK for MWCT2xxxS) must be greater than or equal to STM0_CLK.

23.6.1.1.2 LPI2C_*n* clocking

The following figure shows LPI2C_*n* clocking, and the related table shows the LPI2C SIUL2 configuration.

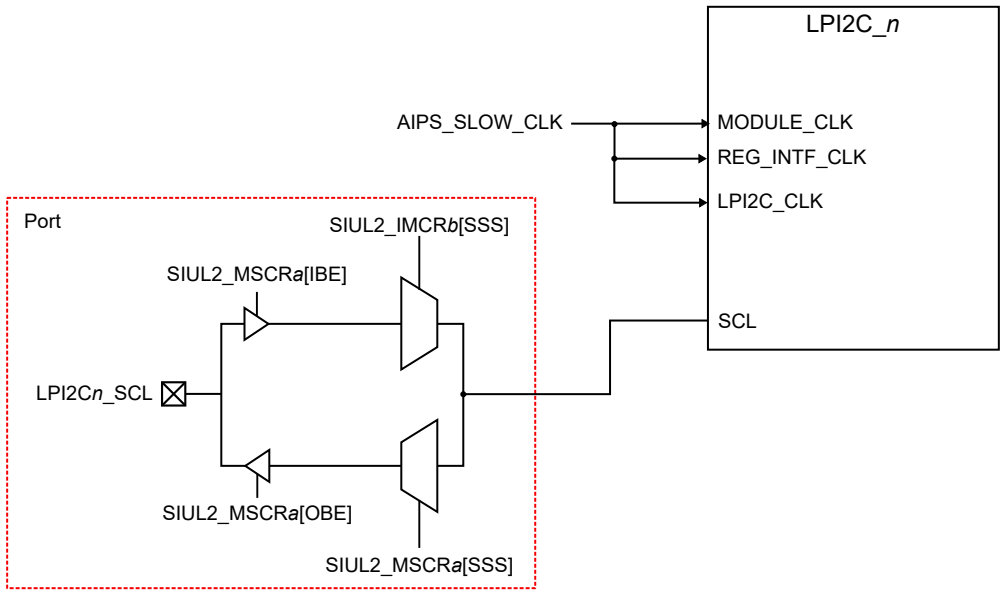

Figure 62. LPI2C clocking

NOTE

- See Feature comparison for details on this module's availability on your chip variant.
- For MC_CGM input sources for different variants, see clocking diagram in 'Clocking Overview' section in 'Clocking' chapter

Table 101. SIUL2 options for LPI2C*n*_SCL clock

I²C_*n* signal	I²C mode	I/O signal	Port	MSCR*a*	MSCR fields			IMCR*b*	IMCR[SSS]

	Master				1	0	011b		X
I2C_1_SCLS	Slave	LPI2C1_SCLS	PTC17	81	0	1	X	218	0010b
	Master				1	0	100b		X

1. PTF20 pad is not present in MWCT2015S and MWCT2016S.
2. PTF7 pad is not present in MWCT2015S and MWCT2016S.

23.6.1.1.3 EMAC clocking

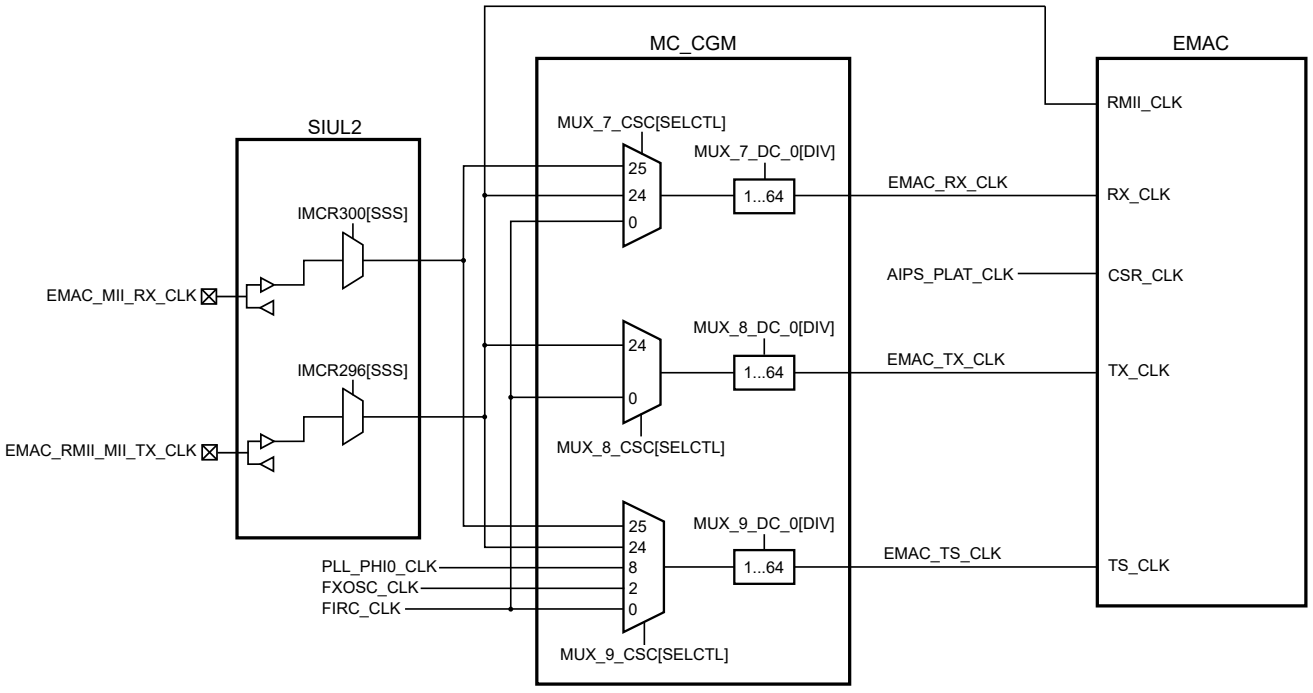

Figure 63. EMAC clocking

NOTE

EMAC operates only in Clock options A and B, since the module clock becomes lower than the protocol clock (RMII/MII clocks) in other modes.

NOTE

- See Feature comparison for details on this module's availability on your chip variant.
- For MC_CGM input sources for different variants, see clocking diagram in 'Clocking Overview' section in 'Clocking' chapter

PLL_AUX should operate in integer mode to meet the RGMII clock accuracy requirements.

PLL_AUX will be a clock source for the GMAC TX and TS clocks, to support 1 GBps Ethernet operation.

23.6.1.1.3.1 EMAC RMII clocking

The following table shows the EMAC RMII clocking, and the related table shows the SIUL2 clock signal configuration for RMII.

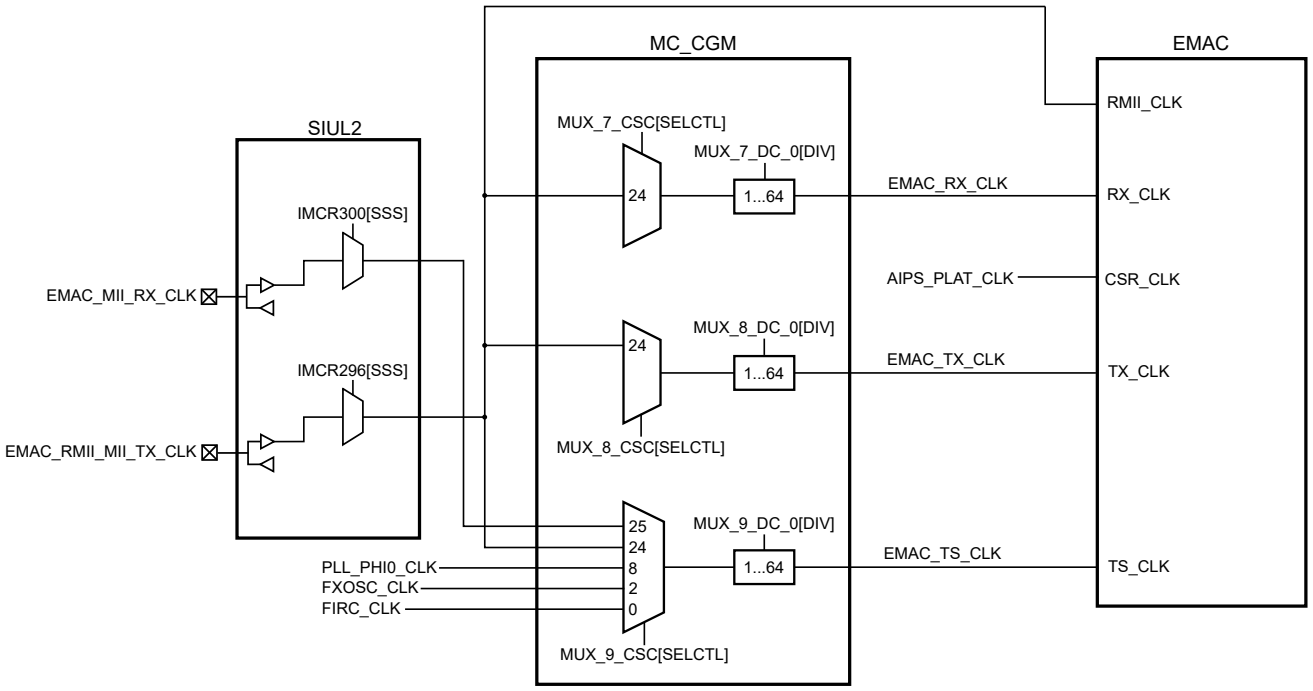

Figure 64. EMAC RMII clocking

Table 102. EMAC RMII clock configuration

Source clock	Destination clock	Port	SIUL2					
			MSCR*a*	MSCR fields			IMCR*b*	IMCR[SSS]
				OBE	IBE	SSS		
EMAC_RMII_MII_TX_CLK	EMAC_RX_CLK	PTC0	64	0	1	X	296	0100b
	EMAC_TX_CLK							
	EMAC_TX_CLK	PTD6	102	0	1	X		0010b
	EMAC_RX_CLK							
	EMAC_TX_CLK	PTD11	107	0	1	X		0001b
	EMAC_RX_CLK							
	EMAC_TX_CLK	PTD12	108	0	1	X		0011b

Table continues on the next page...

Table 102. EMAC RMII clock configuration (continued)

Source clock	Destination clock	Port	SIUL2					
			MSCR*a*	MSCR fields			IMCR*b*	IMCR[SSS]
				OBE	IBE	SSS		
	EMAC_RX_CLK							
EMAC_RMII_MII_TX_CLK (MC_CGM.MUX_9_CSC[SELCTL] = 18h)	EMAC_TS_CLK	PTC0	64	0	1	X	296	0100b
		PTD6	102	0	1	X		0010b
		PTD11	107	0	1	X		0001b
		PTD12	108	0	1	X		0011b
EMAC_MII_RX_CLK (MC_CGM.MUX_9_CSC[SELCTL] = 19h)	EMAC_TS_CLK	PTC1	65	0	1	X	300	0011b
		PTD5	101	0	1	X		0010b
		PTD10	106	0	1	X		0001b

NOTE

The EMAC time-stamp clock (EMAC_TS_CLK) can use either of the source clocks show in the table above, but can also select other clocks as selected in MC_CGM.MUX_9_CSC[SELCTL].

23.6.1.1.3.2 EMAC MII clocking

The following figure shows the EMAC MII clocking, and the related table shows the SIUL2 clock signal configuration for MII.

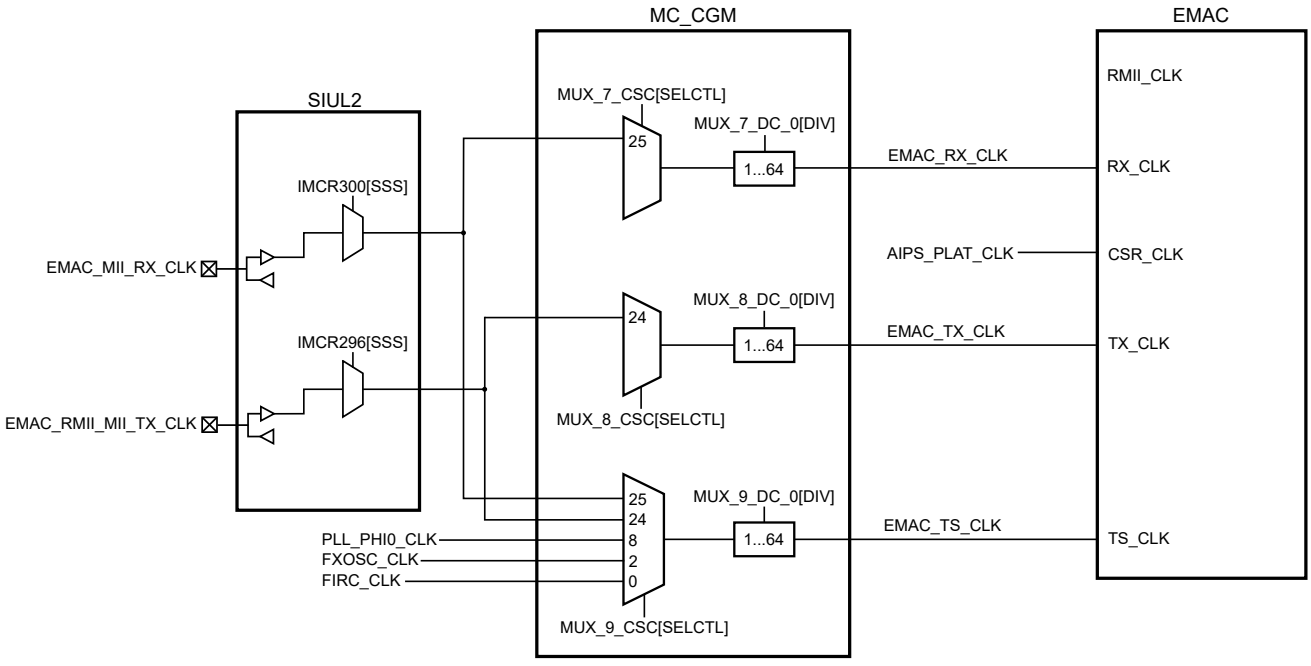

Figure 65. EMAC MII clocking

Table 103. SIUL2 EMAC MII clock configuration

Source clock	Destination	Port	SIUL2					
			MSCR*a*	MSCR fields			IMCR*b*	IMCR[SSS]
				OBE	IBE	SSS		
EMAC_RMII_MII_TX_CLK	EMAC_TX_CLK	PTC0	64	0	1	X	296	0100b
		PTD6	102	0	1	X		0010b
		PTD11	107	0	1	X		0001b
		PTD12	108	0	1	X		0011b
EMAC_MII_RX_CLK	EMAC_RX_CLK	PTC1	65	0	1	X	300	0011b
		PTD5	101	0	1	X		0010b
		PTD10	106	0	1	X		0001b
EMAC_RMII_MII_TX_CLK (MC_CGM.MUX_9_CSC[SELCTL] = 18h)	EMAC_TS_CLK	PTC0	64	0	1	X	296	0100b
		PTD6	102	0	1	X		0010b
		PTD11	107	0	1	X		0001b
		PTD12	108	0	1	X		0011b
EMAC_MII_RX_CLK (MC_CGM.MUX_9_CSC[SELCTL] = 19h)	EMAC_TS_CLK	PTC1	65	0	1	X	300	0011b
		PTD5	101	0	1	X		0010b
		PTD10	106	0	1	X		0001b

NOTE

The EMAC time-stamp clock (EMAC_TS_CLK) can use any of the signals shown in the figure above which includes either EMAC_RX_CLK or EMAC_RMII_MII_TX_CLK source clocks. MC_CGM.MUX_9_CSC[SELCTL] selects the specific source clock for EMAC_TS_CLK.

23.6.1.1.4 LPSPI*n* clocking

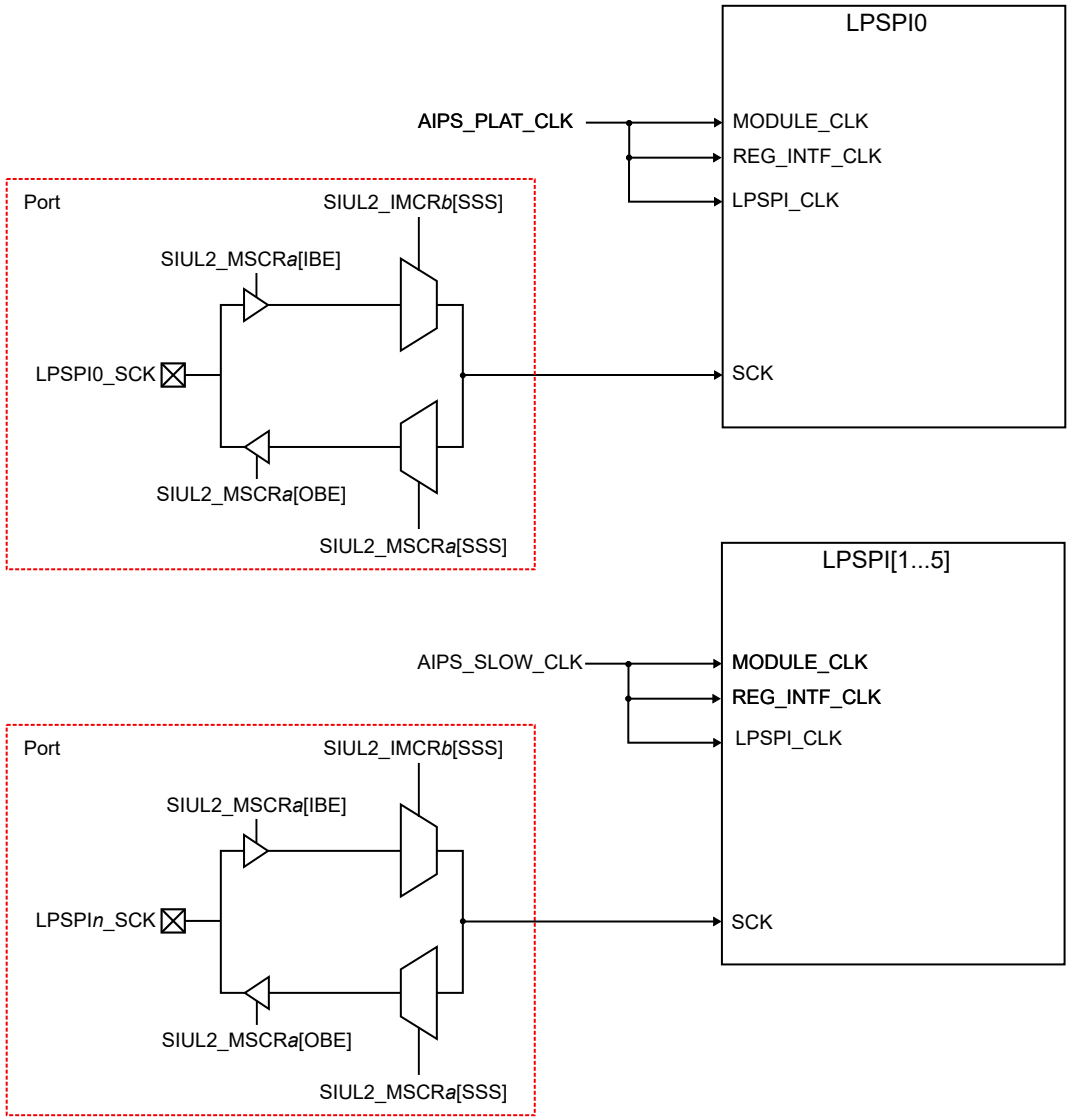

Figure 66. LPSPI*n* clocking

NOTE

- See Feature comparison for details on this module's availability on your chip variant.
- For MC_CGM input sources for different variants, see clocking diagram in 'Clocking Overview' section in 'Clocking' chapter

Table 104. SIUL2 options for LPSPI*n* SCK

23.6.1.1.5 LPUART clocking

The following figure shows the LPUART clocking configuration, and the related table shows LPUART use case baud rates.

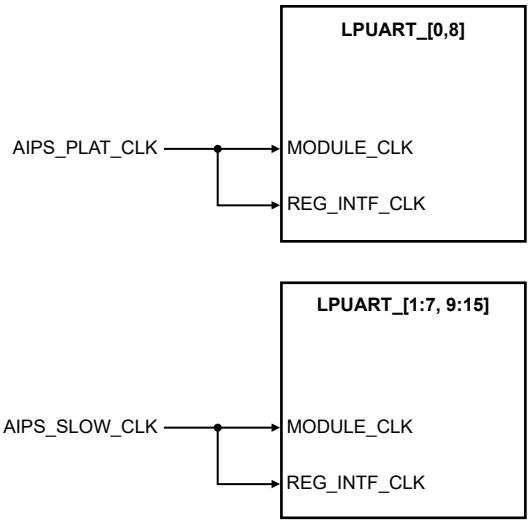

Figure 67. LPUART clocking

NOTE

- See Feature comparison for details on this module's availability on your chip variant.
- For MC_CGM input sources for different variants, see clocking diagram in 'Clocking Overview' section in 'Clocking' chapter

LPUART_0 and LPUART_1 is clocked by AIPS_PLAT_CLK, to support up to 12 Mbps while the core is running at 120 MHz.

Table 105. LPUART baud rate calculation

Required baud rate (bps)	LPUART_CLK (MHz)	OSR	SBR[12:0]	Calculated baud rate (bps) [1]
8192	40	4	976	8196
8192	80	15	610	8196
8192	48	15	366	8196
115200	48	15	26	115384
115200	40	7	43	116279
19200	80	4	833	19207
19200	40	7	260	19230
38400	40	7	130	38461

1. MODULE_CLK ÷ (LPUART.BAUD[SBR] × (LPUART.BAUD[OSR] + 1))

23.6.1.1.6 FlexIO clocking

The following figure shows the FlexIO clocking interface. The related two tables show the FlexIO baud rate use cases.

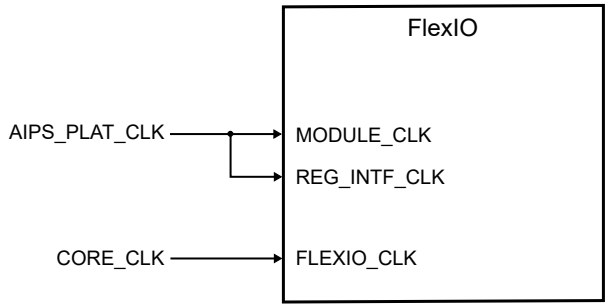

Figure 68. FlexIO clocking

NOTE

- See Feature comparison for details on this module's availability on your chip variant.
- For MC_CGM input sources for different variants, see clocking diagram in 'Clocking Overview' section in 'Clocking' chapter

Table 106. FlexIO baud rate calculation (FlexIO.TIMCFG*n*[TIMDEC] = 101b)

FLEXIO_CLK (CORE_CLK)	Required baud rate	TIMCMP*n*[CMP]		Theoretical baud rate [1]	Bit duration	Observed baud rate
		Hex	Decimal			
88 MHz	9600	0010h	16	10110.29	101.33 µs	9868
88 MHz	19200	0007h	7	21484.37	47.44 µs	21079
88 MHz	57600	0001h	1	85937.50	11.66 µs	85763
88 MHz	115200	0000h	0	171875.00	5.88 µs	170068

1. Theoretical baud rate = Frequency ÷ (256 × 2 × (TIMCMP*n*[CMP] + 1))

Table 107. FlexIO baud rate calculation (FlexIO.TIMCFG*n*[TIMDEC] = 100b)

FLEXIO_CLK (CORE_CLK)	Required baud rate	TIMCMP*n*[CMP]		Theoretical baud rate [1]	Bit duration	Observed baud rate
		Hex	Decimal			
88 MHz	9600	—	—	—	—	—
88 MHz	19200	8Eh	142	19230.77	51.88 µs	19275

88 MHz	115200	16h	22	119565.21	8.44 µs	118483

23.6.1.1.7 QuadSPI clocking

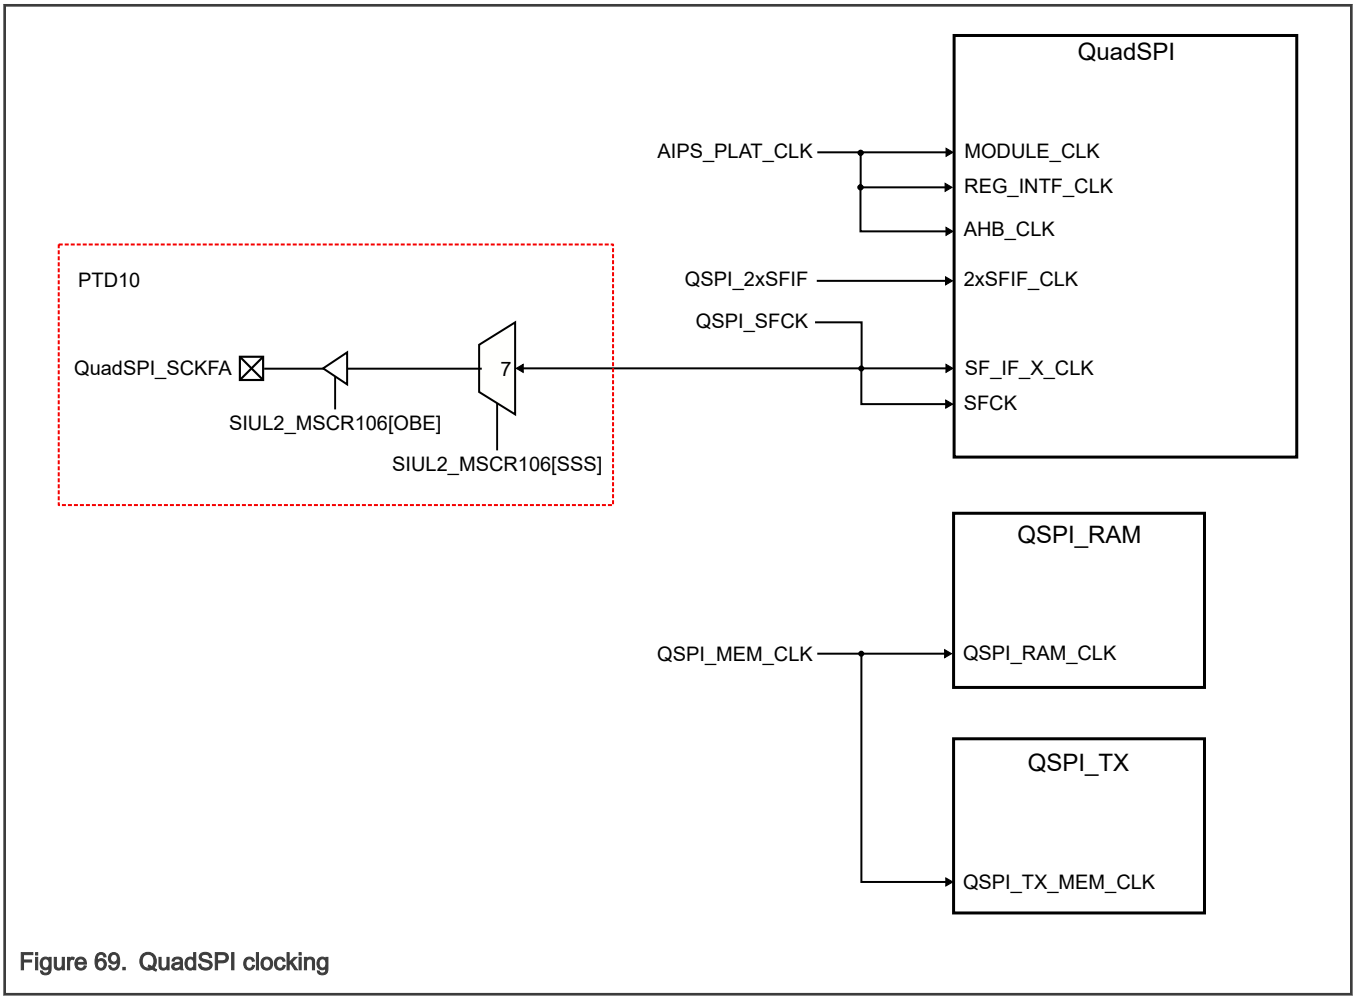

Figure 69. QuadSPI clocking

NOTE

- See Feature comparison for details on this module's availability on your chip variant.
- For MC_CGM input sources for different variants, see clocking diagram in 'Clocking Overview' section in 'Clocking' chapter

Table 108. QuadSPI clocking

Clock option	AIPS_PLAT_CLK	QSPI_SFCK	QSPI_MEM_CLK
See Option A - High Performance mode (CORE_CLK @ 160 MHz)	80 MHz	120 MHz	160 MHz
See Option B - Reduced Speed mode (CORE_CLK @ 120 MHz)	60 MHz	120 MHz or 80 MHz	120 MHz
See Option F - Operation in 1:1 mode with CORE_CLK and AXBS_CLK at same speed	80 MHz	80 MHz	160 MHz

23.6.1.1.8 SAI_*n* clocking

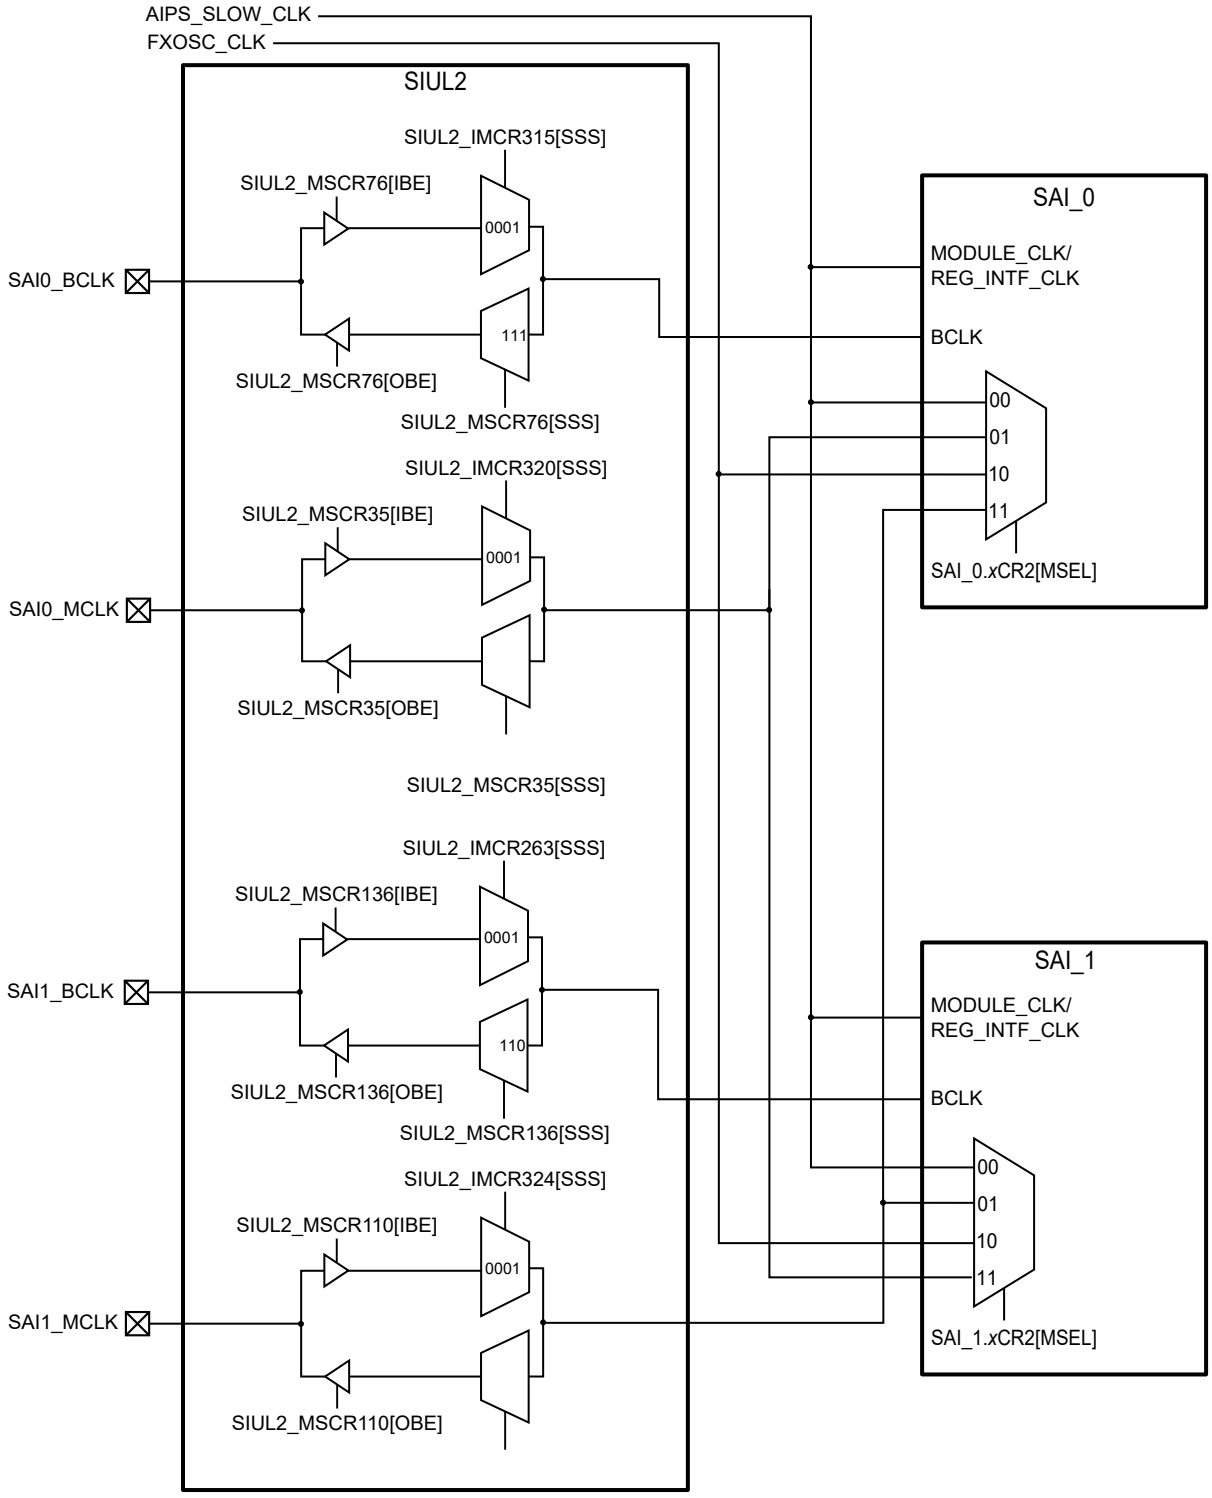

Figure 70. SAI_*n* clocking

NOTE

- See Feature comparison for details on this module's availability on your chip variant.
- For MC_CGM input sources for different variants, see clocking diagram in 'Clocking Overview' section in 'Clocking' chapter

Table 109. SIUL2 options for SAI_*n*

Source	Destination	Port	MSCR *a*	MSCR fields			IMCR *b*	IMCR[SSS]
				OBE	IBE	SSS		
SAI0_MCLK	SAI_0.*x*CR2[MSEL] = 01b SAI_1.*x*CR2[MSEL] = 11b	PTB3	35	0	1	X	320	0001b
				—	—	Not available		X
SAI1_MCLK	SAI_0.*x*CR2[MSEL] = 11b SAI_1.*x*CR2[MSEL] = 01b	PTD14	110	0	1	X	324	0001b
				1	0	Not available		X
SAI0_BCLK	SAI0 BCLK	PTC12	76	0	1	X	315	0001b
SAI0 BCLK	SAI0_BCLK			1	0	111b		X
SAI1_BCLK	SAI1 BCLK	PTE8	136	0	1	X	322	0001b
SAI1 BCLK	SAI1_BCLK			1	0	110b		X

Internally generated MCLK is not supported on the MWCT2xxxS chip family.

23.6.1.2 System modules

Figure 71 shows the REG_INTF_CLK and MODULE_CLK connections, and Table 110 shows the REG_INTF_CLK and MODULE_CLK signals used by these modules. Any module diagram that does not explicitly show a REG_INTF_CLK uses the same source for REG_INTF_CLK as used by MODULE_CLK.

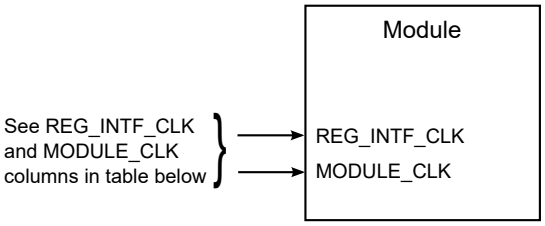

Figure 71. System module clocks

TSPC	AIPS_SLOW_CLK	

23.6.1.8.1 ADC_*n* clocking

The following figure shows ADC_*n* clocking configuration.

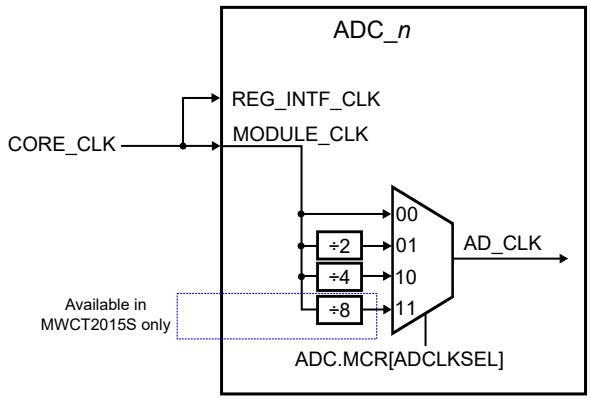

Figure 88. ADC_*n* clocking

NOTE

- See Feature comparison for details on this module's availability on your chip variant.
- For MC_CGM input sources for different variants, see clocking diagram in 'Clocking Overview' section in 'Clocking' chapter

The prescaler can be bypassed when using FIRC_CLK as the source (see MC_CGM mux 0 clocks for FIRC_CLK use details). The prescaler must be controlled such that the AD_CLK frequency is less than or equal to 120 MHz for MWCT2016S/MWCT2015S. For other MWCT2xxxS products the frequency is 80 MHz.

The minimum operating speed of AD_CLK is 6 MHz using the following configuration:

1. Use FIRC_CLK (48 MHz) as clock source (MC_CGM.MUX_0_CSC[SELCTL] equal to 0000b).
2. Divide FIRC_CLK by 2 for CORE_CLK speed (MC_CGM.MUX_0_DC_0[DIV] equal to 1 (FIRC_CLK divide by 2 = 24 MHz)).
3. Write ADC.MCR[ADCCLKSEL] equal to 10b to divide the FIRC_CLK further by 4 (AD_CLK = 6 MHz).

However, at this lower speed, the ADC_*n* results will be degraded.

23.6.1.8.2 eMIOS_*n* clocking

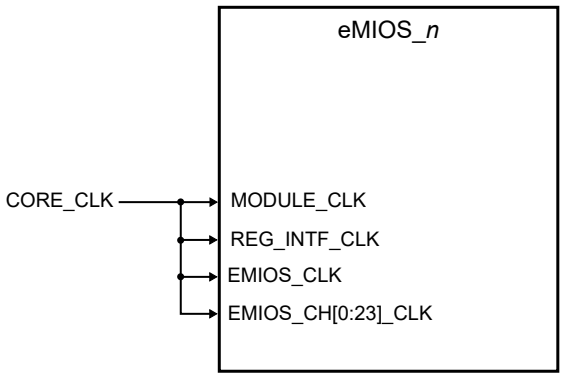

Figure 89. eMIOS_*n* clocking

NOTE

- See Feature comparison for details on this module's availability on your chip variant.
- For MC_CGM input sources for different variants, see clocking diagram in 'Clocking Overview' section in 'Clocking' chapter

23.6.1.8.3 BCTU clocking

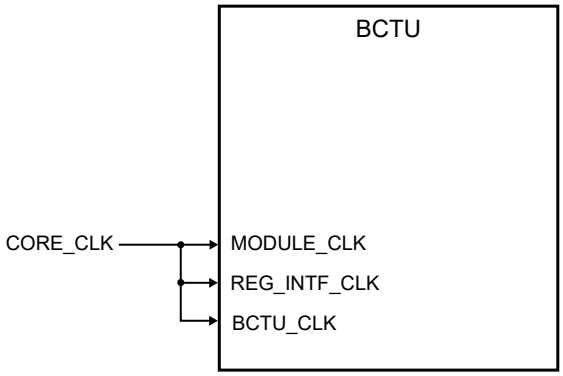

Figure 90. BCTU clocking

23.6.1.9 Timer modules

Figure 91 shows the REG_INTF_CLK and MODULE_CLK connections, and Table 117 shows the REG_INTF_CLK and MODULE_CLK signals used by these modules. Any module diagram that does not explicitly show a REG_INTF_CLK uses the same source for REG_INTF_CLK as used by MODULE_CLK.

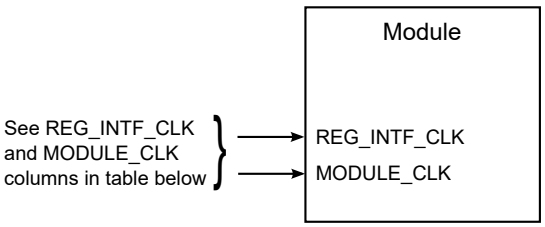

Figure 91. Timer module clocks

Table 117. Timer module clocking

5. See the section Clocks in the "Low Power Serial Peripheral Interface (LPSPI)" chapter.
6. See the section SAI clocking in the "Synchronous Audio Interface (SAI)" chapter and SAI_*n* clocking for details.
7. At least one pair of LPUART instances (LPUART0 and LPUART1) support up to 12 Mbps.
8. See the section Application Information and FlexIO instances and configuration in the "Flexible I/O (FlexIO)" chapter and FlexIO clocking for baud configuration details.

23.6.3 Core and peripheral clock control

The chip provides provisions for core and peripheral clock gating. The next sections describe the details on clock gating possibilities and controls (see Power Management Controller (PMC) and Mode Entry Module (MC_ME) for details).

23.6.3.1 Clock gating

Application core clocks are gated by individual MC_ME core clock enable bits. Additionally, application cores can be clock gated by executing WFI (see the "Mode Entry Module (MC_ME)" chapter for details).

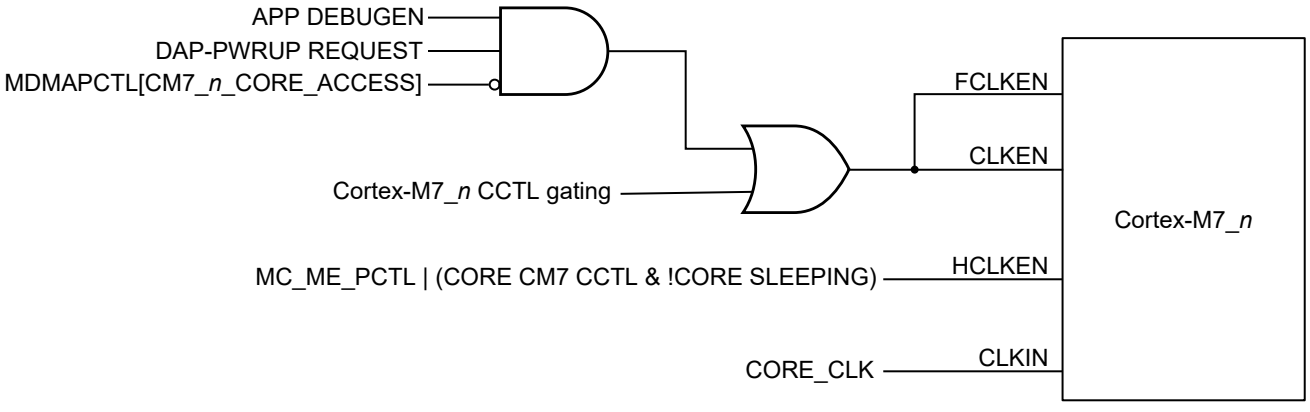

Figure 101. Cortex-M7 core clock gating

To support core debug across functional reset, challenge response done (application debug enable) gating is done so that the debugger can access core debug logic. When the debugger completes its programming with core debug logic, it must program the MDM_AP DAP control bit to shift the control of CLKIN and FCLK to CCTL.

There are two cases in which other masters can access the TCM of each core:

- When the TCM is used as system memory—HCLK will always remain on if TCM PCTL is 1.

- In applications where TCM is not used as system memory, TCM PCTL is written to 0. TCM will then function as the core's memory and HCLK will be gated on WFI.

See the section "MDM_AP register descriptions" in the Debug Subsystem chapter and the Memory Map chapter for details.

23.6.3.2 Peripheral clock gating

See the tables in section "Peripheral clock gating" for the chip partitions, plus peripheral initialization and shutdown details.

23.7 Clocking details

23.7.1 System clock frequency limitations

Table 124. System clock frequency limitations

System clock node	System clock divider	Maximum frequency allowed	Remarks
CORE_CLK	MC_CGM.MUX_0_DC_0[DIV]	• 160 MHz: MWCT2D17S and MWCT2D16S • 120 MHz: MWCT2015S and MWCT2016S	CORE_CLK is always greater than or equal to AIPS_PLAT_CLK.
AIPS_PLAT_CLK	MC_CGM.MUX_0_DC_1[DIV]	• 80 MHz: MWCT2D17S and MWCT2D16S • 60 MHz: MWCT2015S and MWCT2016S	AIPS_PLAT_CLK is always less than or equal to CORE_CLK.
AIPS_SLOW_CLK	MC_CGM.MUX_0_DC_2[DIV]	• 40 MHz: MWCT2D17S and MWCT2D16S • 30 MHz: MWCT2015S and MWCT2016S	AIPS_SLOW_CLK is always less than or equal to AIPS_PLAT_CLK.
HSE_CLK	MC_CGM.MUX_0_DC_3[DIV]	• 120 MHz	When CORE_CLK is equal to or less than 120 MHz, HSE_CLK can be equal to CORE_CLK. When CORE_CLK is higher than 120 MHz, HSE_CLK must be half of the CORE_CLK.
DCM_CLK	MC_CGM.MUX_0_DC_4[DIV]	• 48 MHz	DCM_CLK
LBIST_CLK	MC_CGM.MUX_0_DC_5[DIV]	• 48 MHz: MWCT2D17S, MWCT2D16S,MWCT2015S, and MWCT2016S	LBIST clock
QSPI_MEM_CLK	MC_CGM.MUX_0_DC_6[DIV]	• 160 MHz	QSPI_MEM_CLK is always equal to CORE_CLK except in 1:1 mode (see Option F - Operation in 1:1 mode with CORE_CLK and AXBS_CLK at same speed).

NOTE

The chip supports 1:1 clocking mode, whereby the core(s) are clocked at the same frequency as the slave ports (flash memory, PRAM controller, AIPS controller). Option F - Operation in 1:1 mode with CORE_CLK and AXBS_CLK at same speed supports this requirement.

The frequencies in the table above are maximum frequencies for a specific clock. However, any clock frequency selected must adhere to the same clock divider ratios shown in Clocking use case examples.

23.7.2 Clocking use case examples

The chip supports the clocking modes shown in the subsequent sections, as follows:

- Option A - High Performance mode (CORE_CLK @ 160 MHz) (only available in Run mode)
- Option B - Reduced Speed mode (CORE_CLK @ 120 MHz) (only available in Run mode)
- Option C - Boot Standby mode (CORE_CLK @ 24 MHz)
- Option D - Low-Speed RUN mode (CORE_CLK @ 48 MHz)
- Option E - Low-Speed Run mode (CORE_CLK @ 3 MHz)
- Option E2 - Very-Low-Speed Run mode (CORE_CLK @ 750 kHz)
- Option F - Operation in 1:1 mode with CORE_CLK and AXBS_CLK at same speed (only available in Run mode)

The following list are requirements when configuring the clocking system.

- Configure PRAM/SRAM wait states and flash memory read/write wait cycles in clock configurations where CORE_CLK equals AIPS_PLAT_CLK. See "Option B" in Gasket configurations in various clocking modes for PRAM/SRAM wait states and gasket configurations for clocking options.
- Enable PLL_PHI*n*_CLK only if using it as the system clock source.
- Disable PLL_PHI*n*_CLK when using FIRC_CLK as the system clock, you must.
- Configure the PMC last mile regulator before enabling the PLL. Configure PMC.CONFIG[LMEN] and PMC.CONFIG[LMBCTLEN] (if using an external BJT) to enable the last mile regulator.
- Disable the PLL before disabling the last mile regulator (see PMC last-mile regulator auto-enable feature for last mile regulator details).

23.7.2.1 Option A - High Performance mode (CORE_CLK @ 160 MHz)

Table 125. Option A - High Performance mode (CORE_CLK @ 160 MHz)

Clocking options	Clock frequencies	
	MWCT2D17S and MWCT2D16S [1]	
PLL VCO frequency	960 MHz

LBIST_CLK (MC_CGM.MUX_0_DC_5[DIV])	30 MHz (011b)		30 MHz (011b)	

1. MC_CGM.MUX_10_CSC[SELCTL] and MC_CGM.MUX_11_CSC[SELCTL] must equal 1001b.
2. Do not use the combination of different frequencies mentioned below across the 2x2 matrix. The values shown in each cell are valid and must not be clubbed with the values mentioned in any other cells.
3. MC_CGM.MUX_0_CSC[SELCTL] must equal 1000b.

23.7.2.3 Option C - Boot Standby mode (CORE_CLK @ 24 MHz)

Table 127. Option C - Boot Standby mode (CORE_CLK @ 24 MHz)

Clocking options	Clock frequencies
	MWCT2xxxS
PLL VCO frequency	—
PLLODIV2_CLK (PLLDIG.PLLDV[ODIV2])	—
FIRC_CLK (HSE_B.CONFIG_REG_GPR[FIRC_DIV_SEL])	24 MHz[1] (00b)
PLL_PHI1_CLK-related clocks [2]	
PLL_PHI1_CLK (PLLDIG.PLLODIV_1[DIV])	—
QSPI_SFCK (MC_CGM.MUX_10_DC_0[DIV])	—
TRACE_CLK (MC_CGM.MUX_11_DC_0[DIV])	—

Table continues on the next page...

Table 127. Option C - Boot Standby mode (CORE_CLK @ 24 MHz) (continued)

Clocking options	Clock frequencies
	MWCT2xxxS
PLL_PHI0_CLK-related clocks [3]	
PLL_PHI0_CLK (PLLDIG.PLLODIV_0[DIV])	—
LBIST_CLK (MC_CGM.MUX_0_DC_5[DIV])	—
QSPI_MEM_CLK (MC_CGM.MUX_0_DC_6[DIV])	—
CORE_CLK • Application cores • AXBS • SRAM • Flash memory controller port clock • AIPS0 (high-speed peripheral clock) (MC_CGM.MUX_0_DC_0[DIV])	24 MHz (0000b)
AIPS_PLAT_CLK (medium-speed peripheral clock) (MC_CGM.MUX_0_DC_1[DIV])	24 MHz (0000b)
AIPS_SLOW_CLK (slow-speed peripheral clock) (MC_CGM.MUX_0_DC_2[DIV])	12 MHz (0001b)
DCM_CLK (MC_CGM.MUX_0_DC_4[DIV])	24 MHz (0000b)
HSE_CLK (MC_CGM.MUX_0_DC_3[DIV])	24 MHz (0000b)

1. The FIRC_DIV_SEL is configured by the sBAF code. It is set to 11b after reset or normal standby exit and FIRC_CLK is 48 MHz. In case of fast standby exit, FIRC_DIV_SEL is 00b and FIRC_CLK is 24 MHz.
2. MC_CGM.MUX_10_CSC[SELCTL] and MC_CGM.MUX_11_CSC[SELCTL] values are don't care since QSPI_SFCK and TRACE_CLK are not used in this use case.
3. MC_CGM.MUX_0_CSC[SELCTL] must equal 0.

23.7.2.4 Option D - Low-Speed RUN mode (CORE_CLK @ 48 MHz)

2. See Option C - Boot Standby mode (CORE_CLK @ 24 MHz) for details.
3. See Option D - Low-Speed RUN mode (CORE_CLK @ 48 MHz) for details.
4. See Option E - Low-Speed Run mode (CORE_CLK @ 3 MHz) for details.
5. See Option E2 - Very-Low-Speed Run mode (CORE_CLK @ 750 kHz) for details.
6. See Option F - Operation in 1:1 mode with CORE_CLK and AXBS_CLK at same speed for details.

23.7.4 Default clock configuration

At reset recovery, the chip runs on the FIRC_CLK as the default configuration as shown in Option C - Boot Standby mode (CORE_CLK @ 24 MHz). Clocking configuration Option_C is the default configuration out of reset with the HSE_B core as the boot core. The Cortex-M7_*n* application core clocks are gated by default. You need to enable the core clocks by the configuring the corresponding core clock enable bits shown in Core Clock Gating.

23.7.5 PCFS

The chip supports software-controllable PCFS for MC_CGM MUX_0 (see section "Progressive Clock Frequency Switching (PCFS)" in the "Clock Generation Module (MC_CGM)" chapter for details). PCFS increases and decreases the frequency in steps, avoiding any overshoots or undershoots. When a functional reset event occurs with PCFS enabled, the PCFS process runs and is then followed by the divider configuration updates.

23.7.6 Updating dividers: crossbar halt handshake

The clock divider update process consists of the crossbar halt handshake sequence (see section "Clock dividers update" in the "Clock Generation Module (MC_CGM)" chapter for the clock divider update process). A divider update asserts a request to the crossbar switch to halt any transaction that is in process. The dividers are updated when the crossbar switch acknowledges the request for halt. The halt request disables the crossbar switch gaskets in the following order:

1. Core gaskets (HSE_B gaskets)
2. Crossbar switch (AXBS)
3. Flash AXBS bridge
4. PRAM/SRAM gasket

Dividers are updated after the gaskets acknowledge the halt request.

23.7.7 Changing system clock configurations

Software sequence for switching clock configurations from FIRC to PLL or PLL to PLL:

1. Before changing the system clock dividers or before system clock switching, the communication modules working on the system clock should be disabled by the software to avoid any erroneous communication during the clock transition.
2. The peripherals working on the system clock should be clock-gated used the MC_ME.PRTNx_COFBy_CLKEN configurations. The peripherals working on non-system clocks which are not being switched, can continue to operate.
3. All cores must be clock-gated, except the core being used to control the clock switching.

4. MC_CGM divider configurations can be done to change divider values as described above. The requisite system divider frequency relations must be ensured.
5. Configure MC_CGM_MUX_0_DIV_TRIG_CTRL (enable HHEN and TCTL).
6. Configure MC_CGM_MUX_0_DIV_TRIG.
7. System clock switching can be done by configuration of MC_CGM_MUX_0_CSC[SELCTL]

Software sequence for switching clock configurations from PLL to FIRC clock switching:

1. Before changing the system clock dividers or before system clock switching, the communication modules working on the system clock should be disabled by the software to avoid any erroneous communication during the clock transition.
2. The peripherals working on the system clock should be clock-gated used the MC_ME.PRTNx_COFBy_CLKEN configurations. The peripherals working on non-system clocks which are not being switched, can continue to operate.
3. All cores must be clock-gated, except the core being used to control the clock switching.
4. System clock switching can be done by configuration of MC_CGM_MUX_0_CSC[SELCTL].
5. MC_CGM divider configurations can be done to change divider values as described above. The requisite system divider frequency relations must be ensured.
6. Configure MC_CGM_MUX_0_DIV_TRIG_CTRL (enable HHEN and TCTL).
7. Configure MC_CGM_MUX_0_DIV_TRIG.

NOTE

When enabling PLL, the PMC last mile regulator should be enabled first by configuring PMC_CONFIG[LMEN] and PMC_CONFIG[LMBCTLEN] (if using an external BJT). The last mile regulator must be disabled after PLL is disabled.

23.8 Clock monitoring

The chip contains an independent clock monitoring mechanism which signals malfunctions in the clocking system. This chip consists of six Clock Monitoring Units (CMU_F*x*_[0:6]) for monitoring system clock and clocking module outputs. Figure 102 and Figure 103 show a lower-level view of the clocking monitoring system. Table 134 describes each CMU instance. Each CMU instance provides an independent interrupt or reset indication when the clock signal is out of range or lost. The CMU_FM_*n* provides a timeout indication in case there is a loss of metered clock. Your software must periodically check the CMU_FM_1 and CMU_FM_2 status within the chip FTTI (as specified in the Safety Manual).

NOTE

You must disable the CMU corresponding to the system clocks if the application changes the system clock source or changes the system clock divider configuration.

You must disable the CMU monitoring a clock source before disabling the clock source, then enable it after enabling the clock source.

The CMUs should be turned ON only after device has moved to PLL source (wherein LMR is ON).

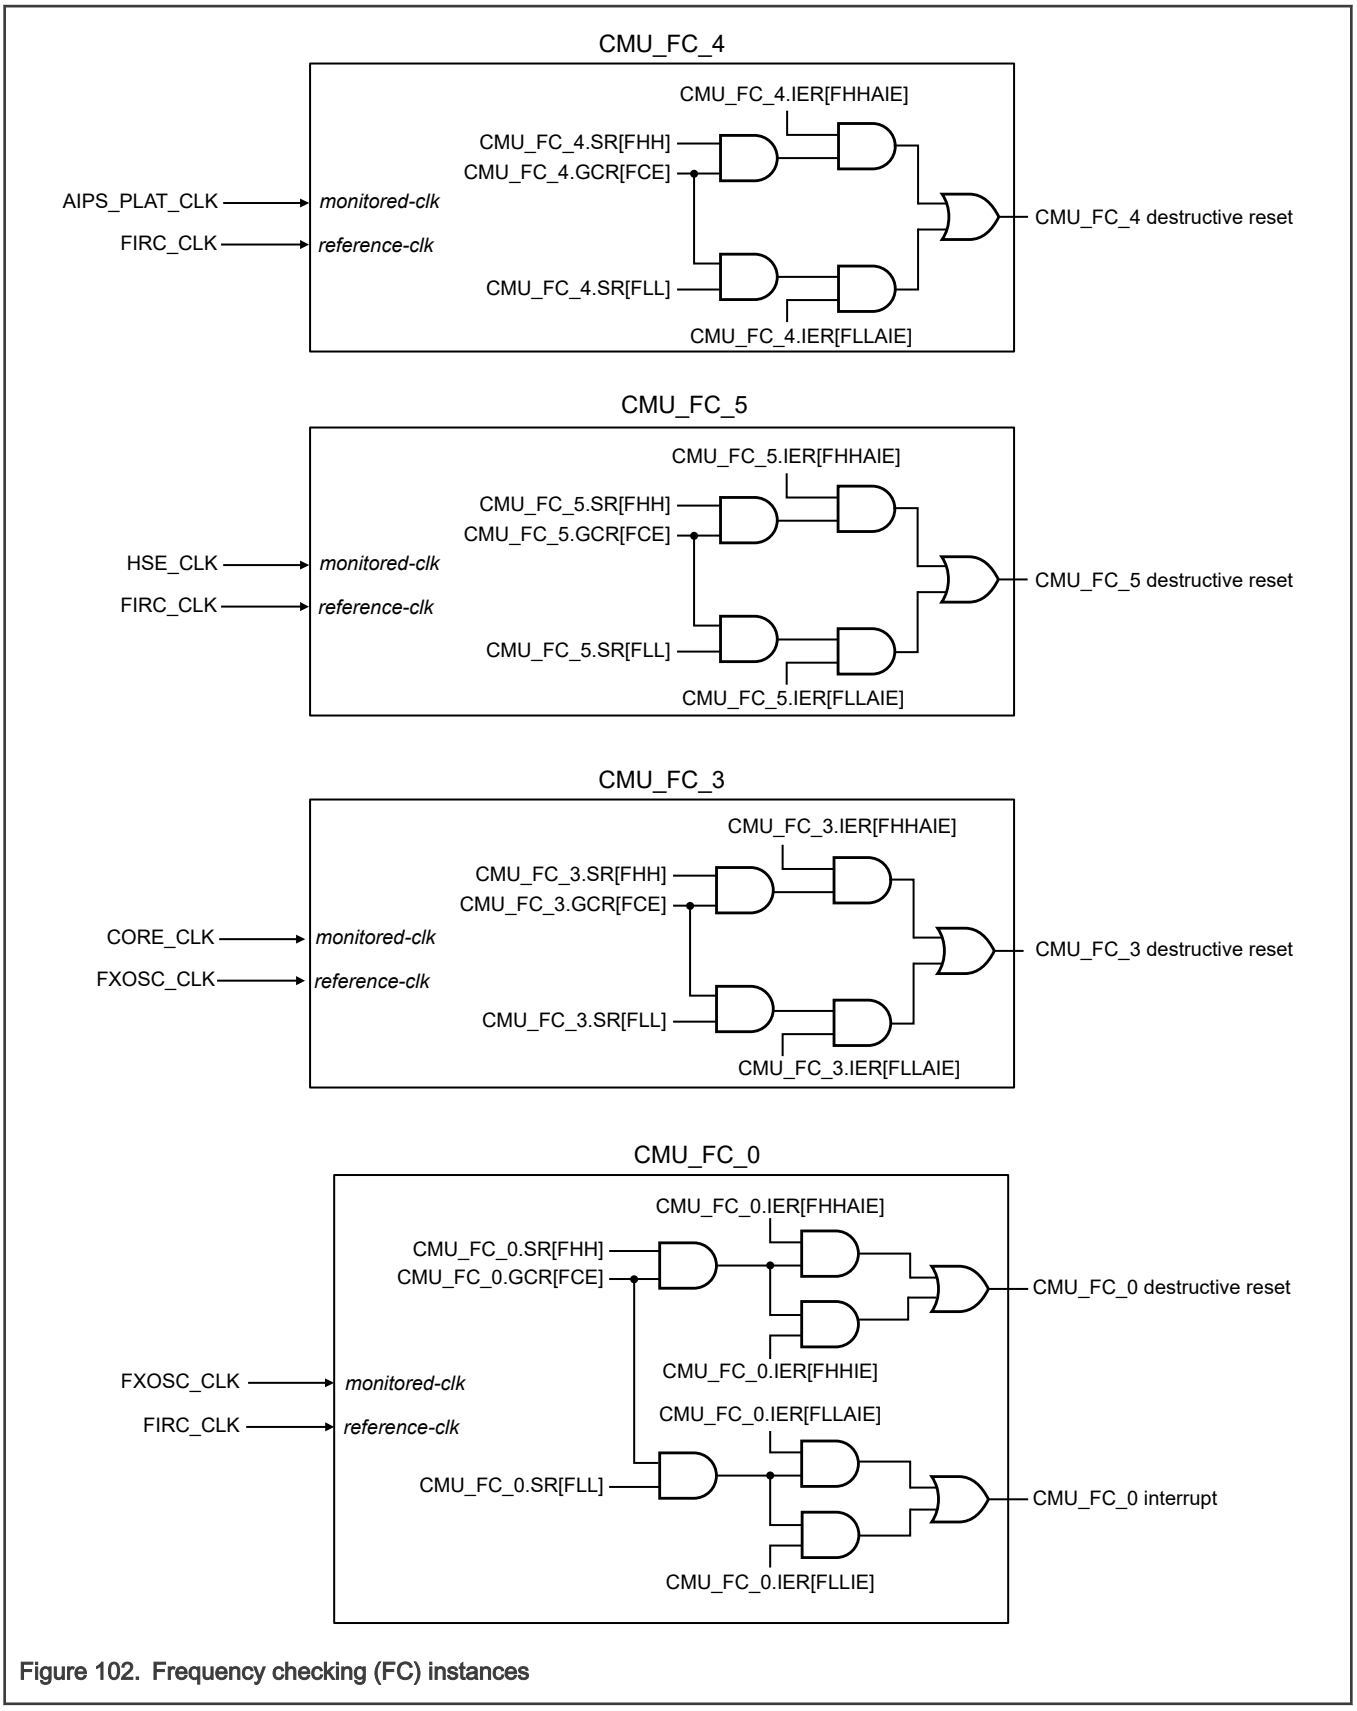

Figure 102. Frequency checking (FC) instances

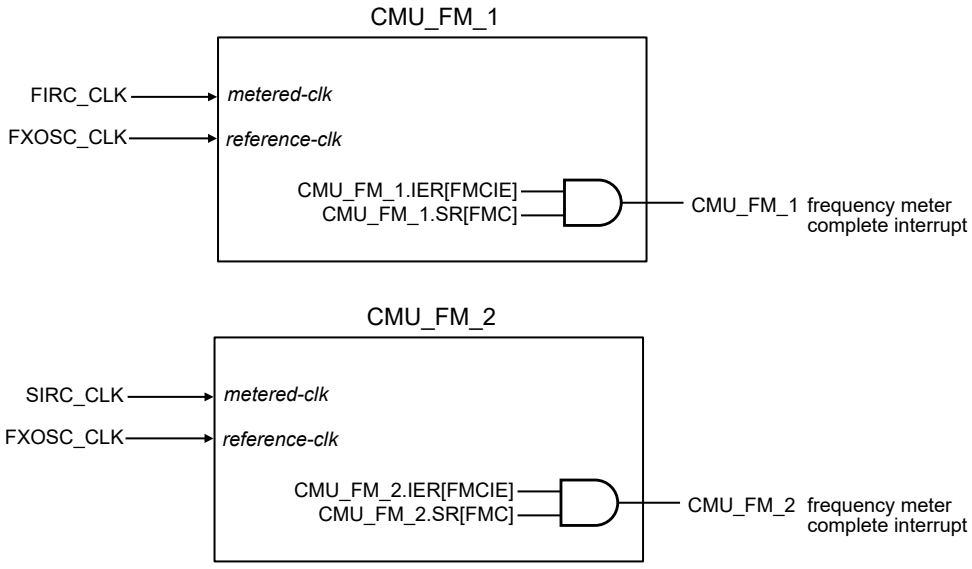

Figure 103. Frequency metering (FM) instances

Table 134. System clock monitors

CMU	Reference clock	Monitored or metered clock	Failure reaction	Monitoring type description
CMU_FC_0	FIRC_CLK	FXOSC_CLK	Destructive reset or interrupt	Precision over and under frequency
CMU_FM_1	FXOSC_CLK	FIRC_CLK	Interrupt	Current frequency measurement periodically triggered by software
CMU_FM_2	FXOSC_CLK	SIRC_CLK	Interrupt	Current frequency measurement periodically triggered by software
CMU_FC_3	FXOSC_CLK	CORE_CLK	Destructive reset	Precision over and under frequency
CMU_FC_4	FIRC_CLK	AIPS_PLAT_CLK	Destructive reset	Precision over and under frequency
CMU_FC_5	FIRC_CLK	HSE_CLK	Destructive reset	Precision over and under frequency

23.9 Glossary

MODULE_CLK	Module operating clock
REG_INTF_CLK	Module register interface clock used for register read and write
PCFS	Progressive Clock Frequency Switching (see section PCFS for details)
POR	Power On Reset
SBC	System Basis Chip (see NXP SBC portfolio)
FLL	Frequency lower than low frequency reference
FHH	Frequency higher than high frequency reference

FTTI	Fault Tolerance Time Interval

Chapter 24
Clock Generation Module (MC_CGM)

24.1 Chip-specific MC_CGM information

24.1.1 Associated content references

See the Clocking chapter for details pertaining to these:

- Chip clocking
- MC_CGM clock source mapping (see the "MC_CGM clock sources mapping" section for this)
- MC_CGM clock multiplexers (see the "MC_CGM clock multiplexers" section for this)

CAUTION

MC_CGM clock multiplexer configurations to non-supported and reserved clock sources are prohibited and can result in chip malfunctioning.

24.2 Introduction

The clock generation module (MC_CGM) is used to set up the configurable clock domains used by various chip blocks as per the application needs. It includes the clock multiplexers that allow software to select the desired clock sources for these domains. This is managed by the MC_CGM to ensure that the changing of the clock selection from one source to another occurs in a glitch-less fashion. In addition, the MC_CGM includes the clock dividers that can be configured by software.

See following figure for the MC_CGM block diagram:

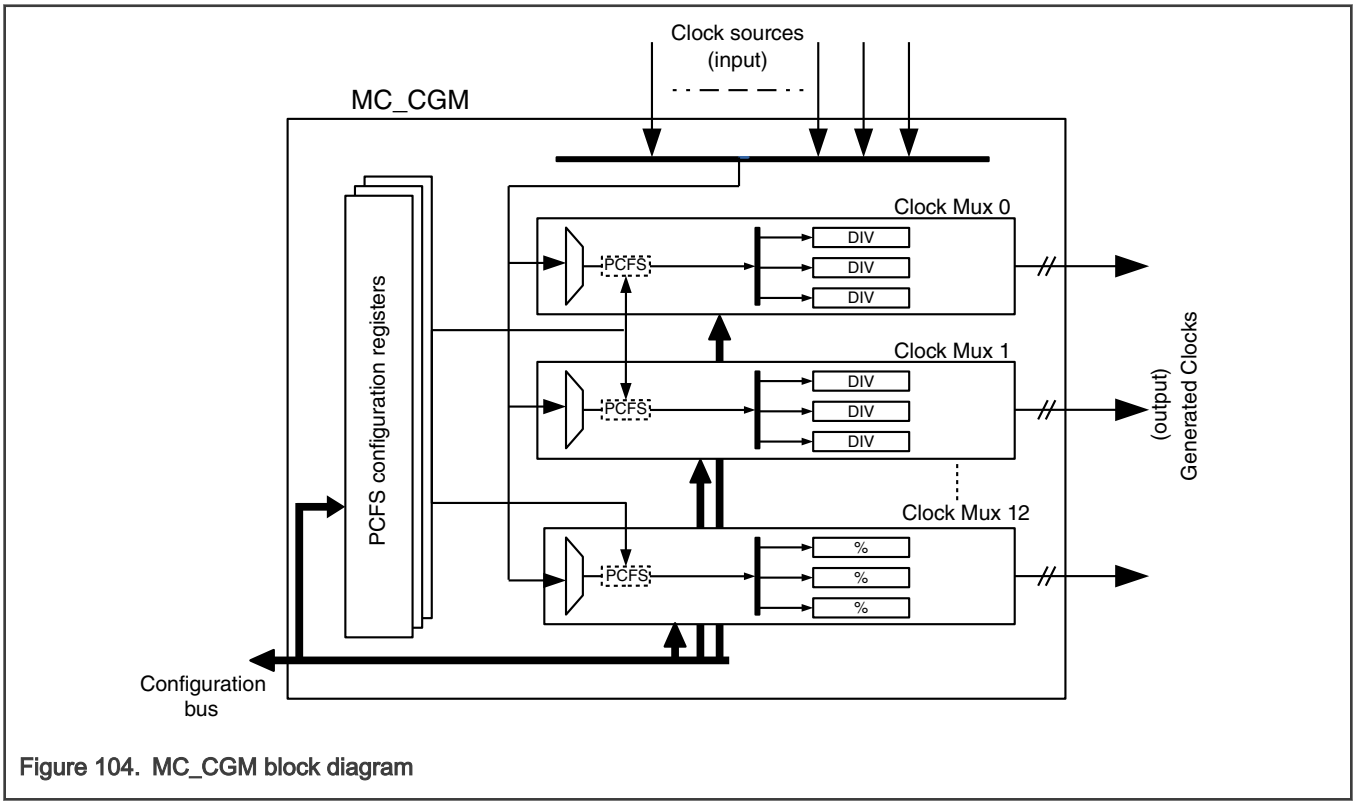

Figure 104. MC_CGM block diagram

NOTE

The block diagram is generic and does not necessarily reflect any specific MC_CGM implementation.

24.3 Features

MC_CGM includes the following features:

- Implements software configurable clock multiplexers for selecting from various clock sources
- Provides hardware-controlled multiplexers that guarantee glitchless transition, while the software-controlled multiplexers need a software sequence to ensure such a transition
- Provides software configurable automatic PCFS on certain clocks to minimize the impact of a sudden power consumption change through a gentle ramp-down and -up of the clock frequency when switching clock sources
- Implements software configurable clock dividers

24.4 Functional description

24.4.1 Clock selection multiplexer

Each of the clock multiplexers inside the MC_CGM either implements a fully hardware-controlled clock multiplexer or a software-controlled clock multiplexer. The following sections describe the two variants of the clock multiplexer.

24.4.1.1 Hardware-controlled clock multiplexer

In hardware-based clock multiplexing, the underlying assumption is that under some conditions, error or reset states, software may not be active. Therefore, the clock switching is fully hardware based and is glitchless. To facilitate clock switching requests with software, the MUX_n_CSC and MUX_n_CSS registers implement request and status for the clock multiplexer, the rest is managed in hardware. Using these registers, the software can monitor the state of the hardware-based clock multiplexer and also make clock switching requests. It is recommended that a new clock switch request is given only when there are no pending/ongoing clock switching requests. However, a switch to the safe clock, that is, FIRC, can be performed at any instance of time. A switch to the safe clock is always completed. Software should ensure that while making a software-based switch to safe clock, the register configuration clock should be available, at least for completing the write to the MUX_n_CSC register. This means that the clock should be running for the register write to complete. Hardware clock multiplexer also supports hardware-based switch to safe clock, which is requested externally to MC_CGM (for example, by MC_RGM). For a hardware-based switch to safe clock, it is not required to have a register configuration clock for MC_CGM.

NOTE

- "Switch to safe clock" from software is requested by programming the MUX_n_CSC[SAFE_SW] bit field only and not by combining the MUX_n_CSC[CLK_SW] and MUX_n_CSC[SELCTL] bit fields of the MUX_n_CSC register. Writes to other fields are ignored when requesting switch for safe clock.
- After the switch to the safe clock requested by the MC_RGM has completed, the MC_RGM also requests the clock dividers to switch to their default values. This hardware-triggered divider update can be monitored in the same manner as for software-configured updates, and software should use it to ensure that the configuration update has completed before reconfiguring the clocks.
- Write accesses to the MUX_n_CSC register with clock select pointing to the "reserved" input clock source are aborted with bus transfer errors.

See Figure 105 that shows the flowchart representation for the sequence of steps to be followed when making a clock switch request to hardware-controlled clock multiplexer. Switch to safe clock can be requested at any instance of time, and for clarity reasons, it is not shown in Figure 105.

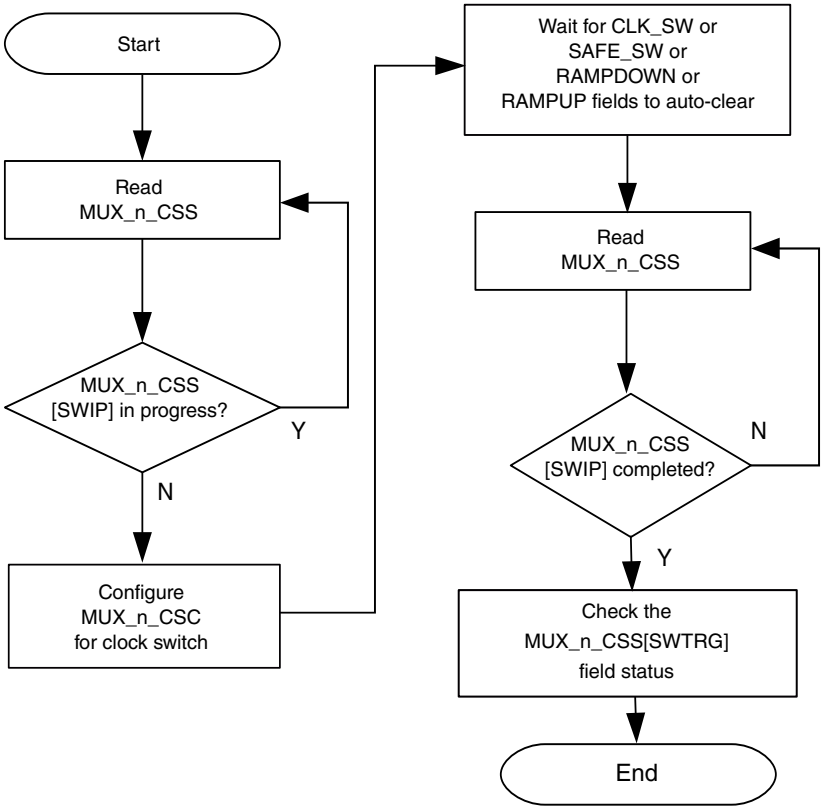

Figure 105. Flow for clock switch request on hardware-controlled clock multiplexer

NOTE

- A switch to the safe clock command always leads to a ramp-down from the currently selected clock and then a switch to "safe clock", except when there is an ongoing clock switch requested by the software without ramp-up and ramp-down. A safe clock switch request when there is an ongoing clock switch without ramp-up or ramp-down results in a switch to the safe clock without performing a ramp-down (either by MC_RGM or provided using the MUX_n_CSC register) does not perform a ramp-down before switching to "safe clock".
- The above flowchart steps can be preceded by points 1 and 3 below:
  1. Disable the divider.
  2. Switch clocks through hardware multiplexer.
  3. Enable and configure the dividers (atomic write instruction).

24.4.1.2 Software-controlled clock multiplexer

In software-based clock multiplexing, the underlying assumption is that the software is always available and there are no error or reset conditions in the chip. This implies that a glitchless switch between input clock sources of MC_CGM MUX can be achieved by following a sequence of steps in software. The software-based clock multiplexer implements a clock gate at the output of the clock mux. The software can gate the selected clock of MC_CGM MUX using a synchronous/graceful clock gate bit (that is, MUX_n_CSC[CG]) or a forced clock gate bit (that is, MUX_n_CSC[FCG]). The hardware does not guarantee that any glitches will escape when using forced clock gating. When a forced clock gate bit is written to 1, the internal clock gate forcefully gates the selected clock to logic-0, therefore, to avoid clock glitches, it should be ensured that the selected clock source is not running. See Figure 106 that shows the flowchart representation for the sequence of steps to be followed when making a clock switch request to software-controlled clock multiplexer. No switch to safe clock is supported in software-controlled clock multiplexer.

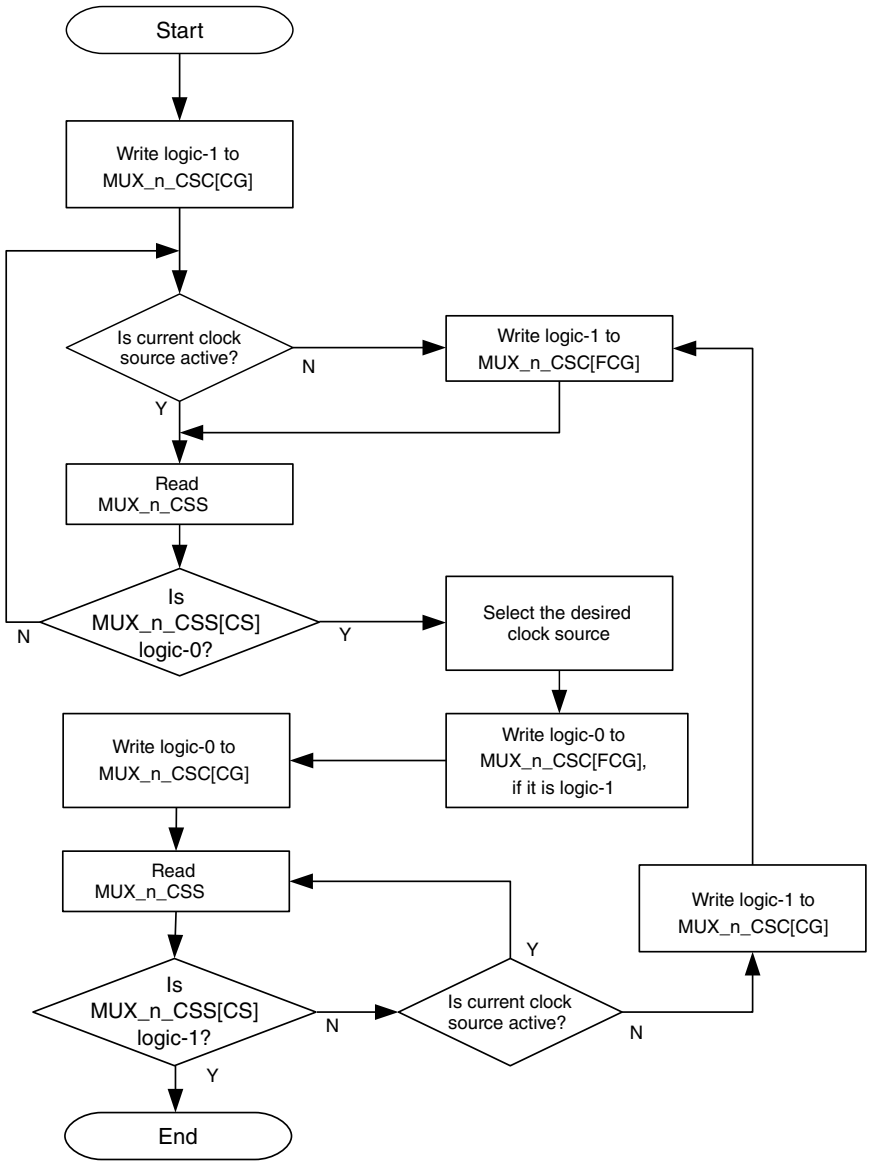

Figure 106. Flow for clock switch request on software controlled clock multiplexer

NOTE

- Ensure that before using the force gate bit, any IP or other logic using the clock of MC_CGM MUX is in the inactive state or a clock glitch resulting from usage of forced gating does not effect the IP (that is, it is clock gated after the MC_CGM).
- In Figure 106, the clock source to be selected should be active at the time of clock switch, else the MUX_n_CSS[CS] field will remain set to logic-0. In case the clock source to be selected becomes inactive (that is, loss of clock, and so on) during the switching operation, the switch to another clock source can be initiated by writing both the MUX_n_CSC[CG] and MUX_n_CSC[FCG] fields to logic-1.
- Writing a 'reserved' value for the MUX_n_CSC[SELCTL] field may result in an unpredictable clock at the output of the clock multiplexer.

NOTE

The above flowchart steps can be preceded by points 1 and 3 below:

1. Disable the divider.
2. Switch clocks through software multiplexer.
3. Enable and configure the dividers (atomic write instruction).

24.4.2 PCFS

MC_CGM implements PCFS when changing clock source at an MC_CGM clock mux. The PCFS is only implemented in a hardware-controlled clock multiplexer and not in a software-controlled clock multiplexer. It allows a gradual load change for a power/voltage supply unit by employing a gradual frequency changeover from one to another. The frequency changeover is achieved by clock division of input clock source with a sequence of division values, where frequency ramp down and ramp up is achieved when the sequence of division values are ascending and descending in nature, respectively. As the clock division (fractional) is implemented in digital logic, therefore, it is a coarse-level clock division rather than being an accurate-level division, implying that the duty cycle of the progressively divided clock can vary with time.

The PCFS feature is utilized when a drain current to frequency relationship is known, that is, for a given drain current what is the maximum allowed change in frequency (f_{chg}). The f_{chg} is the first input parameter for PCFS and other parameters for PCFS are specified or calculated in relation to FIRC.

The PCFS hardware generates the clock division factors based on certain values that are programmed into the PCFS configuration register. The following pseudo codes represent the generation of clock division value sequence (d_i).

```
/* ramp down division values (d_n) with k steps*/
      delta_1 = RATE/1000;
      delta_2 = RATE/1000;
      d_0     = 1.0;
      for i=1 to k-1 do
        d_i = d_i-1 + delta_1;
        delta_1 = delta_1 + delta_2;
      endfor
```

```
/* ramp up division values (d_n) with k steps*/
      delta_1 = RATE*k/1000;
      delta_2 = RATE/1000;
      d_0     = 1.0 + RATE*k*(k+1)/2;
      for i=1 to k-1 do
        d_i = d_i-1 - delta_1;
        delta_1 = delta_1 - delta_2;
    endfor
```

As the generation of clock division values is not a closed-bounded function, calculating RATE for a given f_{chg} is an iterative process. Find a value of RATE that produces a clock division sequence, which when used does not lead to a frequency change greater than f_{chg}. See Table 135 that tabulates some of the RATE values against a_{max}, where

$$a_{max}=f_{chg}/F_i$$

where, F_i is the frequency of i^{th} input clock source of the clock mux.

Table 135. PCFS RATE values

a_{max}	PCFS rate
0.005	12
0.01	48

Table continues on the next page...

Table 135. PCFS RATE values (continued)

a_{max}	PCFS rate
0.15	112
0.20	184

The last clock division factor in case of ramp-down or the first clock in case of ramp-up (following a ramp-down procedure), should be such that clock switch from any input clock source to another should be termed as safe, indicating that load changes have sustainable power effects. This frequency level is referred to as "safe frequency", equivalent to frequency of FIRC referred to as "safe clock" with frequency "safe clock frequency" (f_{safe}). The last clock division factor in the sequence of clock division factors happens after "k" steps. The factor k (=steps) is calculated by using the following formula:

```
k = ceil(0.5 + sqrt(0.25 - (2000 * (1 -(Fi/fsafe)) / RATE)))
```

Using the above formula, all the PCFS register configuration values can be calculated for a given frequency of a clock source:

```
PCFS_DIVEi.DIV = (Fi/fsafe)*1000-1;
        PCFS_DIVCi.INIT = RATE * k;
        PCFS_DIVCi.RATE = RATE;
        PCFS_DIVSi.DIV  = 999 + (RATE * k * (k+1)/2);
```

See Figure 107 that shows a graphical representation of the change in frequency, which happens during PCFS ramp-down and ramp-up.

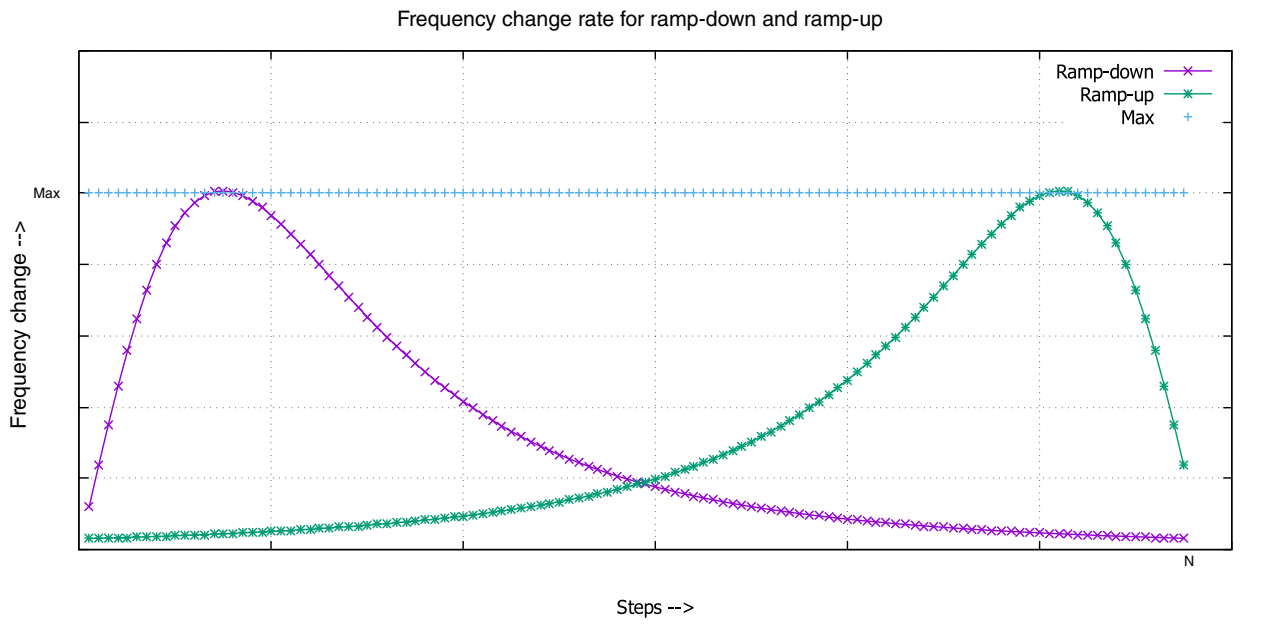

Figure 107. PCFS steps vs frequency changes

For any given clock source, if its frequency is less than that of FIRC, then its corresponding registers should be programmed to default values, where the default values are such that PCFS divider start and PCFS divider end values are same and equal to divide-by-1. The default values ensure that no progressive clock division is done when a clock switch request is given to switch from or to that source.

NOTE

Calculate the minimum frequency during the PCFS RAMPDOWN and RAMPUP operations by using the formula:

```
(FIRC/((PCFS_DIVE+1)/1000)) MHz
```

24.4.2.1 PCFS control

The PCFS operation is configured by a set of configuration registers. One set pertains to the calculation of the clock division factors, which are PCFS_DIVC, PCFS_DIVE, PCFS_DIVS, and PCFS_SDUR, while the registers MUX_n_CSC and MUX_n_CSS implement trigger and status of the PCFS operation. The clock division factors are expected to be programmed before any other MC_CGM operation is initiated and remain unchanged. All the registers corresponding to the clock division factors should be programmed with FIRC as the configuration clock and before doing any clock switch or PCFS operation on any of the MC_CGM mux. It should be noted that the default values of the register corresponding to clock division factors are such that only the clock division factor is calculated by hardware that is divide-by-1. The PCFS operation is always triggered when the safe clock request is generated except when there is an on-going clock switch without ramp-up or ramp-down. Therefore, the software needs to ensure that the PCFS configuration is complete and correct.

While configuring MUX_n_CSC, only valid PCFS and clock switch requests should be provided. PCFS or clock switch requests should only be provided if the PCFS operation is in the idle state. If there is an ongoing PCFS operation, it is recommended not to provide any new PCFS triggers (except switch to safe clock) until the ongoing operation is completed. Switch to safe clock via hardware or by register configuration can be provided at any instance of time and is always completed. Valid combinations of PCFS and clock switches triggers are listed in Table 136. All the PCFS commands should be atomic in nature, which means a single register write should provide complete PCFS sequence to be executed that is ramp-down, clock switch, and ramp-up.

Table 136. Valid PCFS and clock switch requests

PCFS operation state	Command
Idle	Ramp-down, clock switch, and ramp-up
Idle	Clock switch only (without ramp-up or ramp-down)

When a switch to safe clock is provided by writing to MUX_n_CSC, then writes to other register fields are ignored.

24.4.2.2 Clock source powerup and selection

This section provides guidelines for powering up a given clock source and selecting it at the MC_CGM clock multiplexer.

Following is the powerup procedure for a clock source:

1. Configure the parameter, if any.
2. Configure the powerup (or powerdown) control field.
3. Wait for the powerup status indication.

After a powerup indication, the clock source can be selected to provide output clock at an MC_CGM clock multiplexer. A clock-monitoring setup can also be activated on the powered-up clock source.

See Figure 108 that shows a flow chart representation of this sequence.

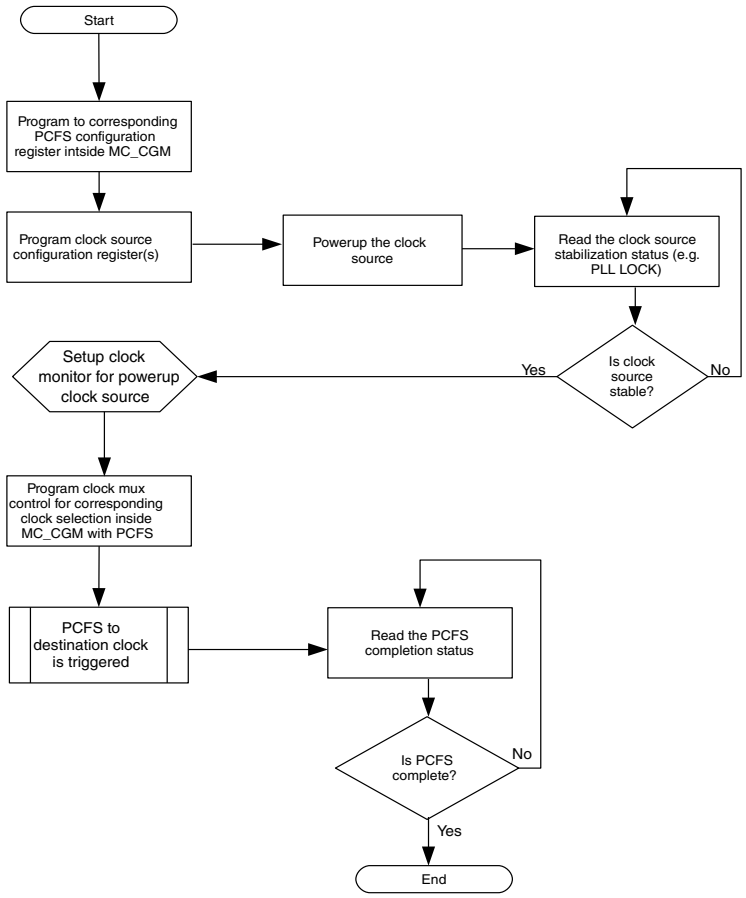

Figure 108. Clock source powerup and selection procedure

24.4.2.3 Clock source powerdown and deselection

This section provides guidelines for powering down a given clock source and deselecting it at MC_CGM clock multiplexer.

Following is the powerdown procedure for a clock source:

1. Deselect the clock source at all MC_CGM clock multiplexers.
2. Configure the powerup (or powerdown) control field.
3. Wait for the powerdown status indication.

See Figure 109 that shows a flow chart representation of this sequence.

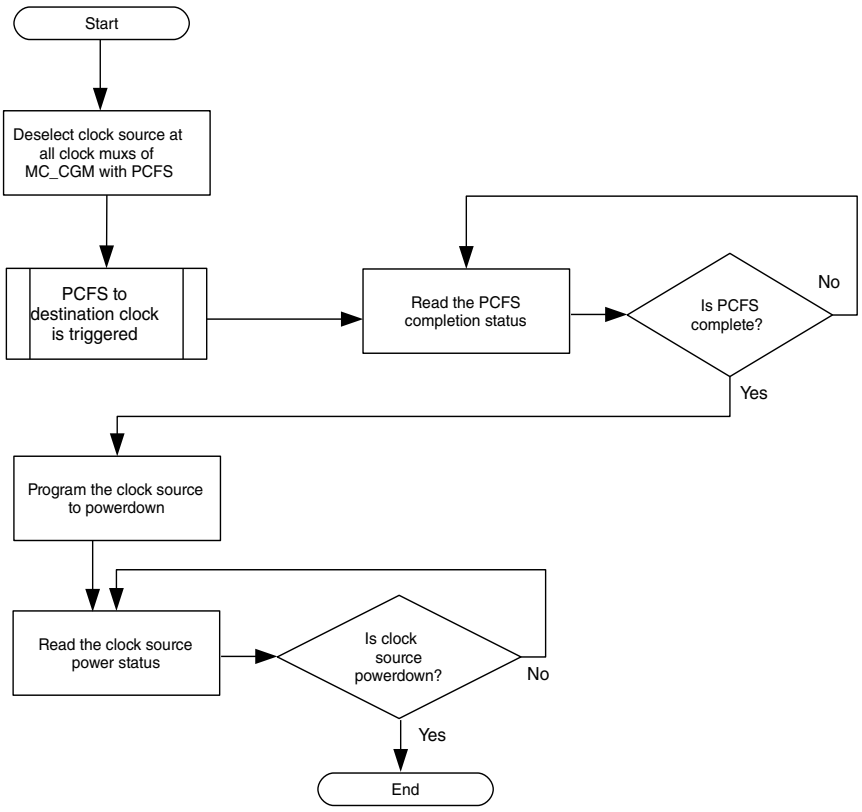

Figure 109. Clock source powerdown and clock source deselection procedure

24.4.2.4 Clock switch with load change

This section provides guidelines to switch between two high-frequency clock sources along with load changes in the system. Load change is referred to switching ON or OFF of logic/peripherals in the system, which has an effect of significant capacitance changes on the chip. This triggers the voltage regulation for the chip.

When a large number of peripherals or digital logic is enabled or disabled, it is recommended that this step should be performed at a low frequency. Independent of whether a clock switch is required, this criteria needs to be met. When a clock switch is required at two high frequencies, the recommended sequence is as follows:

1. Intermediately switch to FIRC.
2. Change load (that is, enable/disable peripherals).
3. Switch to the target clock.

See the following figure that shows a flow chart representation of this sequence.

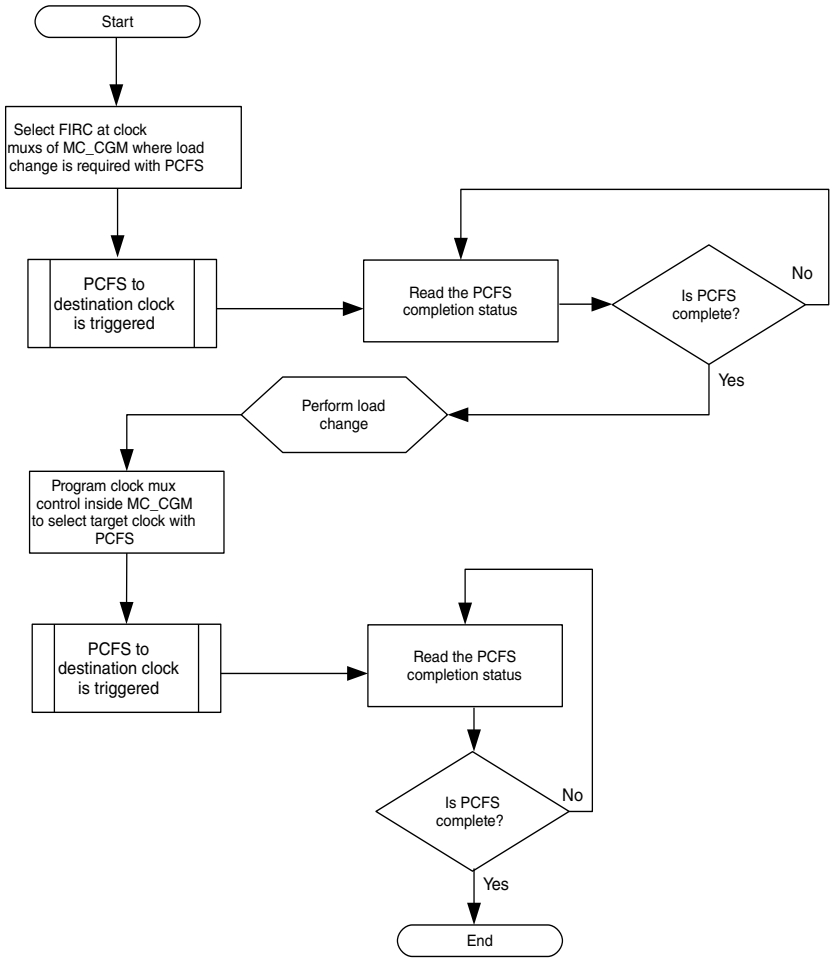

Figure 110. Clock switch with load change procedure

24.4.3 Clock dividers

Clock dividers are used for the generation of a divided clock that is used for running IPs or peripherals. The MC_CGM provides the following built-in dividers at each clock mux:

- 50% clock dividers

Each divider can be controlled by the Divider Enable (DE) bit and the Division Value (DIV) field. If a divider has its DE bit set to logic-0 in the respective configuration register, then that divider is disabled and the output divided clock is held to logic-0. If the DE bit is logic-1, the divider is enabled and provides a divided clock according to the value set in the DIV field.

24.4.3.1 50% clock divider

50% duty cycle dividers generate a real divided clock. The division factor is always an integer but is not restricted to even numbers. The rising edge of the divided clock is always synchronous to the rising edge of the divider source clock, but the falling edge is synchronous to the rising edge or the falling edge depending on whether the division factor is even or odd, respectively. If the input clock has a duty cycle of 50%, the divided output clock maintains the same 50% duty cycle. See Figure 111 that shows the 50% clock divider operation and its associated signals.

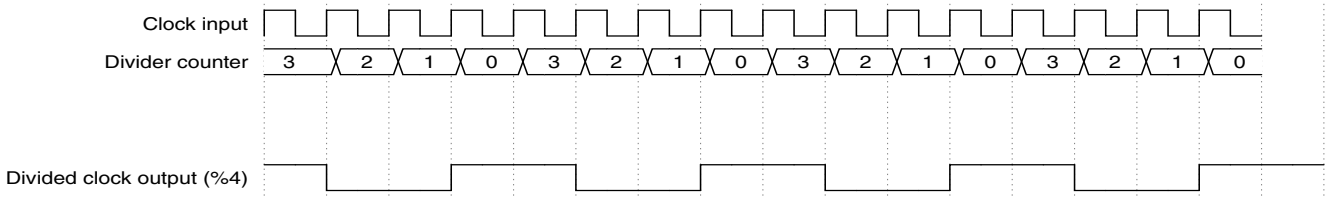

Figure 111. 50% clock divider programmed for divide by 4 (DIV=3)

A 50% divided clock can be considered asynchronous (not edge aligned) to other divided clocks from dividers at the same clock mux. 50% clock dividers are implemented without an active closed loop, and are expected not to get stuck if the input clock glitches for a single cycle.

24.4.3.2 Clock dividers update

To update the division value or the divider enable, the software should follow the procedure as shown in Figure 112. These updates happen only after the current division cycle has elapsed. However, if the phase of the clock divider is updated, the update happens independently from the state of the division cycle. Any update to the clock divider fields does not result in clock glitch either at the divided clock output or the phase-divided clock output.

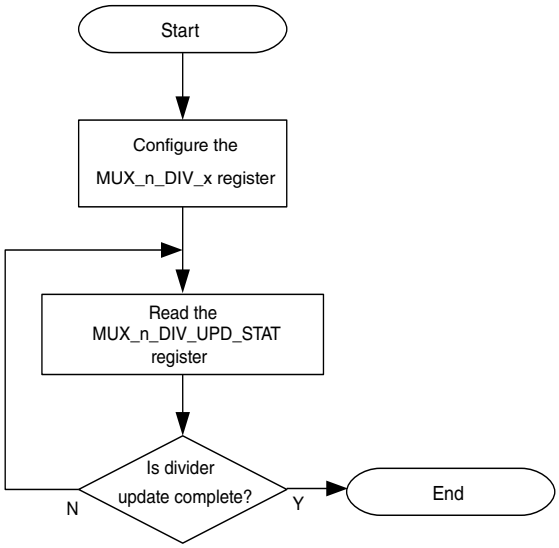

Figure 112. Flow for clock divider programming update

Following is the procedure for updating the dividers using the common trigger update:

1. Configure the MUX_n_DIV_TRIG_CTRL register.
2. Wait for the update to finish (until MUX_n_DIV_UPD_STAT is 0).
3. Update the clock dividers (only 50%) per the divider update procedure.
4. After the divider update is finished, perform a write operation on the MUX_n_DIV_TRIG register.
5. Wait for the update to finish, that is, until MUX_n_DIV_UPD_STAT is 0. During this period, the following process takes place:
   - Halt handshake is initiated if configured in step 1.
   - Clock dividers is updated only when AXBS is halted (that is, halt acknowledgment is received by MC_CGM). It is initiated, else the dividers are updated at alignment.
   - After the clock dividers are updated, MUX_n_DIV_UPD_STAT is asserted to 0.

- When the bit fields MUX_x_DIV_TRIG_CTRL[TCTL] and MUX_x_DIV_TRIG_CTRL[HHEN] are set to 1, then any write operation on trigger register will assert (MUX_n_DIV_UPD_STAT). Once the dividers are updated and aligned (MUX_n_DIV_UPD_STAT) will be deasserted.

NOTE

- The MUX_x_DIV_TRIG_CTRL[HHEN] bit should only be set when MUX_x_DIV_TRIG_CTRL[TCTL] is set, otherwise it may lead to misalignment of the dividers.
- In case of divider initialization by MC_RGM, a halt handshake protocol is initiated if the corresponding register bit is set and the clock dividers are initialized after the halt handshake protocol completion.

6. This completes the divider update.
7. When multiple writes to the dividers of same clock MUX is made without waiting for the previous update status signal to finish may lead to misalignment of the dividers.

For aligned dividers, the LCM of the division values programmed in the dividers of respective clock mux should be less than 100.

NOTE

Performing multiple writes to the divider without waiting for the earlier update to complete can lead to misalignment of the dividers.

Recommended software sequence for ensuring no undivided output at MC_CGM:

1. Reset is de-asserted
2. MC_RGM goes to IDLE
3. Enable the clock dividers of MC_CGM to provide FIRC clock so that reset of fixed dividers can be lifted.
4. Program the MC_CGM as per use case division values.
5. Switch the clock of MC_CGM Mux to desired one, and run the system.

24.5 MC_CGM register descriptions

MC_CGM implements a set of clock multiplexers that share PCFS configuration registers. MC_CGM registers have the following properties:

- All registers are 32-bit wide.
- Only 32-bit read and write accesses are supported.
- Read/write accesses of less than 32 bits terminate with an error.
- Writes to read-only register fields in writable registers are ignored and do not provide an error response.
- Writes to read-only registers are aborted with an error response.

24.5.2 PCFS Step Duration (PCFS_SDUR)

Offset

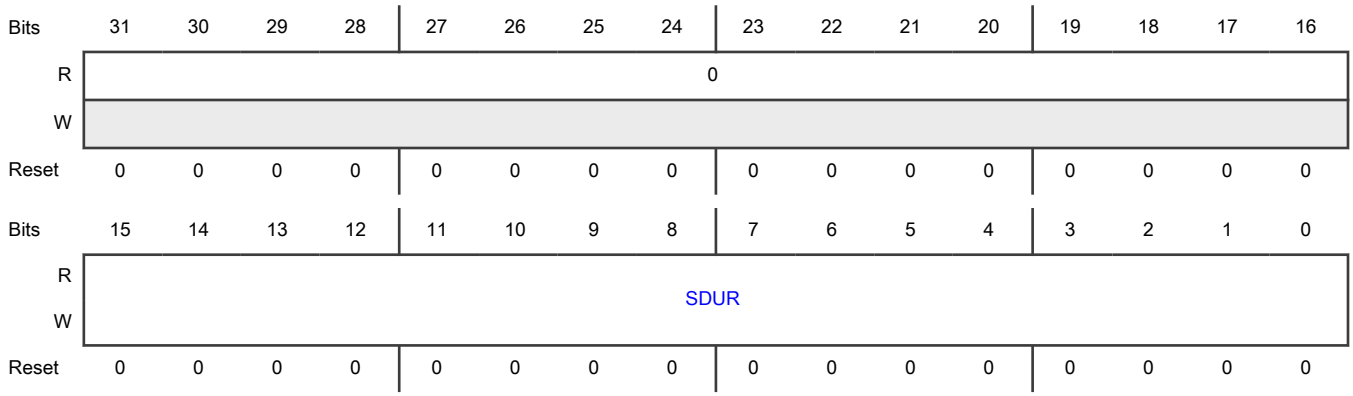
Register	Offset
PCFS_SDUR	0h

Function

This register specifies the step duration of each PCFS step. The value provided in this register specifies the PCFS step duration in terms of the number of cycles of FIRC.

This register is reset only by a destructive reset. For details, see PCFS.

Diagram



Fields

Field	Function
31-16 —	This field is reserved and reads return zeros.
15-0 SDUR	Step duration Count value of the step duration

24.5.3 PCFS Divider Change 8 Register (PCFS_DIVC8)

Offset

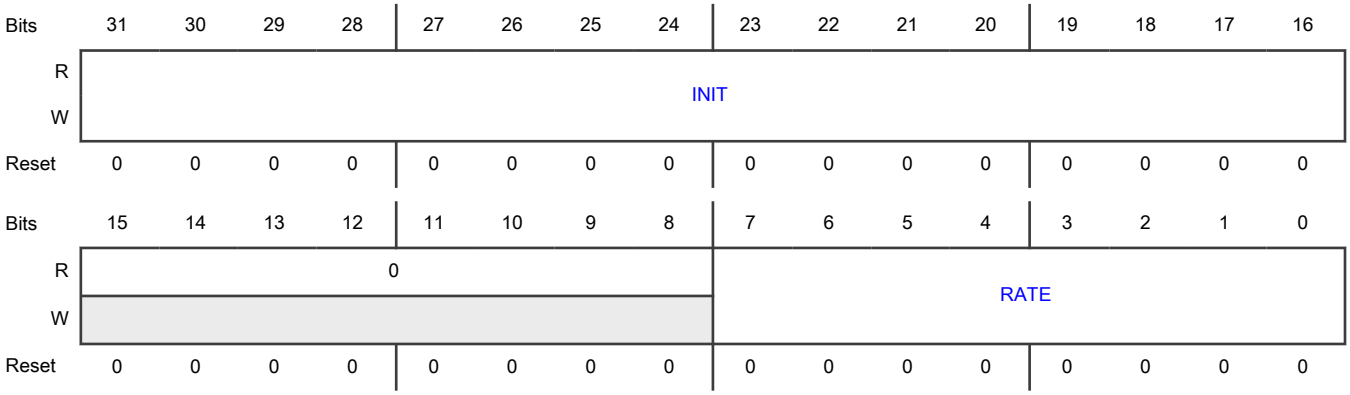
Register	Offset
PCFS_DIVC8	58h

Function

This register defines the rate of frequency change and initial change value on frequency ramp-up for the Progressive Clock Frequency switching of PLL_PHI0_CLK.

This register is reset only on destructive reset.

Diagram



Fields

Field	Function
31-16 INIT	Divider change initial value This field provides the initial change value of the clock divider for the clock ramp-up phase of PLL_PHI0_CLK.
15-8 —	This field is reserved and reads return zeros.
7-0 RATE	Divider change rate This value controls the change value of the clock divider for the clock ramp-up and ramp-down phase of PLL_PHI0_CLK.

24.5.4 PCFS Divider End 8 Register (PCFS_DIVE8)

Offset

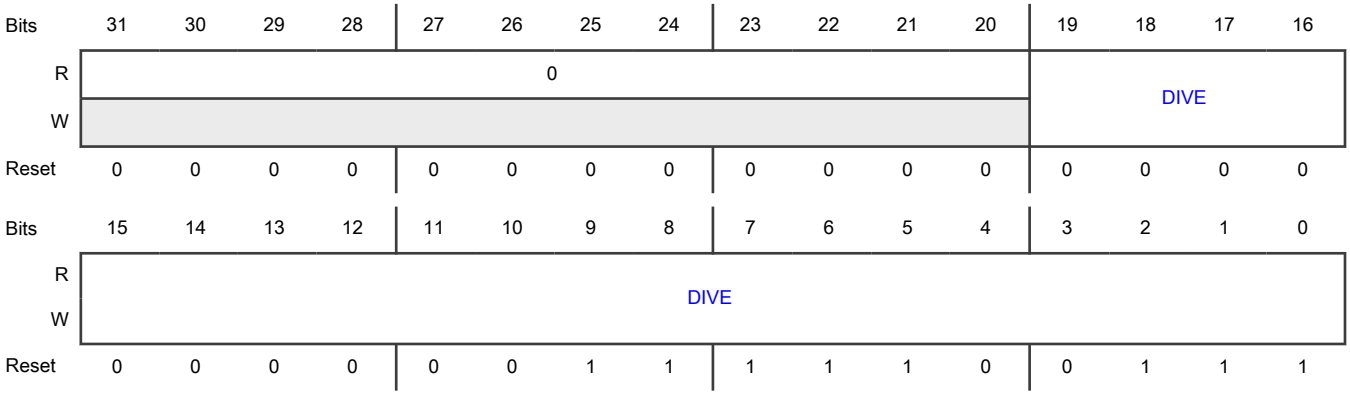
Register	Offset
PCFS_DIVE8	5Ch

Function

This register defines the final division value on frequency ramp-down for the progressive system clock switching of PLL_PHI0_CLK.

This registers is reset only on destructive reset.

Diagram



Fields

Field	Function
31-20 —	This field is reserved and reads return zeros.
19-0 DIVE	Divider end value This field provides the end value of the clock divider for the PLL_PHI0_CLK ramp-down phase.

24.5.5 PCFS Divider Start 8 Register (PCFS_DIVS8)

Offset

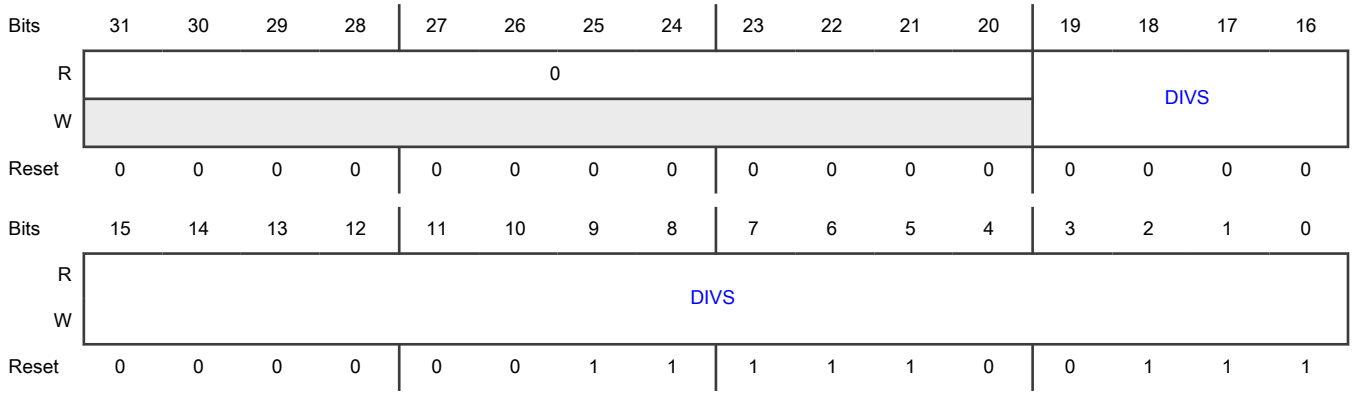
Register	Offset
PCFS_DIVS8	60h

Function

This register defines the initial division value on frequency ramp-up for the progressive system clock switching of PLL_PHI0_CLK.

This register is reset only on destructive reset.

Diagram



Fields

Field	Function
31-20 —	This field is reserved and reads return zeros.
19-0 DIVS	Divider start value This field provides the start value of the clock divider for the PLL_PHI0_CLK ramp-up phase

24.5.6 Clock Mux 0 Select Control Register (MUX_0_CSC)

Offset

Register	Offset
MUX_0_CSC	300h

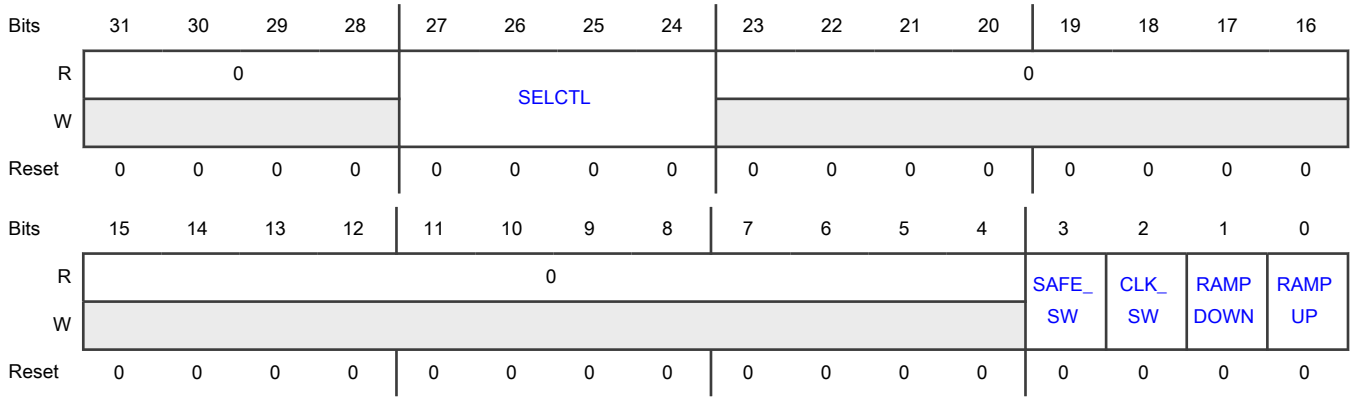
Function

This register provides the clock source selection control for clock mux 0. Clock mux 0 implements hardware control clock switching ensuring that the clock switch happens in a graceful manner (without glitches). See the "Hardware-controlled clock multiplexer" section for details.

This register is reset on destructive reset only.

An update to all the PCFS-related fields of this register must be an atomic write, which means a single write must update the CLK_SW, RAMPDOWN, and RAMPUP fields. It is necessary to set both RAMPUP and RAMPDOWN bits together even if you want to trigger either RAMPUP or RAMPDOWN process otherwise the desired PCFS sequence will not be executed.

Diagram



Fields

Field	Function
31-28 —	This field is reserved and reads return zeros.
27-24 SELCTL	Clock source selection control Selects the source clock for clock mux 0. The reserved values are not displayed. 0000b - FIRC 1000b - PLL_PHI0_CLK
23-4 —	This field is reserved and reads return zeros.
3 SAFE_SW	Safe clock request Writing 1 to this bit makes a safe clock switch request to FIRC. After a safe clock switch operation is requested, this bit is auto cleared and a corresponding bit in the status register is set.
2 CLK_SW	Clock switch Writing 1 to this bit makes a clock switch request to clock mux 0. After a clock switch operation is requested, this bit is auto cleared and a corresponding bit in the status register is set.
1 RAMPDOWN	PCFS ramp-down Writing 1 to this bit makes a PCFS ramp-down request to clock mux 0. After a PCFS ramp-down operation is requested, this bit is auto cleared and a corresponding bit in the status register is set.
0 RAMPUP	PCFS ramp-up Writing 1 to this bit makes a PCFS ramp-up request to clock mux 0. After a PCFS ramp-up operation is requested, this bit is auto cleared and a corresponding bit in the status register is set.

24.5.7 Clock Mux 0 Select Status Register (MUX_0_CSS)

Offset

Register	Offset
MUX_0_CSS	304h

Function

This register provides the current clock source selection status for clock mux 0.

This register is reset on destructive reset only.

Fields

Field	Function
31 DE	Divider enable 0b - Reserved 1b - Divider is enabled.
30-20 —	This field is reserved and reads return zeros.
19-16 DIV	Division value This field provides the division value for the clock divider. The clock period of the clock after division is 'DIV+1' times the time period of the current input clock to the divider.
15-0 —	This field is reserved and reads return zeros.

24.5.11 Clock Mux 0 Divider 3 Control Register (MUX_0_DC_3)

Offset

Register	Offset
MUX_0_DC_3	314h

Function

This register controls the clock divider 3 for clock mux 0.

This divider is a 50% duty cycle divider.

NOTE

The update to the fields of this register should be an atomic write, that is, one single write should update the complete register.

Diagram

2-0 —	Reserved

24.5.14 Clock Mux 0 Divider 6 Control Register (MUX_0_DC_6)

Offset

Register	Offset
MUX_0_DC_6	320h

Function

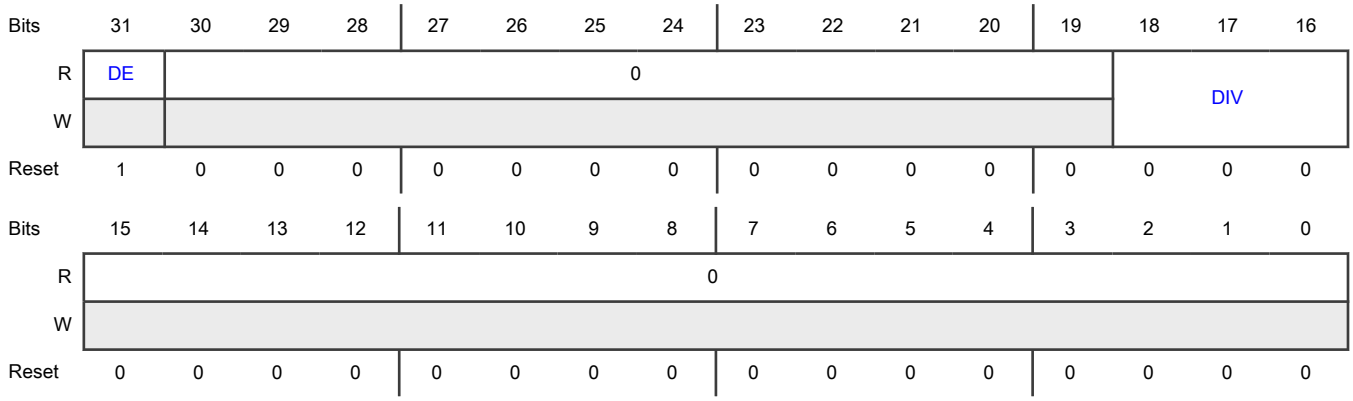
This register controls the clock divider 6 for clock mux 0.

This divider is a 50% duty cycle divider.

NOTE

The update to the fields of this register should be an atomic write, that is, one single write should update the complete register.

Diagram



Fields

Field	Function
31 DE	Divider enable 0b - Reserved 1b - Divider is enabled.
30-19 —	This field is reserved and reads return zeros.
18-16 DIV	Division value This field provides the division value for the clock divider. The clock period of the clock after division is 'DIV+1' times the time period of the current input clock to the divider.
15-0 —	This field is reserved and reads return zeros.

24.5.15 Clock Mux 0 Divider Trigger Control Register (MUX_0_DIV_TRIG_CTRL)

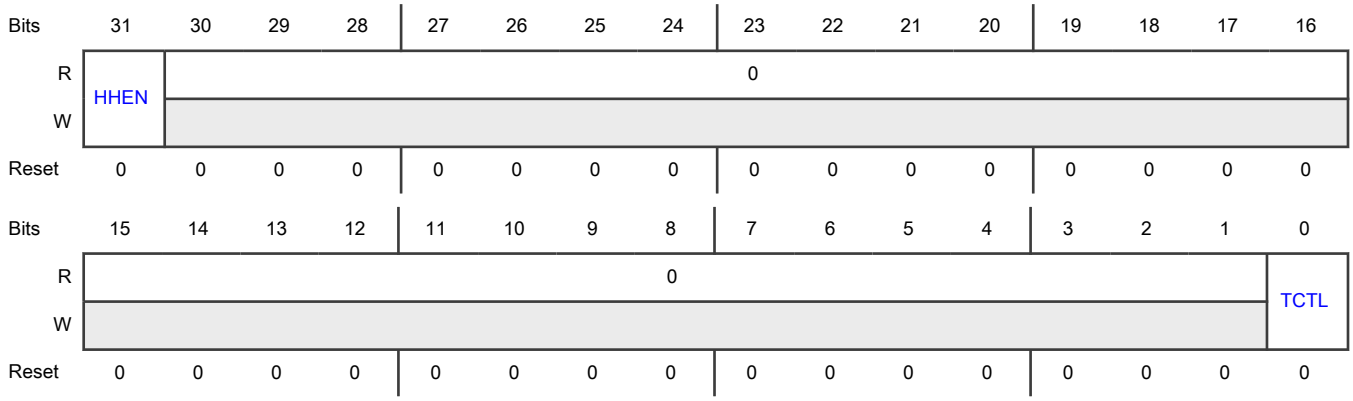
Offset

Register	Offset
MUX_0_DIV_TRIG_CTRL	334h

Function

This register selects whether the dividers associated with clock mux 0 are updated immediately on writing to the corresponding divider configuration register (referred to as immediate divider update) or only on writing to the MC_CGM_MUX_0_DIV_TRIG register (referred to as common trigger update). When common trigger update is configured, this register also controls initiation of the halt handshake protocol with the on-chip AXBS. Software is required to configure HHEN field for handshaking with on-chip AXBS when the ratio of division value among the clock dividers need to be changed.

Diagram



Fields

Field	Function
31 HHEN	Halt handshake enable This field controls the initiation of the halt handshake protocol with AXBS when a common trigger divider update is initiated. 0b - No halt handshake protocol is initiated. 1b - Halt handshake protocol is initiated.
30-1 —	This field is reserved and reads return zeros.
0 TCTL	Trigger control This field controls the divider update configuration between immediate and common update. 0b - Immediate divider update 1b - Common trigger divider update

24.5.16 Clock Mux 0 Divider Trigger Register (MUX_0_DIV_TRIG)

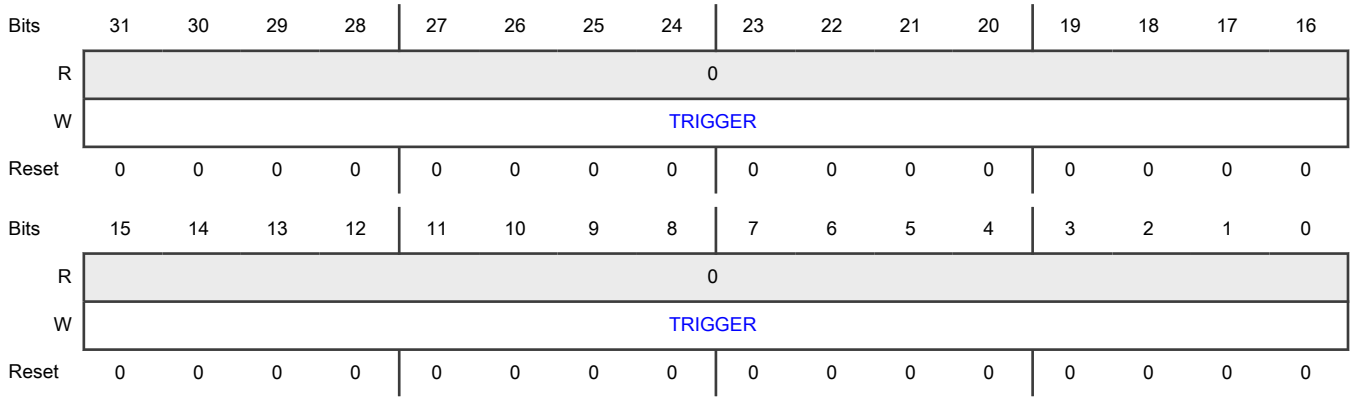
Offset

Register	Offset
MUX_0_DIV_TRIG	338h

Function

This register provides a common trigger for the clock dividers (only 50% duty cycle dividers) of clock mux 0. Writing any value to this register provides a trigger to the dividers. This register should only be written after appropriately configuring the MC_CGM_MUX_0_DIV_TRIG_CTRL register.

Diagram



Fields

Field	Function
31-0 TRIGGER	Trigger for divider update

24.5.17 Clock Mux 0 Divider Update Status Register (MUX_0_DIV_UPD_STAT)

Offset

Register	Offset
MUX_0_DIV_UPD_STAT	33Ch

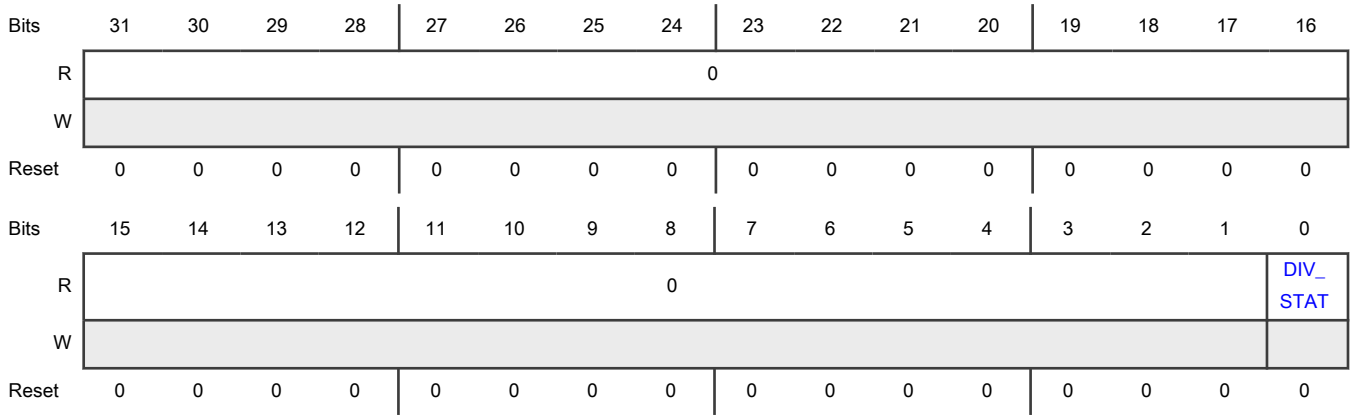
Function

This register provides the update status of the clock dividers corresponding to clock mux 0. When a write operation on any divider control register is performed, the divider status bit in this register is set to logic-1. The bit is set to logic-0 when the divider has sampled the new divider configuration. Performing multiple writes without tracking the status bit on same or other clock dividers inside the same clock mux leads to inconsistent reporting, that is, the divider status maybe be set to logic-0 when the corresponding divider update is pending.

NOTE

Read accesses to MUX_n_DIV_UPD_STAT always complete without returning bus transfer error independent of whether any divider(s) are implemented inside MC_CGM clock mux.

Diagram



Fields

Field	Function
31-1 —	This field is reserved and reads return zeros.
0 DIV_STAT	Divider status for clock mux 0 On reading MUX_n_DIV_UPD_STAT after updating a divider control register, if the value of this field is fixed to 1 because of an error in the selected clock source, perform the following steps to switch the mux to a new clock source: 1. Switch the mux to a working clock source without polling this field. 2. Update MUX_n_DC_m and poll this field. 0b - No divider configuration update is pending. 1b - Divider configuration update on at least one divider associated with this multiplexer is pending.

24.5.18 Clock Mux 1 Select Control Register (MUX_1_CSC)

Offset

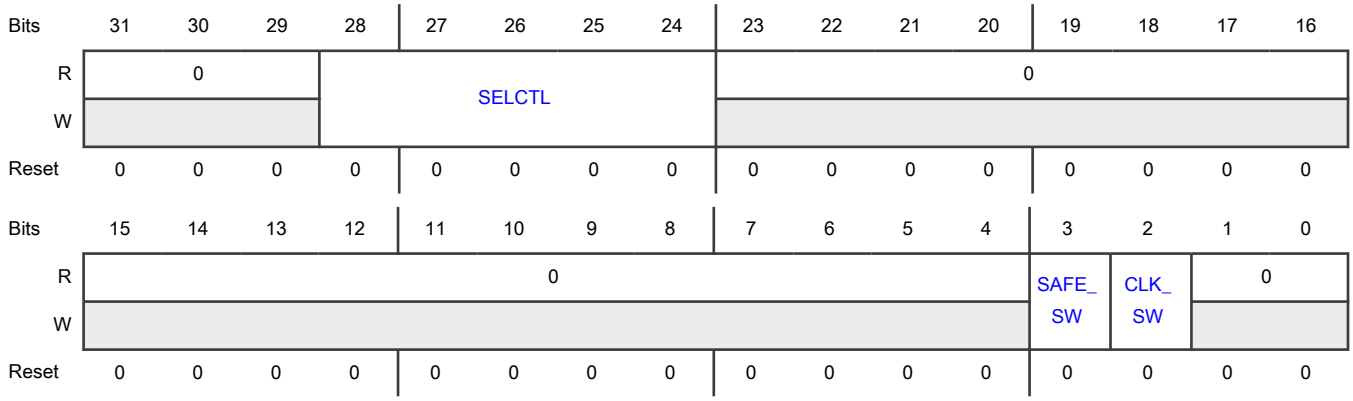
Register	Offset
MUX_1_CSC	340h

Function

This register provides the clock source selection control for clock mux 1. Clock mux 1 implements hardware control clock switching ensuring that the clock switch happens in a graceful manner (without glitches). See the "Hardware-controlled clock multiplexer" section for details.

This register is reset on destructive reset only.

Diagram



Fields

Field	Function
31-29 —	This field is reserved and reads return zeros.
28-24 SELCTL	Clock source selection control Selects the source clock for clock mux 1. The reserved values are not displayed. 0_0000b - FIRC 0_0010b - FXOSC 1_0110b - AIPS_PLAT_CLK
23-4 —	This field is reserved and reads return zeros.
3 SAFE_SW	Safe clock request Writing 1 to this bit makes a safe clock switch request to FIRC. After a safe clock switch operation is requested, this bit is auto cleared and a corresponding bit in the status register is set.
2 CLK_SW	Clock switch Writing 1 to this bit makes a clock switch request to clock mux 1. After a clock switch operation is requested, this bit is auto cleared and a corresponding bit in the status register is set.
1-0 —	This field is reserved and reads return zeros.

24.5.19 Clock Mux 1 Select Status Register (MUX_1_CSS)

Offset

Register	Offset
MUX_1_CSS	344h

Function

This register provides the current clock source selection status for clock mux 1.

This register is reset on destructive reset only.

Fields

Field	Function
31-1 —	This field is reserved and reads return zeros.
0 DIV_STAT	Divider status for clock mux 3 On reading MUX_n_DIV_UPD_STAT after updating a divider control register, if the value of this field is fixed to 1 because of an error in the selected clock source, perform the following steps to switch the mux to a new clock source: 1. Switch the mux to a working clock source without polling this field. 2. Update MUX_n_DC_m and poll this field. 0b - No divider configuration update is pending. 1b - Divider configuration update on at least one divider associated with this multiplexer is pending.

24.5.30 Clock Mux 4 Select Control Register (MUX_4_CSC)

Offset

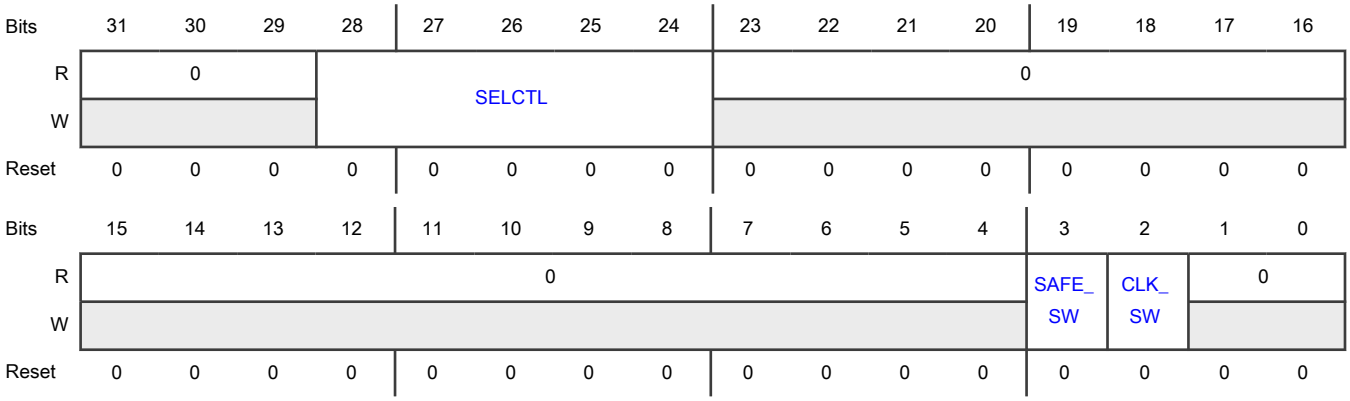
Register	Offset
MUX_4_CSC	400h

Function

This register provides the clock source selection control for clock mux 4. Clock mux 4 implements hardware control clock switching ensuring that the clock switch happens in a graceful manner (without glitches). See the "Hardware-controlled clock multiplexer" section for details.

This register is reset on destructive reset only.

Diagram



Fields

Field	Function
31-29 —	This field is reserved and reads return zeros.
28-24 SELCTL	Clock source selection control Selects the source clock for clock mux 4. The reserved values are not displayed. 0_0000b - FIRC 0_0010b - FXOSC 1_0110b - AIPS_PLAT_CLK
23-4 —	This field is reserved and reads return zeros.
3 SAFE_SW	Safe clock request

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Writing 1 to this bit makes a safe clock switch request to FIRC. After a safe clock switch operation is requested, this bit is auto cleared and a corresponding bit in the status register is set.
2 CLK_SW	Clock switch Writing 1 to this bit makes a clock switch request to clock mux 4. After a clock switch operation is requested, this bit is auto cleared and a corresponding bit in the status register is set.
1-0 —	This field is reserved and reads return zeros.

24.5.31 Clock Mux 4 Select Status Register (MUX_4_CSS)

Offset

Register	Offset
MUX_4_CSS	404h

Function

This register provides the current clock source selection status for clock mux 4.

This register is reset on destructive reset only.

Table continued from the previous page...

Field	Function
28-24 SELSTAT	Clock source selection status This value indicates the current source selected for clock mux 4. The reserved values are not displayed. 0_0000b - FIRC 0_0010b - FXOSC 1_0110b - AIPS_PLAT_CLK
23-20 —	This field is reserved and reads return zeros.
19-17 SWTRG	Switch trigger cause This value indicates the cause for the latest clock source switch. **NOTE** If the clock fails, followed by multiple safe clock switch requests for MC_CGM hardware clock mux, the value of the SWTRG field can be either 4 or 5. 000b - Reserved 001b - Switch after request succeeded. 010b - Switch after the request failed because of an inactive target clock and the current clock is FIRC. 011b - Switch after the request failed because of an inactive current clock and the current clock is FIRC. 100b - Switch to FIRC because of a safe clock request or reset succeeded. 101b - Switch to FIRC because of a safe clock request or reset succeeded, but the previous current clock source was inactive. 110b - Reserved 111b - Reserved
16 SWIP	Switch in progress **NOTE** New clock switch request can only be given three clock cycles after the completion of the previous request. 0b - Clock source switching is complete. 1b - Clock source switching is in progress.
15-4 —	This field is reserved and reads return zeros.
3 SAFE_SW	Safe clock request

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field provides an indication of whether a switch to safe clock operation was requested during the previous/ongoing request on clock mux 4. 0b - No safe clock switch operation was requested. 1b - Safe clock switch operation was requested.
2 CLK_SW	Clock switch This field provides an indication of whether a clock switch operation was requested during the previous/ ongoing request on clock mux 4. 0b - No clock switch operation was requested. 1b - Clock switch operation was requested.
1-0 —	This field is reserved and reads return zeros.

24.5.32 Clock Mux 4 Divider 0 Control Register (MUX_4_DC_0)

Offset

Register	Offset
MUX_4_DC_0	408h

Function

This register controls the clock divider 0 for clock mux 4.

This divider is a 50% duty cycle divider.

NOTE

The update to the fields of this register should be an atomic write, that is, one single write should update the complete register.

Diagram

Fields

Field	Function
31 DE	Divider enable 0b - Divider is disabled. 1b - Divider is enabled.
30-18 —	This field is reserved and reads return zeros.
17-16 DIV	Division value This field provides the division value for the clock divider. The clock period of the clock after division is 'DIV+1' times the time period of the current input clock to the divider.
15-0 —	This field is reserved and reads return zeros.

24.5.33 Clock Mux 4 Divider Update Status Register (MUX_4_DIV_UPD_STAT)

Offset

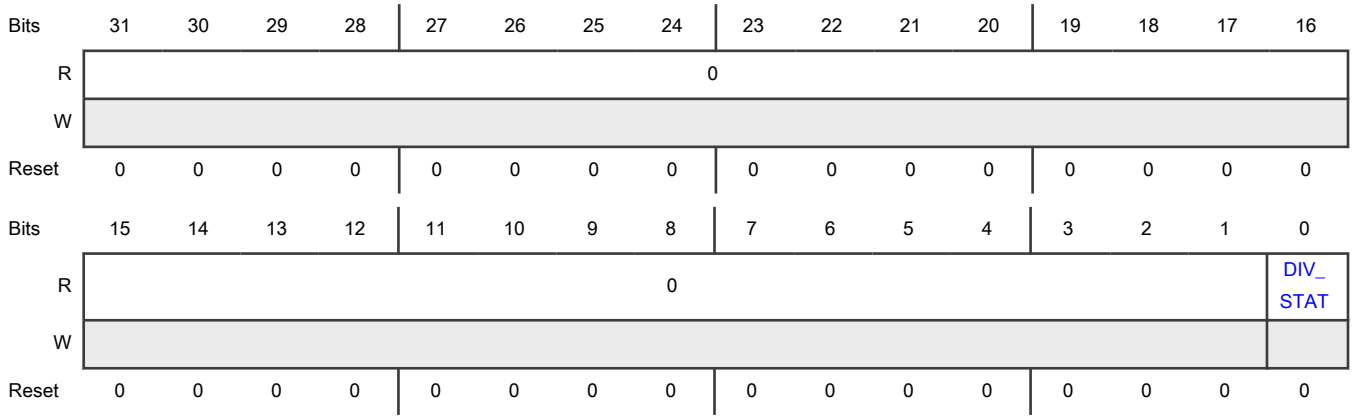
Register	Offset
MUX_4_DIV_UPD_STAT	43Ch

Function
This register provides the update status of the clock dividers corresponding to clock mux 4. When a write operation on any divider control register is performed, the divider status bit in this register is set to logic-1. The bit is set to logic-0 when the divider has sampled the new divider configuration. Performing multiple writes without tracking the status bit on same or other clock dividers inside the same clock mux leads to inconsistent reporting, that is, the divider status maybe be set to logic-0 when the corresponding divider update is pending.

NOTE

Read accesses to MUX_n_DIV_UPD_STAT always complete without returning bus transfer error independent of whether any divider(s) are implemented inside MC_CGM clock mux.

Diagram



Fields

Field	Function
31-1 —	This field is reserved and reads return zeros.
0 DIV_STAT	Divider status for clock mux 4 On reading MUX_n_DIV_UPD_STAT after updating a divider control register, if the value of this field is fixed to 1 because of an error in the selected clock source, perform the following steps to switch the mux to a new clock source: 1. Switch the mux to a working clock source without polling this field. 2. Update MUX_n_DC_m and poll this field. 0b - No divider configuration update is pending. 1b - Divider configuration update on at least one divider associated with this multiplexer is pending.

24.5.34 Clock Mux 5 Select Control Register (MUX_5_CSC)

Offset

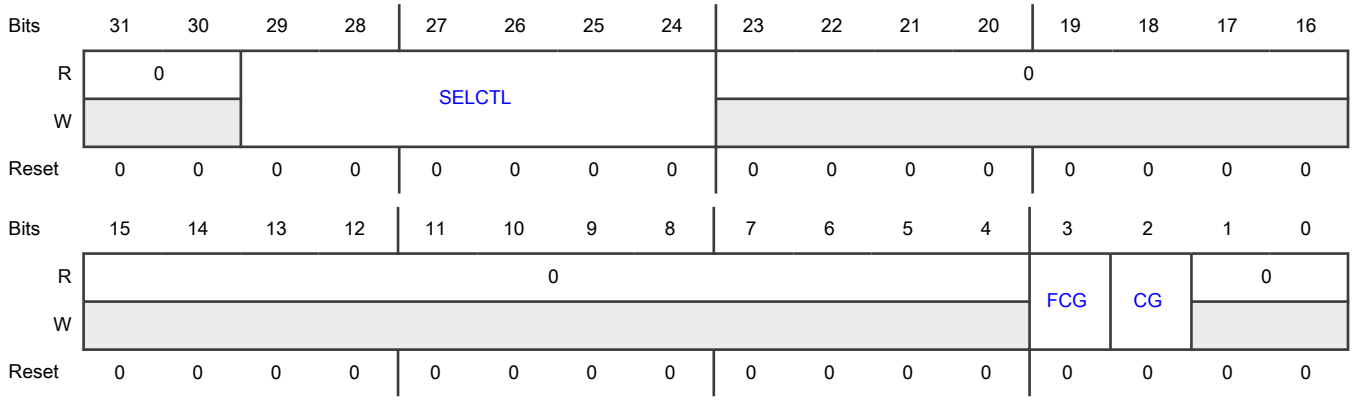
Register	Offset
MUX_5_CSC	440h

Function

This register provides the clock source selection control of clock mux 5. Clock mux 5 implements software control clock switching, and a graceful clock switch can be performed by executing a sequence of steps in software. See "Software-controlled clock multiplexer" section for details.

This register is reset on destructive reset only.

Diagram



Fields

Field	Function
31-30 —	This field is reserved and reads return zeros.
29-24 SELCTL	Clock source selection control Selects the source clock for clock mux 5. The reserved values are not displayed. 00_0000b - FIRC 00_0001b - SIRC 00_0010b - FXOSC 00_0100b - SXOSC 01_0111b - AIPS_SLOW_CLK 11_0010b - Reserved
23-4 —	This field is reserved and reads return zeros.
3 FCG	Force clock gate Writing 1 to this bit gates the clock at the output of clock mux 5 to logic-0 irrespective of the logic level of the currently selected clock. Clock gating using this bit should only be performed when it is insured that current clock source is inactive.
2 CG	Clock gate Writing 1 to this bit gates the clock at the output of clock mux 5 to logic-0. Using this bit it is insured that no glitches are resulted when gating the clock.
1-0 —	This field is reserved and reads return zeros.

24.5.35 Clock Mux 5 Select Status Register (MUX_5_CSS)

Offset

Register	Offset
MUX_5_CSS	444h

Function

This register provides the current clock source selection status for clock mux 5.

This register is reset on destructive reset only.

31-29 —	This field is reserved and reads return zeros.
28-24 SELSTAT	Clock source selection status This value indicates the current source selected for clock mux 8. The reserved values are not displayed. 0_0000b - FIRC 1_1000b - EMAC_RMII_TX_CLK
23-20 —	This field is reserved and reads return zeros.
19-17 SWTRG	Switch trigger cause This value indicates the cause for the latest clock source switch. **NOTE** If the clock fails, followed by multiple safe clock switch requests for MC_CGM hardware clock mux, the value of the SWTRG field can be either 4 or 5. 000b - Reserved 001b - Switch after request succeeded. 010b - Switch after the request failed because of an inactive target clock and the current clock is FIRC. 011b - Switch after the request failed because of an inactive current clock and the current clock is FIRC. 100b - Switch to FIRC because of a safe clock request or reset succeeded. 101b - Switch to FIRC because of a safe clock request or reset succeeded, but the previous current clock source was inactive. 110b - Reserved 111b - Reserved
16 SWIP	Switch in progress **NOTE** New clock switch request can only be given three clock cycles after the completion of the previous request. 0b - Clock source switching is complete. 1b - Clock source switching is in progress.
15-4 —	This field is reserved and reads return zeros.
3	Safe clock request

Table continues on the next page...

Table continued from the previous page...

Field	Function
SAFE_SW	This field provides an indication of whether a switch to safe clock operation was requested during the previous/ongoing request on clock mux 8. 0b - No safe clock switch operation was requested. 1b - Safe clock switch operation was requested.
2 CLK_SW	Clock switch This field provides an indication of whether a clock switch operation was requested during the previous/ ongoing request on clock mux 8. 0b - No clock switch operation was requested. 1b - Clock switch operation was requested.
1-0 —	This field is reserved and reads return zeros.

24.5.48 Clock Mux 8 Divider 0 Control Register (MUX_8_DC_0)

Offset

Register	Offset
MUX_8_DC_0	508h

Function

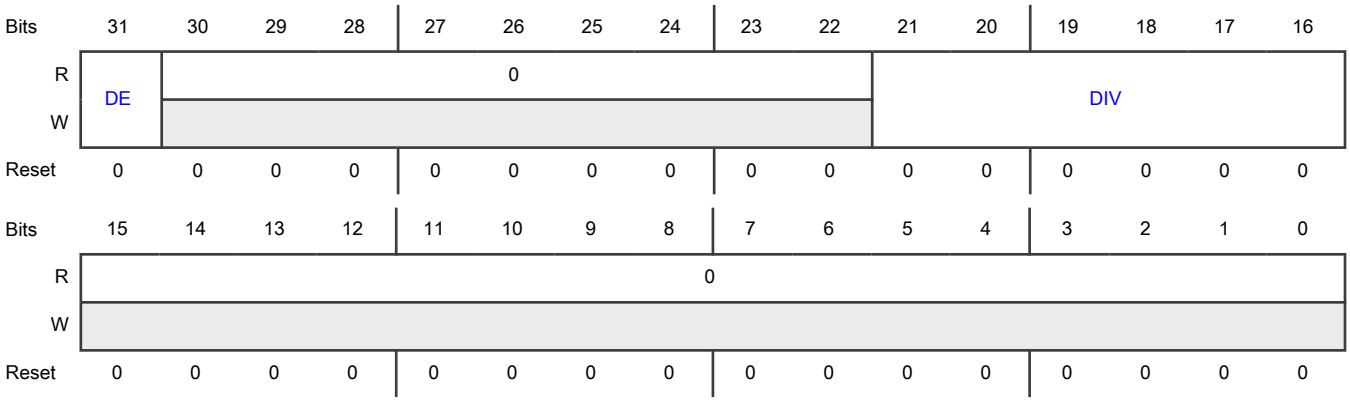
This register controls the clock divider 0 for clock mux 8.

This divider is a 50% duty cycle divider.

NOTE

The update to the fields of this register should be an atomic write, that is, one single write should update the complete register.

Diagram



Fields

Field	Function
31 DE	Divider enable 0b - Divider is disabled. 1b - Divider is enabled.
30-22 —	This field is reserved and reads return zeros.
21-16 DIV	Division value This field provides the division value for the clock divider. The clock period of the clock after division is 'DIV+1' times the time period of the current input clock to the divider.
15-0 —	This field is reserved and reads return zeros.

24.5.49 Clock Mux 8 Divider Update Status Register (MUX_8_DIV_UPD_STAT)

Offset

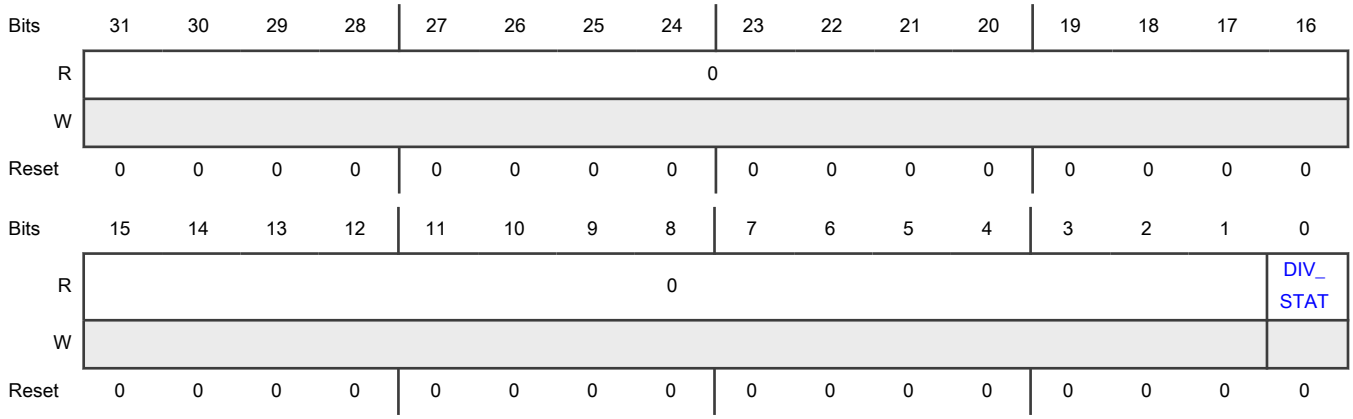
Register	Offset
MUX_8_DIV_UPD_STAT	53Ch

Function
This register provides the update status of the clock dividers corresponding to clock mux 8. When a write operation on any divider control register is performed, the divider status bit in this register is set to logic-1. The bit is set to logic-0 when the divider has sampled the new divider configuration. Performing multiple writes without tracking the status bit on same or other clock dividers inside the same clock mux leads to inconsistent reporting, that is, the divider status maybe be set to logic-0 when the corresponding divider update is pending.

NOTE

Read accesses to MUX_n_DIV_UPD_STAT always complete without returning bus transfer error independent of whether any divider(s) are implemented inside MC_CGM clock mux.

Diagram



Fields

Field	Function
31-1 —	This field is reserved and reads return zeros.
0 DIV_STAT	Divider status for clock mux 8 On reading MUX_n_DIV_UPD_STAT after updating a divider control register, if the value of this field is fixed to 1 because of an error in the selected clock source, perform the following steps to switch the mux to a new clock source: 1. Switch the mux to a working clock source without polling this field. 2. Update MUX_n_DC_m and poll this field. 0b - No divider configuration update is pending. 1b - Divider configuration update on at least one divider associated with this multiplexer is pending.

24.5.50 Clock Mux 9 Select Control Register (MUX_9_CSC)

Offset

Register	Offset
MUX_9_CSC	540h

Function

This register provides the clock source selection control for clock mux 9. Clock mux 9 implements hardware control clock switching ensuring that the clock switch happens in a graceful manner (without glitches). See the "Hardware-controlled clock multiplexer" section for details.

This register is reset on destructive reset only.

Diagram

Chapter 26
Slow Internal RC Oscillator (SIRC)

26.1 Introduction

The SIRC digital interface controls the slow internal on-chip 32 KHz RC oscillator system.

26.2 Features

The SIRC module:

- Status register provides the current operating state:
  - On and stable
  - Off or on but not stable
- Operates at a frequency of 32 kHz in Functional mode

26.3 Operating mode

Only a POR reset will initialize the SIRC. Destructive or Functional resets do not impact the SIRC functionality.

SIRC stabilization occurs after 96 SIRC_CLK cycles.

The SIRC output clock remains invalid until the analog SIRC stabilizes. The output clock does not glitch or overshoot its frequency during enabling or disabling. Also, the clock does not get stuck or produce glitches on a very short hardware disable pulse.

26.4 SIRC register descriptions

26.4.1 SIRC memory map

Access to registers use 8-bit, 16-bit, or 32-bit addressing.

SIRC base address: 402C_8000h

Offset	Register	Width (In bits)	Access	Reset value
4h	Status Register (SR)	32	RO	0000_0001h

Chapter 27
Fast Crystal Oscillator Digital Controller (FXOSC)

27.1 Chip-specific FXOSC information

27.1.1 Chip-specific FXOSC information

For MWCT2D17S: For bypass mode applications, the EXTAL pin should be driven low when FXOSC is in off/disabled state.

- While initializing FXOSC: When the FXOSC is used in Bypass mode, the external clock source can only be enabled after the FXOSC is enabled.
- While disabling FXOSC: When the FXOSC is used in Bypass mode, the external clock source must already be inactive before disabling the FXOSC.

27.2 Introduction

27.2.1 Overview

This module provides the fast crystal oscillator to the chip.

27.2.2 Features

FXOSC features are as follows:

- Status register shows current module state.
- Control register can:
  - Select a mode of operation:
    - Crystal mode
    - Single-Input Bypass mode using EXTAL clock input
  - Disable the module (Power-Down mode)

27.3 Functional description

The table below shows configuration settings for the different FXOSC modes set by the CTRL register:

Table 137. FXOSC operation mode settings

Mode	CTRL[OSCON]	CTRL[OSC_BYP]	CTRL[COMP_EN]	FXOSC_CLK
Power-Down mode	0	X	X	0
Crystal mode	1	0	1	Crystal clock
Single-Input Bypass mode	1	1	0	EXTAL

Power-Down mode is the FXOSC default condition after any reset: POR, Destructive, or Functional.

27.3.1 Clock generation in Crystal mode

Counter logic and FXOSC_CLK start when counter value reaches EOCV × 128.

27.3.2 Clock generation in Single-Input Bypass mode

This mode bypasses the oscillator and uses a single-input external clock (EXTAL input) for FXOSC_CLK.

27.4 Initialization information

Initializing FXOSC

Initialize FXOSC as follows:

1. Write the desired value to CTRL[OSC_BYP] and CTRL[COMP_EN] to select an operation mode as shown in Table 137.

   NOTE

   FXOSC must be disabled when the operation mode is modified.

2. Configure CTRL[GM_SEL].
   - In Crystal mode configure the transconductance based on the module specification in the chip data sheet.
   - In Single-Input Bypass mode write 0000b to this field.

   NOTE

   In Crystal mode FXOSC will not function with zero transconductance (GM_SEL = 0000b).

3. Set CRTL[EOCV] calculating the value as follows:
   - EOCV (in decimal) = (stabilization time in ns) ÷ (4 × 128 × (period of clock in ns))
4. Write 1 to CRTL[OSCON] to enable FXOSC.
5. Confirm the clock is stable (STAT[OSC_STAT] = 1) before using it.

Disabling FXOSC

Write 0 to CRTL[OSCON] to disable FXOSC when FXOSC_CLK is running and stable.

FXOSC enters Power-down mode after at least four crystal clocks. No glitches occur during the transition to Power-Down mode because synchronizers are used.

NOTE

After disabling FXOSC:

- Wait for at least 2 µs before enabling FXOSC again.
- You must not change other values in FXOSC registers for at least 16 FXOSC_CLK cycles.

27.5 FXOSC register descriptions

This section provides the descriptions of all registers used for configuring the FXOSC.

27.5.1 FXOSC memory map

Use 8-bit, 16-bit, or 32-bit addressing to access registers.

FXOSC base address: 402D_4000h

Offset	Register	Width (In bits)	Access	Reset value
0h	FXOSC Control Register (CTRL)	32	RW	019D_00C0h
4h	Oscillator Status Register (STAT)	32	RO	0000_0000h

27.5.2 FXOSC Control Register (CTRL)

Field	Function
25 —	Reserved
24 COMP_EN	Comparator enable Enables or disables the comparator. • For Crystal mode set this field to 1. • For Single-Input Bypass mode set this field to 0. 0b - Comparator disabled 1b - Comparator enabled
23-16 EOCV	End of count value Specifies the end-of-count. The oscillator counter runs on the crystal clock divided by 4 and counts up to EOCV × 128. This counting period ensures that the external oscillator clock signal is stable before the system selects FXOSC as a source. **NOTE** • You must set EOCV to the appropriate value to allow clock and duty cycle to stabilize and guarantee that OSC_STAT becomes set within the crystal startup time. — In Crystal mode, EOCV value must to be calculated to appropriate value based on the crystal specification using the equation in Initializing FXOSC. — In Single-Input Bypass mode, EOCV value is irrelevant. FXOSC holds the counter in reset. • Before modifying EOCV, FXOSC must be disabled.
15-8 —	Reserved
7-4 GM_SEL	Crystal overdrive protection Selects the transconductance applied by the FXOSC amplifier. This setting depends on crystal specification. **NOTE** • In Crystal mode FXOSC will not function with zero transconductance (GM_SEL = 0000b). • For details on how to set this field, see Initializing FXOSC. 0000b - 0x 0001b - 0.1004x 0010b - 0.2009x 0011b - 0.3013x

30-0 —	Reserved

Chapter 28
Slow Crystal Oscillator Digital Controller (SXOSC)

28.1 Introduction

SXOSC:

- Controls the functioning of the analog oscillator
- Provides a register interface for programmable features
- Controls the power-down function of the oscillator

28.2 Features

- Generates a 32 KHz clock output in Functional Oscillator mode
- Contains a status register, the value of which becomes 1 when the crystal stabilization time is complete
- Contains an oscillator that can be powered down

28.3 Modes of operation

- Functional Oscillator—In this mode, the external crystal generates the clock.

28.4 Functional description

SXOSC generates control signals to configure the analog module to operate in specific modes.

The following table shows the mode of operation available for selection and its settings.

Table 138. Operation mode settings

Mode	Value of SXOSC_CTRL[OSCON]	Output clock
Functional Oscillator	0 (oscillator switched off)	0 (indicates no output)
	1 (oscillator switched on)	Crystal clock

28.4.1 Clock generation in Functional Oscillator mode

After hard reset, the crystal oscillator is switched off by default. For clock generation in Functional Oscillator mode, see Table 138. The counter logic starts counting and the stable clock starts running one clock cycle after reaching the value of SXOSC_CTRL[EOCV] x 128 counter value. The module writes 1 to SXOSC_STAT[OSC_STAT] after two module clock cycles.

28.4.2 Clock stopping in Functional Oscillator mode

To stop a stable, running clock, configure the mode as specified in Table 138. A glitch does not occur because synchronizers are used.

28.5 Initialization information

Perform the following steps to initialize SXOSC:

1. Write an appropriate value to SXOSC_CTRL[EOCV].
2. Write 1 to SXOSC_CTRL[OSCON]. This enables the oscillator. The value of this field defaults to 0, which means the oscillator is off by default.
3. Confirm the clock is stable (SXOSC_STAT[OSC_STAT] = 1) before using it.

Be aware that:

- A functional reset does not affect any mode settings.
- Functional Oscillator is the only available mode of operation.
- To calculate EOCV of the crystal from start-up time, use the following formula:

  EOCV = (stabilisation time in ns) ÷ (4 × 128 × time period of clock in ns).

28.6 SXOSC register descriptions

This section provides the description of registers that are used for configuring SXOSC.

28.6.1 SXOSC memory map

Addresses are provided as offsets from the module base address. You can access all the registers using 8-bit, 16-bit, or 32-bit addressing. Using external configuration signals or parameters, you can configure some of the register reset values according to the requirements of individual chips.

SXOSC base address: 402C_C000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Oscillator Control (SXOSC_CTRL)	32	RW	007D_0000h
4h	Oscillator Status (SXOSC_STAT)	32	RO	0000_0000h

28.6.2 Oscillator Control (SXOSC_CTRL)

Chapter 29
PLL Digital Interface (PLLDIG)

29.1 Chip-specific PLLDIG information

29.1.1 PLLDIG instances

This chip supports up to one instances of PLLDIG.

Table 139. PLLDIG instances

Instance	MWCT2014S/MWCT2015S/MWCT2016S/MWCT2D16S/MWCT2D17S
PLL	Yes

Table 140. PLLDIG configuration

Instance	Frequency modulation supported	Number of reference clocks supported	Number of clock outputs supported
PLL	Yes	1[1]	2

1. For MWCT2015S: 2

29.1.2 PLL-supported accesses and frequencies

The PLLODIV_0 and PLLODIV_1 registers support only word accesses. When you write to these registers, you must retain the default values of the reserved fields.

PLLDIG supports a down-spread modulation of up to 160 MHz PLL PHI clock output only.

29.2 Introduction

PLL can multiply or divide the frequency of a given clock input.

29.2.1 Features

PLL includes the following features:

- Programmable frequency modulation
- Multiple integer dividers on PLL outputs
- Lock detection circuitry reports when PLL achieves frequency lock
- Continuous monitoring of lock status to report Loss of Lock (LOL) condition
- Powering down the module for low-power operation (Power-Down mode)

29.2.2 Block diagram

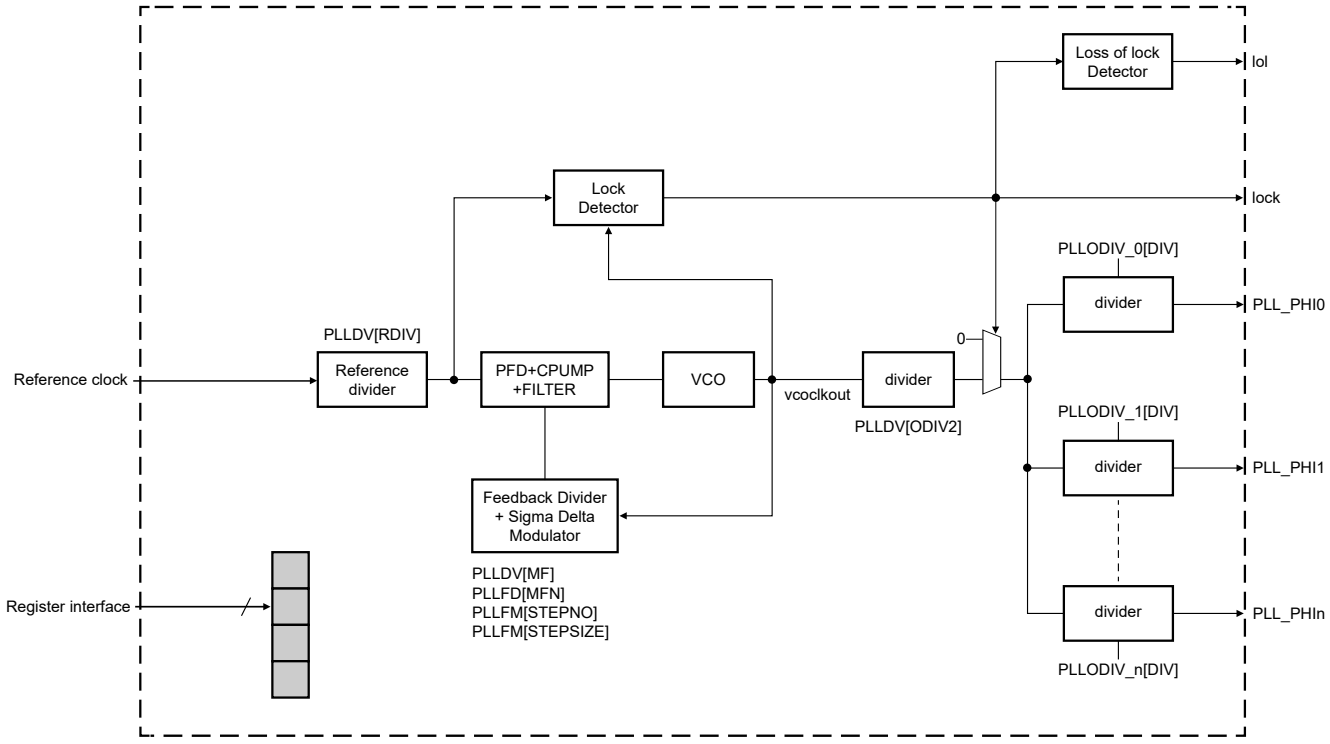

Figure 113. Block diagram

The number of output dividers can vary with the module instance. See the Clocking chapter to confirm the number of PLL output dividers.

29.3 Modes of operation

Table 141. Modes of operation

PLLCR[PLLPD]	PLLFD[SDMEN]	PLLFM[SSCGBYP]	Description
1	x	x	PLL is disabled.
0	0	1	Functional mode – PLL operates in integer-only mode. See Clock configuration.
0	1	1	Functional mode – PLL operates in Fractional mode (non-Frequency modulation). See Clock configuration.
0	1	0	Functional mode – PLL operates in Frequency Modulation mode. See Frequency modulation.

29.4 Functional description

This section explains PLL operation and configuration.

29.4.1 Input clock frequency

PLL is designed to operate over a specified input clock frequency range. PLL source frequency limits are discussed in this chip's data sheet.

29.4.2 Clock configuration

See the equations below and the corresponding register configuration that determine the relationship between VCO frequency (f_{VCO}) and PLL reference frequency.

- Integer-only mode:
  - When PLLDV[RDIV] is 0:

$$f_{\text{pll\_VCO}} = f\text{pll\_ref} \times \text{PLLDV[MFI]}$$

Equation 1. PLL VCO frequency in integer-only mode when PLLDV[RDIV] is 0

  - When PLLDV[RDIV] is not 0:

$$f_{\text{pll\_VCO}} = \frac{f_{\text{pll\_ref}}}{\text{PLLDV[RDIV]}} \times \text{PLLDV[MFI]}$$

Equation 2. PLL VCO frequency in integer-only mode when PLLDV[RDIV] is not 0

- Fractional mode:
  - When PLLDV[RDIV] is 0:

$$f_{\text{pll\_VCO}} = f_{\text{pll\_ref}} \times \left(\text{PLLDV[MFI]} + \frac{\text{PLLFD[MFN]}}{18432}\right)$$

Equation 3. PLL VCO frequency in Fractional mode when PLLDV[RDIV] is 0

  - When PLLDV[RDIV] is not 0:

$$f_{\text{pll\_VCO}} = \frac{f_{\text{pll\_ref}}}{\text{PLLDV[RDIV]}} \times \left(\text{PLLDV[MFI]} + \frac{\text{PLLFD[MFN]}}{18432}\right)$$

Equation 4. PLL VCO frequency in Fractional mode when PLLDV[RDIV] is not 0

See the equation below and the corresponding register configuration that determine the relationship between reference and PLL_PHI*n* output frequencies.

$$f_{\text{pll\_phi}} = \frac{f_{\text{pll\_VCO}}}{\text{PLLDV[ODIV2]} \times \left(\text{PLLDIV\_}n\text{[DIV]} + 1\right)}$$

Equation 5. PLL PHI output frequency

When configuring PLL, you must not violate the maximum system clock frequency or maximum and minimum VCO frequency specification of PLL (see this chip's data sheet for frequency limits).

You must disable PLL by writing 1 to PLLCR[PLLPD] before any PLL configuration or input clock are modified.

You must disable PLL by writing 1 to PLLCR[PLLPD] for at least 5 µs before writing 0 to PLLCR[PLLPD] to enable PLL.

The recommended procedure to program PLL and enter Normal mode is shown in Initialization information.

29.4.3 LOL

PLL provides LOL indication. The LOL indication can only be generated when PLL is in Functional mode (see Modes of operation). When PLL detects a LOL, it asserts its LOL event output.

PLL does not detect loss of reference clock. If the reference clock stops after PLL achieves lock, PLL continues to indicate lock. It is assumed that monitoring of PLL's reference clock that is done outside PLL is enabled while PLL is in operation.

PLL LOL is intended for detection of gross failures. Use CMUs for accurate frequency monitoring.

29.4.4 Frequency modulation

In Frequency Modulation mode, PLL generates a frequency-modulated clock. The modulation depth and modulation frequency are calculated using the equations shown in Frequency modulation programming.

Write 1 to PLLFM[SPREADCTL] to select down-spread modulation. See Figure 114 that shows an example of down-spread modulation.

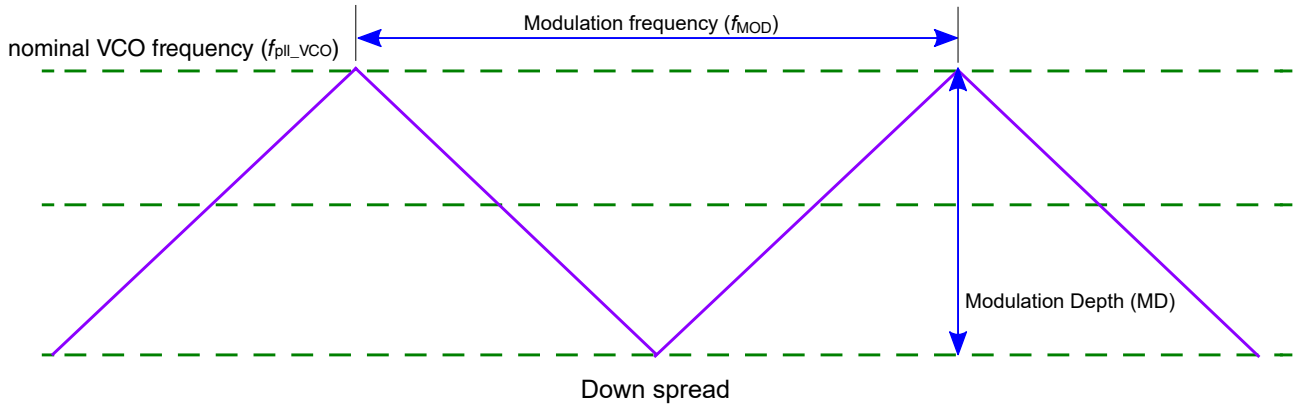

Figure 114. Frequency modulation

29.4.4.1 Frequency modulation programming

Modulation depth and modulation frequency programming uses step number (PLLFM[STEPNO]) and step size (PLLFM[STEPSIZE]). The table below shows variables used during calculations when programming PLL for frequency modulation.

Table 142. Variables for configuring modulation depth and frequency

Variable	Description
f_{REF}	Input clock frequency
f_{MOD}	Expected modulation frequency
MD	Expected modulation depth in percentage
LDF	Loop division factor

Use the following equations to configure PLL for frequency modulation.

$$LDF = PLLDV[MFI] + \frac{PLLFD[MFN]}{18432}$$

Equation 6. LDF

$$PLLFM[STEPNO] = \frac{f_{REF}}{\left(2 \times f_{MOD} \times PLLDV[RDIV]\right)}$$

Equation 7. Step number

$$\text{PLLFM[STEPSIZE]} = \frac{\text{MD} \times \text{LDF}}{100 \times \text{PLLFM[STEPNO]}} \times 18432$$

Equation 8. Step size

Frequency modulation is only possible if the condition shown in Equation 9 is met.

$$(\text{PLLFM[STEPSIZE]} \times \text{PLLFM[STEPNO]}) < 18432$$

Equation 9. Requirement to achieve FM

You must write 0 to PLLFM[SSCGBYP] and write 1 to PLLFD[SDMEN] to enable frequency modulation.

CAUTION

The effective modulation depth may differ from the intended modulation depth because of rounding operations applied to PLLFM[STEPSIZE] and PLLFM[STEPNO].

29.5 Initialization information

Perform the following steps to initialize PLL:

1. Confirm that PLLODIV_*n*[DE] is 0 for all dividers.
2. Confirm that PLLCR[PLLPD] is 1.
3. Program the following as needed:
   - PLLDV
   - PLLFD
   - PLLFM to the desired value
4. Program PLLDV[ODIV2] and PLLODIV_*n*[DIV] to the desired values.
5. Wait for the PLL reference clock to be stable.
6. Write 0 to PLLCR[PLLPD].
7. Wait for PLLSR[LOCK] to be 1.
8. Write 1 to PLLODIV_*n*[DE].

Perform the following steps to shut down PLL:

1. Write 0 to PLLODIV_n[DE] for all dividers.
2. Write 1 to PLLCR[PLLPD].

29.6 PLLDIG register descriptions

This section provides the memory map and detailed descriptions of registers used for configuring PLL. The table below shows the memory map. Addresses are given as offsets from the module base address. All registers are accessed using 8-bit, 16-bit, or 32-bit addressing.

29.6.1 PLLDIG memory map

29.6.8 PLL Output Divider (PLLODIV_0 - PLLODIV_1)

Offset

Register	Offset
PLLODIV_0	80h
PLLODIV_1	84h

Function

Controls the PLL output clock divider settings.

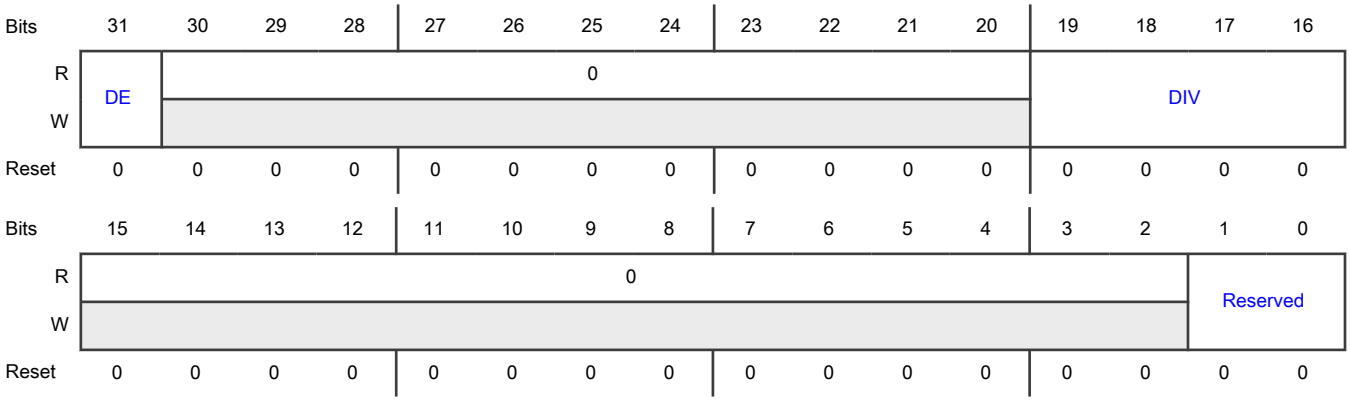
This divider has a 50% duty cycle.

NOTE

These registers support only word accesses. Other write accesses lead to the following:

- Unpredictable behavior
- No transfer error generated

Diagram



Fields

Field	Function
31 DE	Divider Enable Enables PLL output divider. Divider must be disabled before disabling PLL. 0b - Disabled 1b - Enabled
30-20 —	Reserved
19-16 DIV	Division Value Provides the division value for the output clock divider. The clock period of the clock after division is DIV + 1 times the time period of the divider input clock.
15-2 —	Reserved
1-0 —	Reserved Do not write any value other than the reset value.

Chapter 30
Reset Overview

30.1 Introduction

This chip's reset logic consists of a reset sequence that leads the chip to a fixed deterministic state after predefined reset events occur. These events can pertain to chip failure events, the chip's special operating conditions, or certain software-governed events to initiate a chip reset sequence. This chapter discusses the chip reset scheme and related topics such as:

- Types of reset reactions
- Reset event sources
- Chip reset sequences
  - POR
  - Destructive reset
  - Functional reset
- RAM retention across functional reset
- Reset pin (RESET_b) behavior
- Debug system reset
- Signal-level reset flow

30.2 Chip reset types and reactions

30.2.1 Chip reset blocks

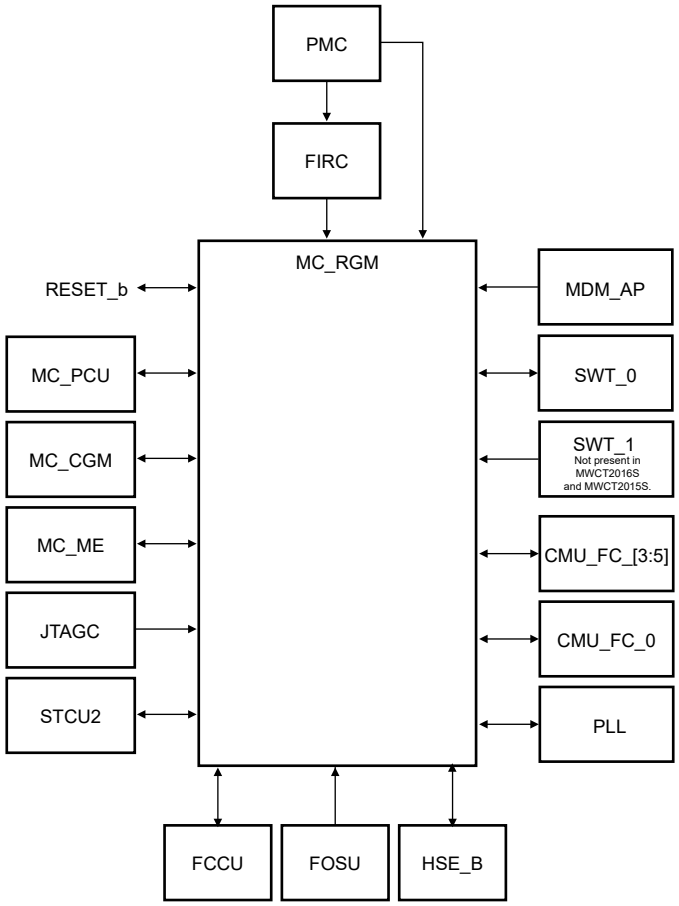


Figure 115. Chip reset blocks

30.2.2 Chip reset types

Table 143. Chip reset types

Reset event type	Functional description
POR	Leads to a complete chip reset.
Destructive	Leads most parts of the chip, except a few modules, to reset. SRAM content is lost after this reset event.
Functional	Leads all the communication peripherals and cores to reset. The communication protocols' sanity is not guaranteed and they are assumed to be reinitialized after reset. The SRAM content, and the functionality of certain modules, is preserved across functional reset.

30.2.3 High-level reset sequence overview

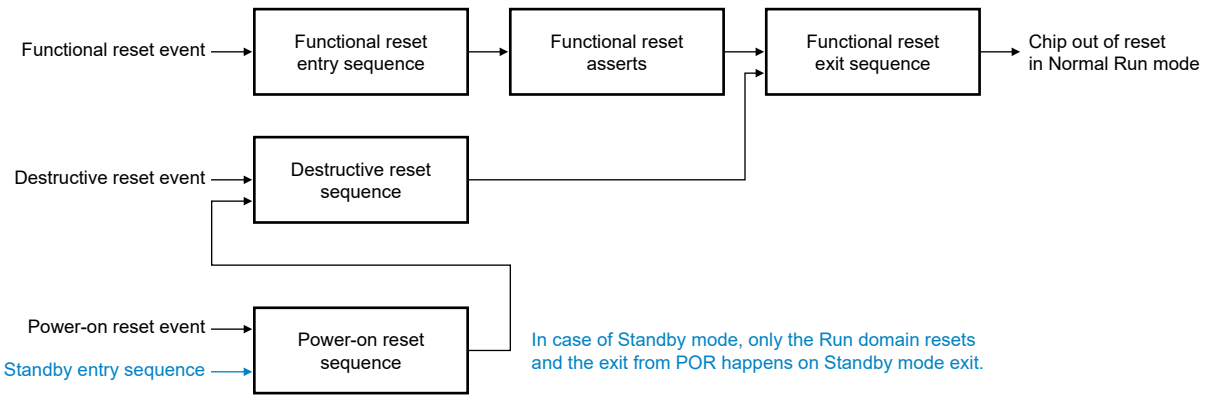

Figure 116. High-level reset sequence overview

30.2.3.1 Reset event reactions

Table 144. Reset event reactions

Reset event type	Triggered from	Reaction
POR	Anywhere	Moves to the beginning of the power-on sequence
Destructive reset	Power-on sequence	No reset sequence change
	Anywhere in the chip operation except in the power-on-sequence	Moves to the beginning of the destructive reset sequence
Functional reset	Out-of-reset	Moves to the beginning of the functional reset entry sequence
	Anywhere within the functional reset sequence	No reset sequence change

30.2.3.2 Chip action after reset event

For each reset event, immediately after MC_RGM captures it, the chip performs these actions:

1. Writes 1 to the corresponding reset event status fields in MC_RGM.DES and MC_RGM.FES (see the MC_RGM chapter for more information).
2. Places its pins in their default states (see the IOMUX file attached to this document for more information).
3. Asserts the RESET_b pin.

NOTE

After self-test completes, you can configure RESET_b assertion using MC_RGM.FES[ST_DONE].

4. Enters the reset sequence as described in Reset event reactions, depending on the current state and reset event type.

30.3 Reset sources—POR, destructive, and functional

MC_RGM records reset events in MC_RGM.FES and MC_RGM.DES, indicating the source of functional reset events and destructive reset events, respectively. You must read these fields to identify the reset source on reset recovery.

30.3.1 POR sources

Table 145. POR sources

Source module	Field in MC_RGM.DES	RESET_b assertion	Description
PMC	F_POR	Always	VDD_LV POR
			LVR on 1.1 V supply in Standby mode
			LVR on 1.1 V supply in Run mode
			LVR on 2.5 V supply in Standby mode
			LVR on 2.5 V supply in Run mode
			LVR on VDD_HV_A supply in Standby mode
			LVR on VDD_HV_A supply in Run mode
			LVR on VDD_HV_B supply in Standby mode [1]
			LVR on VDD_HV_B supply in Run mode [1]
POR_WDG			POR_WDG timeout (see the POR_WDG chapter for more information)

1. LVR on VDD_HV_B run mode and LVR on VDD_HV_B standby mode are not present in MWCT2016S and MWCT2015S.

NOTE

You cannot escalate or demote POR to an interrupt.

30.3.2 Stages of the POR sequence

Table 146. Stages of the POR sequence

Stage	Process
PWRUP	1. Starts after a POR event (for example, a POR source assert). 2. Waits for the power-up sequence to complete. 3. Exits when all the POR sources clear. 4. Transitions to the FIRC_STRT stage after the procedure completes.
FIRC_STRT	1. Enters this stage after exiting the PWRUP stage. **NOTE** FIRC_CLK, if enabled, becomes available after it is stable. The duration depends on the clock startup time (see the chip datasheet for more information). The MC_RGM state machine proceeds further after FIRC_CLK is available. 2. Transitions to the destructive reset sequence after the procedure completes.

30.3.3 Destructive reset sources

Table 147. Destructive reset sources

Source module[1]	Field in MC_RGM.DES	Description
FOSU	FCCU_FTR	FCCU failure to react
STCU2	STCU_URF	STCU2 unrecoverable fault
MC_RGM	MC_RGM_FRE	Functional reset escalation
CMU_FC_0	FXOSC_FAIL	FXOSC failure
PLL	PLL_LOL	PLL loss of lock
CMU_FC_3	CORE_CLK_FAIL	Core clock failure
CMU_FC_4	AIPS_PLAT_CLK_FAIL	AIPS_PLAT_CLK failure
CMU_FC_5	HSE_CLK_FAIL	HSE_CLK failure
CMU_FC_6	CM7_CORE CLK FAIL	CM7_CORE_CLK Failure
MC_CGM	SYS_DIV_FAIL	System clock dividers alignment failure
HSE_B	HSE_TMPR_R ST	HSE_B tamper detect reset
HSE_B	HSE_SNVS_RST	HSE_B SNVS tamper detection
MC_ME	SW_DEST	Software destructive reset
MDM_AP	DEBUG_DEST	Debug destructive reset
RESET_b pin	EXT_RST	RESET_b pin assertion

1. All destructive resets can be escalated, but only the PLL LOL destructive reset can be demoted to an interrupt (see Destructive reset event bypass for PLL LOL destructive reset bypass details).

NOTE

All reset sources in the table above assert the RESET_b pin.

30.3.4 Destructive sequence stage description

Table 148. DEST0 description

Stage	Process
DEST0	1. Asserts reset to the entire chip, except logic running on POR. 2. Waits for all the destructive reset events to clear. 3. Waits for the minimum destructive reset assertion duration of eight FIRC_CLK cycles. 4. Deasserts after stage completion.

30.3.5 Functional reset sources

Table 149. Functional reset sources

Source module	Field in MC_RGM.FES	RESET_b assertion	Demotable to IRQ[1]	Escalation[2]	Description
FCCU soft reaction[3]	FCCU_RST	Always	Yes[4]	Yes	FCCU reset reaction
STCU2	ST_DONE	Configurable	No	No	Self-test done
SWT_0	SWT0_RST	Always	Yes[5]	Yes	SWT reset request
SWT_1[6]	SWT1_RST	Always	Yes[7]	Yes	SWT reset request
JTAGC	JTAG_RST	Always	Yes [8]	No	JTAG reset
HSE_B	HSE_SWT_RST	Always	No	Yes	HSE_B SWT timeout
HSE_B	HSE_BOOT_RST	Always	No	Yes	HSE_B boot reset
MC_ME	SW_FUNC	Always	No	Yes	Software functional reset
MDM_AP	DEBUG_FUNC	Always	Yes [9]	Yes	Debug functional reset

1. See Functional reset demotion to an interrupt for more information.
2. See Reset escalation for more information.
3. An FCCU soft functional reset is a chip functional reset (see the FCCU chapter for more information).
4. Controlled by MC_RGM.FERD[D_FCCU_RST].
5. Controlled by MC_RGM.FERD[D_SWT0_RST].
6. SWT_1 is not present in MWCT2016S and MWCT2015S.
7. Controlled by MC_RGM.FERD[D_SWT1_RST].
8. Controlled by MC_RGM.FERD[D_JTAG_RST].
9. Controlled by MC_RGM.FERD[D_DEBUG_FUNC].

30.3.6 Functional reset sequence descriptions

Table 150. Functional reset sequence descriptions

Stage	Series of events
Functional reset entry sequences	
FUNC0	This stage starts after any functional reset event. The FCCU fault monitoring and CMU_F*x_n* monitoring for FLL events is masked in this step to avoid any false fault or reset.
FUNC1	In this stage, a halt sequence that includes daisy chaining of all the gaskets halts, disabling the crossbar. The stage completes after the halt-handshake sequence completes.
FUNC2	In this stage, MC_RGM triggers the MC_CGM hardware clock multiplexers to switch to FIRC_CLK. • Software-based clock multiplexers do not support switching to FIRC_CLK on functional reset. • If PCFS is enabled, the system clock switching can be done via PCFS. This stage completes after MC_CGM switches the system clock to FIRC.

Table continues on the next page...

Table 150. Functional reset sequence descriptions (continued)

Stage	Series of events
FUNC3	In this stage, MC_RGM triggers all the MC_CGM hardware-based clock multiplexers with PCFS enabled or disabled to move their dividers to default values. • Software-based clock multiplexers do not support this feature. This stage completes after all the clock multiplexer dividers initialize to their corresponding default values.
FUNC4	In this stage, PLLDIG turns off synchronously. The stage completes after PLLDIG turns off.
FUNC5	FXOSC_CLK switches off synchronously. The FUNC4 and FUNC5 stages ensure that PLLDIG disables cleanly to ensure there are no glitches on the PLLDIG clock because of reset. The stage completes after FXOSC switches off.
FUNC6	In this stage, clocks of modules that are a part of LBIST and working on the destructive reset are enabled to meet their synchronous reset requirements, if any. For the self-test logic, in self-test, the destructive reset deasserts after this stage completes and after safe stating is removed. **NOTE** In the self-test sequence, the logic, which is a part of self-test (LBIST logic) resets when self-test completes. All the parts of logic in self-test (POR, destructive, and functional reset) reset after self-test completes whereas the rest of the chip undergoes a functional reset sequence because of self-test completion (MC_RGM.FES[ST_DONE] = 1). See the Safety Overview and STCU2 chapters for more information on the self-test operation.
FUNC7	MC_RGM asserts the functional reset and triggers a counter running on FIRC_CLK (for up to 64 cycles) to enable clocks for the modules having synchronous reset requirements. Flash memory comes out of reset after this stage completes. **NOTE** The flash memory resets after a functional reset event but comes out of reset, before the rest of the modules do, at the start of the functional reset exit sequence. The rest of the modules reset when the functional reset comes out of reset at the end of the functional reset exit sequence. Therefore, the reset to flash memory is an early functional reset that deasserts earlier than the functional reset, even if asserted at the same time.
Functional reset exit sequences	
FUNC8	This stage consists of flash memory and MC_RGM handshaking. Flash memory indicates the completion of its initialization to MC_RGM.
FUNC9	DCM initiates the scanning of flash memory DCF records. This state completes after the flash memory scanning completes. See the DCF clients file attached to this document for more information.
FUNC10	After DCM scans the DCF records from the flash memory, DCM initiates the trim loading sequence for analog blocks.

Table continues on the next page...

Table 150. Functional reset sequence descriptions (continued)

Stage	Series of events
	The analog blocks are loaded with the configured trimmed values in this stage, which completes after a trim-loading sequence completes.
FUNC11	In this stage, MG_RGM stops driving RESET_b and checks that the signal does not assert externally. If you enable low-power debug, MC_RGM waits for a debug acknowledge. The completion of this stage indicates that MC_RGM completed the reset sequence, deasserting the functional reset to the system.

30.4 Reset and boot sequence

The chip reset sequence consists of several reset stages based on the occurrence of a particular reset event. All reset events follow the same chip reset sequence; only the entry points vary depending on the type of reset event. MC_RGM triggers each stage after the previous stage completes. These stages execute in a specific order, which ensures a deterministic state of the chip when a reset event completes.

Figure 117 shows a high-level representation of the chip startup sequence.

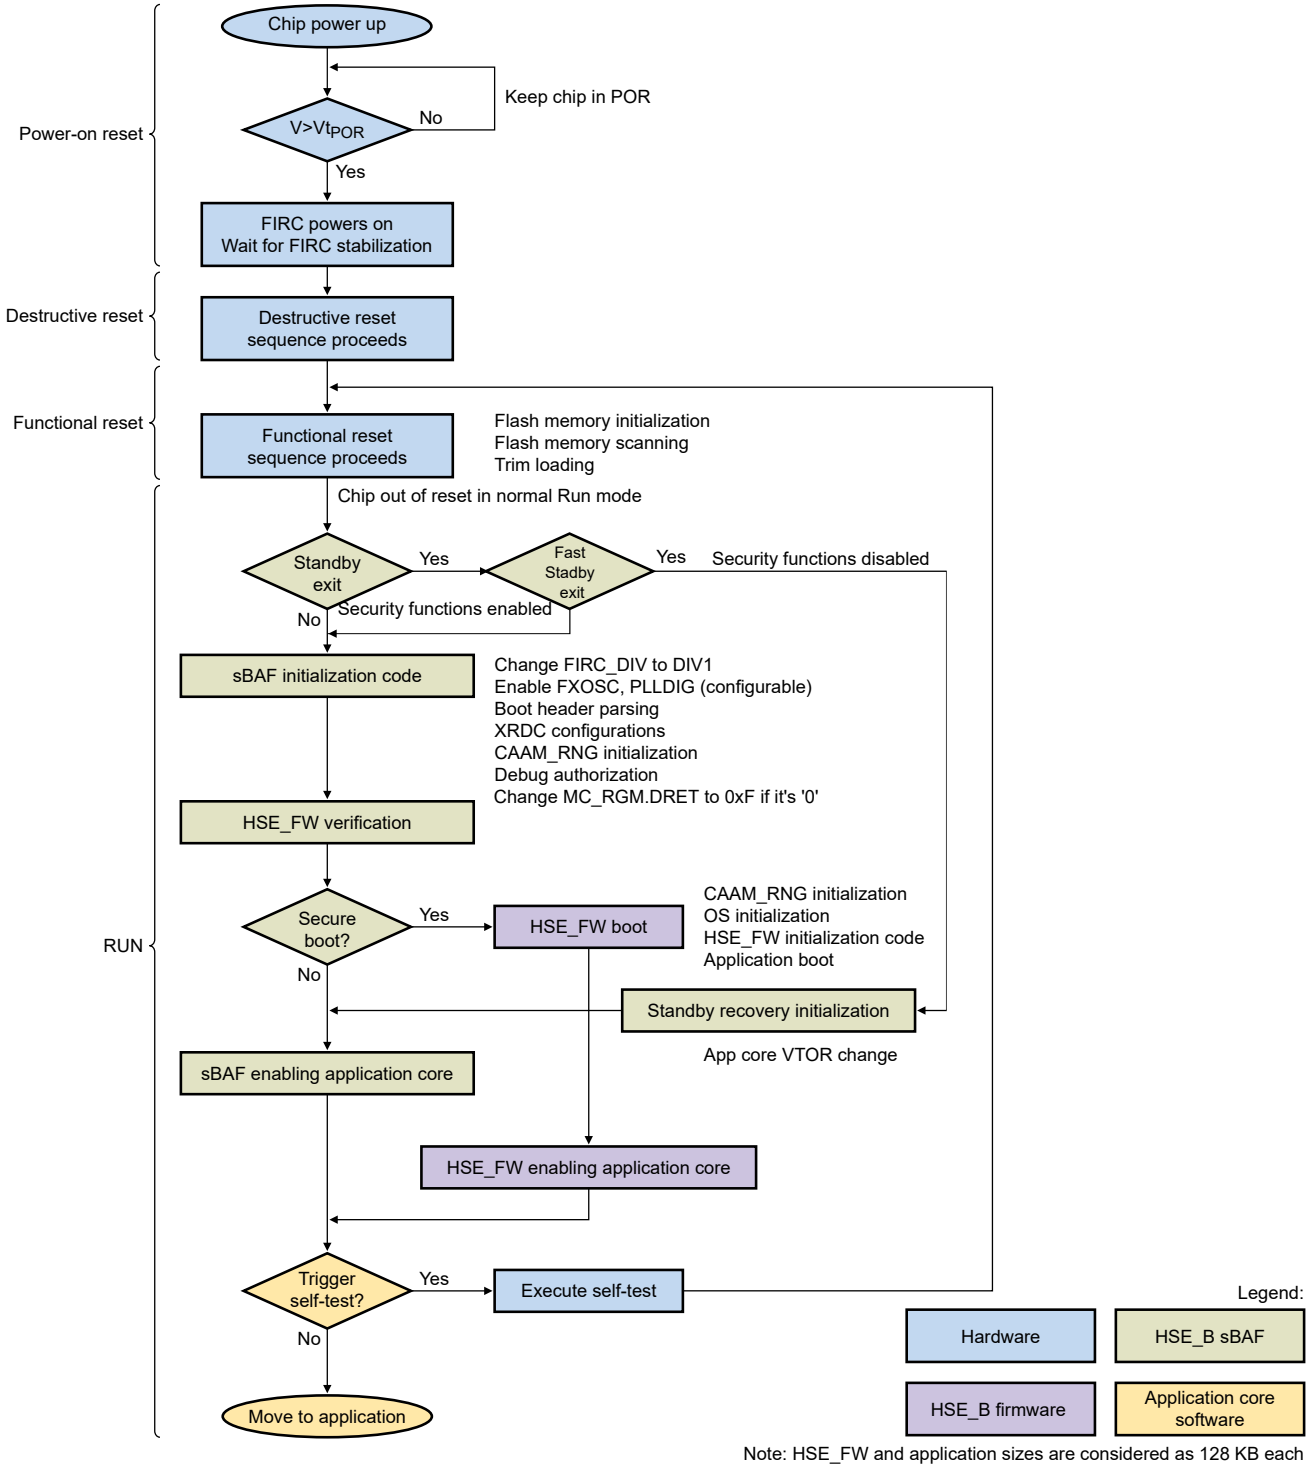

Figure 117. Chip reset and boot overview

30.4.1 POR

This stage starts when the POR event occurs, that is, when a POR source asserts. The logic within the Run power domain running on POR also resets in the chip Standby entry sequence.

NOTE

The logic in the Standby power domain does not reset in the chip Standby mode entry sequence.

The POR sequence consist of two stages:

1. Power-up (PWRUP)
2. FIRC oscillator start (FIRC_STRT)

See POR sequence for more information and Stages of the POR sequence for POR stages and their descriptions.

30.4.1.1 POR sequence

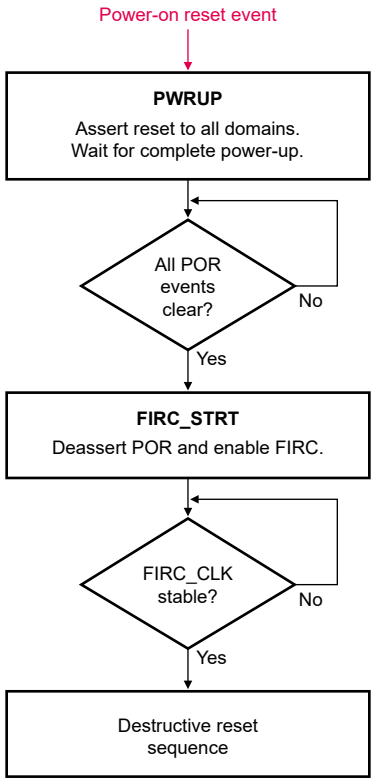

Figure 118. POR flow

30.4.2 Destructive reset

The chip enters a destructive reset sequence after the POR sequence or any destructive reset event completes. Destructive reset sequence illustrates the destructive reset sequence and Destructive sequence stage description discusses the stages of destructive sequence.

30.4.2.1 Destructive reset sequence

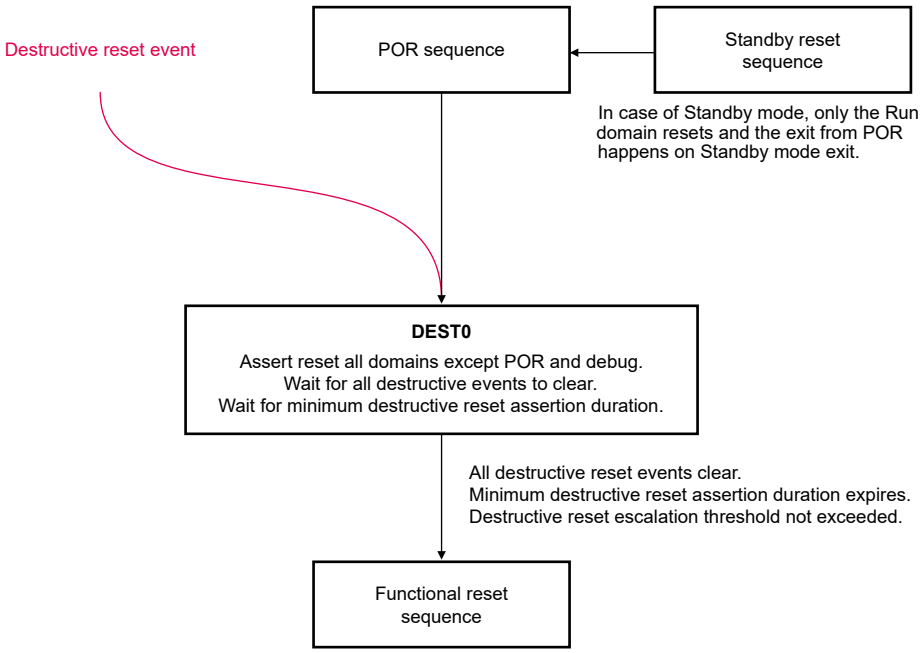

Figure 119. Destructive reset sequence

30.4.2.1.1 Destructive sequence stage description

Table 151. DEST0 description

Stage	Process
DEST0	1. Asserts reset to the entire chip, except logic running on POR. 2. Waits for all the destructive reset events to clear. 3. Waits for the minimum destructive reset assertion duration of eight FIRC_CLK cycles. 4. Deasserts after stage completion.

30.4.2.2 Destructive reset event bypass

This chip supports a destructive reset event demotion mechanism that the application software configures. The destructive reset bypasses and an interrupt event occurs (demotion). Table 152 discusses details related to GPR configuration and corresponding interrupt identification.

A successful chip operation is not guaranteed if a destructive reset event is bypassed.

Table 152. Destructive reset event bypass

Destructive reset event	Destructive reset event description	DCM field to bypass reset event	NVIC interrupt ID
MC_RGM.DES[PLL_LOL]	PLL loss of lock	DCM.DCMRWP3[9]	212

30.4.3 Functional reset

The chip enters the functional reset sequence when any of the following events occur:

- Functional reset
- POR or destructive reset (after the DEST0 stage completion)

On any functional reset event, the chip starts a functional reset entry sequence before the functional reset asserts and ensures the stability of logic running on a destructive reset and POR. On a destructive reset event or POR events the functional reset entry sequence does not execute.

The functional reset exit sequence consists of steps that ensure proper initialization of the chip after functional reset recovery.

30.4.3.1 Functional reset sequence

Functional reset flow illustrates the functional reset flow and Functional reset sequence descriptions discusses the functional reset stages and their descriptions.

Stages FUNC0 to FUNC6 present the functional reset entry sequence. It occurs on any functional reset event before the functional reset. In other words, when a functional reset event occurs, MC_RGM holds the asserted reset and executes the functional reset entry sequence. After the sequence completes, MC_RGM resets the chip, which remains in Run mode during the functional reset entry sequence.

Stages FUNC7 to FUNC11 present the functional reset exit sequence, which occurs after a functional reset event before deasserting the chip reset. This includes handshaking with the flash memory and analog blocks, ensuring correct operation after reset exit.

30.4.3.1.1 Functional reset flow

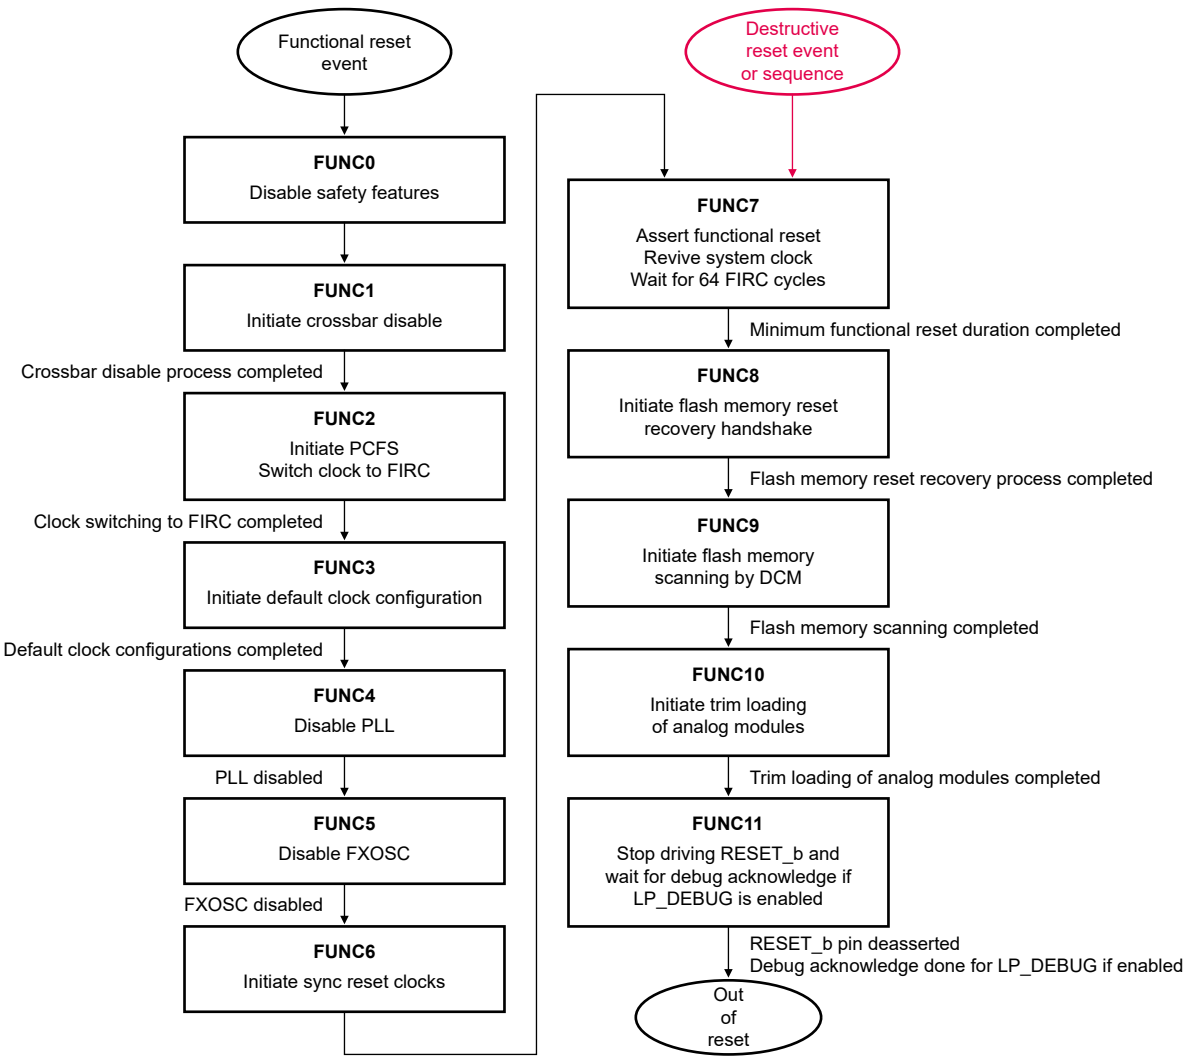

Figure 120. Functional reset flow

30.4.3.2 FUNC9 and FUNC10 stage bypass for faster Standby mode exit

The chip supports optional bypassing of the FUNC9 and FUNC10 (only FIRC and PMC phases) stages on Standby mode exit to considerably reduce the Standby mode exit duration. This feature is recommended only for Standby mode exit and must be configured on:

- Standby mode entry sequence
- SW3
- Disabled on Standby mode exit

See the "Faster Standby recovery" section in the "Power Management" chapter for more information.

30.4.3.3 Standby reset sequence

The logic within Run domain is reset additionally apart from the reset sequence in the chip standby entry sequence, wherein all the resets assert (POR, destructive, and functional) to the Run domain logic. The chip standby entry sequence does not have any impact on the logic in Standby power domain.

Wake-up from Standby mode removes the resets to the Run domain in the standby entry sequence.

See the "Peripheral reset status" section in the "Reset Overview" chapter for the logic present in Run domain.

30.4.3.4 Reset function redirection

Resets may escalate or demote to an IRQ, depending on the chip configuration.

30.4.3.4.1 Functional reset demotion to an interrupt

This chip supports the reset sequence demotion feature for functional resets. You can configure a functional reset to create an interrupt instead of a reset (see the MC_RGM chapter for details).

30.4.3.4.2 Reset escalation

The chip supports the reset escalation feature. If multiple functional or destructive resets occur, the related reset can escalate to a higher priority reset sequence (see the "Functional reset escalation" and "Destructive reset escalation" sections in the MC_RGM chapter).

30.4.3.4.2.1 Destructive reset escalation

You can enable destructive reset escalation by configuring a DCF client. You must also configure the destructive count threshold in MC_RGM.DRET (see "Destructive Reset Escalation Enable Register (DEST_RST_ESC):dcf_client_dest_rst_esc" in the DCF file attached to this document). The escalation event can individually be enabled or disabled for each reset source, and the fields in the dcf_client_dest_rst_esc register correspond with the fields in MC_RGM.DES register.

After being configured, MC_RGM immediately asserts a destructive reset escalation when the destructive event count reaches the threshold count in MC_RGM.DRET[DRET]. When the destructive and escalation reset assert, the reset sequence immediately enters the DEST0 state. The reset sequencing remains in DEST0 until a POR event occurs. If enabled, the destructive reset escalation counter increments with each destructive reset event. The application software clears the destructive reset escalation counter by writing any value to MC_RGM.DRET[DRET].

NOTE

You can configure GPR settings to allow demotion of destructive resets to interrupts instead of escalation (DCMRWP3[DEST_RST9_AS_IPI]). See Destructive reset event bypass for more information.

30.5 Reset timing diagram

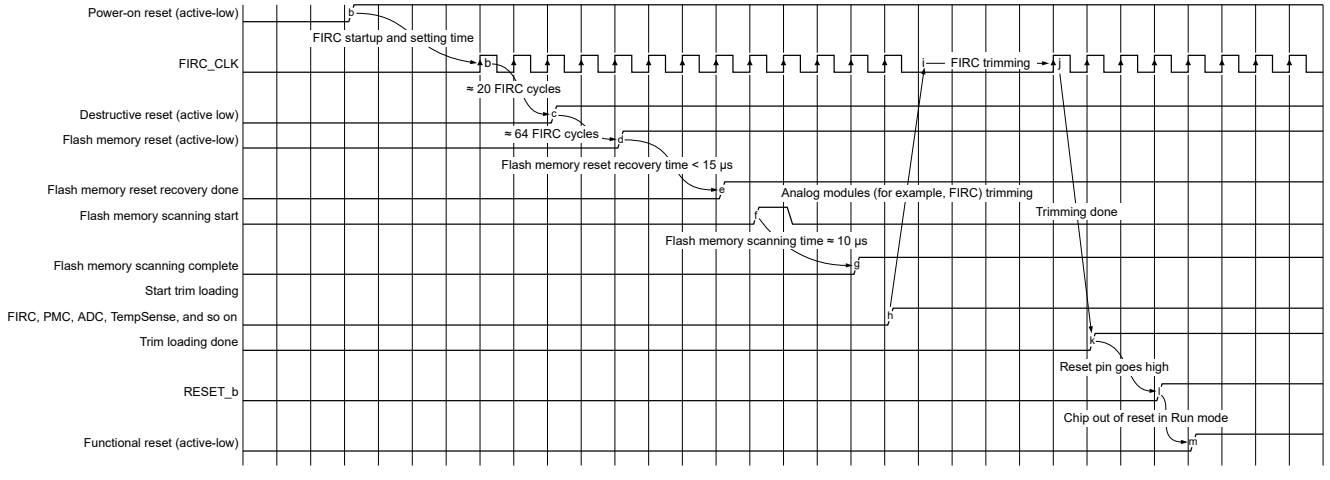

Figure 121. Reset timing diagram

30.6 Chip status after reset deassertion

Table 153. Chip status after reset deassertion

Function or feature	After POR deassertion	After destructive reset deassertion	After functional reset deassertion
Clock sources	• FIRC_CLK and SIRC_CLK on • Others off	• FIRC_CLK and SIRC_CLK on • Others off	• FIRC_CLK and SIRC_CLK on • SXOSC_CLK same as before functional reset • FXOSC_CLK and PLL_PHIn_CLK off
Clock selection	FIRC_CLK	FIRC_CLK	FIRC_CLK
Clock dividers	Default configuration	Default configuration	Default configuration
Reset status flags	MC_RGM.DES[F_POR] equals 1, others equal 0	MC_RGM.DES[F_DR_n] equals 1, others equal 0	MC_RGM.FES[F_FR_n] equals 1, others equal 0
MC_ME previous mode	Reset	Reset	Reset
FCCU fault information	Cleared	Cleared	Retained
HSE_B RAM	Initialized	Initialized	Initialized
SRAM content	Invalid	Invalid	Retained
DCF configurations in DCM	Reset value	Existing loaded value (reset value after POR)	Reloaded from flash memory
Cores	All off	All off	HSE_B core on, others off
Logic on POR[1]	Out of reset with default configuration	Out of reset with default configuration	Out of reset with default configuration
Logic on destructive reset [1]	Under reset with default configuration	Out of reset with default configuration	Out of reset with default configuration
Logic on functional reset [1]	Under reset with default configuration	Under reset with default configuration	Out of reset with default configuration

Table continues on the next page...

Table 154. Module reset status (continued)

Module instances[1]	Destructive	Functional	Power domain[2]	Part of LBIST[3]
N	No portion of the module resets on this particular reset			

1. All the modules listed in this table are reset on a POR event. See the memory map file attached to this document for the availability of modules across various parts in the MWCT2xxxS family.
2. The modules in the RUN domain get reset on standby exit. The modules in STANDBY domain are not impacted by standby exit and retain their contents. However in case of standby exit via functional reset or destructive reset event, the corresponding flops within the STANDBY domain modules will also get reset.
3. The modules in the LBIST logic get reset on selftest completion.
4. Flash memory scanning logic is available in the Run domain. GPRs and LC decode logic are available in Standby domain.
5. All memory-mapped registers are on functional reset. The trimming logic is on destructive reset. Rest of counter and other stuff is on POR.
6. During functional reset stages FUNC2 and FUNC3 (see the Functional reset sequence descriptions for functional reset stage descriptions), MC_CGM.MUX_*n*_CSC and MC_CGM.MUX_*n*_DIV_*m* are automatically set to their default values. The default value of the MC_CGM.MUX_*n*_CSC[SELCTL] selects FIRC_CLK as the source clock for all multiplexers. The default value of the MC_CGM.MUX_*n*_DIV_*m* is register instance specific (see the "MC_CGM register descriptions" section in the Clock Generation Module (MC_CGM) chapter).
7. Only PIT_0 supports the RTI feature, and exists in the Standby domain.
8. The system domain is reset on functional reset. A POR will reset it completely.
9. PMC registers are reset on a destructive reset except PMC.LVSC, which is reset only by own PMC.LVSC[PORF] flag. The LVR and POR logic is reset on an LVR or own PORF (see PMC.CONFIG and PMC.LVSC descriptions for details).
10. Reset on a functional reset; however, reset recovery occurs before the chip functional reset recovery, at the functional reset exit sequence start, for proper trim scanning and loading.
11. SXOSC is reset on a destructive reset so that the RTC operates properly across a functional reset.
12. RTC operates during a functional reset.
13. The functional reset maps to nSYSRESET to Arm Cortex-M7 and the destructive reset maps to nPORESET to Arm Cortex-M7. See the Cortex-M7 TRM for further description on part of logic on different domains within Cortex-M7.

30.8 System RAM retention across functional reset

System RAM retains content during functional reset through the crossbar halt handshake. The system crossbar halts during the functional reset entry sequence. Therefore, the accesses do not cause any content corruption (see Functional reset sequence for more information).

Follow this sequence for the crossbar halt handshake (see Halt handshake using the daisy-chaining method for gasket locations):

1. Send a halt request to the HSE_B AXBS, DMA AXBS, and EMAC IAHB bridges in parallel.
2. Wait for a halt acknowledgement from HSE_AXBS and DMA AXBS.
3. Send a halt request to the DMA IAHB and HSE_B IAHB gaskets.
4. Wait for a halt acknowledgement from all the gaskets listed in the aforementioned steps.
5. Send a halt request to the system AXBS.
6. Wait for a halt acknowledgement from the system AXBS.
7. Send a halt request to a peripheral AXBS.
8. Wait for a halt acknowledgement from a peripheral AXBS.
9. Send a halt request to the TCM IAHB and QSPI IAHB gaskets.
10. Wait for a halt acknowledgement from all the gaskets listed in the aforementioned steps.
11. Send a halt request to the AIPS0 IAHB and AIPS1 IAHB gaskets.
12. Wait for a acknowledgement from all of the gaskets listed in the aforementioned steps.
13. Send a halt request to TCM AXBS.
14. Wait for a halt acknowledgement from TCM AXBS.

NOTE

AXBS halt handshake sequence is automatically performed by the hardware.

After this halt sequence completes, the crossbar halt acknowledgement sequence also completes and the chip proceeds to the FUNC1 stage in the functional reset entry sequence.

NOTE

RAM retention is supported across the functional reset event for system RAMs only and not for HSE_B or peripheral memories.

30.8.1 Halt handshake using the daisy-chaining method

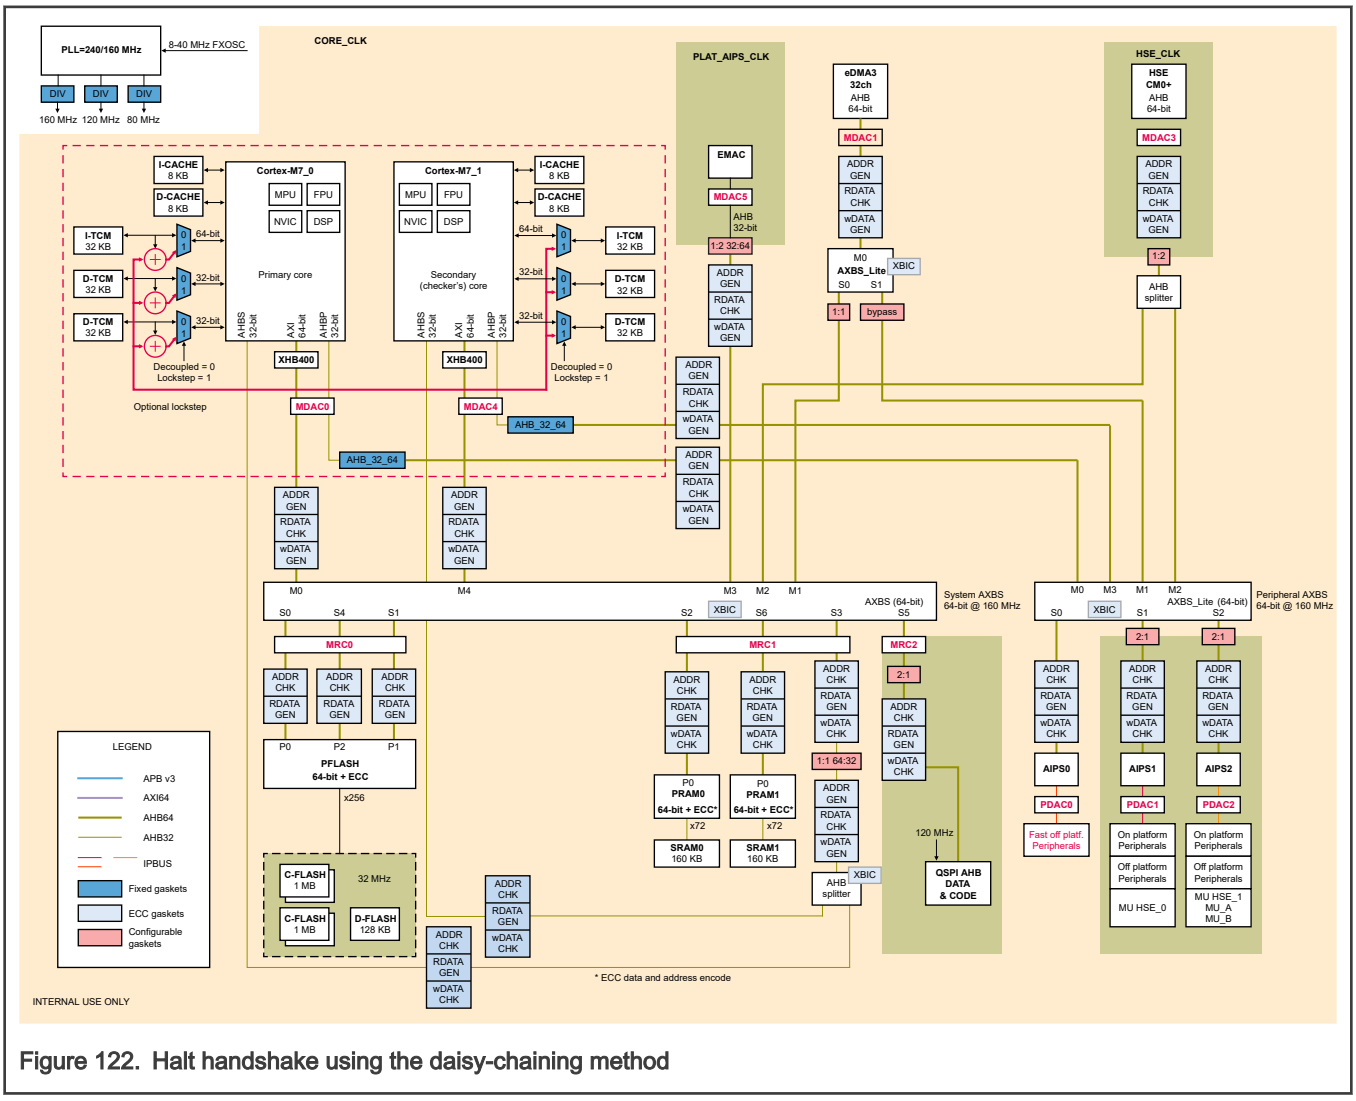

Figure 122. Halt handshake using the daisy-chaining method

30.9 Pad state during reset and after reset

SIUL2 controls the GPIO functionality. It sets to its default state on a functional reset, and ensures that every pad initializes to its default state (see the default configurations and reset states of the chip's GPIO in the IOMUX file attached to this document).

30.10 Reset pin

This chip contains a bidirectional reset pin (RESET_b) indicating the reset state. RESET_b multiplexes with the other functions on port PTA5 (see the IOMUX file attached to this document).

The DCF configuration controls the multiplexing capabilities of RESET_b. The default configuration of the RESET_b port is that of a dedicated reset signal (for example, not multiplexed. See the DCF clients file attached to this document for more information).

The RESET_b pin offers the following uses if you configure it for the reset functionality:

- Acts as an external destructive reset source
- Acts as an indicator for the chip reset sequence for both functional and destructive reset sequences

NOTE

MC_RGM.FES[F_EXR] captures an externally sourced RESET_b assertion for a destructive reset.

The RESET_b pin also indicates an internally asserted reset to external modules. It has a weak internal pullup. In normal Run mode, it keeps the chip out of reset.

30.10.1 Reset pin control during self-test

You can write 1 to MC_RGM.ERCTRL[ERASSERT] to assert RESET_b (writes only in Supervisor mode), before LBIST or MBIST executes. MC_RGM then asserts RESET_b and tristates the GPIO pins placing them in a safe state. Tristating GPIO ensures a safe state for the chip pins when LBIST or MBIST executes. Following BIST, the chip executes a reset sequence. The chip configures again for the application software, before executing the safety function. MC_RGM.ERCTRL[ERASSERT] clears on a functional reset. See Figure 8 for an illustration.

NOTE

Writing 1 to SIUL2.MSCR*n*[SMC] enables the GPIO pins and the chip continues its normal I/O functionality.

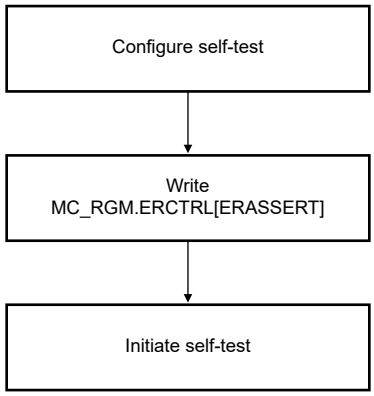

Figure 123. Reset pin control before self-test

Multiple chip configuration scenarios cause RESET_b to react differently after self-test completion:

- You can write 1 to MC_RGM.ERCTRL[ERASSERT] causing RESET_b to assert. This assertion does not impact the reset sequence, and the reset indicates that the chip is not available in Functional mode (although the chip is not in reset sequence).

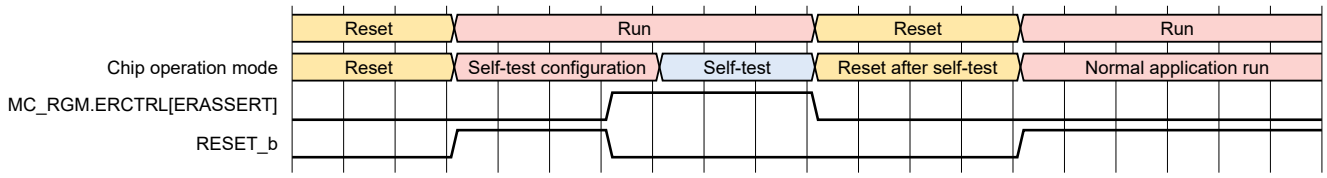

Figure 124. Reaction when MC_RGM.ERCTRL[ERASSERT] = 1

- If MC_RGM.ERCTRL[ERASSERT] = 0 (the default value), the RESET_b pin goes low after self-test completes. After self-test, the chip undergoes a functional reset in which the chip hardware writes 0 to MC_RGM.ERCTRL[ERASSERT]. The RESET_b pin goes high after the reset deasserts.

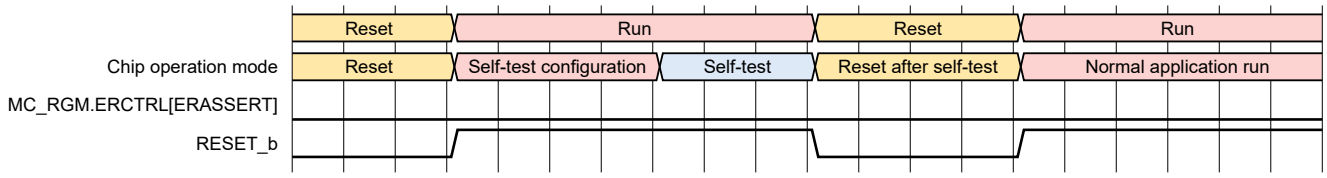

Figure 125. Reaction when MC_RGM.ERCTRL[ERASSERT] = 0

- If MC_RGM.ERCTRL[ERASSERT] = 0 (the default value), but you write 1 to MC_RGM.FBRE[ST_DONE], the RESET_b pin does not assert after self-test completes.

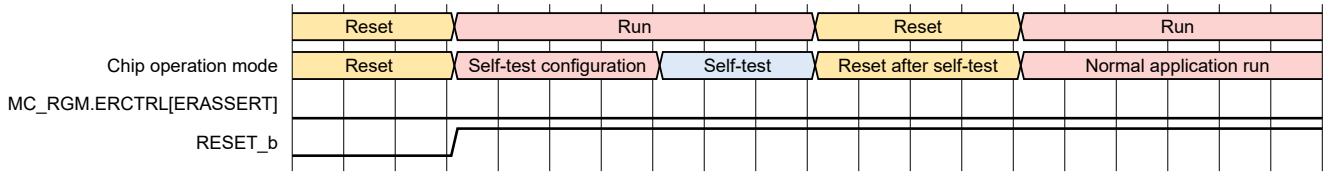

Figure 126. Reaction when MC_RGM.ERCTRL[ERASSERT] = 0 and MC_RGM.FBRE[ST_DONE] = 1

30.11 Reset control in Lockstep mode

In Lockstep mode, a two-cycle delayed lockstep implementation controls the reset to both the application cores, Cortex-M7_0 and Cortex-M7_1. This lockstep implementation means Cortex-M7_0 starts two clock cycles before Cortex-M7_1. You can configure the dcf_client_utest_misc[LOCSTEP_EN] field to control the lockstep (see the DCF clients file attached to this document for more information).

The Cortex-M7 cores consist of two reset domains:

- PORESETn (see PORESETn control in Lockstep mode)
- SYSRESETn (see SYSRESETn control in lockstep)

.

30.11.1 PORESETn control in Lockstep mode

PORESETn includes debug modules that work across chip warm resets. The PORESETn domain resets on any destructive reset event. PORESETn deasserts after two cycles of reset deassertion synchronization delay, as soon as destructive reset sequence exits. In Lockstep mode, the reset deassertion to Cortex-M7_1 is further delayed by two CORE_CLK cycles as shown in PORESETn control in Lockstep mode.

30.11.1.1 PORESETn control in Lockstep mode

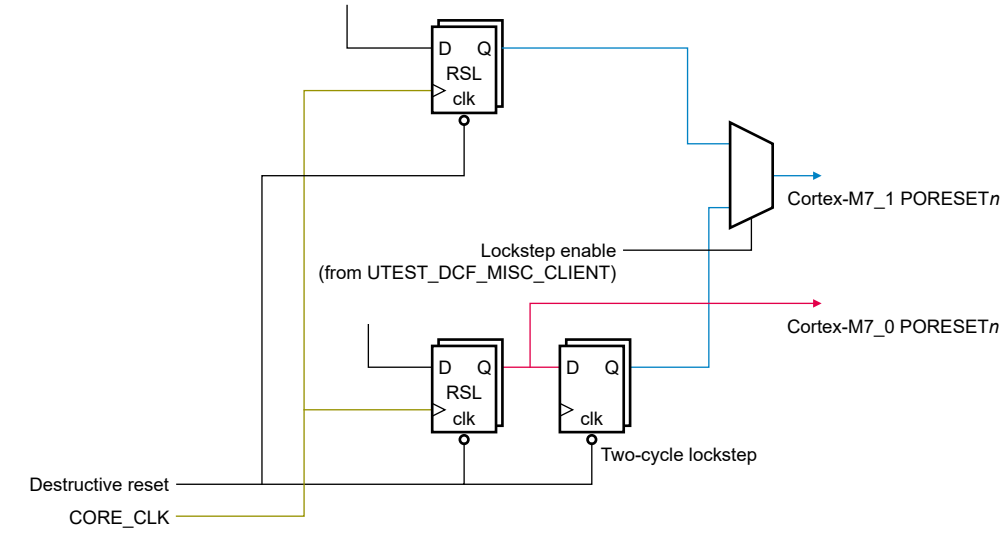

Figure 127. PORESETn control in Lockstep mode

30.11.2 SYSRESETn control in lockstep

Most of the components within the Cortex-M7 cores reside in the SYSRESETn domain, except the debug modules. These components reset on any functional reset event. The SYSRESETn reset remains gated even if it exits the functional reset until MC_ME.PRTN0_COREn_PCONF[CCE] enables the core clocks. The debugger can hold the core's SYSRESETn domain in reset, as described in section Application core debug from first instruction.

After a chip's functional reset deasserts, the core clocks are functional, and there is no gating from the debugger, the application core's SYSRESETn is released after a two-cycle reset deassertion synchronizer delay. In Lockstep mode, the reset deassertion to Cortex-M7_1 is delayed by two CORE_CLK cycles, as shown in SYSRESETn control in Lockstep mode.

30.11.2.1 SYSRESETn control in Lockstep mode

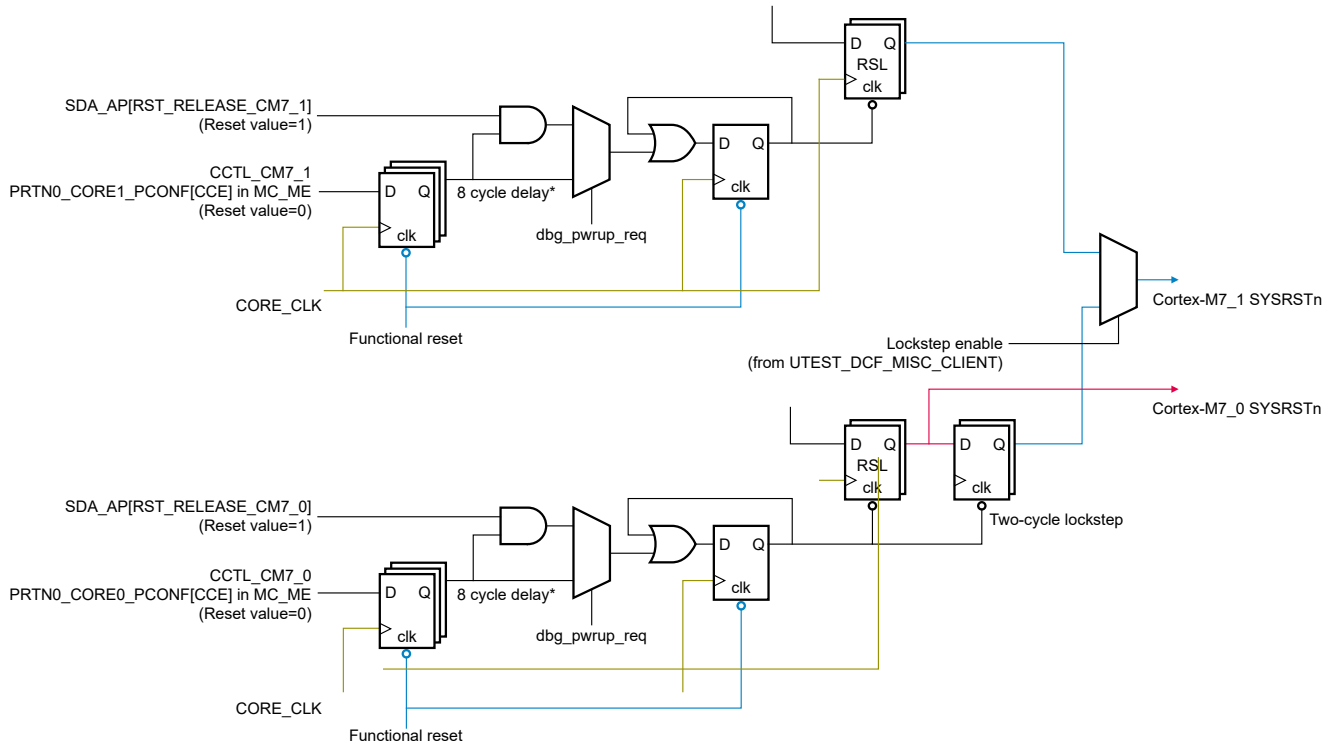

Figure 128. SYSRESETn control in Lockstep mode

30.12 Application core debug from first instruction

The chip supports application core debug starting on the first instruction. This is supported on any functional reset and through a RESET_b pin destructive reset for debug from destructive reset onwards using the following sequence (see SYSRESETn control in lockstep for more information on implementation).

30.12.1 Debug from first instruction on power-up or destructive reset onwards

1. When RESET_b is held low, the chip goes through a destructive reset sequence.
2. When you pull down the RESET_b pin, the chip goes through a destructive reset sequence, exits from the destructive reset, and remains in functional reset, until the reset pin is released.
3. When the RESET_b pin remains pulled down, the debugger configures SDA_AP.SDAAPRSTCTRL[RSTRELTLCM70], SDA_AP.SDAAPRSTCTRL[RSTRELTLCM71] and SDA_AP.SDAAPRSTCTRL[RSTRELTLCM72] according to the requirements. To enable debug from first instruction, you write 0 to these fields. To disable, you write 1. By default, the debug disables from the first instruction.
4. On releasing the reset pin, the chip exits from the functional reset sequence and HSE_B starts executing.
5. The PORESETn deassertion occurs for the application cores simultaneously (in case of lockstep, Cortex-M7_1 PORESETn deasserts after a two-cycle delay). The corresponding core clock enable gates the deassertion of SYSRESETn to cores. The SYSRESETn to the cores deasserts as follows.
6. On the basis of whether the debugger authentication is performed via challenge, response, or neither of them, you can consider these scenarios:
    a. Debugger not connected (DBG_PWRUP_REQ = 0):
        i. BAF or FW writes to the clock enable control field in MC_ME for application cores, that is, to MC_ME.PRTN0_CORE0_PCONF[CCE] for Cortex-M7_0, MC_ME.PRTN0_CORE1_PCONF[CCE] for

Cortex-M7_1 and MC_ME.PRTN0_CORE2_PCONF[CCE] for Cortex-M7_2 or to all the three fields as required.

ii. The clock enables in the subsequent clock cycle.

iii. SYSRESETn deasserts after ten clock cycles (adding eight clock cycles of delay ensures that reset always deasserts when the clock is available; two cycle of reset deassertion delay). In case of lockstep, Cortex-M7_1 reset is delayed by two additional clock cycles.

b. Debugger connected (DBG_PWRUP_REQ = 1):

i. BAF or FW writes to the clock enable control field in MC_ME for application cores, that is, to MC_ME.PRTN0_CORE0_PCONF[CCE] for Cortex-M7_0,MC_ME.PRTN0_CORE1_PCONF[CCE] for Cortex-M7_1 and MC_ME.PRTN0_CORE2_PCONF[CCE] for Cortex-M7_2 or to all the three fields as required.

ii. The clock is enabled.

iii. The debugger waits for sometime (at least ten clock cycles) and then writes 1 to SDA_AP.SDAAPRSTCTRL[RSTRELTLCM70] for Cortex-M7_0, SDA_AP.SDAAPRSTCTRL[RSTRELTLCM71] for Cortex-M7_1 and SDA_AP.SDAAPRSTCTRL[RSTRELTLCM72] for Cortex-M7_2, for releasing SYSRESETn of the corresponding core.

iv. SYSRESETn deasserts after ten clock cycles (adding eight clock cycles of delay ensures that the reset always deasserts when the clock is available; two cycle of RSL delay). In case of lockstep, the Cortex-M7_1 reset is delayed by two additional clock cycles.

NOTE

- CortexM7_1 is present in MWCT2D16S.

30.12.2 Debug from first instruction on functional reset onwards

If you enable debug, on functional reset, the debug connection is retained. That is because the complete debug infrastructure is on destructive reset domain.

30.12.3 Debug on standby exit by wake-up or functional reset

If you enable debug before standby entry, then the Standby domain stores the final status. The configuration for reset release is reset (SDA_AP.SDAAPRSTCTRL[RSTRELTLCM70], SDA_AP.SDAAPRSTCTRL[RSTRELTLCM71] and SDA_AP.SDAAPRSTCTRL[RSTRELTLCM72]. The reset value of the three fields is 1), which defaults to debug from the first instruction disabled.

You must configure the reset release on standby exit. It uses MC_RGM's low-power debug protocol before ungating the reset deassertion.

30.13 Glossary

DCF	Device configuration format
POR	Power-on reset

Chapter 31
Boot Overview

31.1 Overview

31.1.1 Introduction

This chapter describes the system boot sequence and provides details about boot options.

After the hardware reset sequence completes, the only CPU available is in the HSE subsystem that is referred to as the HSE CPU.

The HSE CPU starts executing firmware code in the HSE code flash memory from a fixed location that contains the SBAF code. This code provides the boot sequence until the control is passed, based on the type of boot:

- Nonsecure boot: Passes control to the customer software that executes on one or all the application cores.
- Secure boot: Passes control to the HSE firmware running on the HSE CPU.

31.2 Appendix

SBAF takes into account the following scenarios to prevent stuck in reset of chip:

- After observing the eight functional resets in the chip, BAF enters Recovery mode sequence to recover the application core's failing status.
- SBAF does not allow the chip's LC to advance to the OEM_PROD or IN_FIELD stage, if the application does not program CUST_DB_PSWD/A.
- SBAF boots the application from the system-RAM during recovery mode sequence to avoid unpredictable behavior.

31.2.1 Features

The features of SBAF are as follows:

- Supports secure and nonsecure boot modes
- Supports application boot core selection
- Allows chip LC advancement
- Supports debug authorization
- Supports XRDC configuration

31.3 Chip configuration

This section describes the chip configuration details for MWCT2xxxS variants after you program SBAF and clear the HSE firmware feature flag.

If the security is enabled, see the HSE Firmware Reference manual for more information. Please contact NXP sales executive for details.

31.3.1 Memory map

This section explains the memory sections used by SBAF in various configurations.

31.3.1.1 Configuration details when the HSE firmware usage feature flag is disabled

Table 155. Configuration details when the HSE firmware usage feature flag is disabled

Memory section	MWCT2015S	MWCT2016S, MWCT2D16S	MWCT2D17S
Flash memory	1 MB	2 MB	4 MB
IVT locations in priority order	0040_0000h, 0048_0000h, 1000_0000h	0040_0000h, 0050_0000h, 1000_0000h	0040_0000h, 0050_0000h, 0060_0000h, 0070_0000h, 1000_0000h
Reserved	004F_4000h to 004F_FFFFh (48 KB)	005F_4000h to 005F_FFFFh (48 KB)	007F_4000h to 007F_FFFFh (48 KB)
Application flash memory area	0040_0000h to 004F_3FFFh (976 KB)	0040_0000h to 005F_3FFFh (2000 KB)	0040_0000h to 007F_3FFFh (4048 KB)
Application data flash memory	1000_0000h to 1000_FFFFh (64 KB)	1000_0000h to 1001_FFFFh (128 KB)	

31.3.1.2 Configuration details when the HSE_B firmware usage feature flag is enabled

The following table explains the memory sections used by the SBAF in case HSE firmware feature flag is enabled in UTEST.

Table 156. Configuration details when the HSE_B firmware usage feature flag is enabled

Memory section	MWCT2015S	MWCT2016S, MWCT2D16S,	MWCT2D17S
Flash memory	1 MB	2 MB	4 MB
IVT locations in priority order	0040_0000h, 0048_0000h, 1000_0000h (256 Bytes)	0040_0000h, 0050_0000h, 1000_0000h (256 Bytes)	0040_0000h, 0050_0000h, 0060_0000h, 0070_0000h 1000_0000h (256 Bytes)

31.4 Common configuration pertaining to the chip

31.4.1 Feature configuration in CUST_DEL Device Life Cycle

The following table describes the status of various features when chip's LC is in the CUST_DEL stage. The application software configures features directly or indirectly.

Table 158. Feature configuration in CUST_DEL Device Life Cycle

Feature	Configuration information	Status	Configurability
OTA functionality		Disabled	Yes Application requests the HSE firmware or SBAF to enable this feature.
HSE firmware usage feature flag	Indicates whether the firmware installation is allowed in the chip. By default, this flag is unprogrammed, and SBAF assumes that the firmware installation is not allowed.	Unprogrammed	Yes To enable this feature, program in the UTEST location (see UTEST flag description for more information).

Table continues on the next page...

Table 158. Feature configuration in CUST_DEL Device Life Cycle (continued)

Feature	Configuration information	Status	Configurability
SBAF firmware		Programmed	No
HSE firmware	You must program the HSE firmware. An encrypted and signed firmware image is always delivered to you.	Not programmed	Yes SBAF can install this feature when the application software requests.
Image vector table		Not programmed	Yes The application software can program this feature.
SWT0		Disabled	By SWT bit in boot configuration word.
Boot sequence	Boot sequence is a nonsecure boot, which means, the SBAF boots the application without any authentication.	Nonsecure boot	Yes It can be changed to secure boot by programming the BOOT_SEQ bit in IVT.
Life Cycle		Customer delivery	Yes Advance by SBAF or HSE firmware when requested by application software.
Application core enablement status	Applications cores are booted in recovery mode sequence at address 2040_0100h.	Recovery mode sequence	Yes Program the required fields in the IVT to enable single or all application cores at the required address.
FIRC frequency value		48 MHz	Yes The application can configure after SBAF moves to WFI.
Application debug authorization mode	This mode is password-based. You can program the configuration in UTEST to change the mode to Challenge Response.	Password-based approach	When the HSE firmware feature flag clears, you cannot change Debug Authorization mode. When the HSE firmware feature flag is set, you can request the HSE firmware to change

Table continues on the next page...

Table 158. Feature configuration in CUST_DEL Device Life Cycle (continued)

Feature	Configuration information	Status	Configurability
			Debug Authorization mode to Challenge Response mode.
Application core debug status	Debug of application cores is enabled in the customer delivery life cycle.	Enabled	No

31.4.2 UTEST memory location usage by SBAF

Table 159. UTEST memory location usage by SBAF

Start address	End address	Size (bytes)	Description	Programmed by	Write protected
1B00_0000h	1B00_0007h	8	HSE firmware feature usage flag. See UTEST flag description for more information.	Application software	No
1B00_0040h	1B00_0047h	8	Unique Chip Identifier (UID)	NXP	No
1B00_0050h	1B00_0057h	8	FXOSC configuration flag See UTEST flag description for more information.	Application software	No
1B00_0080h	1B00_009Fh	32	Debug password (CUST_DB_PSWD_A) After the HSE firmware usage feature flag clears, SBAF uses this location to run the debug authorization feature. SBAF copies this value in the application expected response register, which derives the HSE expected response register. The size of this register is 16 bytes, and 1B00_0090h – 1B00_009Fh is reserved. After the HSE firmware usage feature flag sets, the HSE firmware programs the password at a different location. DCM scans the password during reset only and retains the password in standby.	Application software	No

See the DCF clients file attached to this document for more information.

31.4.3 UTEST flag description

31.4.3.1 HSE firmware usage feature flag

This flag indicates to SBAF that the application intends to use the HSE firmware on the chip. By default, this flag is unprogrammed, and SBAF assumes that the HSE firmware installation is not allowed in the secure samples. However, if application allows the installation of the HSE firmware, the HSE firmware usage feature flag can be programmed in the UTEST at the 1B00_0000h location.

Table 160. HSE firmware usage feature flag

Field type	Description	Remarks
Size	64 bits	
Default value	0xFFFFFFFFFFFFFFFF	SBAF does not allow the installation of HSE firmware.
UTEST location	0x1B000000	
Configurability	Application software in CUST_DEL lifecycle	
Enable flag	Program any value other than the default value	This enables the installation of the HSE firmware.

31.4.3.2 Crystal oscillator configuration flag

See the below table for description of the flag:

Table 161. Flag fields

Field type	Description
Size	64 bits
Default value	FFFF_FFFF_FFFF_FFFFh (Boot via FIRC)
UTEST location	1B00_0050h
Configurability	Application software in any LC

Table 162. Crystal oscillator configuration flag in UTEST

Field	Description
63 - 33	FXOSC_ENABLE_MAGIC_NUMBER AAAA_5555h – Enable (FXOSC.CTRL[OSCON] = 1h) FFFF_FFFFh – Disable (FXOSC.CTRL[OSCON] = 0h)
31 - 28	Crystal overdrive protection (GMSEL) For values = 0h or Fh Uses the default value, Ch.
27 - 20	End Of Count Value (EOCV) For value = 0h Uses the default value, 9Dh.
19 - 16	Reserved
15 - 0	CRYSTAL_OSCILLATOR_FREQUENCY Frequency value of used external crystal oscillator in kHz. The valid crystal frequency range is 8000–40000 kHz.

31.5 Image vector table

The following section describes the fields in the image vector table that the application programs. SBAF scans the IVT after the chip is out of reset. The structure is 256 bytes in size. This structure contains application cores start addresses. IVT must be programmed at least at one of the locations described in Chip configuration.

After reset, SBAF searches for the first valid IVT starting from the lowest address. If there are multiple valid IVT at IVT locations at the same time, the IVT with lowest address is used.

Table 164. Image vector table

Address offset	Size in bytes	Content	Comments
00h	4	Image vector table marker	marks the starting of the image vector table location. Its value must be 5AA5_5AA5h.

Table continues on the next page...

Table 164. Image vector table (continued)

Address offset	Size in bytes	Content	Comments
04h	4	Boot configuration word	Indicates the configuration word that allows you to select the various configurations in which you can boot the chip. See the upcoming section for more information.
08h	4	Reserved	
0Ch	4	Cortex-M7_0 core start address	Specifies the boot address of the Cortex-M7_0 core in the code flash memory area. It must honor core Vector Table Offset Register (VTOR) alignment restrictions. SBAF uses this field only when the HSE firmware usage feature flag is enabled and BOOT_SEQ field is 0.
10h	4	Reserved	
14h	4	Cortex-M7_1 core start address	Specifies the boot address of the Cortex-M7_1 core in the code flash memory area. It must honor core VTOR register alignment restrictions. SBAF uses this field only when the HSE firmware usage feature flag is enabled and BOOT_SEQ field is 0.
18h	4	Reserved	
1Ch	4	Cortex-M7_2 core start address	Specifies the boot address of the Cortex-M7_2 core in the code flash memory area. It must honor core VTOR register alignment restrictions. SBAF uses this field only when the HSE firmware usage feature flag is enabled and BOOT_SEQ field is 0.
20h	4	Reserved	
24h	4	Address of LC configuration	Specifies the address of the configuration word that allows you to advance the LC. See the upcoming section for more information.
28h	216	Reserved	

31.5.1 Boot configuration word

This register informs SBAF to allow booting of selected applications.

Table 165. Boot configuration register

Table continues on the next page...

Table 165. Boot configuration register (continued)

R											APP_SWT_INIT	RESERVED	BOOT_SEQ	CM7_2_ENABLE	CM7_1_ENABLE	CM7_0_ENABLE
W																

Table 166. Boot configuration register field definition

Field	Description
31 – 6	Reserved
5	APP_SWT_INIT Controls the SWT0 enablement before passing the control to the application core(s). 0b - Disables 1b - Enables SBAF initializes SWT0 before enabling the application cores. SBAF scans this field only when the HSE firmware usage feature flag is enabled and the BOOT_SEQ field is 0.
4	Reserved
3	BOOT_SEQ Controls the boot flow of the application when HSE Firmware usage feature flag is enabled. 0b - Nonsecure boot: SBAF starts the application image without any authentication in parallel to the HSE firmware. 1b - Secure boot: The HSE firmware executes the application image after authentication. SBAF only starts the HSE firmware after successful authentication.
2	CM7_2_ENABLE Indicates whether the Cortex-M7_2 application core clock is gated after boot. 0b - Gated 1b - Ungated
1	CM7_1_ENABLE Indicates whether the Cortex-M7_1 application core clock is gated after boot. 0b - Gated 1b - Ungated
0	CM7_0_ENABLE Indicates whether the Cortex-M7_0 application core clock is gated after boot. 0b - Gated 1b - Ungated

31.5.2 Address LC configuration word

This field allows you to advance the LC. To advance LC, you must program a valid 32-bit wide value at an address given in IVT at an address offset of 24h. This address must be 4 bytes aligned and should not lie in HSE reserved area.

The following table shows the valid values for advancement in the next LCs. For all other values at the given address, LC advancement is not allowed.

Table 167. Valid values for LC advancement

Life cyle stage	Valid values for LC advancement
OEM_PROD	DADA_DADAh
IN_FIELD	BABA_BABAh

Depending on the HSE firmware feature flag, the application password on the location must program before LC advancement; otherwise, SBAF does not attempt LC advancement.

The chip provides an LC mechanism for an irreversible progression of restrictions to access the chip's security-related content. You cannot reverse the chip's LC, so it is only possible to mature the chip. SBAF advances the chip through the LC:

- CUST_DEL --> OEM_PROD or IN_FIELD
- OEM_PROD --> IN_FIELD

To advance the LC through SBAF involves inserting the LC configuration word address in the IVT. SBAF issues a destructive reset on successful advancement. If the chip is found in the same LC as the IVT indicated, you can ignore LC advancement.

31.5.3 Structure definition of image vector table

Application can use the following structure to configure the IVT.

```
typedef const struct image_vector_table
{
uint32_t Header; /*Header of IVT Structure */
uint32_t BootConfig; /*Boot Configuration Word */
const uint32_t Reserved1; /* Reserved */
const uint32_t * CM7_0_StartAddress; /*Start Address of Application on CM7_0 Core */
const uint32_t Reserved2; /* Reserved */
const uint32_t * CM7_1_StartAddress; /*Start Address of Application on CM7_1 Core */
const uint32_t Reserved3; /* Reserved */
const uint32_t * CM7_2_StartAddress; /*Start Address of Application on CM7_2 Core */
const uint32_t * Reserved4; /* Reserved */
const uint32_t * LCConfig; /*Address of LC configuration Word */
uint8_t Reserved5[216]; /* Reserved */
}ivt_t;
```

31.6 Boot flow

Below diagram explains boot sequence flow of SBAF.

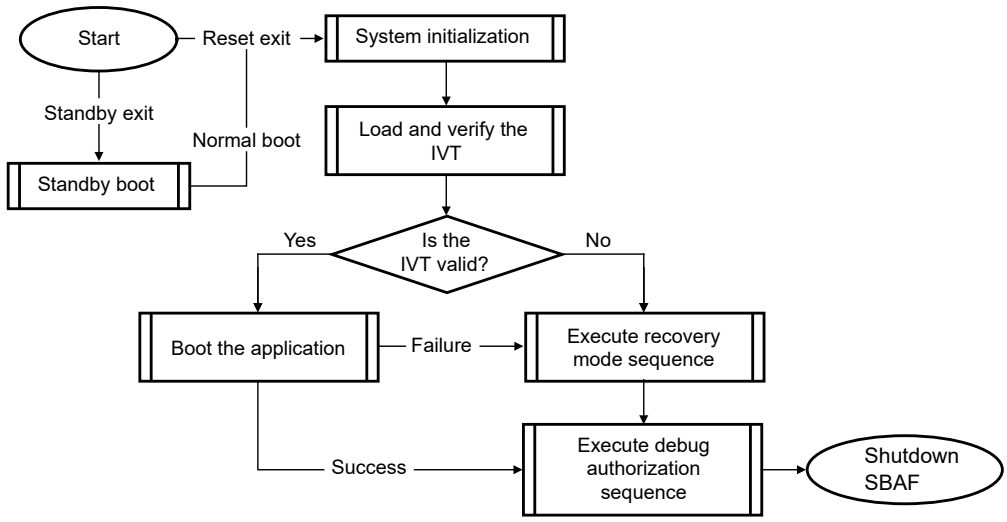

Figure 129. Boot flow

31.7 Standby boot

SBAF supports boot from standby exit. Chip register DCM.DCMRWF5 (address 402AC610h) supports boot on standby exit. This register clears on POR. See the "Device Configuration Module (DCM)" chapter in the MWCT2xxxS reference manual for more information.

You must program this register before entering Standby mode.

There are two types of boot mode on exit from standby.

- Fast Standby
- Normal boot on exit from standby

In Fast Standby mode, the SBAF boots the Cortex-M7_0 core and halts the HSE CPU. The flow of Standby Boot is explained below:

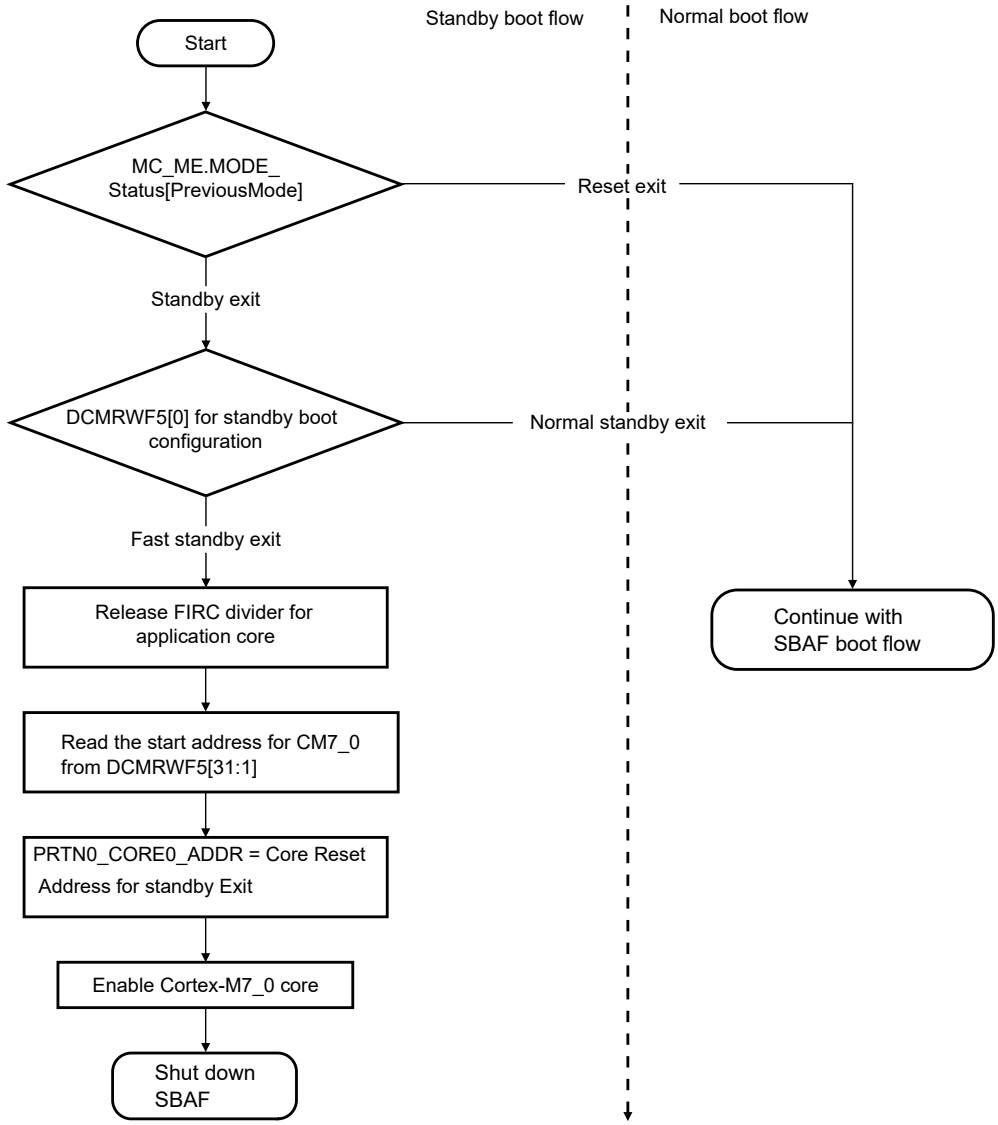

Figure 130. Standby boot flow

31.8 Reduced clock mode configuration

If you use clocking option B (Reduced clock mode configuration), the application sets the “dcf_client_utest_misc” DCF record to enable Reduced Clock mode. See the DCF clients file attached to the MWCT2xxxS reference manual for more information on DCF records.

After reset, SBAF checks for DCMROF21[HSE_CLK_MODE_OPTION]. If you configure this field for clocking option B, the SBAF configures the following dividers in MC_CGM:

- MUX_0_DC_1
- MUX_0_DC_2

Below figure explains steps for reduced clock mode configuration steps by SBAF.

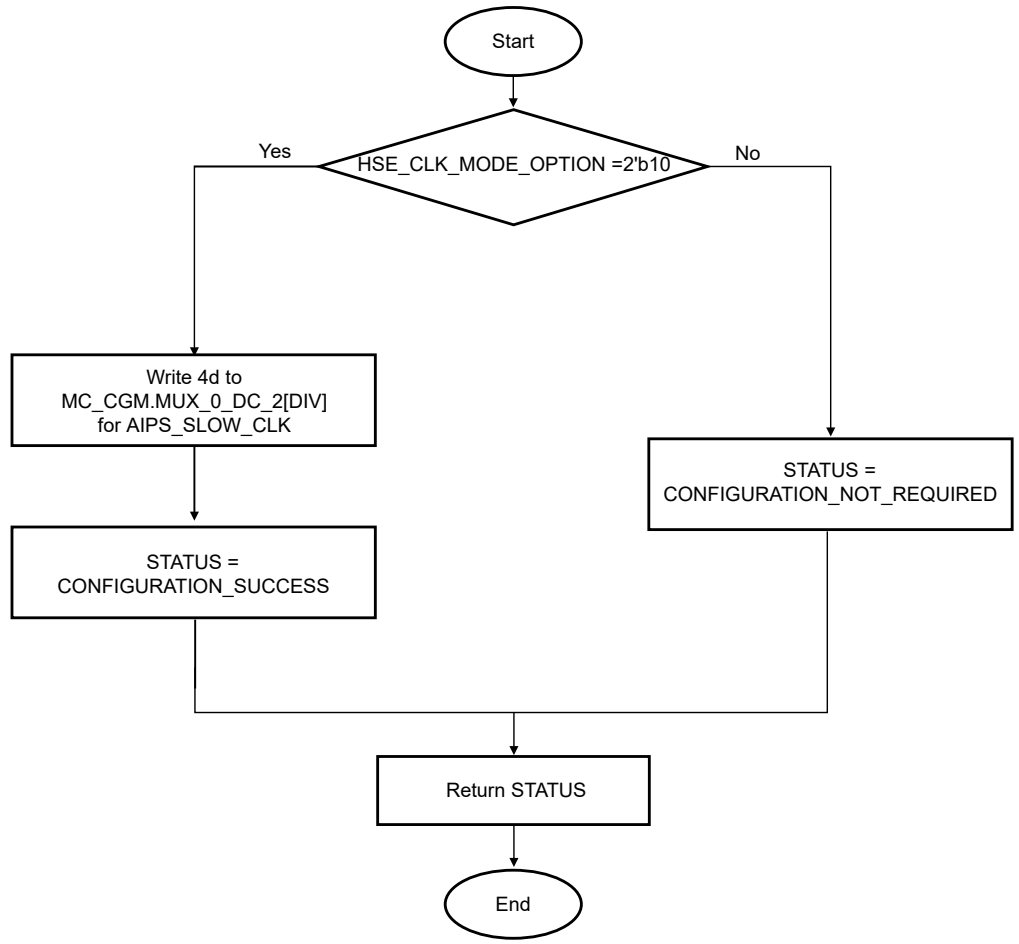

Figure 131. Reduced clock mode configuration

31.9 Debug authorization

You must program CUST_DB_PSWD_A at location 1B00_0080h. The application core debug is always password-based if the HSE firmware usage feature flag is cleared. See UTEST memory location usage by SBAF for more information.

31.10 FIRC divider register control

HSE.CONFIG_REG_GPR, at register address 4039C064h, controls the FIRC divider. This register is write-protected by default for the FIRC divider, and you cannot modify its settings.

After SBAF executes WFI, it provides write access to HSE.CONFIG_REG_GPR[FIRC_DIV_SEL], and you can configure this register. Before accessing this register, you must wait for the SBAF to enter WFI by reading core status register of HSE CPU (PRTN0_CORE2_STAT).

31.11 Application boot

The HSE firmware is responsible for securely booting the application image and not the SBAF. If secure boot is not requested (by writing 0 to the BOOT_SEQ field in Boot configuration word in IVT structure), SBAF always loads the application image, without authentication, in all chips, LC. By default, SBAF releases the reset of every core that you configure to enable.

Following flow chart explains the steps of application boot performed by SBAF.

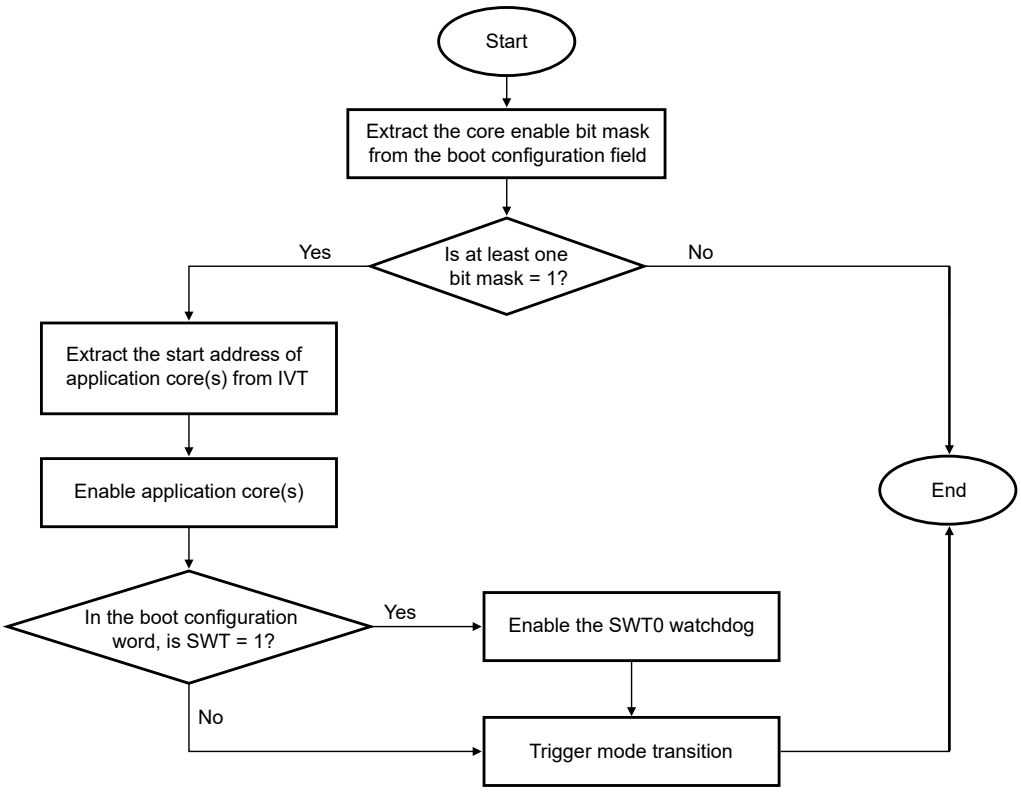

Figure 132. Application boot sequence

Before configuring HSE_CLK, you must wait for the SBAF to enter WFI by reading core status register of HSE CPU (PRTN0_CORE2_STAT).

31.12 Recovery mode sequence

This feature allows you to program the application image in LC = MCU_PROD and LC = CUST_DEL and debug the reason of corruption of IVT and re-program the IVT in other LC.

The following scenarios take place when SBAF executes the recovery mode sequence.

- Valid IVT is not found (corrupted or not programmed).
- SBAF does not boot the application.
- Boot configuration word in IVT does not program the application enablement field.
- The application issued more than eight functional resets and Disable Recovery mode on functional reset field is not set in DCM.DCMRWP1.
- The application issued more than eight destructive resets and Disable Recovery mode on destructive reset field is not set in DCM.DCMRWP1.

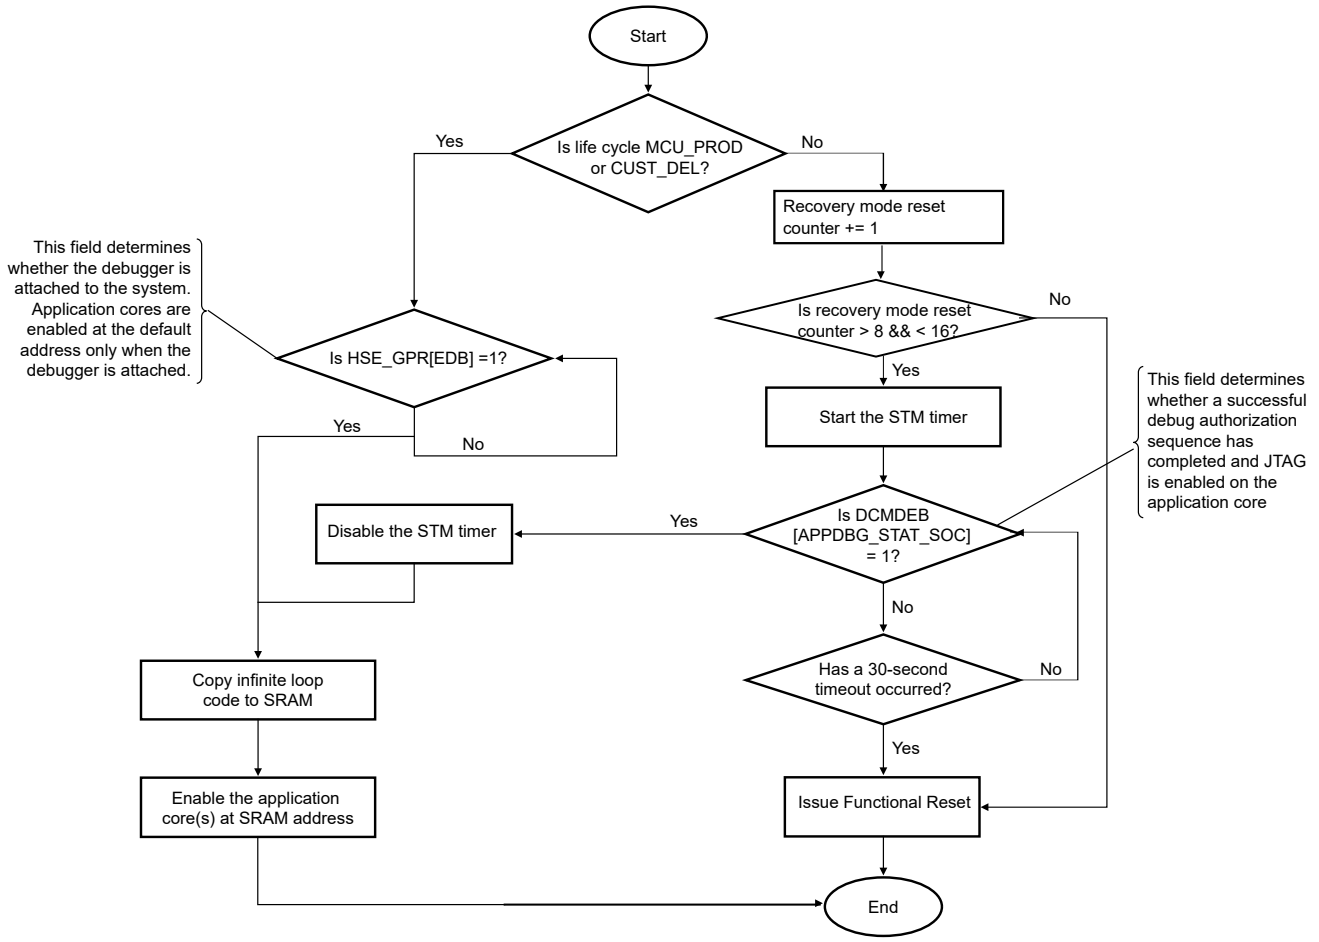

Figure 133. Recovery mode sequence

The infinite loop with the WFI code copies to SRAM1 that is 2040_0100h, and the code size is 16 bytes. To prevent prefetching errors in the application cores, place the infinite loop instruction at 2040_012Ch.

31.13 XRDC configuration

SBAF ensures that it has access to its resources and the application does not have access to area reserved for SBAF.
The following sections describe the XRDC default configuration values when you clear the HSE firmware usage feature flag.
Application should configure its XRDC and enable the XRDC by itself as SBAF does not enable the XRDC.

31.13.1 XRDC configuration of MDAC

Following table list down the default configuration of MDAC by SBAF.

Table 168. XRDC configuration of MDAC

Serial No.	Chip variant	MDAC register HSE CPU	Value	Domain number assigned to HSE CPU
1	MWCT201xS	MDA_W0_3_DFMT0	C000_0001h	1
2	MWCT2D1xS	MDA_W0_3_DFMT0	C000_0002h	2

31.13.2 XRDC configuration of MRC

Following table list down the MRC used by SBAF.

Table 169. XRDC configuration of MRC

MRC number	Region descriptor number	Remarks
0	14	Reserved for application
0	15	Reserved for application

31.13.3 XRDC configuration of PDAC

SBAF configures and lock the following peripherals for its use. SBAF provides all permissions to all domains.

Table 170. XRDC configuration of PDAC

Serial No.	Peripheral name	Peripheral PDAC number
1	Flash controller alternate	155
2	Flash memory alternate	188
3	HSE_GPR	231

31.14 BAF flash programming controls

The platform flash controller generates an exception of read-while-write if you simultaneously perform read and write on the same block. HSE CPU uses the Configuration PE Lock Register (CONFIG_PE_LOCK) in the HSE space to control the block program and erase for application.

BAF locks the high addressing code flash memory block during its execution, and it is cleared when the HSE CPU enters WFI. See the "Chip Configuration" chapter for the address of the high addressing code flash memory area.

Before programming, erasing, or executing from this address space, the application core polls for PRTN0_CORE2_STAT[WFI] to ensure that the HSE CPU is in the WFI state.

For boot sequence 1 or flash synchronization with the HSE firmware, see the HSE Firmware Reference Manual.

Below table explains PE lock bits setting in CONFIG_PE_LOCK register of HSE GPR during SBAF execution.

Table 171. PE lock fields setting in HSE.CONFIG_PE_LOCK

Chip	UTEST block	Data flash block	Code flash block 3	Code flash block 2	Code flash block 1	Code flash block 0
MWCT2015S	1	0	NA	NA	NA	1
MWCT2x16S	1	0	NA	NA	1	1
MWCT2D17S	1	0	1	0	0	1

31.15 Status registers for application usage

This section explains various status registers to provide status information to the application.

31.15.1 SBAF version information

The SBAF version is a 64-bit field. The application can read the SBAF from address 4039_C020h. The following table describes the version information.

Table 172. SBAF version information

Bits	Field name	Description
0 – 7	Reserved	Reserved
8 - 15	SOC_TYPE_ID	This field represents the SBAF firmware, which is targeted for MWCT2xxxS chip variant. Values of this field are: 0xB - used for HSE-B MWCT2014S 0xC - used for HSE-B MWCT2015S 0xD - used for HSE-B MWCT2x16S
16 - 31	FW_TYPE	This field represents the SBAF firmware type. Values of this field are: 0 – used for standard generic firmware targeting all customers 1-7 – Reserved >=8 used for Custom 1, Custom 2 (for example: Custom 1 = customer X's project A, Custom 2 = customer Y's project B)
32 - 39	Reserved	Reserved
40 - 47	BASELINE_NUMBER	Incremented when the compatibility with the previous version is broken.
48 - 55	INCREMENTAL_ NUMBER	Incremented when new features are added but compatibility kept.
56 - 63	RC_NUMBER	Release Candidate Number

31.15.2 DCM.DCMRWP1

The application can disable Recovery mode entry by SBAF after programming bits 23 and 22 of DCM.DCMRWP1.

Table 173. DCM.DCMRWP1 (address 0x402AC400)

Bits	Number of bits	R/W access by application	Description
24-31	8		Reserved
23	1	R/W	Disable Recovery Mode On Destructive Reset Indicates that this field resets by default, and SBAF allows Recovery mode sequence if the application issues > 8 destructive resets. The application can set this field to disable Recovery mode when the application issues > 8 destructive resets.
22	1	R/W	Disable Recovery Mode On Functional Reset

Table continues on the next page...

Table 173. DCM.DCMRWP1 (address 0x402AC400) (continued)

Bits	Number of bits	R/W access by application	Description
			Indicates that this field resets by default, and SBAF allows Recovery mode sequence if the application issues > 8 functional resets. The application can set this field to disable Recovery mode when the application issues > 8 functional resets.
21	1	R	Reserved
16-20	5	R	Recovery Mode Reset Counter Indicates that to enable Recovery mode functionality for the OEM_PROD and IN_FIELD LC stages, SBAF increments this counter when a functional or destructive reset is issued.
15	1	R	Reserved
11-14	4	R	Destructive Reset Counter Indicates that SBAF increments this counter when a destructive reset is issued.
0-10	11	R	Reserved

31.15.3 Status bits on HSE.GPR

SBAF writes HSE.GPR at address 4039_C028h to show status information as described in the following table.

Table 174. Status bits on HSE.GPR

Bit	Description
0	Indicates that SBAF presents and boots the HSE FW.
1-4	Reserved.
5	Indicates that SBAF boots the application cores in Recovery mode sequence.
6	Indicates that SBAF performs the debug authentication.
7-31	Reserved.

31.16 Interrupt and exception handling

- **Interrupt handling:** No special interrupt handling routines are required during the boot process. Interrupts are disabled during SBAF execution.
- **Exception handling:** SBAF enters the recovery mode sequence after enabling debug authorization. After eight consecutive functional resets or destructive resets from Application Firmware, the device enters the recovery mode sequence.
- **Boot target watchdog:** SBAF enables/disables SWT0 watchdog with default timeout, that is 25 ms according to the boot configuration word, before enabling the application core(s). It is expected that the application services this watchdog before expiration.

31.17 Hardware modules used by SBAF

- **MC_ME:** SBAF uses MC_ME to enable the application cores, mode switch, and other operations during its execution.

- **FXOSC:** SBAF configures FXOSC according to the crystal oscillator configuration flag in UTEST.
- **Clock Generation Module (MC_CGM):** SBAF configures MC_CGM in Reduced clock mode configuration.
- **DCM:** SBAF uses the DCM to identify the Life Cycle, standby boot mode configuration, lockstep, and clock mode configuration.
- **HSE_GPR:** SBAF configures hardware protection, program erase lock, FIRC divider control, and SBAF version number.
- **XRDC:** SBAF configures the XRDC module.
- **Flash Module:** SBAF always perform the write and erase operation on alternate interface. See Chip configuration for details of flash memory usage by SBAF.

31.18 Hardware IP registers details modified by SBAF

Below table summarizes the registers which are modified by SBAF when HSE Firmware usage feature flag is disabled.

Table 175. Hardware IP registers modified by SBAF

IP	Register Name	Default value (hex)	Modified value (hex)
MC_ME	MC_ME.PRTN1_COFB1_STAT	1CFE_2FFCh	FXOSC and MC_CGM clocks are enabled by default. However, for 120 MHz clock requests, SBAF ensures if the MC_CGM clock is enabled.
	MC_ME.PRTN0_COREx_ADDR	0040_0000h	SBAF updates this address if you request the application core 0 boot during the normal boot sequence in IVT or Recovery mode (0x2040012C).
	MC_ME.PRTN0_COREx_PCONF	0000_0000h	The core clock is enabled when the recovery mode sequence is executed or when the clock is enabled in Boot configuration word.
	MC_ME.PRTN0_COREx_PUPD	0000_0000h	
	MC_ME.CTL_KEY	0000_5AF0h	SBAF updates this register if SBAF boots any one of the application core. 0000_5AF0h and then 0000_A50Fh.
FXOSC	FXOSC.CTRL	019D_00C0h	See Crystal oscillator configuration flag
MC_RGM	MC_RGM.DRET	0000_0000h	0000_000Fh
SWT_0	SWT_0.CR	FF00_010Ah	FF00_000Bh, when SWT_0 is enabled in the boot configuration word and FF00_000Ah when the SWT_0 is disabled in the boot configuration word.

Table continues on the next page...

Table 175. Hardware IP registers modified by SBAF (continued)

IP	Register Name	Default value (hex)	Modified value (hex)
	SWT_0.IR	0000_0000h	0000_0001h

Chapter 32
Reset Generation Module (MC_RGM)

32.1 Chip-specific MC_RGM information

32.1.1 MC_RGM configuration

The "Reset sources—POR, Destructive, and Functional" section of the "Reset Overview" chapter provides information about MC_RGM's reset sources. The chapter also provides details about the chip's reset architecture.

NOTE

The ERCTRL register configuration takes several cycles to be effective. Any further access to MC_RGM must happen after at least nine AIPS_SLOW_CLK cycles of writing to ERCTRL.

Table 176. Register fields and applicability

Register	Bit field	Chips where applicable
Functional /External Reset Status Register (FES)	SWT1_RST	MWCT2D17S, MWCT2D16S
Functional Event Reset Disable Register (FERD)	D_SWT1_RST	MWCT2D17S, MWCT2D16S

32.1.2 Functional reset entry timer implementation

The default timeout value of the functional reset entry timer is 2048 clocks of MC_RGM clock (FIRC). If the RGM entry sequence hangs, then POR_WDG would trigger and the status of this functional reset entry sequence timeout is indicated at chip-level status register. The status of timeout in such case, is indicated at DCM.DCMROPP1[28]. There is no impact to the device behavior if the functional reset entry sequence gets completed within the POR_WDG timeout window.

32.1.3 MWCT2xxxS reset state machine

The reset sequence of the MWCT2xxxS products is depicted in the figure below:

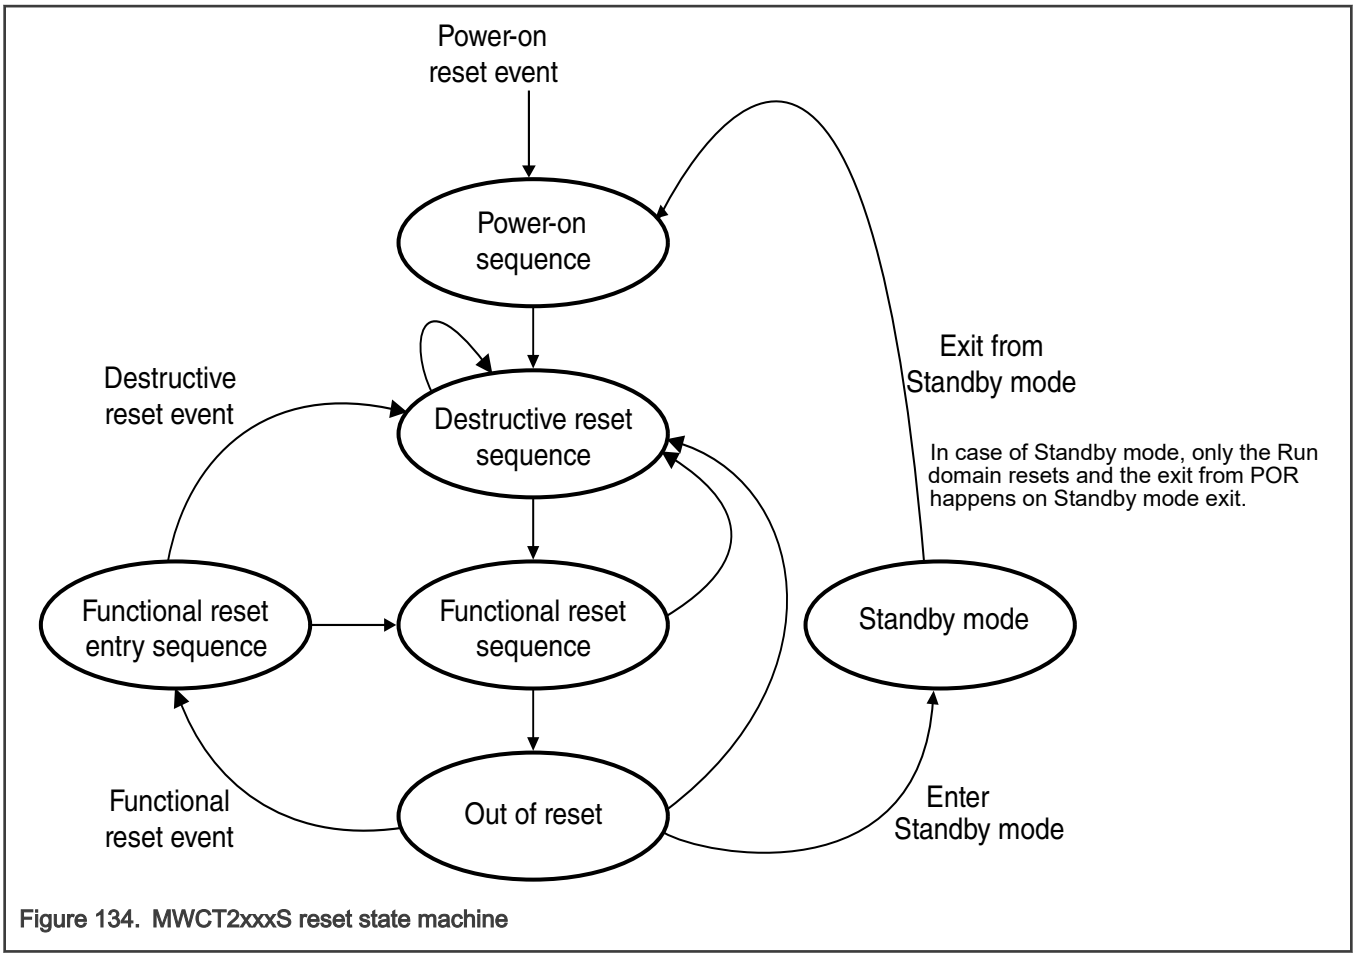

Figure 134. MWCT2xxxS reset state machine

32.2 Introduction

The Reset Generation Module (MC_RGM) centralizes the different reset sources and manages the reset sequence of the chip. It provides a register interface and the reset sequencer. There are various registers available in this module to monitor and control the chip reset sequence.

The following figure shows the block diagram of MC_RGM.

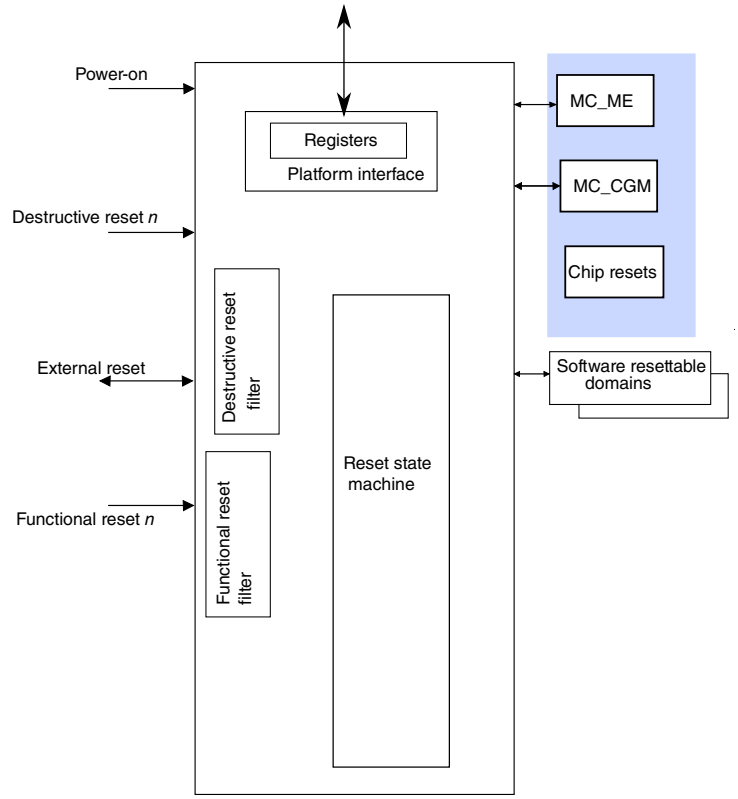

Figure 135. MC_RGM block diagram

32.3 Features

Here are the key features of MC_RGM:

- Support for destructive reset management
- Support for functional reset management
- Signaling of reset events after each reset sequence (reset status flags)
- Configurable escalation of recurring 'functional' resets to 'destructive' reset
- Configurable escalation of recurring 'destructive' resets to keep the chip in the reset state until the next power-on reset
- Software controllable reset assertion
- Pad safe state control generation

32.4 Reset sources

The different reset sources are organized in three categories: power-on, destructive, and functional.

A power-on reset source is associated with an event typically related to power-up or low-voltage scenarios. When a power-on reset occurs, the full reset sequence is applied to the chip. This resets the full chip, including the MC_RGM, and the memory content must be considered to be unknown.

A destructive reset source is associated with an event related to a critical, usually hardware, error or dysfunction. When a destructive reset event occurs, the full reset sequence is applied to the chip. This resets the full chip (except for a small portion, for example FIRC, JTAG interface, and the MC_RGM itself) ensuring a safe start-up state for both digital and analog modules, and the memory content must be considered to be unknown.

A functional reset source is associated with an event related to a less-critical, usually non-hardware, error or dysfunction. When a functional reset event occurs, a partial reset sequence is applied to the chip. In this case, most digital modules are reset normally, while the state of analog modules or specific digital modules (for example, debug modules, flash modules) as well as the system memory content is preserved.

32.5 External signal description

The MC_RGM interfaces with the RESET_B pin.

The following table describes the signals that are connected to the I/O pad ring.

Table 177. MC_RGM external signals

Signal name	Reset value	Description
RESET_B	0	Active low external reset

32.6 RESET_B pin assertion and pin safe state control

The MC_RGM asserts the RESET_B pin when the device is in a reset sequence, and it remains asserted until the end of the reset sequence. During this reset sequence, most of the chip's pins are safe-stated according to the values shown in the IOMUX table. Note that the safe state values may vary according to the reset sequence type.

In addition, the MC_RGM has a feature to assert the RESET_B pin through software, without initiating a reset sequence. This is achieved by writing 1b to the ERCTRL[ERASSERT]. When this occurs, most of the chip's pins are safe-stated according to the values shown in the IOMUX table. The RESET_B assertion and pin safe-stating remain active until the end of the next reset sequence.

This feature is intended for use only in conjunction with self-test of the main reset domain. See STCU2 chapter for more details on its usage.

32.7 Functional description

32.7.1 Reset state machine

The main role of MC_RGM is the generation of the reset sequence that ensures that the correct parts of the chip are reset based on the reset source event.

For each reset event, immediately after it is captured by the MC_RGM, the following takes place:

1. The corresponding reset event status bit is set in the MC_RGM_DES and MC_RGM_FES registers.
2. The pins are put into their default states
3. The RESET_B pin is asserted.

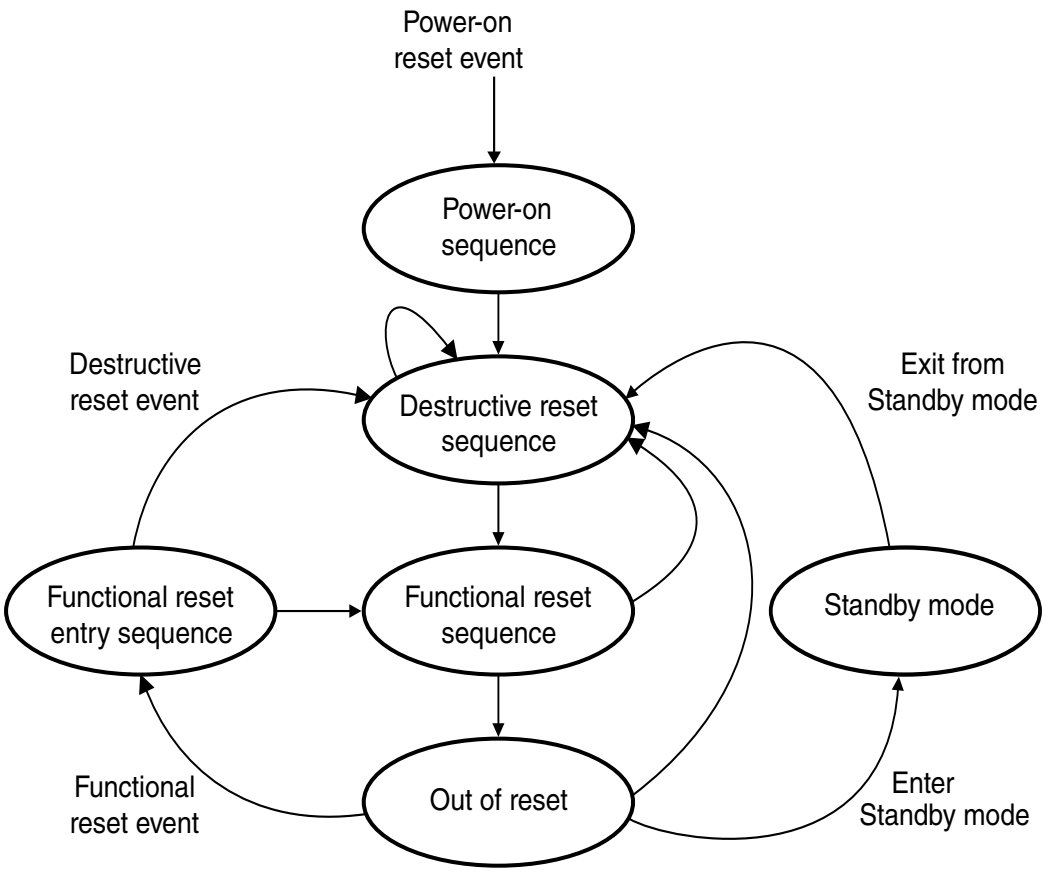

Figure 136. Reset sequence

32.7.1.1 Power-on reset sequence

A reset is always generated when the power-on reset source is asserted, and it has priority over all other reset sources. Such a power-on reset forces the reset state machine to enter the power-on sequence resulting in the assertion of all reset signals. The reset state machine starts progressing when the following two conditions are verified:

1. All the power-on reset events are cleared
2. The MC_RGM's clock source (the FIRC) has started up and stabilized

If a power-on reset event has occurred, the DES[F_POR] bit is set.

The power-on reset cannot be demoted by the software.

32.7.1.2 Destructive reset sequence

The 'Destructive reset sequence' is comprised of a number of phases, where DEST0 is the first phase and is followed by DEST1 and so forth.

This phase is entered immediately from any phase on a power-on, standby reset sequence, or enabled destructive reset event . A destructive reset counter starts immediately on entry in the DEST0 phase . The DEST0 state is exited to the DEST1 state on the rising edge of FIRC_CLK immediately after all of the following conditions have been established:

- the DEST0 duration time has expired
- all dest_rst inputs are deasserted

The DEST0 state is immediately exited to the power-on state after if a power-on reset event occurrs

The reset state machine exits the destructive reset sequence and enters the functional reset sequence when:

- All the destructive reset events are cleared.
- All the processes that take place during the destructive reset sequence have completed. For details on completed destructive reset sequence, see "Reset process sequence" section in the Reset chapter.
- The 'destructive' reset escalator counter has not reached the value in the DRET field of the RGM_DRET resister.

32.7.1.3 Functional reset sequence

There are two categories of functional reset sequence, the functional reset entry sequence and the functional reset exit sequence.

32.7.1.3.1 Functional reset entry sequence

The functional reset entry sequence is only entered when a functional reset event occurs during the idle phase.

If a functional reset event occurs during an ongoing reset sequence, the corresponding event status flag is set, and the RESET_B pin is asserted per the reset event's configuration. However, the reset sequence is not influenced, and it continues to progress without interruption.

No reset is asserted during the functional reset entry sequence.

The functional reset entry sequence is exited to the DEST0 on the next clock rising edge if a destructive reset event has occurred. The sequence enters the power up sequence if a POR event occurs

In all other cases, the sequence exits to the first stage of functional reset exit sequence.

32.7.1.3.2 Functional reset exit sequence

The functional reset exit sequence is entered either on exit from the destructive reset sequence or on completion of the functional reset entry sequence. The reset state machine exits this sequence and enters the idle phase on verification of the following:

- All the functional reset events are cleared.
- All the processes that take place during the destructive reset sequence have completed. For details on completed destructive reset sequence, see "Reset process sequence" section in the Reset chapter.

If a functional reset event occurs during an ongoing reset sequence, the corresponding event status flag is set, and the RESET_B pin is asserted per the reset event's configuration. However, the reset sequence is not influenced, and it continues to progress without interruption.

32.7.1.4 Idle phase

This is the final phase and is entered on exit from the functional reset exit sequence . When this phase is reached, MC_RGM releases control of the system to the platform and waits for the new reset events that can trigger a reset sequence.

32.7.2 Destructive resets

A destructive reset indicates that an event has occurred after which critical register or memory content can no longer be guaranteed.

The status flag associated with a given destructive reset event (Destructive Event Status Register (DES)) is set when the destructive reset is asserted and the power-on reset is not asserted. It is possible for multiple status bits to be set simultaneously and the software determines which reset source is the most critical for the application.

The low-voltage detector threshold ensures that when the reset corresponding to the core supply low-voltage detect is enabled, the supply is sufficient to have the destructive event correctly propagated through the digital logic. Therefore, if a given destructive reset is enabled, MC_RGM ensures that the associated reset event is correctly triggered to the full system.

An enabled destructive reset triggers a reset sequence starting from the beginning of DEST0.

32.7.3 External reset

MC_RGM manages the external reset coming from RESET_B. The detection of a falling edge on RESET_B starts the reset sequence from the beginning of the destructive reset entry sequence.

The status flag associated with the external reset falling edge event (the RGM_FES[F_EXR] bit) is set when the external reset is asserted and the power-on reset is not asserted.

MC_RGM asserts the external reset if the reset sequence is triggered by one of the following:

- A power-on reset
- A destructive reset event
- A functional reset event

In this case, external reset is asserted until all conditions for the exiting functional reset sequence have been met, with the exception of the RESET_B assertion check

32.7.4 Functional resets

A functional reset indicates that an event has occurred after which it can be guaranteed that critical register and memory content is still intact.

The status flag associated with a given functional reset event (Functional /External Reset Status Register (FES)) is set when the functional reset is asserted and the power-on reset is not asserted. It is possible for multiple status bits to be set simultaneously and the software determines which reset source is the most critical for the application.

An enabled functional reset triggers a reset sequence starting from the beginning of the functional reset entry sequence.

32.7.5 Functional reset entry timer

The purpose of Functional Reset Entry Timer feature is to indicate any scenario wherein functional reset entry sequence doesn't get completed in prerequisite time.

The functional reset entry timer starts from functional reset event point and gets terminated if the functional reset entry sequence is successfully completed or when it reached to the timeout value.

The timeout value is controlled by FRENTC[FRET_TIMEOUT]. The FRENTC[FRET_TIMEOUT] value should be greater than zero. If configured as zero, the default timeout (fixed for the chip) gets used. See the chip-specific section for the default value of timeout value and the details on the chip behavior in case of functional reset entry timer timeout.

32.7.6 External reset assertion control

The software indicates to the MC_RGM that the RESET_B is to be asserted by writing to the **ERASSERT** bit in the RGM_ERCTRL register. When this bit is set by the software, RESET_B gets asserted. Setting of this field does not impact the reset sequence in any way.

An example where the **ERASSERT** bit could be set by the software is when entering the self test sequence, during which RESET_B is to be asserted. This indicates the chip is not available in the functional mode although a reset sequence is not in progress. The deassertion of RESET_B is not controlled by the software. Instead, the RESET_B pin remains asserted until the next time the chip exits a reset sequence.

ERASSERT bit is also cleared during the reset sequence.

32.7.7 Functional reset escalation

Functional reset escalation can be used to generate a destructive reset if a number of functional resets is occurred between software writes to the RGM_FRET register. This function is enabled by writing a non-zero value to the FRET field of this register.

After the functional reset escalation is enabled, MC_RGM increases a counter on each functional reset that causes a reset sequence to be initiated (which means, entrance into FUNC0 from the IDLE phase). This counter is cleared on a write of any value to the RGM_FRET register and on any power-on or destructive reset. If the counter reaches the value in the FRET field of the RGM_FRET register, MC_RGM asserts a destructive reset.

The following figure shows the functional reset escalation counter.

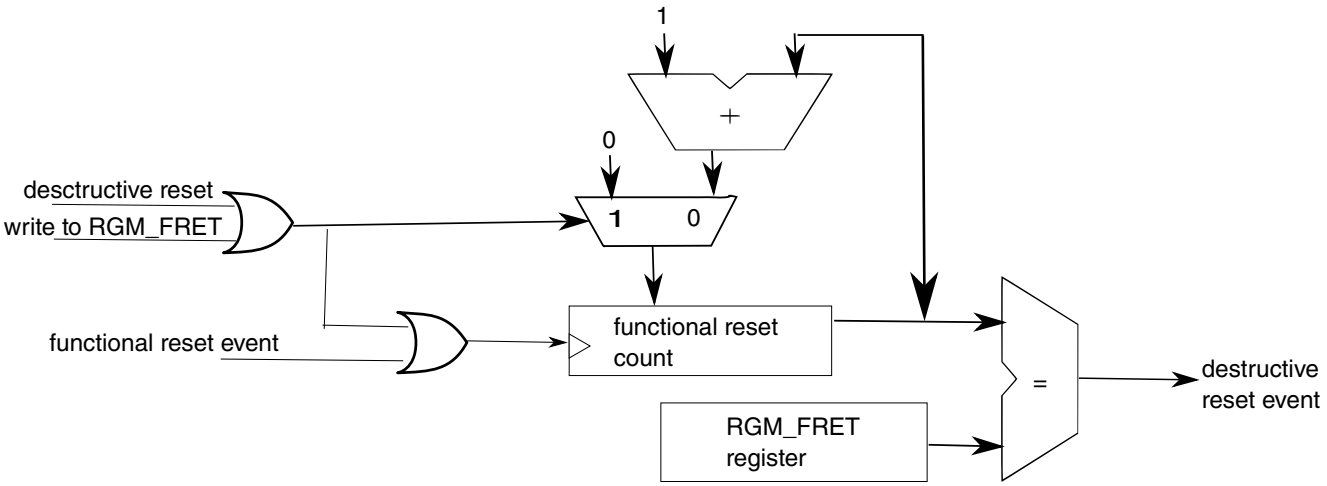

Figure 137. Functional reset escalation counter

32.7.8 Destructive reset escalation

Destructive reset escalation can be used to keep the chip in the reset state until the power-on triggers a reset sequence if a number of destructive resets are occurred between software writes to the RGM_DRET register. This function is enabled by writing a non-zero value to the DRET field of this register.

After destructive reset escalation is enabled, MC_RGM increases a counter on each destructive reset that is enabled to increment the escalator. . This causes a reset sequence to be initiated (that is, entrance into DEST0 from the idle phase) or an ongoing reset sequence to restart (that is, entrance into DEST0 from any other reset phase). This counter is cleared on a write of any value to the RGM_DRET register and on any power-on reset. If the counter reaches the value in the DRET field of the RGM_DRET register, MC_RGM enters reset DEST0 and stays there until the next power-on reset occurs .

The following figure shows the destructive reset escalation counter.

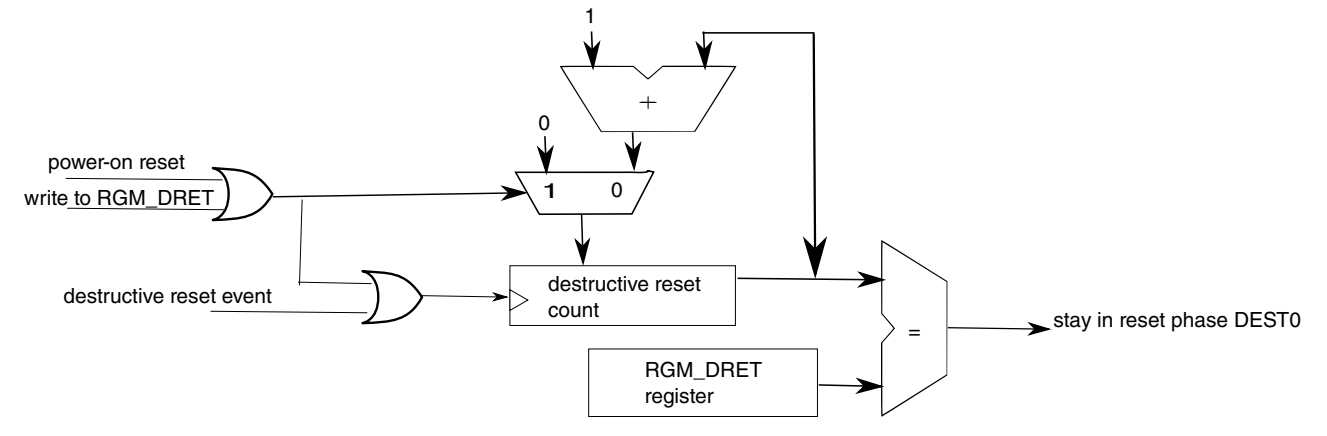

Figure 138. Destructive reset escalation counter

32.8 MC_RGM register descriptions

32.8.1 MC RGM Register Map memory map

MC_RGM base address: 4028_C000h

Offset	Register	Width (In bits)	Access	Reset value

32.8.3 Functional /External Reset Status Register (FES)

Offset

Register	Offset
FES	8h

Function

This register contains the status of the 'functional' and external reset sources. It can be accessed in read/write, either in supervisor mode. It can be accessed in read-only in the user mode. Register bits are cleared on write '1' if the triggering event has already been cleared at the source.This register is reset only on power-on reset.

NOTE

The status of this register must be ignored if the fields of Destructive Event Status Register (DES) other than DES[F_POR] are set. In this case, a destructive reset had occurred while functional reset source was active.

32.8.4 Functional Event Reset Disable Register (FERD)

Offset

Register	Offset
FERD	Ch

Function

This register provides dedicated fields to disable functional reset sources. When any of these reset sources are disabled, the associated functional event is demoted to trigger an interrupt request. The register can be read and written to in Supervisor mode and only read in User mode. Each byte can be written to only once after a destructive or power-on reset and this register is reset only on power-on and any destructive reset.

NOTE

It is important to clear the Functional /External Reset Status Register (FES) before writing 1 to any of the fields in this register. Otherwise a interrupt request may occur.

32.8.6 Functional Reset Escalation Counter Register (FREC)

Offset

Register	Offset
FREC	14h

Function

This register provides the current count of functional reset escalation counter. It can be accessed in read/write, either in supervisor mode. It can be accessed in read in the user mode. This register is reset only on power-on reset or destructive reset. This register is also reset when you reconfigure the FREC field to Fh.

Diagram

3-0 FREC	Functional' Reset Escalation Counter This bit field provides the value of functional reset escalation counter.

32.8.7 Functional Reset Escalation Threshold Register (FRET)

Offset

Register	Offset
FRET	18h

Function

This register sets the threshold for 'functional' reset escalation to a 'destructive' reset. It can be accessed in read/write, either in supervisor mode. It can be accessed in read-only in the user mode. Writing a non-zero value to the FRET field enables the

'functional' reset escalation function. Writing any value to this register resets the 'functional' reset counter. See Functional reset escalation for details on the 'functional' reset escalation function. This register is reset only on power-on and any 'destructive' reset.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-4 —	Reserved
3-0 FRET	'Functional' Reset Escalation Threshold If the value of this field is 0, the 'functional' reset escalation function is disabled. Any other value is the number of 'functional' resets that causes a 'destructive' reset if the FRET register isn't written to beforehand.

32.8.8 Destructive Reset Escalation Threshold Register (DRET)

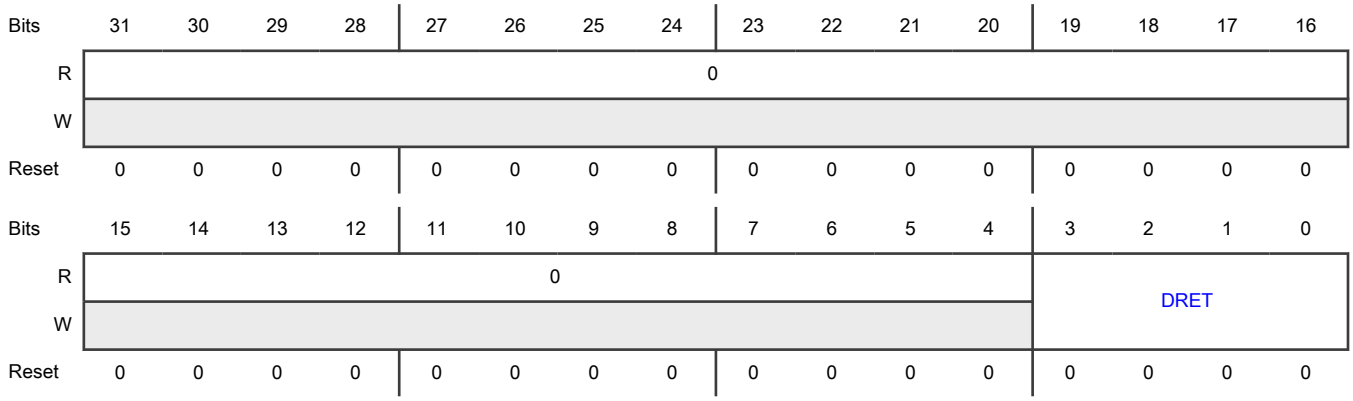
Offset

Register	Offset
DRET	1Ch

Function

This register sets the threshold for 'destructive' reset escalation to keeping the chip in the reset state until the next power-on reset triggers a new reset sequence. It can be accessed in read/write, either in supervisor mode. It can be accessed in read-only in the user mode. Writing a non-zero value to the DRET field enables the 'destructive' reset escalation function. Writing any value to this register resets the 'destructive' reset counter. See Destructive reset escalation for details on the 'destructive' reset escalation function. This register is reset only on power-on reset.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 DRET	'Destructive' Reset Escalation Threshold If the value of this field is 0, the 'destructive' reset escalation function is disabled. Any other value is the number of 'destructive' resets which keeps the chip in the reset state until the next power-on reset triggers a new reset sequence if the DRET register isn't written to beforehand.

32.8.9 External Reset Control Register (ERCTRL)

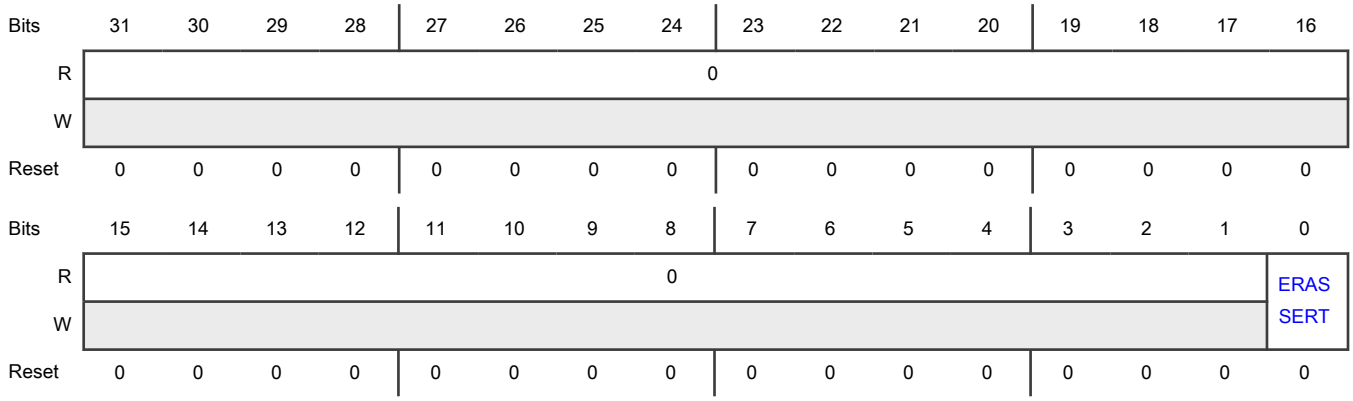
Offset

Register	Offset
ERCTRL	20h

Function

This register allows software to control the assertion of External reset pin. It can be accessed in read/write, in supervisor mode. It can be accessed in read-only in the user mode. This register is reset on all resets.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 ERASSERT	ERASSERT **NOTE** Setting ERASSERT to 1b also safe states most of the chip's pins. See the IOMUX table for each pin's safe state value. Software must use the ERASSERT bit for this purpose only as part of the main reset domain self-test entry procedure. Using it at any other time may result in unpredictable system behavior. 0b - No change 1b - External reset is asserted

32.8.10 Reset During Standby Status Register (RDSS)

Offset

Register	Offset
RDSS	24h

Function

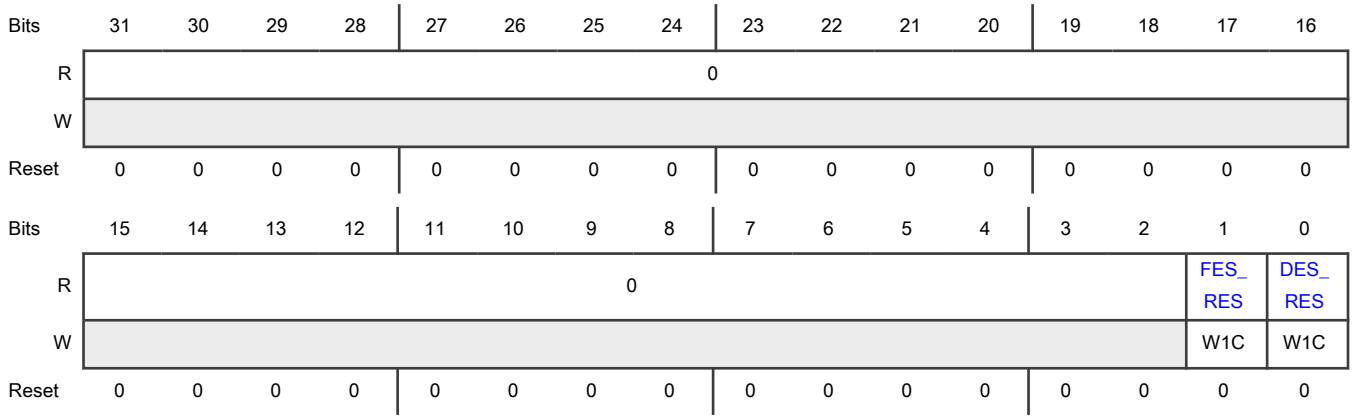
This register provides status of whether a reset event occurred during standby mode. Register bits are cleared on write '1'. This register is reset only on power-on reset.

NOTE

On exiting a reset sequence after standby exit, the software must perform a read operation on MC_ME[PREV_MODE] and RDSS register. If any bit of the RDSS register is set, the software must ignore the status reported by MC_ME[PREV_MODE] register otherwise the status of MC_ME[PREV_MODE] register reports the device status.

If MC_ME indicates last mode as RESET, then perform a reset exit in software else a standby exit.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 FES_RES	FES_RES 0b - No functional reset event occurred during standby mode. 1b - Functional reset event occurred during standby mode.
0 DES_RES	DES_RES 0b - No destructive reset event occurred during standby mode. 1b - Destructive reset event occurred during standby mode.

32.8.11 Functional Reset Entry Timeout Control Register (FRENTC)

Offset

Register	Offset
FRENTC	28h

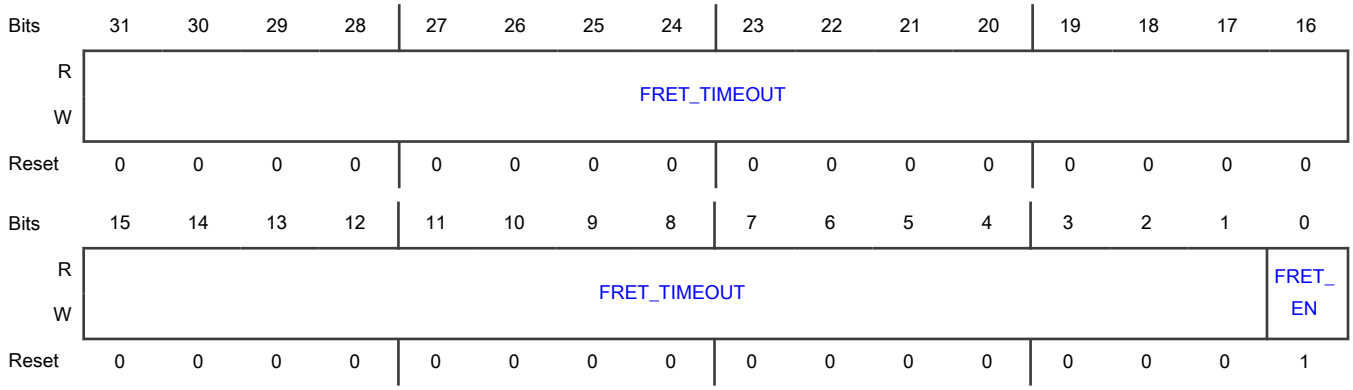
Function

This register provides control for functional reset entry timeout counter. This register is reset on power-on and destructive reset events. This is a word accessible register. Byte or word accesses are not allowed on this register.

NOTE

This field should be set a value greater than one.

Diagram



Fields

Field	Function
31-1 FRET_TIMEOUT	Functional Reset Entry Timer Value This field allows to override the timeout duration of the functional reset entry timer. The counter value is in terms of the Fast IRC clock cycles (typical clock frequency of 48 MHz). A non zero value of this field would indicate the timer value to be used during the functional reset entry sequence.
0 FRET_EN	Functional Reset Entry Timer Enable/Disable 0b - Functional reset entry timer is disabled. 1b - Functional reset entry timer is enabled

32.8.12 Low Power Debug Control Register (LPDEBUG)

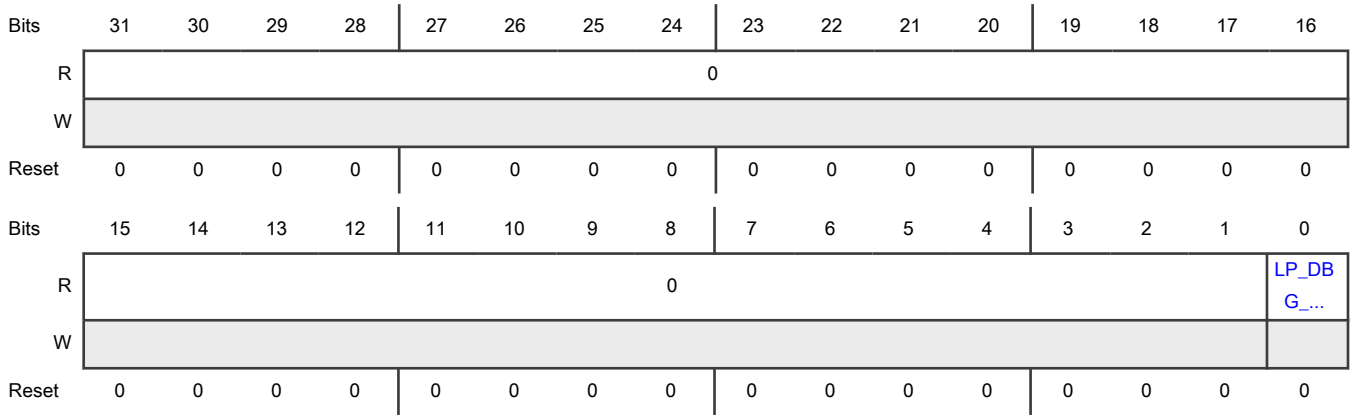
Offset

Register	Offset
LPDEBUG	2Ch

Function

This register provides control when the low-power debug is enabled and you need to wait for debug data collection before moving into standby. This register is reset on functional reset.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 LP_DBG_EN	Low-Power Debug Enable/Disable Control 0b - Low-power debug disabled 1b - Debug data collection enabled before entering low-power debug

Chapter 33
Power-on Reset Watchdog (POR_WDG)

33.1 Introduction

POR_WDG monitors the chip for stuck or hang scenarios when in reset and standby sequences. It generates a chip power-on-reset event to recover the chip in case it remains stuck in reset or standby entry/exit duration for a pre-configured period of time.

POR_WDG consists of a watchdog counter with a configurable threshold. After the threshold is reached POR_WDG generates a chip power-on-reset event.

SIRC clocks POR_WDG.

33.2 Features

- Counter with four possible configurable threshold limits
- Associate register interfaces to capture the status of input signals
- Monitors reset, standby entry, and standby exit

33.3 Configurations

POR_WDG is enabled by default out of reset to actively monitor the chip reset sequence with the default timeout threshold duration. The POR_WDG configuration controls support provisions for enabling or disabling POR_WDG and the counter threshold, as described in the following sections.

33.3.1 Enable/disable configurations

By default POR_WDG is enabled for reset sequence monitoring, as well as standby entry/exit sequence monitoring for stuck scenarios. The following table describes the controls to enable or disable POR_WDG operation.

Table 178. POR_WDG enable/disable control

POR_WDG monitoring	Default configuration	Enable/disable
Reset monitoring	Enabled	dcf_client_utest_misc[16] Enables or disables POR_WDG for reset monitoring. 0: Disable 1: Enable See the DCF clients file attached to this document for details.
Standby entry/exit monitoring	Disabled	DCM's DCMRWP1[8] Enables or disables POR_WDG for standby entry/exit monitoring. 0: Enable 1: Disable See the DCM chapter for details.

33.3.2 Timeout configurations

POR_WDG supports four configurable counter threshold levels for its counter, as listed in the table below. The default POR_WDG timeout is 25 ms.

Table 179. POR_WDG timeout configuration

DCM's DCMRWP1[10]	DCM's DCMRWP1[9]	POR_WDG timeout
0	0	6.25 ms
0	1	12.50 ms
1	0	25.00 ms
1	1	50.00 ms

33.3.3 Event and status registers

POR_WDG provides indication of a POR_WDG event along with the status of the chip at the point when the POR_WDG counter overflows.

POR_WDG event status register: A POR_WDG event is captured in DCM status register DCMROPP4[0].

POR_WDG status registers: The status of the chip at the POR_WDG event is captured in DCM status registers DCMROPP1–DCMROPP3. See the DCM chapter for details.

DCM's DCMROPP*n* are reset on a POR caused by PMC and are unaffected by a POR_WDG reset.

33.4 Reset sequence monitoring

33.4.1 Introduction

At power-up POR_WDG is enabled for reset monitoring (DCF record in UTEST Misc can bypass POR_WDG, as described in Table 178).

On every reset event, POR_WDG starts monitoring the reset sequence (including the functional reset entry sequence, in case of functional reset event).

If the chip does not exit the reset sequence within the POR_WDG timeout threshold, then POR_WDG initiates a POR sequence to recover the chip from a stuck or hung scenario. You can view the POR_WDG status in DCM's DCMROPPn registers to obtain:

- Diagnostic status
- Chip details in the event of a POR_WDG reset

33.4.2 Inactive windows or bypass operation

POR_WDG monitoring of the reset sequence is inactive in the following conditions:

- POR_WDG is disabled for reset monitoring by chip configuration in UTEST via dcf_client_utest_misc[16]. See the DCF clients file attached to this document for details.
- MC_RGM destructive reset escalation (ensures that the chip stays in reset).
- Extend pin reset by keeping it pressed externally.
- During selftest, when MC_RGM.RGM_ERCTRL[ERASSERT] is configured as 1.

33.4.3 Windows of operation

POR_WDG monitors the reset sequence in the following scenarios:

- Reset pin is active (when chip is in reset, including the functional reset entry sequence).
- Standby domain functional reset is asserted (when reset pad is pulled up but functional reset is asserted).
- RUN domain destructive reset is asserted but flash memory is not in Low-Power mode (when RUN domain destructive reset fires unexpectedly in Run mode).

- RUN domain functional reset is asserted but flash memory is not in Low-Power mode (when RUN domain functional reset fires unexpectedly in RUN mode).

33.5 Standby entry/exit sequence monitoring

33.5.1 Introduction

On every low-power entry or exit event, POR_WDG starts monitoring the low-power sequence (standby entry and standby exit sequence).

If the chip does not exit the standby entry or exit sequence within the POR_WDG timeout threshold, POR_WDG initiates a POR sequence to recover the chip from the stuck or hung scenario. You can then check the POR_WDG status registers in DCM to check the chip status when POR_WDG raised the POR to the chip.

33.5.2 Inactive windows/bypass operation

You can configure DCM's DCMRWP1[8] to disable POR_WDG for standby entry and exit sequence monitoring.

33.5.3 Windows of operation

POR_WDG monitors the standby sequence (standby entry and standby exit) in these scenarios:

- Standby entry sequence monitoring: Monitoring from main core WFI execution until PMC acknowledges Low-Power mode entry.
- Standby exit sequence monitoring: Monitoring from wakeup event until the RUN domain reset recovery.

33.6 Glossary

WFI	Wait for Interrupt

Chapter 34
Security Overview

34.1 Introduction

This chip has a comprehensive set of customer-configurable security features designed to protect code and data from unauthorized access. The content of this section is for non-secure operation only. Contact your NXP representative for details if you need secure operation.

34.2 Security features

MWCT2xxxS:

- Exceeds the EVITA- full [5] functionality and offers high performance for edge nodes applications.
- Bases its chip censorship on the life cycle model. Access to chip code and data becomes progressively more restricted as the chip matures through a defined set of life cycle steps.
- Offers these memory security features:
  - NVM censorship support
  - Debug password protection
  - OTP flash memory areas
- Supports a unique ID—The chip has a unique ID stored in an OTP flash memory area. Any core on the chip can read this unique ID.
- Includes HSE_B, which is a dedicated security system providing:
  - A processor core
  - Dedicated SRAM
  - Symmetric Hardware Accelerator
  - Asymmetric Hardware Accelerator
  - True Random Number Generator (TRNG)
  - Pseudo Random Number Generator (PRNG)
  - Exclusive access to secure areas of the chip's flash memory
  - OTA : In Field Secure Code/Data updates

NOTE

Refer Security Reference Manual and Firmware Reference Manual for the details on OTA.

Also, HSE_B runs NXP firmware independently from the main chip processor cores and can implement advanced security and monitoring functions.

[5] EVITA was a European research project existing from 2008 to 2011. There is no standard or a specification to test compliancy. However, HSE_B meets the common expectations often described in the industry as EVITA Full and exceeds them in these cases:
- HSE_B supports up to AES-256 instead of AES-128
- HSE_B supports up to ECC-521 instead of ECC-256
- HSE_B supports SHA-2/Miyaguchi-Preneel instead of Whirlpool

- Includes AES_ACCEL, which provides an independent DMA-controlled crypto accelerator with security features. AES_ACCEL provides timeout counters. You can transfer keys from HSE_B to the AES_ACCEL keystore, which can hold 80 keys.
- Supports a secure debugger interface.
- Provides boot modes:
  - Trusted and secure boot support
  - Handshake that supports BAF
- Monitors operating conditions to maximize tampering resistance.
- Includes basic debugger restrictions (on and off via censorship mode).

When HSE_B detects a security failure, it moves the chip to a secure state. The chip secure states comply with the chip safe states. You enter a safe state as reset when there are security errors leading to reset. Moreover, if the chip stays in Run mode and the lifecycle moves to the IN_FIELD phase in reaction to errors, the safety application can continue running without glitches.

34.3 Security information

Chip security feature details are published in the HSE firmware reference manual and HSE service interface manual. Contact your NXP sales representative for more information.

34.4 Glossary

AES	Advanced encryption standard
BAF	Boot assist flash
ECC	Elliptic curve cryptography
EVITA	E-safety vehicle intrusion protected applications
NVM	Nonvolatile memory
OTP	One-time programmable

Chapter 35
Hardware Security Engine (HSE_B)

35.1 HSE subsystem

HSE is a security subsystem. It runs security functions for applications having stringent confidentiality and authenticity requirements. HSE has the following objectives:

- Isolating security-sensitive information (for example, secret keys) from the application (the host)
- Transferring the cryptographic operations from application cores and processing them
- Accelerating cryptographic operations with dedicated coprocessors
- Enforcing security measures on the application, during runtime and system startup

The HSE subsystem is the only master that is unconditionally released from reset after POR. It then releases the CPU subsystems in the host from reset, with the opportunity to apply certain checks beforehand (secure system startup). Based on certain conditions, HSE can also trigger interrupts and reset signals to the host during runtime.

35.1.1 CPU subsystem

The HSE CPU subsystems process the security functions and control system resources to provide security services to the application domain (the host).

35.1.2 Cryptographic accelerators

The HSE subsystem supports the following cryptographic accelerators:

- An AES engine supporting all standard key sizes (128, 192, 256 bits) and various complex ciphering modes (ECB, CBC, CTR, OFB, CFB, CCM, CMAC)
- A hash engine that supports standard several primitives: MD5, SHA-1, SHA-224, SHA-256
- PKC which accelerates RSA and ECC operations (key generation, signature generation, signature verification, ciphering)
  - RSA (1024, 2048, 3072, 4096-bit)
  - ECC over prime numbers
    - BN P256, P638
    - ANSI X9P192 to X9P512
    - Brainpool P160 to P512
    - Sec P128 to P521
    - TU Darmstadt prime Curve 1 to 35
    - Ed25519

The HSE subsystem supports several other cryptographic primitives through the software. See HSE firmware for more information.

35.1.3 Random number generator (RNG)

The RNG in this chip consists of a TRNG and a DRBG. Both are designed to be compliant to the highest strength in security as specified in

- BSI AIS20/31
- NIST SP800-90a,b,c

The TRNG function provides a seed for the DRBG, while the DRBG is available to the host via dedicated random number generation services.

35.1.4 Timers

The HSE subsystem features:

- An independent dedicated system timer
- HSE_STM (apart from chip timer resources), that allows recurring autonomous functions such as runtime memory verification checks
- A watchdog timer to reset the HSE subsystem in case of unexpected runtime failure

35.1.5 Memory resources

See Configuration_GPR memory map for more information on configuration controls related to HSE functions.

35.1.5.1 Secure RAM

Secure RAM refers to RAM area that the HSE subsystem access exclusively. The HSE firmware use it to operate as well as to store a copy of the cryptographic keys in service.

35.1.5.2 Secure NVM

Secure NVM refers to nonvolatile memory that the HSE subsystem accesses exclusively. It stores the HSE firmware and the security assets (for example, keys and private data).

The size of the secure NVM is configurable by the HSE firmware.

35.2 HSE interface

35.2.1 Messaging unit (MU)

The HSE subsystem has two messaging units:

- HSE_MU0
- HSE_MU1

See the "Messaging Unit (MU)" chapter for more information.

35.2.1.1 Overview

MU is the communication interface between the host and the HSE subsystem. The host uses MU to trigger service requests and to receive service responses. The HSE firmware uses MU to receive service requests, return service responses, and provide a general status of the HSE subsystem.

Each of the two MU instances available in the HSE subsystem has:

- Two sides:
  - MUA: Only the HSE subsystem accesses it.
  - MUB: The host accesses it.

    The registers on one side have corresponding registers on the other side.
- A set of 32-bit readable and writable transmit registers (MUB_TRn), which the host uses to transfer the address of the service descriptor to the HSE firmware. The HSE firmware retrieves the address of the service descriptor in the corresponding registers MUA_RRn.
- A set of 32-bit read-only receive registers (MUB_RRn), which the host uses to retrieve the response to the service requests. The HSE firmware provides the response to service requests in the corresponding registers MUA_TRn.

- Control and status registers to manage MU and the access to transmit and receive registers.

The advantages of using the MU to manage the HSE service requests and responses are:

- Hardware mechanisms are in place on the transmit registers to avoid service request overrun.
- Interrupt signals are available to allow asynchronous management of the requests (avoiding active waiting loops).
- Freedom from interference between different application cores. You can configure each MU instance with specific access restrictions that can be used, for example, to isolate the requests that different masters make (in different MU instances). You configure such access controls using XRDC.

35.2.2 HSE interface RAM

The HSE interface RAM (also known as host interface RAM) is a secure RAM area. The host accesses it with the restrictions that HSE set via XRDC. This RAM area is a part of chip RAM and the size is configurable by secure core using CONFIG_RAMPR[SECURE_SIZE].

35.3 Debug

35.3.1 HSE subsystem debug

The debugging of the HSE subsystem and associated firmware is restricted to NXP engineering teams.

35.3.2 Host debug

The host debug is either open or protected, depending on the device Lifecycle state. See the ‘Life cycle’ section in ‘Device Configuration Module’ chapter for details on device lifecycle advancement and decoding. The details of the device security features is published in a separate document, the Security Reference Manual. Please contact your NXP sales representative for details. See the Debug chapter for details on host/application core debug.

The debug protection consists of locking the debugger access through the JTAG interface until the HSE firmware authenticates the debugger. This authentication is based on ADK/P, a 16-byte region within UTEST used for application core debug. See UTEST memory map in the DCF clients file attached to this document.

The authentication method can be:

- Static: In this case, ADK/P is a password which the debugger provides in plain form.
- Dynamic: In this case, ADK/P is a cryptographic key which the debugger uses to calculate a cryptographic response to a random challenge.

35.4 HSE firmware

Factory supplied firmware that runs in the HSE subsystem controls HSE functionality. It essentially serves the host with a set of security services as described in Table 180.

Table 180. Summary of firmware security services

Service	Summary
Administration	Install, configure, update, and test the HSE firmware
Key management	Available for the application to manage different sets of keys that the HSE firmware manages, for example, cryptographic services
Cryptographic	Provide the application with cryptographic primitives that high level security stacks use in the application
Random number	Generate random streams that can be used in various security protocols

Table continues on the next page...

Table 180. Summary of firmware security services (continued)

Service	Summary
Memory verification	Allow the application to verify different memory areas at startup (after reset) and during runtime
Monotonic counter	Provide the application with a set of monotonic counters that can be read and only incremented
Secure time	Allow the configuration of a secure tick to be signaled to the application

Table 181 provides an overview of services and features that the HSE firmware supports.

Table 181. HSE firmware features

Service	Category	Feature
Cryptography	Ciphers	AES: ECB, CBC, CFB, OFB, CTR, XTS[1] RSAES: PKCS1-v1_5, OAEP
	Message Authentication Code (MAC)	AES: CMAC, XCBC-MAC[1], HMAC[1]
	Hashing	SHA1 SHA224, SHA256, SHA384, SHA512 SHA3_224[1], SHA3_256[1], SHA3_384[1], SHA3_512[1] MD5 Miyaguchi-Preneel Compression
	Authenticated ciphers	AES: CCM, GCM[1]
	Digital signature generation and verification	RSASSA_PSS RSASSA_PKCS1-v1_5 ECDSA – ECC over GF(P) with all prime standard curve supported EdDSA - Ed25519 pre-hashed curve
Key management	Max key sizes	AES: 256 bits RSA: 4096 bits ECC: 521 bits DH: 4096 bits
	Key generation	Permanent and ephemeral RSA and ECC key pair generation
	Key import or export	Plain or encrypted form, with optional authentication tag. SHE key update protocol
	Key derivation	NIST 800-108, PBKDF2, and so on
	Key exchange	ECDH and Classic DH
	Certificate handling	Key Installation from X.509 and CVC certificates Certificate installation for Root of Trust establishment.

Table continues on the next page...

Table 181. HSE firmware features (continued)

Service	Category	Feature
Boot and memory verification	Authentication schema	AES CMAC, XCBC-MAC RSA & ECC signatures
	Verification flow	Before application startup (strict secure boot) In parallel to the application startup On the application demand
	Sanctions	No startup (strict secure boot) Chip reset Key usage restrictions
Monotonic counter	Counter management	Incrementing and reading volatile and non-volatile counters
Random number	Deterministic random bit generation	Based on a True Random Number AIS31 Class P2 high and FIPS 140-2 compliant
Secure time	Secure tick	Application interrupts at configurable frequency
Administration services	HSE administration	Firmware installation and update Subsystem configuration and testing

1. Software implementation of cryptographic primitives.

See documents in Table 182 for more information about how to install, configure, and use the HSE firmware that NXP provides.

Table 182. References

HSEFWRM	HSE Firmware Reference Manual	Contains details about how to install, configure, and use the HSE subsystem.
HSESIRM	HSE Service Interface Reference Manual	Security firmware API reference for non-AUTOSAR users.

35.5 General purpose registers with write access by HSE core

This is a general purpose register bank that only the HSE core can write. Secure master ID gating allows only the secure core to write in these registers, whereas any application core can read.

35.6 Configuration_GPR register descriptions

35.6.1 Configuration_GPR memory map

This section describes the chip configurations that only the HSE core manages. These constitute control of peripherals, secure size configurations for SRAM and flash memory, flash memory program or erase control, and so on.

NOTE

Write accesses to configuration registers apart from 32-bit accesses might result in unpredictable chip behavior, therefore must not be done.

Configuration_GPR base address: 4039_C000h

35.7 Glossary

ADK/P	Application debug key/password
AES	Advanced encryption standard
CBC	Cipher block chaining
CCM	Counter with CBC MAC (Cipher block chaining message authentication code)
CFB	Cipher feedback mode
CMAC	Cipher-based message authentication code
CTR	Counter-based block cipher mode

CVC	Card verifiable certificates
Classic DH	Classical Diffie–Hellman, a key exchange method
DRBG	Deterministic random bit generator
ECB	Electronic code book
ECC	Elliptic curve cryptography
ECDSA	Elliptic curve digital signature algorithm
ECDH	Elliptic-curve Diffie–Hellman, a key exchange method
EdDSA	Edwards-curve digital signature algorithm
FIPS	Federal information processing standards
MUA	Messaging unit A interface
MUB	Messaging unit B interface
NIST	National institute of standards and technology
OAEP	Optimal asymmetric encryption padding
OFB	Output feedback based block cipher mode
GCM	Galois/counter mode
HMAC	Keyed-hash message authentication code
PKC	Public key cryptographic engine
PKCS1	Public-key cryptography standards. PKCS provides the basic definitions of, and recommendations for implementing the RSA algorithm.
POR	Power-on reset
RNG	Random number generator
RSA	Rivest–Shamir–Adleman (a public key cryptosystem)
SHE	Secure hardware extension
TRNG	True random number generator
XCBC-MAC	Extended ciphertext block chaining MAC
XTS	XEX (XOR encrypt XOR) based tweaked-codebook mode with ciphertext stealing

Chapter 36
Device Configuration Format (DCF) records

36.1 Introduction

DCF configures certain registers of this chip during system boot while the reset signal asserts. An individual DCF record points to an internal register in the chip and the data to be written to that register.

UTEST DCF—The UTEST DCF clients are present within the UTEST region of the flash and programmed during production testing. You may write the other records and program them at the same time the application code is programmed in the flash memory. See the DCF client file attached to this document for the description on the UTEST DCF records.

System boot is a complex process that requires you to initialize the chip properly before releasing reset. Before using the chip, the user writes the application specific code into the flash memory. The user can also update the DCF records from their initial settings as per application requirements, in case if needed.

After power is supplied to an appropriately configured chip, PMC controls the chip, and after the system power supplies reach predefined levels, PMC signals MC_RGM to start the boot sequence. During this sequence, MC_RGM enables DCM to read the chip configuration records and then write the configuration information to the specified registers.

36.2 DCF clients

These are 32-bit wide hardware registers inside a module that receive and store data from a DCF record. This stored data is used to initialize registers and configure features.

DCF clients:

- Are assigned a default value before any DCF records are written.
- May have special writing constraints, such as:
  - Write once.
  - Change from 1 to 0 only.
  - Change from 0 to 1 only.
- May not implement all 32 bits.

36.2.1 Safety features of DCF clients

Depending on the DCF client's role in the chip, the client may be equipped with a safety feature or a combination of these features.

36.2.1.1 Parity

If a DCF client implements parity checking, the client receives a parity bit in addition to its data in the DCF record. During chip operation, the client continuously monitors whether the data it stores matches the parity. The parity scheme used is even parity. So, the number of 1s in the WDATA and parity field needs to be even. For example, if the WDATA field has the value 0000_0001h, the value of the parity field needs to be 1 so that the total number of 1s is even. It also reports errors to DCM in case of discrepancies.

36.2.1.2 Triple voting

DCF clients that use triple voting have three copies of the register. DCM writes to all the three registers in a single write cycle. During chip operation, the DCF client continuously monitors whether all these three copies match. In case of discrepancies, the client reports errors to DCM. The chip uses the majority result, so single errors do not affect the chip's operation. If case of single error, since the chip uses the majority result, there will be no impact to the chip's behavior.

36.2.2 DCF client modification rules

Depending on its role in the chip, a DCF client may implement one or a combination of modification rules. If a modification rule is in effect, the order in which DCF records are placed in the record list may be important.

36.2.2.1 Write once

A DCF client using the write once rule can only be written with a single DCF record. The records that are appended later in the list are ignored and do not change the value of the client.

36.2.2.2 Write 0 only

A field in a DCF client can only be changed from 1 to 0. Therefore, if the value of a field in the previous DCF record is 0, an attempt by a later record to write 1 to it is ignored.

36.2.2.3 Write 1 only

A field in a DCF client can only be changed from 0 to 1. Therefore, if the value of a field in the previous DCF record is 1, an attempt by a later record to write 0 to the field is ignored.

36.3 DCF record structure

A DCF record is a double-word (64-bit) entry that consists of the following:

- Control word—This provides information to locate the corresponding DCF client internal to the chip (pointer to the location of a register internal to the chip).
- Data word—This contains the data to be written to the DCF client.

DCF records select the target DCF client using a 30-bit field in the DCF record that consists of a 15-bit chip select field and a 15-bit address field. All modules that include DCF clients are assigned a chip select during chip definition. The address field is only relevant for address decoding within that module and may not necessarily relate to the address of a register that is visible to you.

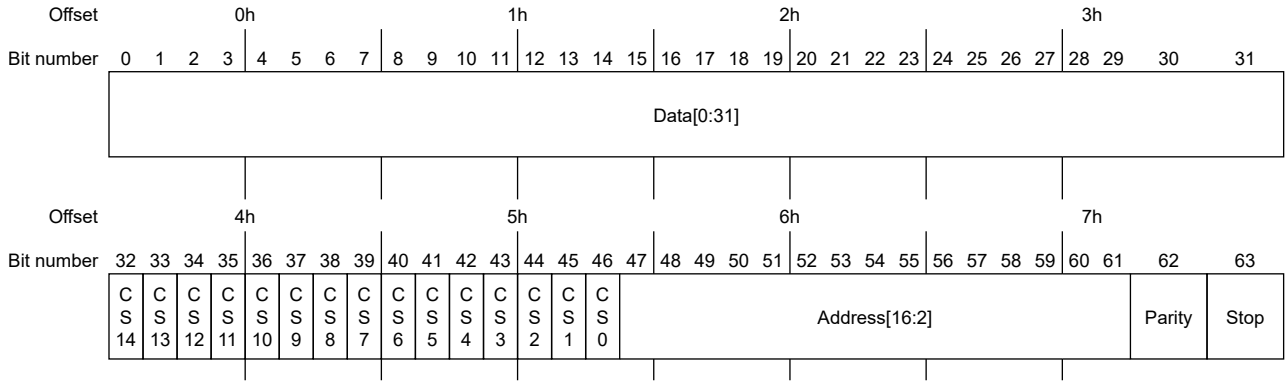

Figure 139. DCF record structure

Table 183. DCF record field descriptions

Field	Name	Description
0-31	Data[0:31]	Provides the data that is to be written to the DCF client.
32-46	CS*n*	Indicates chip select *n*. The value 1 is written to a chip select per DCF record to select the target module for the DCF client. The value 0 must be written to all other chip selects.

Table continues on the next page...

Table 183. DCF record field descriptions (continued)

Field	Name	Description
47-61	Address[16:2]	Contains the address of the DCF client within the selected module. Address decoding for DCF clients may not match the standard software address map decoding. For details, see the DCF client addresses provided with each module.
62	Parity	Indicates parity for the DCF record.
63	Stop	Indicates the end of the list for DCF records. 0 – Not the end 1 – End The erased state of flash memory is FFFF_FFFF_FFFF_FFFFh. Therefore, the list ends with the first unprogrammed double word. This location can be programmed with a new record to extend the list.

36.4 DCF records sequence

An individual DCF record contains information to locate the corresponding DCF client internal to the chip (control word) and the data to be written to that client (data word).

DCF records appear as contiguous series of entries programmed at a specific address within UTEST flash memory, and must present the following pattern:

- The first DCF record must be a start record. This record must be placed at the beginning of a DCF area in UTEST flash memory to indicate to the chip that the specified records must be processed.
- DCF records containing configuration data must immediately follow the start record with no blank records in between. An unprogrammed record is interpreted as a stop record and no DCF records following that are processed. This allows you to program the records in several sessions, appending new records at the end of the list each time.
- DCF stop record with bit set indicates the end of configuration records. It is not recommended to set STOP bit in last DCF record programmed during production because that prevents appending additional DCFs records. The UTEST flash memory location following the last DCF record programmed at the factory is an unprogrammed location, which has FFFF_FFFFh as its content. Thus, the stop bit location in this unprogrammed flash memory location is logic 1, signifying that this is the last DCF record and it is not to be acted upon.

Table 184 shows the record that DCM recognizes as a start record.

Table 184. DCF start record

0h (0:31)	4h (32:63)
05AA_55AFh	0000_0000h

The factory sets the DCF start record at the beginning of the UTEST flash memory area.

Table 185 shows the record that DCM recognizes as a stop record.

Table 185. DCF stop record

0:31	32:62	63
Ignored	Ignored	1

The DCF records that you supply must be added in a contiguous manner immediately following the factory-written DCF records. You must never have an unprogrammed record in the series of DCF records because that is interpreted as a stop record.

Table 186 shows the series of DCF records when *n* data records are stored in the UTEST flash memory.

Table 186. Series of DCF records in UTEST flash memory

Record type	Address offset	Data			
Start	0h	05AA_55AFh			
	4h	0000_0000h			STOP = 0
Data	8h	WDATA[31:0]			
	Ch	CS[14:0]	ADDR[16:2]	Parity	STOP = 0
	10h	WDATA[31:0]			
	14h	CS[14:0]	ADDR[16:2]	Parity	STOP = 0
	...	...			
Stop	8(*n*-1) + 0h	Reserved			
	8(*n*-1) + 4h	Reserved			1
Ignored	8*n* + 0h				
	8*n* + 4h				

More than one DCF records can write to the same DCF client. In this case, the later record usually overrides a DCF client value defined by a previous record. However, not all DCF clients allow overwrites; this depends on individual implementation of DCF clients.

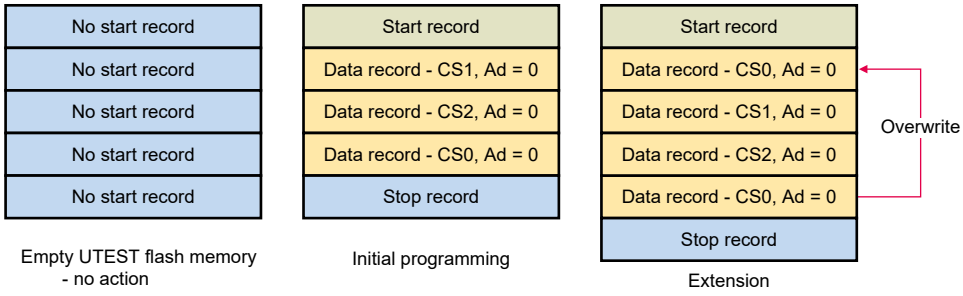

Figure 140. Appending DCF records

36.5 Chip configuration records

The DCF clients table contains information on DCF clients available in the chip. See the DCF clients file attached to this document.

Table 187. Integration of DCF information

Type	Data(n) assuming Quad page program	Data	Comment
Reset pad dedicated control DCF client (dcf_client_reset_pad_dedicated - column D in the "Utest DCF Clients" sheet)	Data word (determined base on the DCF record description in the "Utest DCF Client Register Bits" sheet)	0000_0001h	Data to enable pad as dedicated reset pad
	Control word (without parity) (selected from column C in the "Utest DCF Clients" sheet)	0010_0008h	Chip Select is 3 and address is 8, 0010_0000h+ 8h

36.6 Glossary

UTEST User test. Refers to UTEST region of the flash.

Chapter 37
Device Configuration Module General-Purpose Registers (DCM_GPR)

37.1 DCM controlled features and availability in product family

Based on the chip features described in 'Feature comparison' section in 'Introduction' chapter, there are some features which are present only in specific parts in the MWCT2xxxS product family. The following table summarizes the corresponding DCM register fields along with the parts wherein the corresponding register fields are available. In rest of the parts within the product family, the corresponding fields are reserved.

Table 188. DCM controlled features and availability in product family

Register field	Register field abbreviation	Parts wherein this field is available
DCMRWD3[1]	CM7_1_LOCKUP_EN	MWCT2D17S, MWCT2D16S

37.2 DCM_GPR register descriptions

Before you start to work with the GPR register take care about the following:

- Do not modify the reserved locations, registers, or reserved bits with respect to their default configurations. Chip behavior is not guaranteed in case of such writes.

- The writes to the DCM Read Write registers (DCMRWPx, DCMRWDx, DCMRWFx and DCMRWPPx) are synchronized and take up to 4 cycles of CORE_CLK. Hence the user should wait for at least 4 CORE_CLK cycles after configuring these registers for these to get effective.
- The DCM registers are present in Standby domain and retain values across Standby mode. Therefore, reading the status registers after exiting Standby mode may indicate a previously latched value. To read these status registers after a reset event or after exiting Standby mode, you must first write 0 to the fields of these registers. This clears the previous status or transient information because of the reset event, and specifies the correct status.
- You must access DCM after at least 92 AIPS_SLOW_CLK cycles of writing to MC_RGM.ERCTRL because the configuration of MC_RGM.ERCTRL takes several cycles to be effective. Also, the DCMRW *n* registers are synchronized; therefore, changes to them may take up to four CORE_CLK cycles to be effective.

37.2.1 DCM_GPR memory map

DCM_GPR base address: 402A_C000h

Offset	Register	Width (In bits)	Access	Reset value

37.2.2 Read-Only GPR On Destructive Reset 1 (DCMROD1)

Offset

Register	Offset
DCMROD1	200h

Function

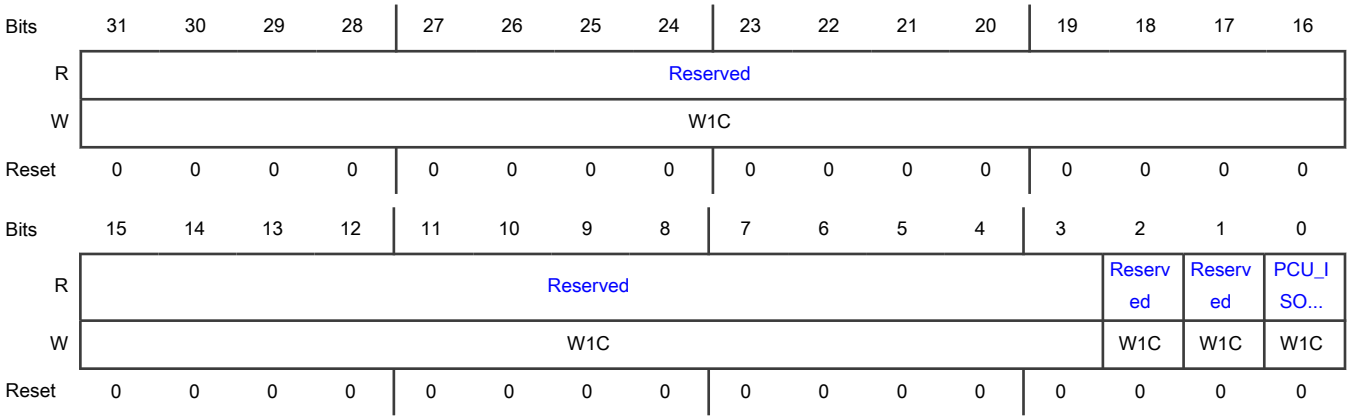
Contains information related to:

- Key response ready status.
- DCF violation from HSE_B.

- PCU input isolation status.

This register resets after destructive reset 1.

Diagram



Fields

Field	Function
31-3 —	Reserved
2 —	Reserved
1 —	Reserved
0 PCU_ISO_STATUS	PCU Input Isolation Status On Previous Standby Entry Specifies whether input isolation was enabled in the previous standby entry. 0b - No 1b - Yes

37.2.3 Read-Only GPR On Destructive Reset 3 (DCMROD3)

Offset

Register	Offset
DCMROD3	208h

Function

Contains information related to:

- ECC and life cycle errors.

- AXBS, RCCU, and gasket alarms.

This register resets after destructive reset 3.

Fields

Field	Function
31 CM7_1_ICDATA_ECC_ERR	Cortex-M7_1 I-cache Multi-Bit ECC Error Specifies whether the Cortex-M7_1 core's I-cache data memory detected a multi-bit ECC error. Read this field to identify the reason for a fault in case of FCCU noncritical fault (NCF) 2. 0b - No 1b - Yes
30 CM7_0_ICDATA_ECC_ERR	Cortex-M7_0 I-cache Data ECC Error Specifies whether the Cortex-M7_0 core's I-cache data memory detected a multi-bit ECC error. Read this field to identify the reason for a fault in case of FCCU NCF 2. 0b - No 1b - Yes
29 CM7_1_DCTAG_ECC_ERR	Cortex-M7_1 D-cache Tag ECC Error Specifies whether the Cortex-M7_1 core's D-cache tag memory detected a multi-bit ECC error. Read this field to identify the reason for a fault in case of FCCU NCF 2. 0b - No 1b - Yes
28 CM7_0_DCTAG_ECC_ERR	Cortex-M7_0 D-cache Tag ECC Error Specifies whether the Cortex-M7_0 core's D-cache tag memory detected a multi-bit ECC error. Read this field to identify the reason for a fault in case of FCCU NCF 2.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No 1b - Yes
27 CM7_1_DCDATA_ECC_ERR	Cortex-M7_1 D-cache Data Memory ECC Error Specifies whether the Cortex-M7_1 core's D-cache data memory detected a multi-bit ECC error. Read this field to identify the reason for a fault in case of FCCU NCF 2. 0b - No 1b - Yes
26 CM7_0_DCDATA_ECC_ERR	Cortex-M7_0 D-cache Data Memory ECC Error Specifies whether the Cortex-M7_0 core's D-cache data memory detected a multi-bit ECC error. Read this field to identify the reason for a fault in case of FCCU NCF 2. 0b - No 1b - Yes
25 PRAM0_ECC_ERR	Multi-Bit ECC Error From PRAM0 Specifies whether a multi-bit ECC error occurred from PRAM0. Read this field to identify the reason for a fault in case of FCCU NCF 2. 0b - No 1b - Yes
24 PRAM1_ECC_ERR	Multi-Bit ECC Error From PRAM1 Specifies whether a multi-bit ECC error occurred from PRAM1. Read this field to identify the reason for a fault in case of FCCU NCF 2. 0b - No 1b - Yes
23 —	Reserved
22 LC_ERR	Error In Life Cycle Scanning Specifies whether an error occurred during life-cycle scanning. Read this bit to identify the reason of fault in case of FCCU NCF 3. 0b - No error while lifecycle scanning. 1b - Error while lifecycle scanning
21-20 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
19 PERIPH_AXBS_ALARM	Peripheral AXBS_Lite Safety Alarm Status Specifies whether peripheral AXBS_Lite reported a safety alarm. Read this field to identify the reason for a fault in case of FCCU NCF 1. 0b - No 1b - Yes
18 EMAC_GSKT_ALARM	EMAC IAHB Gasket Alarm Status Specifies whether the EMAC IAHB gasket reported an alarm. Read this field to identify the reason for a fault in case of FCCU NCF 1. 0b - No 1b - Yes
17 TCM_AXBS_ALARM	TCM AHB Splitter Safety Alarm Status Specifies whether the TCM AHB splitter reported a safety alarm. Read this field to identify the reason for a fault in case of FCCU NCF 1. 0b - No 1b - Yes
16 DATA_EDC_ERR	Data EDC Error Specifies whether an integrity error occurred on address for safety. Read this field to identify the reason for a fault in case of FCCU NCF 1. 0b - No 1b - Yes
15 ADDR_EDC_ERR	Address EDC Error Status Specifies whether an integrity error occurred on address for safety. Read this field to identify the reason for a fault in case of FCCU NCF 1. 0b - No 1b - Yes
14 AIPS2_GSKT_ALARM	AIPS2 IAHB Gasket Alarm Status. Read this bit to identify the reason for a fault in case of FCCU NCF 1. 0b - No alarm indicated by AIPS2 IAHB gasket. 1b - Alarm indicated by AIPS2 IAHB gasket.
13 AIPS1_GSKT_ALARM	AIPS1 IAHB Gasket Alarm Status. Read this bit to identify the reason for a fault in case of FCCU NCF 1. 0b - No alarm indicated by AIPS1 IAHB gasket. 1b - Alarm indicated by AIPS1 IAHB gasket.
12	QuadSPI IAHB Gasket Alarm Status

Table continues on the next page...

Table continued from the previous page...

Field	Function
QSPI_GSKT_ALARM	Specifies whether the QuadSPI IAHB gasket reported an alarm. Read this field to identify the reason for a fault in case of FCCU NCF 1. 0b - No 1b - Yes
11 HSE_GSKT_ALARM	HSE IAHB Gasket Alarm Status Specifies whether the HSE_B IAHB gasket reported an alarm. Read this field to identify the reason for a fault in case of FCCU NCF 1. 0b - No 1b - Yes
10 —	Reserved
9 DMA_AXBS_ALARM	eDMA AXBS_Lite Safety Alarm Status Specifies whether eDMA AXBS_Lite reported a safety alarm. Read this field to identify the reason for a fault in case of FCCU NCF 1. 0b - No 1b - Yes
8 SYS_AXBS_ALARM	System AXBS Safety Alarm Status Specifies whether the system AXBS indicated a safety alarm. Read this field to identify the reason for a fault in case of FCCU NCF 1. 0b - No 1b - Yes
7 DMA_PERIPH_GSKT_ALARM	eDMA Peripheral Gasket Alarm Status Specifies whether the eDMA peripheral AXBS IAHB gasket reported a safety alarm. Read this field to identify the reason for a fault in case of FCCU NCF 1. 0b - No 1b - Yes
6 DMA_SYS_GSKT_ALARM	eDMA System Gasket Alarm Status Specifies whether the IAHB gasket safety alarm, from the eDMA system AXBS IAHB gasket, reported a safety alarm. Read this field to identify the reason for a fault in case of FCCU NCF 1. 0b - No 1b - Yes

Table continues on the next page...

Table continued from the previous page...

Field	Function
5 TCM_GSKT_ALARM	TCM IAHB Gasket Monitor Alarm Status Specifies whether the TCM IAHB gasket reported an alarm. If the value of this field is 1, the gasket reports a monitor alarm. Read this field to identify the reason for a fault in case of FCCU NCF 1. 0b - No 1b - Yes
4 —	Reserved
3 —	Reserved
2 HSE_LOCKUP	HSE_B Core Lockup Status Specifies whether the HSE_B core is in the Lockup state. Read this field to identify the reason for a fault in case of FCCU NCF 0. 0b - No 1b - Yes
1 CM7_1_LOCKUP	Cortex-M7_1 Core Lockup Status Specifies whether the Cortex_M7_1 core is in the Lockup state. Read this field to identify the reason for a fault in case of FCCU NCF 0. 0b - No 1b - Yes
0 CM7_0_LOCKUP	Cortex-M7_0 Core Lockup Status Specifies whether the Cortex-M7_0 core is in the Lockup state. Read this field to identify the reason for a fault in case of FCCU NCF 0. 0b - No 1b - Yes

37.2.4 Read-Only GPR On Destructive Reset 4 (DCMROD4)

Offset

Register	Offset
DCMROD4	20Ch

Function

Contains information related to:

- Accidental partial test activation errors.
- Go/No-go indicator supply statuses.
- Flash memory errors.
- Alarm statuses.

This register resets after destructive reset 4.

Fields

Field	Function
31 —	Reserved
30 TEST_ACTIVATION_1_ERR	Accidental Partial Test Activation 1 Error Specifies whether partial test 1 is activated accidentally. Read this field to identify the reason for a fault in case of FCCU NCF 5. 0b - No 1b - Yes
29 TEST_ACTIVATION_0_ERR	Accidental Partial Test Activation 0 Error Specifies whether partial test 0 is activated accidentally. Read this field to identify the reason for a fault in case of FCCU NCF 5. 0b - No 1b - Yes
28 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
27 VDD2P5_GNG_ERR	Go/No-go Indicator For VDD_HV_FLA Specifies whether the VDD_HV_FLA (double-bond) supply going to XOSC and PLL is clean. Read this field to identify the reason for a fault in case of FCCU NCF 4. If this field = 1, the "go" indication specifies a clean supply, and if this field = 0, the "no-go" indication specifies an unclean supply with a fault in the double-bond connection or its routing within the chip. 0b - Yes 1b - No
26 VDD1P1_GNG_ERR	Go/No-go Indicator For VDD1PD1 Specifies whether the VDD1PD1 (double-bond) supply going to PLL is clean. Read this field to identify the reason for a fault in case of FCCU NCF 4. If this field = 1, the "go" indication specifies a clean supply, and if this field = 0, the "no-go" indication specifies an unclean supply with a fault in the double-bond connection or its routing within the chip. 0b - Yes 1b - No
25 FLASH_ECC_ERR	ECC Error From Flash Controller This alarm Specifies that the flash controller detected an error in the address ECC manipulation logic through EDC. Read this bit to identify the reason for a fault in case of FCCU NCF 3. 0b - No ECC error from flash controller. 1b - ECC error from flash controller.
24 —	Reserved
23 —	Reserved
22 FLASH_SCAN_ERR	Flash Memory Scan Error Status Specifies whether the flash memory encountered an error during the DCM flash scanning process because of invalid data. Read this field to identify the reason for a fault in case of FCCU NCF 3. 0b - No 1b - Yes
21 FLASH_RST_ERR	Flash Reset Error Status Specifies whether the flash memory encountered a flash memory reset error during its reset reads. Read this field to identify the reason for a fault in case of FCCU NCF 3.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No 1b - Yes
20 FLASH_REF_ERR	Flash Memory Reference Error Status Specifies whether the flash memory encountered a reference current loss or read voltage error during previous read(s). Read this field to identify the reason for a fault in case of FCCU NCF 3. 0b - No 1b - Yes
19 FLASH_ADDR_ENC_ERR	Flash Memory Address Encode Error Status Specifies whether FMU reported an address encode error in the flash memory. During address decoding, if multiple or no address line is selected, FMU reports an address encode error. Read this field to identify the reason for a fault in case of FCCU NCF 3. 0b - No 1b - Yes
18 FLASH_EDC_ERR	Flash Memory EDC Error Status Specifies whether FMU reported an integrity error after an ECC correction error in the flash memory. Read this field to identify the reason for a fault in case of FCCU NCF 3. 0b - No 1b - Yes
17 PF2_DATA_ECC_ERR	Program Flash Memory 2 Data ECC Error Status Specifies whether FMU reported uncorrectable errors in the flash memory controller port 2 data memory. These errors are connected to FCCU NCFs and to ERM. See the "Error Reporting Module (ERM)" chapter for memory errors and mapping onto ERM channels. Read this field to identify the reason for a fault in case of FCCU NCF 3. 0b - No 1b - Yes
16 PF2_CODE_ECC_ERR	Program Flash Memory 2 Code ECC Error Status Specifies whether FMU reported uncorrectable errors in the flash memory controller port 2 code memory. These errors are connected to FCCU NCFs and to ERM. See the "Error Reporting Module (ERM)" chapter for memory errors and mapping onto ERM channels. Read this field to identify the reason for a fault in case of FCCU NCF 3. 0b - No 1b - Yes

Table continues on the next page...

Table continued from the previous page...

Field	Function
15 PF1_DATA_ECC_ERR	Program Flash Memory 1 Data ECC Error Status Specifies whether FMU reported uncorrectable errors in the flash memory controller port 1 data memory. These errors are connected to FCCU NCFs and to ERM. See the "Error Reporting Module (ERM)" chapter for memory errors and mapping onto ERM channels. Read this field to identify the reason for a fault in case of FCCU NCF 3. 0b - No 1b - Yes
14 PF1_CODE_ECC_ERR	Program Flash Memory 1 Code ECC Error Status Specifies whether FMU reported uncorrectable errors in the flash memory controller port 1 code memory. These errors are connected to FCCU NCFs and to ERM. See the "Error Reporting Module (ERM)" chapter for memory errors and mapping onto ERM channels. Read this field to identify the reason for a fault in case of FCCU NCF 3. 0b - No 1b - Yes
13 PF0_DATA_ECC_ERR	Program Flash Memory 0 Data ECC Error Status Specifies whether FMU reported uncorrectable errors in the flash memory controller port 0 data memory. These errors are connected to FCCU NCFs and to ERM. See the "Error Reporting Module (ERM)" chapter for memory errors and mapping onto ERM channels. Read this field to identify the reason for a fault in case of FCCU NCF 3. 0b - No 1b - Yes
12 PF0_CODE_ECC_ERR	Program Flash Memory 0 Code ECC Error Status Specifies whether FMU reported uncorrectable errors in the flash memory controller port 0 code memory. These errors are connected to FCCU NCFs and to ERM. See the "Error Reporting Module (ERM)" chapter for memory errors and mapping onto ERM channels. Read this field to identify the reason for a fault in case of FCCU NCF 3. 0b - No 1b - Yes
11 HSE_RAM_ECC_ERR	HSE_B RAM Uncorrectable ECC Status Specifies whether HSE_B RAM reported an uncorrectable ECC error. Read this field to identify the reason for a fault in case of FCCU NCF 2. 0b - No 1b - Yes

Table continues on the next page...

Table continued from the previous page...

Field	Function
10 PRAM1_FCCU_ALARM	PRAM1 FCCU Alarm Status Specifies whether PRAM1 reported a safety alarm. This field specifies the status of the PRAM1 safety alarm, whether the alarm is set on faulty PRAM1 read or read-modify error. Read this field to identify the reason for a fault in case of FCCU NCF 2. 0b - No 1b - Yes
9 PRAM0_FCCU_ALARM	PRAM0 FCCU Alarm Status Specifies whether PRAM0 reported a safety alarm. This field specifies the status of the PRAM0 safety alarm, whether the alarm is set on faulty PRAM0 read or read-modify error. Read this field to identify the reason for a fault in case of FCCU NCF 2. 0b - No 1b - Yes
8 DMA_TCD_RAM_ECC_ERR	eDMA TCD RAM ECC Error Specifies whether the eDMA_TCD memory detected an uncorrectable ECC error. This uncorrectable ECC error consists of a multi-bit data ECC error and an address ECC error. Read this field to identify the reason for a fault in case of FCCU NCF 2. 0b - No 1b - Yes
7 CM7_1_DTCM1_ECC_ERR	Cortex-M7_1 DTCM 1 ECC Error Specifies whether the Cortex-M7_1 core's DTCM block 1 detected an uncorrectable ECC error. This uncorrectable ECC error consists of a multi-bit data ECC error and an address ECC error. The Cortex-M7_1 core's DTCM consists of two physical blocks. Read this field to identify the reason for a fault in case of FCCU NCF 2. 0b - No 1b - Yes
6 CM7_1_DTCM0_ECC_ERR	Cortex-M7_1 DTCM 0 ECC Error Specifies whether the Cortex-M7_1 core's DTCM block 0 detected an uncorrectable ECC error. This uncorrectable ECC error consists of a multi-bit data ECC error and an address ECC error. The Cortex-M7_1 core's DTCM consists of two physical blocks. Read this field to identify the reason for a fault in case of FCCU NCF 2. 0b - No 1b - Yes
5	Cortex-M7_1 ITCM ECC Error Specifies whether the Cortex-M7_1 core's ITCM detected an uncorrectable ECC error.

Table continues on the next page...

Table continued from the previous page...

Field	Function
CM7_1_ITCM_ECC_ERR	This uncorrectable ECC error consists of a multi-bit data ECC error and an address ECC error. Read this field to identify the reason for a fault in case of FCCU NCF 2. 0b - No 1b - Yes
4 CM7_0_DTCM1_ECC_ERR	Cortex-M7_0 DTCM 1 ECC Error Specifies whether the Cortex-M7_0 core's DTCM block 1 detected an uncorrectable ECC error. This uncorrectable ECC error consists of a multi-bit data ECC error and an address ECC error. The Cortex-M7_0 core's DTCM consists of two physical blocks. Read this field to identify the reason for a fault in case of FCCU NCF 2. 0b - No 1b - Yes
3 CM7_0_DTCM0_ECC_ERR	Cortex-M7_0 DTCM 0 ECC Error Specifies whether the Cortex-M7_0 core's DTCM block 0 detected an uncorrectable ECC error. This uncorrectable ECC error consists of a multi-bit data ECC error and an address ECC error. The Cortex-M7_0 core's DTCM consists of two physical blocks. Read this field to identify the reason for a fault in case of FCCU NCF 2. 0b - No 1b - Yes
2 CM7_0_ITCM_ECC_ERR	Cortex-M7_0 ITCM ECC Error Specifies whether the Cortex-M7_0 core's ITCM detected an uncorrectable ECC error. This uncorrectable ECC error consists of a multi-bit data ECC error and an address ECC error. Read this field to identify the reason of fault in case of FCCU NCF 2. 0b - No 1b - Yes
1 CM7_1_ICTAG_ECC_ERR	Cortex-M7_1 I-cache Tag ECC Error Specifies whether the Cortex-M7_1 core's I-cache tag memory detected a multi-bit ECC error. Read this field to identify the reason for a fault in case of FCCU NCF 2. 0b - No 1b - Yes
0 CM7_0_ICTAG_ECC_ERR	Cortex-M7_0 I-cache Tag ECC Error Specifies whether the Cortex-M7_0 core's I-cache tag memory detected a multi-bit ECC error. Read this field to identify the reason for a fault in case of FCCU NCF 2. 0b - No 1b - Yes

37.2.5 Read-Only GPR On Destructive Reset 5 (DCMROD5)

Offset

Register	Offset
DCMROD5	210h

Function

Contains information related to:

- ECC and EDC errors.
- Activation and bus errors.

This register resets after destructive reset 5.

23 —	Reserved
22 HSE_RDATA_EDC_ERR	HSE_B Read Data EDC Error Specifies whether an integrity error is reported on the HSE_B read data for safety. Read this field to identify the reason for a fault in case of FCCU NCF 1. 0b - No 1b - Yes
21 CM7_0_AHBM_RDATA_EDC_ERR	Cortex-M7_0 AHBM Read Data EDC Error Specifies whether an integrity error is reported on the Cortex-M7_0 core's main read data for safety. Read this field to identify the reason for a fault in case of FCCU NCF 1. 0b - No 1b - Yes
20 CM7_0_AHBP_RDATA_EDC_ERR	Cortex-M7_0 AHBP Read Data EDC Error Specifies whether an integrity error is reported on the Cortex-M7_0 core's peripheral read data for safety. Read this field to identify the reason for a fault in case of FCCU NCF 1. 0b - No 1b - Yes
19 CM7_1_AHBM_RDATA_EDC_ERR	Cortex-M7_1 AHBM Read Data EDC Error Specifies whether an integrity error is reported on the Cortex-M7_1 core's main read data for safety. Read this field to identify the reason for a fault in case of FCCU NCF 1. 0b - No 1b - Yes
18	Cortex-M7_1 AHBP Read Data EDC Error Specifies whether an integrity error is reported on the Cortex-M7_1 core's peripheral read data for safety.

Table continues on the next page...

Table continued from the previous page...

Field	Function
CM7_1_AHBP_RDATA_EDC_ERR	Read this field to identify the reason for a fault in case of FCCU NCF 1. 0b - No 1b - Yes
17 DMA_RDATA_EDC_ERR	eDMA Read Data EDC Error Specifies whether an integrity error is reported on the eDMA read data for safety. Read this field to identify the reason for a fault in case of FCCU NCF 1. 0b - No 1b - Yes
16 —	Reserved
15 EMAC_RDATA_EDC_ERR	EMAC Read Data EDC Error Specifies whether an integrity error is reported on the EMAC read data for safety. Read this field to identify the reason for a fault in case of FCCU NCF 1. 0b - No 1b - Yes
14 TCM_RDATA_EDC_ERR	TCM Read Data EDC Error Specifies whether an integrity error is reported on the TCM read data for safety. Read this field to identify the reason for a fault in case of FCCU NCF 1. 0b - No 1b - Yes
13 DEBUG_ACTIVATION_ERR	Debug Activation Error Specifies whether an unintended debug is activated. This field monitors unintended debug activation. It displays 1 as its value when the core is in halted state with the application debug or debugger request not enabled. Read this field to identify the reason for a fault in case of FCCU NCF 5. 0b - No 1b - Yes
12 MCT_BUS_ERR	MCT Bus Error Fault reported due to illegal access on MBIST controller (MCT). This fault is reported via a transfer error indication to the system. Read this bit to identify the reason of fault in case of FCCU NCF 5. 0b - No transfer error indicated from MCT. 1b - Transfer error indicated from MCT.

Table continues on the next page...

Table continued from the previous page...

Field	Function
11 STCU_BIST_USER_CF	STCU2 BIST User Critical Fault (CF) Specifies whether MBIST is enabled accidentally when the fault condition is detected in Run mode. Read this field to identify the reason for a fault in case of FCCU NCF 5. 0b - No 1b - Yes
10 MBIST_ACTIVATION_ERR	MBIST Activation Error Specifies whether an accidental backdoor access is enabled on memories. DCMRWD5[MBIST_ACTIVATION_ERR_EN] needs to be disabled on FCCU when performing a fault injection. Read this field to identify the reason for a fault in case of FCCU NCF 5. 0b - No 1b - Yes
9 STCU_NCF	STCU2 NCF Result Error Specifies whether STCU2 NCF, which is a BIST result error, is reported. Read this field to identify the reason for a fault in case of FCCU NCF 5. 0b - No 1b - Yes
8 SW_NCF_3	Software NCF3 Status Specifies whether DCMRWF1[FCCU_SW_NCF3] is enabled. Read this field to identify the reason for a fault in case of FCCU NCF 7. 0b - No 1b - Yes
7 SW_NCF_2	Software NCF2 Status Specifies whether DCMRWF1[FCCU_SW_NCF2] is enabled. Read this field to identify the reason for a fault in case of FCCU NCF 7. 0b - No 1b - Yes
6 SW_NCF_1	Software NCF1 Status Specifies whether DCMRWF1[FCCU_SW_NCF1] is enabled. Read this field to identify the reason for a fault in case of FCCU NCF 7. 0b - No 1b - Yes

Table continues on the next page...

Table continued from the previous page...

Field	Function
5 SW_NCF_0	Software NCF 0 Status Specifies whether DCMRWF1[FCCU_SW_NCF0] is enabled. Read this field to identify the reason for a fault in case of FCCU NCF 7. 0b - No 1b - Yes
4 INTM_3_ERR	INTM_3 Error Specifies whether INTM_3 reported an error. The reported error is recorded in INTM.INTM_STATUS3. See the "Functional description" section of the "Interrupt Monitor (INTM)" chapter for details. Read this field to identify the reason for a fault in case of FCCU NCF 6. 0b - No 1b - Yes
3 INTM_2_ERR	INTM_2 Error Specifies whether INTM_2 reported an error. The reported error is recorded in INTM.INTM_STATUS2. See the "Functional description" section of the "Interrupt Monitor (INTM)" chapter for details. Read this field to identify the reason for a fault in case of FCCU NCF 6. 0b - No 1b - Yes
2 INTM_1_ERR	INTM_1 Error Specifies whether INTM_1 reported an error. The reported error is recorded in INTM.INTM_STATUS1. See the "Functional description" section of the "Interrupt Monitor (INTM)" chapter for details. Read this field to identify the reason for a fault in case of FCCU NCF 6. 0b - No 1b - Yes
1 INTM_0_ERR	INTM_0 Error Specifies whether INTM_0 reported an error. The reported error is recorded in INTM.INTM_STATUS0. See the "Functional description" section of the "Interrupt Monitor (INTM)" chapter for details. Read this field to identify the reason for a fault in case of FCCU NCF 6. 0b - No 1b - Yes

Table continues on the next page...

Table continued from the previous page...

Field	Function
0 TEST_ACTIVATION_3_ERR	Accidental Partial Test Activation 3 Error Specifies whether partial test 3 is activated accidentally. Read this field to identify the reason for a fault in case of FCCU NCF 5. 0b - No 1b - Yes

37.2.6 Read-Only GPR On Functional Reset 1 (DCMROF1)

Offset

Register	Offset
DCMROF1	300h

Function

Specifies current transfer channel ID.

This register resets after functional reset 1.

Diagram

37.2.7 Read-Only GPR On Functional Reset 2 (DCMROF2)

Offset

Register	Offset
DCMROF2	304h

Function

Specifies the SDID0 contents that DCM scans from the flash memory.

This register resets after functional reset 2.

NOTE

See the DCF clients file attached to this document for more information. The Utest section contains chip-configurable ID information, captured as status on read-only GPR in functional reset.

Diagram

37.2.23 Read-Only GPR On Functional Reset 19 (DCMROF19)

Offset

Register	Offset
DCMROF19	348h

Function

Contains information related to:

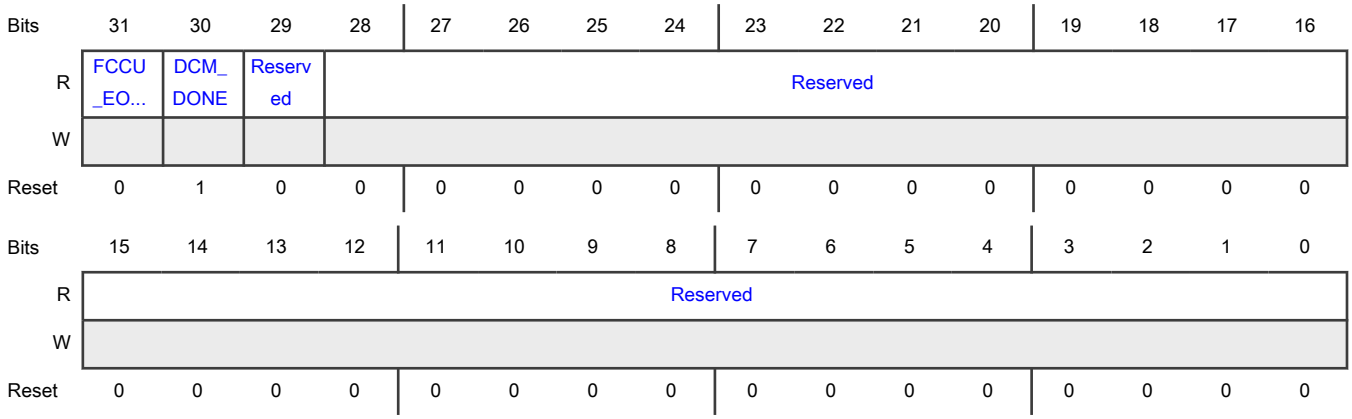
- FCCU EOUT status.
- Flash memory scanning status.
- Lockstep enable.

This register resets after functional reset 19.

NOTE

The reset value is undefined on reset and is loaded from the flash memory contents at the end of the reset sequence.

Diagram



Fields

Field	Function
31 FCCU_EOUT_DEDICATED	FCCU EOUT Status Specifies the status of FCCU_EOUT pins on GPIO_2 and GPIO_3 as configured in the DCF record, UTEST_MISC[FCCU_EOUT_DEDICATED]. See the DCF clients file attached to this document for more information. 0b - General purpose, supporting all functions 1b - Dedicated EOUT pins
30 DCM_DONE	Flash Memory Scanning Status Specifies the status of flash memory scanning by DCM. 0b - Incomplete 1b - Complete
29 —	Reserved
28-0 —	Reserved

37.2.24 Read-Only GPR On Functional Reset 20 (DCMROF20)

Offset

Register	Offset
DCMROF20	34Ch

Function

Specifies the information of chip destructive reset escalation support for destructive reset sources as configured in the DCF record, DEST_RST_ESC[13:0]. See the DCF clients file attached to this document for the mapping of corresponding destructive reset events.

This register resets after functional reset 20.

Diagram

31	Cortex-M7_1 I-cache ECC Error Enable Specifies whether the Cortex-M7_1 core's I-cache data memory detected a multi-bit ECC error.

Table continues on the next page...

Table continued from the previous page...

Field	Function
CM7_1_ICDATA_ECC_ERR_EN	This field enables fault monitoring at FCCU NCF 2 if there is a multi-bit ECC error from the Cortex-M7_1 core's I-cache data memory. 0b - No 1b - Yes
30 CM7_0_ICDATA_ECC_ERR_EN	Cortex-M7_0 I-cache ECC Error Enable Specifies whether the Cortex-M7_0 core's I-cache data memory detected a multi-bit ECC error. The field enables fault monitoring at FCCU NCF 2 if there is a multi-bit ECC error from the Cortex-M7_0 core's I-cache data memory. 0b - No 1b - Yes
29 CM7_1_DCTAG_ECC_ERR_EN	Cortex-M7_1 D-cache Tag ECC Error Enable Specifies whether the Cortex-M7_1 core's D-cache tag memory detected a multi-bit ECC error. The field enables fault monitoring at FCCU NCF 2 if there is a multi-bit ECC error from the Cortex-M7_1 core's D-cache tag memory. 0b - No 1b - Yes
28 CM7_0_DCTAG_ECC_ERR_EN	Cortex-M7_0 D-cache Tag ECC Error Enable Specifies whether the Cortex-M7_0 core's D-cache tag memory detected a multi-bit ECC error. The field enables fault monitoring at FCCU NCF 2 if there is a multi-bit ECC error from the Cortex-M7_0 core's D-cache tag memory. 0b - No 1b - Yes
27 CM7_1_DCDATA_ECC_ERR_EN	Cortex-M7_1 D-cache Data ECC Error Enable Specifies whether the Cortex-M7_1 core's D-cache data memory detected a multi-bit ECC error. The field enables fault monitoring at FCCU NCF 2 if there is a multi-bit ECC error from the Cortex-M7_1 core's D-cache data memory. 0b - No 1b - Yes
26 CM7_0_DCDATA_ECC_ERR_EN	Cortex-M7_0 D-cache Data ECC Error Enable Specifies whether the Cortex-M7_0 core's D-cache data memory detected a multi-bit ECC error. The field enables fault monitoring at FCCU NCF 2 if there is a multi-bit ECC error from the Cortex-M7_0 core's D-cache data memory. 0b - No 1b - Yes

Table continues on the next page...

Table continued from the previous page...

Field	Function
25 PRAM0_ECC_ERR_EN	PRAM0 ECC Error Enable Specifies whether a multi-bit ECC error occurred from PRAM0. The field enables fault monitoring at FCCU NCF 2 if there is a multi-bit ECC error from PRAM0. 0b - No 1b - Yes
24 PRAM1_ECC_ERR_EN	PRAM1 ECC Error Enable Specifies whether a multi-bit ECC error occurred from PRAM1. The field enables fault monitoring at FCCU NCF 2 if there is a multi-bit ECC error from PRAM1. 0b - No 1b - Yes
23 —	Reserved
22 LC_ERR_EN	Life Cycle Scanning Error Enable Specifies whether an error is encountered during life-cycle scanning. The field enables fault monitoring at FCCU NCF 3 if there is an error in life-cycle scanning. **NOTE** On any POR or destructive reset event, because this field becomes 0, the field has no effect. A life-cycle error (in case it is present) is not disabled. 0b - No 1b - Yes
21-20 —	Reserved
19 PERIPH_AXBS_ALARM_EN	Peripheral AXBS Alarm Enable Specifies whether peripheral AXBS_Lite reported a safety alarm. The field enables fault monitoring at FCCU NCF 1 in case of a peripheral AXBS_Lite safety alarm. 0b - No 1b - Yes
18 EMAC_GSKT_ALARM_EN	EMAC Gasket Alarm Enable Specifies whether the EMAC IAHB gasket reported an alarm. The field enables fault monitoring at FCCU NCF 1 in case of an EMAC IAHB gasket alarm. 0b - No 1b - Yes

Table continues on the next page...

Table continued from the previous page...

Field	Function
17 TCM_AXBS_ALARM_EN	TCM AXBS Alarm Enable Specifies whether the TCM AHB splitter reported a safety alarm. The field enables fault monitoring at FCCU NCF 1 in case of a TCM AHB splitter safety alarm. 0b - No 1b - Yes
16 DATA_EDC_ERR_EN	Data EDC Error Enable Specifies whether a data EDC error occurred. The field enables fault monitoring at FCCU NCF 1, in case of an integrity error on data, for safety. 0b - No 1b - Yes
15 ADDR_EDC_ERR_EN	Address EDC Error Enable Specifies whether an address integrity (EDC) error occurred. The field enables fault monitoring at FCCU NCF 1, in case of an integrity error on address, for safety. 0b - No 1b - Yes
14 AIPS2_GSKT_ALARM_EN	Enable bit for enabling the fault monitoring at FCCU NCF 1 for the fault: AIPS2 IAHB gasket alarm. 0b - No alarm indicated by AIPS2 IAHB gasket. 1b - Alarm indicated by AIPS2 IAHB gasket.
13 AIPS1_GSKT_ALARM_EN	Enable bit for enabling the fault monitoring at FCCU NCF 1 for the fault: AIPS1 IAHB gasket alarm. 0b - No alarm indicated by AIPS1 IAHB gasket. 1b - Alarm indicated by AIPS1 IAHB gasket.
12 QSPI_GSKT_ALARM_EN	QuadSPI Gasket Alarm Enable Specifies whether the QuadSPI IAHB gasket reported an alarm. The field enables fault monitoring at FCCU NCF 1 in case of QuadSPI IAHB gasket alarm. 0b - No 1b - Yes
11 HSE_GSKT_ALARM_EN	HSE_B Gasket Alarm Enable Specifies whether the HSE_B IAHB gasket reported an alarm. The field enables fault monitoring at FCCU NCF 1 in case of HSE_B IAHB gasket alarm. 0b - No 1b - Yes
10	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
9 DMA_AXBS_ALARM_EN	DMA AXBS Alarm Enable Specifies whether eDMA AXBS_Lite reported a safety alarm. The field enables fault monitoring at FCCU NCF 1 in case of an eDMA AXBS_Lite safety alarm. 0b - No 1b - Yes
8 SYS_AXBS_ALARM_EN	System AXBS Alarm Enable Specifies whether the system AXBS reported a safety alarm. The field enables fault monitoring at FCCU NCF 1 in case of a system AXBS safety alarm. 0b - No 1b - Yes
7 DMA_PERIPH_GSKT_ALARM_EN	TCM Gasket Alarm Enable Specifies whether the eDMA-peripheral AXBS IAHB gasket reported a safety alarm. The field enables fault monitoring at FCCU NCF 1 in case of IAHB gasket safety alarm from the eDMA peripheral AXBS IAHB gasket. 0b - No 1b - Yes
6 DMA_SYS_GSKT_ALARM_EN	DMA System Gasket Alarm Enable Specifies whether the eDMA-system AXBS IAHB gasket reported a safety alarm. The field enables fault monitoring at FCCU NCF 1 in case of IAHB gasket safety alarm from the eDMA-system AXBS IAHB gasket. 0b - No 1b - Yes
5 TCM_GSKT_ALARM_EN	TCM Gasket Alarm Enable Specifies whether the TCM IAHB gasket reported an alarm. If this field = 1, the gasket reports a monitor alarm. The field enables fault monitoring at FCCU NCF 1 in case of TCM IAHB gasket monitor alarm. 0b - No 1b - Yes
4 —	Reserved
3	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
2 —	Reserved
1 CM7_1_LOCKUP_EN	Cortex-M7_1 Lockup Enable Specifies whether the Cortex-M7_1 core is in the Lockup state. The field enables fault monitoring at FCCU NCF 0 in case of the Cortex-M7_1 core lockup. 0b - No 1b - Yes
0 CM7_0_LOCKUP_EN	Cortex-M7 Lockup Enable Specifies whether the Cortex-M7_0 core is in the Lockup state. The field enables fault monitoring at FCCU NCF 0 in case of the Cortex-M7_0 core lockup. 0b - No 1b - Yes

37.2.30 Read Write GPR On Destructive Reset 4 (DCMRWD4)

Offset

Register	Offset
DCMRWD4	50Ch

Function

Contains information related to:

- Test activation errors.
- Fault monitoring.
- DCM flash memory scanning.
- ECC errors.

This register resets after destructive reset 4.

Fields

Field	Function
31 —	Reserved
30 TEST_ACTIVATION_1_ERR_EN	Test Activation 1 Error Enable Specifies whether a partial test is activated accidentally. The field enables fault monitoring at FCCU NCF 5 in case of an accidental partial test activation 1. 0b - No 1b - Yes
29 TEST_ACTIVATION_0_ERR_EN	Test Activation 0 Error Enable Specifies whether a partial test is activated accidentally. The field enables fault monitoring at FCCU NCF 5 in case of an accidental partial test activation 0. 0b - No 1b - Yes
28 —	Reserved
27 VDD2P5_GNG_ERR_EN	VDD2P5 Go/No-go Error Enable Specifies whether the VDD2P5 (double bond) supply is clean. The field enables fault monitoring at FCCU NCF 4 if there is a "go/no-go" indicator for VDD_HV_FLA (double bond) going to FXOSC and PLL. If the value of this field = 0, there is a "go" indication that the supply if clean; if it = 1, there is a "no-go" indication that the supply is unclean and there is a fault in double-bond connection or its routing within the chip. 0b - Clean 1b - Unclean
26	VDD1PD1 Go/No-go Error Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
VDD1P1_GNG_ERR_EN	Specifies whether the VDD1PD1 (double bond) supply is clean. The field enables fault monitoring at FCCU NCF 4 if there is a "go/no-go" indicator for VDD1PD1 (double bond) supply going to PLL. If the value of this field = 0, there is a "go" indication that the supply if clean; if it = 1, there is a "no-go" indication that the supply is unclean and there is a fault in double-bond connection or its routing within the chip. 0b - Clean 1b - Unclean
25 —	Reserved
24 FLASH_ACCESS_ERR_EN	Flash Memory Access Error Enable Specifies whether a transaction monitor mismatch error occurred from the flash memory controller. The field enables fault monitoring at FCCU NCF 3 in case of a transaction monitor mismatch error from the flash memory controller. The alarm indicates that the flash memory controller detected a transaction monitor mismatch when compared to the flash memory safety feedback output. The flash memory specifies where the reconstructed address is compared with the address that invoked the flash memory access. 0b - No 1b - Yes
23 —	Reserved
22 FLASH_SCAN_ERR_EN	Flash Memory Scanning Error Enable Specifies whether an error occurred during DCM flash memory scanning. The field enables fault monitoring at FCCU NCF 3 in case of an error during the DCM flash memory scanning process because of invalid data. **NOTE** On a POR or destructive reset event, because this field becomes 0, the field has no effect. A life-cycle error (in case it is present) is not disabled. 0b - No 1b - Yes
21 FLASH_RST_ERR_EN	Flash Memory Reset Error Enable Specifies whether a flash memory reset error occurred. The field enables fault monitoring at FCCU NCF 3 in case of a flash memory reset error. This error indication is set when the flash memory encounters errors during its reset reads. 0b - No 1b - Yes

Table continues on the next page...

Table continued from the previous page...

Field	Function
20 FLASH_REF_ERR_EN	Flash Memory Reference Error Encode Specifies whether a reference current loss or read voltage error occurred during previous read(s). The field enables fault monitoring at FCCU NCF 3 if there is a flash memory reference current loss or read voltage error during previous read(s). 0b - No 1b - Yes
19 FLASH_ADDR_ENC_ERR_EN	Flash Memory Address Encode Error Enable Specifies whether an address encode error occurred in the flash memory. The field enables fault monitoring at FCCU NCF 3 if there is a flash memory address encode error. During address decoding, if multiple or no address line is selected, FMU reports an address encode error. 0b - No 1b - Yes
18 FLASH_EDC_ERR_EN	Flash Memory EDC Error Enable Specifies whether EDC after ECC error is reported in the flash memory. The field enables fault monitoring at FCCU NCF 3 in case of a flash memory ECC correction error via EDC, reported by FMU. 0b - No 1b - Yes
17 PF2_DATA_ECC_ERR_EN	PF2 Data ECC Error Enable Specifies whether FMU reported an uncorrectable error in the flash memory controller port 2 data memory. The field enables fault monitoring at FCCU NCF 3 in case of Flash2 data ECC uncorrectable error. 0b - No 1b - Yes
16 PF2_CODE_ECC_ERR_EN	PF2 Code ECC Error Enable Specifies whether FMU reported an uncorrectable error in the flash memory controller port 2 code memory. The field enables fault monitoring at FCCU NCF 3 in case of Flash2 code ECC uncorrectable error. 0b - No 1b - Yes
15 PF1_DATA_ECC_ERR_EN	PF1 Data ECC Error Enable Specifies whether FMU reported an uncorrectable error in the flash memory controller port 1 data memory. The field enables fault monitoring at FCCU NCF 3 in case of Flash1 data ECC uncorrectable error. 0b - No 1b - Yes

Table continues on the next page...

Table continued from the previous page...

Field	Function
14 PF1_CODE_ECC_ERR_EN	PF1 Code ECC Error Enable Specifies whether FMU reported an uncorrectable error in the flash memory controller port 1 code memory. The field enables fault monitoring at FCCU NCF 3 in case of Flash1 code ECC uncorrectable error. 0b - No 1b - Yes
13 PF0_DATA_ECC_ERR_EN	PF0 Data ECC Error Enable Specifies whether FMU reported an uncorrectable error in the flash memory controller port 0 data memory. The field enables fault monitoring at FCCU NCF 3 in case of Flash0 data ECC uncorrectable error. 0b - No 1b - Yes
12 PF0_CODE_ECC_ERR_EN	PF0 Code ECC Error Enable Specifies whether FMU reported an uncorrectable error in the flash memory controller port 0 code memory. The field enables fault monitoring at FCCU NCF 3 in case of Flash0 code ECC uncorrectable error. 0b - No 1b - Yes
11 —	Reserved
10 PRAM1_FCCU_ALARM_EN	PRAM1 FCCU Alarm Enable Specifies whether PRAM1 reported a safety alarm. The field enables fault monitoring at FCCU NCF 2 in case of PRAM1 safety alarm. This alarm is set on faulty SRAM1 read or read-modify error. 0b - No 1b - Yes
9 PRAM0_FCCU_ALARM_EN	PRAM0 FCCU Alarm Enable Specifies whether PRAM0 reported a safety alarm. The field enables fault monitoring at FCCU NCF 2 in case of PRAM0 safety alarm. This alarm is set to faulty SRAM0 read or read-modify error. 0b - No 1b - Yes
8 DMA_TCD_RAM_ECC_ERR_EN	eDMA TCD RAM ECC Error Enable Specifies whether uncorrectable ECC error detection is enabled at FCCU.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	The field enables fault monitoring at FCCU NCF 2 in case of an uncorrectable ECC error reported from the eDMA_TCD memory. This uncorrectable ECC error consists of a multi-bit data ECC error and an address ECC error. 0b - No 1b - Yes
7 CM7_1_DTCM1_ECC_ERR_EN	Cortex-M7_1 DTCM 1 ECC Error Enable Specifies whether uncorrectable ECC error detection is enabled at FCCU. The field enables fault monitoring at FCCU NCF 2 in case of an uncorrectable ECC error from the Cortex-M7_1 core's DTCM block 1. This uncorrectable ECC error consists of a multi-bit data ECC error and an address ECC error. The Cortex-M7_1 core's DTCM 1 consists of two physical blocks. 0b - No 1b - Yes
6 CM7_1_DTCM0_ECC_ERR_EN	Cortex-M7_1 DTCM 0 ECC Error Enable Specifies whether uncorrectable ECC error detection is enabled at FCCU. This uncorrectable ECC error consists of a multi-bit data ECC error and an address ECC error. The Cortex-M7_1 core's DTCM consists of two physical blocks. This field enables fault monitoring at FCCU NCF 2 in case of an uncorrectable ECC error from the Cortex-M7_1 core's DTCM block 0. 0b - No 1b - Yes
5 CM7_1_ITCM_ECC_ERR_EN	Cortex-M7_1 ITCM ECC Error Enable Specifies whether uncorrectable ECC error detection is enabled at FCCU. The field enables fault monitoring at FCCU NCF 2 in case of an uncorrectable ECC error from the Cortex-M7_1 core's ITCM. This uncorrectable ECC error consists of a multi-bit data ECC error and an address ECC error. 0b - No 1b - Yes
4 CM7_0_DTCM1_ECC_ERR_EN	Cortex-M7_0 DTCM 1 ECC Error Enable Specifies whether uncorrectable ECC error detection is enabled at FCCU. The field enables fault monitoring at FCCU NCF 2 in case of an uncorrectable ECC error from the Cortex-M7_0 core's DTCM block 1. This uncorrectable ECC error consists of a multi-bit data ECC error and an address ECC error. The Cortex-M7_0 core's DTCM consists of two physical blocks. 0b - No 1b - Yes

Table continues on the next page...

Table continued from the previous page...

Field	Function
3 CM7_0_DTCM0_ECC_ERR_EN	Cortex-M7_0 DTCM 0 ECC Error Enable Specifies whether uncorrectable ECC error detection is enabled at FCCU. The field enables fault monitoring at FCCU NCF 2 in case of an uncorrectable ECC error from the Cortex-M7_0 core's DTCM block 0. This uncorrectable ECC error consists of a multi-bit data ECC error and an address ECC error. The Cortex-M7_0 core's DTCM consists of two physical blocks. 0b - No 1b - Yes
2 CM7_0_ITCM_ECC_ERR_EN	Cortex-M7 ITCM ECC Error Enable Specifies whether uncorrectable ECC error detection is enabled at FCCU. The field enables fault monitoring at FCCU NCF 2 in case of an uncorrectable ECC error from the Cortex-M7_0 core's ITCM. This uncorrectable ECC error consists of a multi-bit data ECC error and an address ECC error. 0b - No 1b - Yes
1 CM7_1_ICTAG_ECC_ERR_EN	Cortex-M7_1 I-cache Tag ECC Error Enable Specifies whether the Cortex-M7_1 core's I-cache tag memory detected a multi-bit ECC error. This field enables fault monitoring at FCCU NCF 2 if there is a multi-bit ECC error from the Cortex-M7_1 core's I-cache tag memory. 0b - No 1b - Yes
0 CM7_0_ICTAG_ECC_ERR_EN	Cortex-M7_0 I-cache Tag ECC Error Enable Specifies whether the Cortex-M7_0 core's I-cache tag memory detected a multi-bit ECC error. The field enables fault monitoring at FCCU NCF 2 if there is a multi-bit ECC error from the Cortex-M7_0 core's I-cache tag memory. 0b - No 1b - Yes

37.2.31 Read Write GPR On Destructive Reset 5 (DCMRWD5)

Offset

Register	Offset
DCMRWD5	510h

Function

Contains information related to:

- Uncorrectable ECC error detection.
- I-cache and D-cache ECC errors.
- Fault monitoring.

This register resets after destructive reset 5.

22 —	Reserved
21 CM7_0_AHBM_RDATA_EDC_ERR_EN	Cortex-M7_0 AHBM Read Data EDC Error Enable Specifies whether an integrity error is reported on the Cortex-M7_0 core's main read data. The field enables fault monitoring at FCCU NCF 1, if there is an integrity error on the Cortex-M7_0 core's main read data, for safety. 0b - No 1b - Yes
20 CM7_0_AHBP_RDATA_EDC_ERR_EN	Cortex-M7_0 AHBP Read Data EDC Error Enable Specifies whether an integrity error is reported on the Cortex-M7_0 core's peripheral read data. The field enables fault monitoring at FCCU NCF 1, if there is an integrity error on the Cortex-M7_0 core's peripheral read data, for safety. 0b - No 1b - Yes
19	Cortex-M7_1 AHBM Read Data EDC Error Enable Specifies whether an integrity error is reported on the Cortex-M7_1 core's main read data.

Table continues on the next page...

Table continued from the previous page...

Field	Function
CM7_1_AHBM_RDATA_EDC_ERR_EN	The field enables fault monitoring at FCCU NCF 1, if there is an integrity error on the Cortex-M7_1 core's main read data, for safety. 0b - No 1b - Yes
18 CM7_1_AHBP_RDATA_EDC_ERR_EN	Cortex-M7_1 AHBP Read Data EDC Error Enable Specifies whether an integrity error is reported on the Cortex-M7_1 core's peripheral read data. The field enables fault monitoring at FCCU NCF 1, if there is an integrity error on the Cortex-M7_1 core's peripheral read data, for safety. 0b - No 1b - Yes
17 DMA_RDATA_EDC_ERR_EN	eDMA Read Data EDC Error Enable Specifies whether an integrity error is reported on the eDMA read data. The field enables fault monitoring at FCCU NCF 1, if there is an integrity error on the eDMA read data, for safety. 0b - No 1b - Yes
16 —	Reserved
15 EMAC_RDATA_EDC_ERR_EN	EMAC Read Data EDC Error Enable Specifies whether an integrity error is reported on the EMAC read data. The field enables fault monitoring at FCCU NCF 1, if there is an integrity error on the EMAC read data, for safety. 0b - No 1b - Yes
14 TCM_RDATA_EDC_ERR_EN	TCM Read Data EDC Error Enable Specifies whether an integrity error is reported on the TCM read data. The field enables fault monitoring at FCCU NCF 1, if there is an integrity error on the TCM read data, for safety. 0b - No 1b - Yes
13 DEBUG_ACTIVATION_ERR_EN	Debug Activation Error Enable Specifies whether unintended debug is activated.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	The field enables fault monitoring at FCCU NCF 5 for monitoring of unintended debug activation. The value of this field is 1 when the core is in the Halted state with application debug not enabled or debugger request not enabled. **NOTE** While the debugger is connected, DEBUG_ACTIVATION_ERR_EN must be 0 to disable debug activation error monitoring because the debugger is intentionally connected to the chip. 0b - No 1b - Yes
12 MCT_BUS_ERR_EN	MCT Bus Error Enable Enable bit for enabling the fault monitoring at FCCU NCF 5 for the fault: Fault reported due to illegal access on MBIST controller (MCT). This fault is reported via a transfer error indication to the system. 0b - No transfer error indicated from MCT. 1b - Transfer error indicated from MCT.
11 STCU_BIST_USER_CF_EN	STCU2 BIST User CF Enable Specifies whether MBIST is enabled accidentally (a fault condition is detected in Run mode). The field enables fault monitoring at FCCU NCF 5 if MBIST is enabled accidentally. 0b - No 1b - Yes
10 MBIST_ACTIVATION_ERR_EN	MBIST Activation Error Enable Specifies whether accidental backdoor is enabled on memories. The field enables fault monitoring at FCCU NCF 5 in case of an accidental backdoor access on memories. This monitor needs to be disabled on FCCU when performing a fault injection. 0b - No 1b - Yes
9 STCU_NCF_EN	STCU2 NCF Enable Enables fault monitoring at FCCU NCF 5 for STCU2 NCF, that is, BIST result error. 0b - Disables 1b - Enables
8 SW_NCF_3_EN	Software NCF 3 Enable Enables fault monitoring at FCCU NCF 7 for software NCF3 (DCMRWF1[FCCU_SW_NCF3]). 0b - Disables 1b - Enables

Table continues on the next page...

Table continued from the previous page...

Field	Function
7 SW_NCF_2_EN	Software NCF 2 Enable Enables fault monitoring at FCCU NCF 7 for software NCF2 (DCMRWF1[FCCU_SW_NCF2]). 0b - Disables 1b - Enables
6 SW_NCF_1_EN	Software NCF 1 Enable Enables fault monitoring at FCCU NCF 7 for software NCF1 (DCMRWF1[FCCU_SW_NCF1]). 0b - Disables 1b - Enables
5 SW_NCF_0_EN	Software NCF 0 Enable Enables fault monitoring at FCCU NCF 7 for software NCF0 (DCMRWF1[FCCU_SW_NCF0]). 0b - Disables 1b - Enables
4 INTM_3_ERR_EN	INTM 3 Error Enable Specifies whether interrupt monitor 3 reported an error. The field enables fault monitoring at FCCU NCF 6 if INTM reports an interrupt monitor 3 error. This error is also reported in INTM.INTM_STATUS3. See the "Functional description" section in the INTM chapter for details. 0b - No 1b - Yes
3 INTM_2_ERR_EN	INTM 2 Error Enable Specifies whether interrupt monitor 2 reported an error. The field enables fault monitoring at FCCU NCF 6 if INTM reports an interrupt monitor 2 error. This error is also reported in INTM.INTM_STATUS2. See the "Functional description" section in the INTM chapter for details. 0b - No 1b - Yes
2 INTM_1_ERR_EN	INTM 1 Error Enable Specifies whether interrupt monitor 1 reported an error. The field enables fault monitoring at FCCU NCF 6 if INTM reports an interrupt monitor 1 error. This error is also reported in INTM.INTM_STATUS1. See the "Functional description" section in the INTM chapter for details. 0b - No 1b - Yes

Table continues on the next page...

Field	Function
31	SAI1 debug disable bit for CM7_0. Set this bit 1 to disable the debug of IP.

Table continues on the next page...

Table continued from the previous page...

Field	Function
SAI1_DBG_DIS_CM7_0	0b - SAI1 enters debug mode when CM7_0 enters debug mode. 1b - SAI1 remains functional and is not impacted when CM7_0 enters debug mode.
30 SAI0_DBG_DIS_CM7_0	SAI0 debug disable bit for CM7_0. Set this bit 1 to disable the debug of IP. 0b - SAI0 enters debug mode when CM7_0 enters debug mode. 1b - SAI0 remains functional and is not impacted when CM7_0 enters debug mode.
29 FLEXCAN5_DBG_DIS_CM7_0	FlexCAN_5 Debug Disable Cortex-M7_0 Specifies whether FlexCAN_5 enters Debug mode or remains functional and unimpacted when the Cortex-M7_0 core enters Debug mode. Write 1 to this field to disable debug. 0b - Enters Debug mode 1b - Remains functional and unimpacted
28 FLEXCAN4_DBG_DIS_CM7_0	FlexCAN_4 Debug Disable Cortex-M7_0 Specifies whether FlexCAN_4 enters Debug mode or remains functional and unimpacted when the Cortex-M7_0 core enters Debug mode. Write 1 to this field to disable debug. 0b - Enters Debug mode 1b - Remains functional and unimpacted
27 FLEXCAN3_DBG_DIS_CM7_0	FlexCAN_3 Debug Disable Cortex-M7_0 Specifies whether FlexCAN_3 enters Debug mode or remains functional and unimpacted when the Cortex-M7_0 core enters Debug mode. Write 1 to this field to disable debug. 0b - Enters Debug mode 1b - Remains functional and unimpacted
26 FLEXCAN2_DBG_DIS_CM7_0	FlexCAN_2 Debug Disable Cortex-M7_0 Specifies whether FlexCAN_2 enters Debug mode or remains functional and unimpacted when the Cortex-M7_0 core enters Debug mode. Write 1 to this field to disable debug. 0b - Enters Debug mode 1b - Remains functional and unimpacted
25 FLEXCAN1_DBG_DIS_CM7_0	FlexCAN_1 Debug Disable Cortex-M7_0 Specifies whether FlexCAN_1 enters Debug mode or remains functional and unimpacted when the Cortex-M7_0 core enters Debug mode. Write 1 to this field to disable debug.

Table continued from the previous page...

Field	Function
	0b - Enters Debug mode 1b - Remains functional and unimpacted
24 FLEXCAN0_DBG_DIS_CM7_0	FlexCAN_0 Debug Disable Cortex-M7_0 Specifies whether FlexCAN_0 enters Debug mode or remains functional and unimpacted when the Cortex-M7_0 core enters Debug mode. Write 1 to this field to disable debug. 0b - Enters Debug mode 1b - Remains functional and unimpacted
23 FLEXIO_DBG_DIS_CM7_0	FlexIO Debug Disable Cortex-M7_0 Specifies whether FlexIO enters Debug mode or remains functional and unimpacted when the Cortex-M7_0 core enters Debug mode. Write 1 to this field to disable debug. 0b - Enters Debug mode 1b - Remains functional and unimpacted
22 LPI2C1_DBG_DIS_CM7_0	LPI2C_1 Debug Disable Cortex-M7_0 Specifies whether LPI2C_1 enters Debug mode or remains functional and unimpacted when the Cortex-M7_0 core enters Debug mode. Write 1 to this field to disable debug. 0b - Enters Debug mode 1b - Remains functional and unimpacted
21 LPI2C0_DBG_DIS_CM7_0	LPI2C_0 Debug Disable Cortex-M7_0 Specifies whether LPI2C_0 enters Debug mode or remains functional and unimpacted when the Cortex-M7_0 core enters Debug mode. Write 1 to this field to disable debug. 0b - Enters Debug mode 1b - Remains functional and unimpacted
20 LPSPI5_DBG_DIS_CM7_0	LPSPI_5 Debug Disable Cortex-M7_0 Specifies whether LPSPI_5 enters Debug mode or remains functional and unimpacted when the Cortex-M7_0 core enters Debug mode. Write 1 to this field to disable debug. 0b - Enters Debug mode 1b - Remains functional and unimpacted
19	LPSPI_4 Debug Disable Cortex-M7_0

Table continues on the next page...

Table continued from the previous page...

Field	Function
LPSPI4_DBG_DIS_CM7_0	Specifies whether LPSPI_4 enters Debug mode or remains functional and unimpacted when the Cortex-M7_0 core enters Debug mode. Write 1 to this field to disable debug. 0b - Enters Debug mode 1b - Remains functional and unimpacted
18 LPSPI3_DBG_DIS_CM7_0	LPSPI_3 Debug Disable Cortex-M7_0 Specifies whether LPSPI_3 enters Debug mode or remains functional and unimpacted when the Cortex-M7_0 core enters Debug mode. Write 1 to this field to disable debug. 0b - Enters Debug mode 1b - Remains functional and unimpacted
17 LPSPI2_DBG_DIS_CM7_0	LPSPI_2 Debug Disable Cortex-M7_0 Specifies whether LPSPI_2 enters Debug mode or remains functional and unimpacted when the Cortex-M7_0 core enters Debug mode. Write 1 to this field to disable debug. 0b - Enters Debug mode 1b - Remains functional and unimpacted
16 LPSPI1_DBG_DIS_CM7_0	LPSPI_1 Debug Disable Cortex-M7_0 Specifies whether LPSPI_1 enters Debug mode or remains functional and unimpacted when the Cortex-M7_0 core enters Debug mode. Write 1 to this field to disable debug. 0b - Enters Debug mode 1b - Remains functional and unimpacted
15 LPSPI0_DBG_DIS_CM7_0	LPSPI_0 Debug Disable Cortex-M7_0 Specifies whether LPSPI_0 enters Debug mode or remains functional and unimpacted when the Cortex-M7_0 core enters Debug mode. Write 1 to this field to disable debug. 0b - Enters Debug mode 1b - Remains functional and unimpacted
14 PIT2_DBG_DIS_CM7_0	PIT_2 Debug Disable Cortex-M7_0 Specifies whether PIT_2 enters Debug mode or remains functional and unimpacted when the Cortex-M7_0 core enters Debug mode. Write 1 to this field to disable debug.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Enters Debug mode 1b - Remains functional and unimpacted
13 PIT1_DBG_DIS_CM7_0	PIT_1 Debug Disable Cortex-M7_0 Specifies whether PIT_1 enters Debug mode or remains functional and unimpacted when the Cortex-M7_0 core enters Debug mode. Write 1 to this field to disable debug. 0b - Enters Debug mode 1b - Remains functional and unimpacted
12 PIT0_DBG_DIS_CM7_0	PIT_0 Debug Disable Cortex-M7_0 Specifies whether PIT_0 enters Debug mode or remains functional and unimpacted when the Cortex-M7_0 core enters Debug mode. Write 1 to this field to disable debug. 0b - Enters Debug mode 1b - Remains functional and unimpacted
11 STM1_DBG_DIS_CM7_0	STM_1 Debug Disable Cortex-M7_0 Specifies whether STM_1 enters Debug mode or remains functional and unimpacted when the Cortex-M7_0 core enters Debug mode. Write 1 to this field to disable debug. 0b - Enters Debug mode 1b - Remains functional and unimpacted
10 STM0_DBG_DIS_CM7_0	STM_0 Debug Disable Cortex-M7_0 Specifies whether STM_0 enters Debug mode or remains functional and unimpacted when the Cortex-M7_0 core enters Debug mode. Write 1 to this field to disable debug. 0b - Enters Debug mode 1b - Remains functional and unimpacted
9 SWT1_DBG_DIS_CM7_0	SWT_1 Debug Disable Cortex-M7_0 Specifies whether SWT_1 enters Debug mode or remains functional and unimpacted when the Cortex-M7_0 core enters Debug mode. Write 1 to this field to disable debug. 0b - Enters Debug mode 1b - Remains functional and unimpacted
8	SWT_0 Debug Disable Cortex-M7_0

Table continues on the next page...

Table continued from the previous page...

Field	Function
SWT0_DBG_DIS_CM7_0	Specifies whether SWT_0 enters Debug mode or remains functional and unimpacted when the Cortex-M7_0 core enters Debug mode. Write 1 to this field to disable debug. 0b - Enters Debug mode 1b - Remains functional and unimpacted
7 RTC_DBG_DIS_CM7_0	RTC Debug Disable Cortex-M7_0 Specifies whether RTC enters Debug mode or remains functional and unimpacted when the Cortex-M7_0 core enters Debug mode. Write 1 to this field to disable debug. 0b - Enters Debug mode 1b - Remains functional and unimpacted
6 EMIOS2_DBG_DIS_CM7_0	EMIOS2 debug disable bit for CM7_0. Set this bit 1 to disable the debug of IP. 0b - eMIOS2 enters debug mode when CM7_0 enters debug mode. 1b - eMIOS2 remains functional and is not impacted when CM7_0 enters debug mode.
5 EMIOS1_DBG_DIS_CM7_0	EMIOS1 debug disable bit for CM7_0. Set this bit 1 to disable the debug of IP. 0b - eMIOS1 enters debug mode when CM7_0 enters debug mode. 1b - eMIOS1 remains functional and is not impacted when CM7_0 enters debug mode.
4 EMIOS0_DBG_DIS_CM7_0	eMIOS_0 Debug Disable Cortex-M7_0 Specifies whether eMIOS_0 enters Debug mode or remains functional and unimpacted when the Cortex-M7_0 core enters Debug mode. Write 1 to this field to disable debug. 0b - Enters Debug mode 1b - Remains functional and unimpacted
3 LCU1_DBG_DIS_CM7_0	LCU_1 Debug Disable Cortex-M7_0 Specifies whether LCU_1 enters Debug mode or remains functional and unimpacted when the Cortex-M7_0 core enters Debug mode. Write 1 to this field to disable debug. 0b - Enters Debug mode 1b - Remains functional and unimpacted
2 LCU0_DBG_DIS_CM7_0	LCU_0 Debug Disable Cortex-M7_0 Specifies whether LCU_0 enters Debug mode or remains functional and unimpacted when the Cortex-M7_0 core enters Debug mode. Write 1 to this field to disable debug.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Enters Debug mode 1b - Remains functional and unimpacted
1 FCCU_DBG_DIS_CM7_0	FCCU Debug Disable Cortex-M7_0 Specifies whether FCCU enters Debug mode or remains functional and unimpacted when the Cortex-M7_0 core enters Debug mode. Write 1 to this field to disable debug. 0b - Enters Debug mode 1b - Remains functional and unimpacted
0 EDMA_DBG_DIS_CM7_0	eDMA Debug Disable Cortex-M7_0 Specifies whether eDMA enters Debug mode or remains functional and unimpacted when the Cortex-M7_0 core enters Debug mode. Write 1 to this field to disable debug. 0b - Enters Debug mode 1b - Remains functional and unimpacted

Chapter 38
Device Configuration Module (DCM)

38.1 Introduction

38.1.1 Overview

DCM controls:

- LC
- DCF client population
- Debug authorization (Export Control mode)

The module also establishes a RoT for the chip by parsing the master root key and other security records.

This figure is a pictorical representation of DCM:

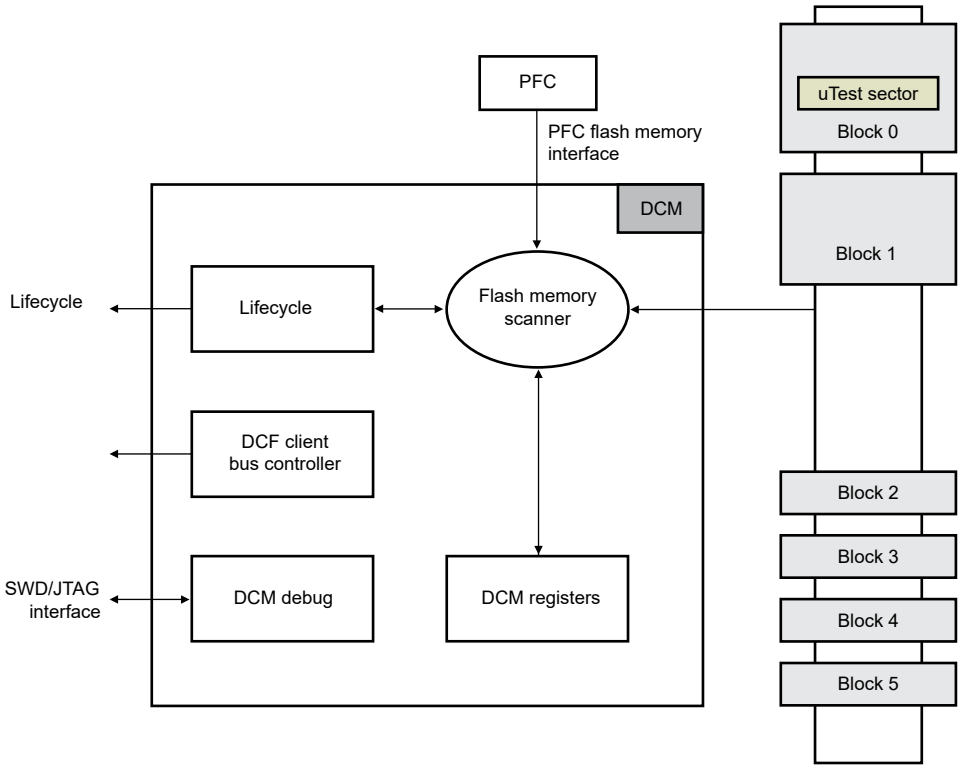

Figure 141. DCM block diagram

38.1.2 Features

- Scans flash memory and configures the system for:
  - LC detection
  - DCF records configuration using flash memory
- Allows debug features for flash memory content and the chip

- Provides debug enable control
- Provides a valid boot address detection
- Enables the DCF client to be writable via the IPS bus
- Parameterizes control to mask a set of DCF client chip select
- Supports temporary advancement of the LC
- Controls chip debug enablement

38.1.3 Modes of operation

DCM operates identically in all system modes of operation.

38.2 Functional description

DCM provides information about the current state and configuration of the system that you could use to:

- Configure the application software.
- Debug the system.

38.2.1 DCF mechanism

The DCF mechanism handles chip parameter settings via the OTP flash memory.

You can store a series of DCF records in flash memory, and each record is 64 bits in length. The chip processes these records during the system reset sequence before the CPU leaves reset.

A DCF record contains:

- A start record. Placed at UTEST_OFFSET, it indicates to the chip that the specified data records must be processed. See Table 189 that shows a general format of the start record.
- Application-specific number of data records. These follow the start record, as required.
- A stop record. Its presence indicates that the processing must stop. See Table 191 for a general format of the stop record. Only the STOP field needs to be 1 to form a stop record—all other fields are ignored. Also, an unprogrammed location in Utest flash memory is interpreted as a stop record.

Table 189. DCF start record

05AA 55AFh
0000 0000h

Table 190. DCF stop record

Reserved	1
Reserved	

A data record is structured in a way similar to a CPU-write instruction—comprising a 15-bit client select field, a 15-bit address field, and a 32-bit payload data field plus a STOP field. See Table 191 for details.

In a data record, the value of the STOP field must always be 0. Some clients support a parity (PRTY) field too.

Table 191. Format of a DCF data record

WDATA[31:0]			
CS[14:0]	ADDR[16:2]	PRTY	STOP

If *n* data records are to be stored in Utest, the data structure must be as shown in the next table.

Table 192. Series of DCF records in Utest

Address offset	Data			
00h	05AA 55AFh			
04h	0000 0000h			STOP = 0
08h	WDATA[31:0]			
0Ch	CS[14:0]	ADDR[16:2]	PRTY	STOP = 0
10h	WDATA[31:0]			
14h	CS[14:0]	ADDR[16:2]	PRTY	STOP = 0
8n - 1 + 0h	Reserved			
8n - 1 + 4h	Reserved			1
8n + 0h				
8n + 4h				

An unprogrammed record must not exist in the data structure because that is interpreted as a stop record. This leads to the subsequent records being ignored. In this case:

- You need to program the records in several sessions, each time appending new records at the end of the list, as shown in the next figure.
- A record may overwrite a client's value defined by a previous record. However, not all clients allow overwrites— that depends on their individiual implementation.

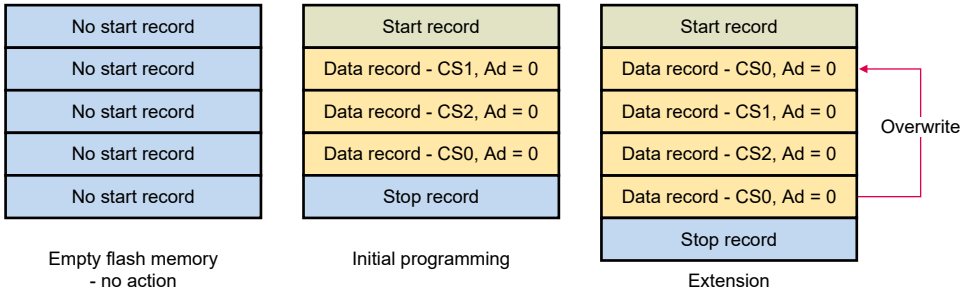

Figure 142. Appending DCF records

Some of the DCF records require parity bits, and the parity scheme used is even parity. So, the number of 1s in the WDATA and PRTY fields needs to be even. For example, if the WDATA field has the value 0000_0001h, the value of the PRTY field needs to be 1 so that the total number of 1s is even.

NOTE

You must ensure that DCF records are programmed uninterruptedly and the process completes without an error.

38.2.2 DCF error recording

DCF errors are recorded in DCM for both types of clients—spread spectrum safe and normal. See DCF client error mechanism for details on spread spectrum safe clients.

38.2.3 DCF client error mechanism

The DCM consists of DCMMISC[DCMCERS] for detecting faulty DCF records. The DCMSRRn registers capture the details up to 16 faulty records. The CERS bit can be cleared by writing 1 to it.

While scanning the flash, in case if a faulty record is encountered, the DCMMISC[DCMCERS] gets set indicating that there is atleast one faulty record. In such a case, the user can identify the details about the faulty record in the DCMSRRn registers and should update the flash memory with a new record, provided the record is not write-once.

For example, in the image below, if the faulty DCF record is DCF2, then the correct DCF record must also be DCF2. Even in case if the faulty record is updated, the DCM stores the faulty record via the DCMMISC[CERS] and DCMSRRn registers.

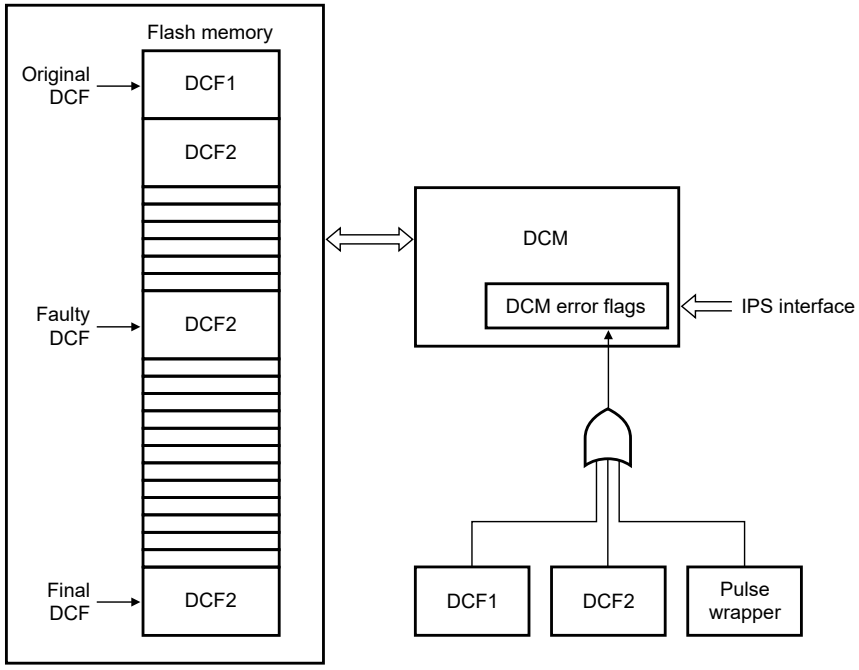

Figure 143. DCF error and CERS handling

38.2.4 DCF error detection mechanism

This figure shows that a faulty DCF record is loaded between the original and final DCF record sets.

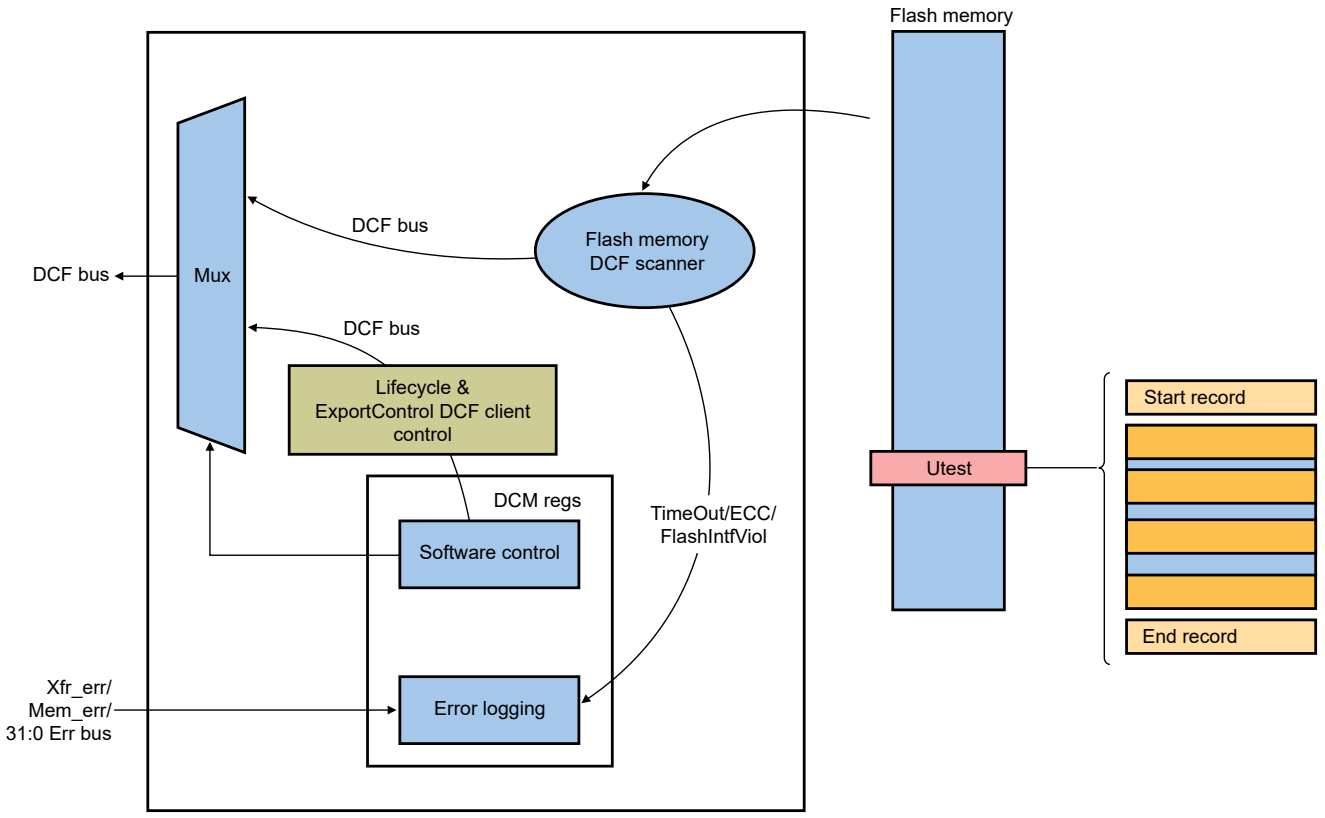

Figure 144. DCF error detection mechanism

38.2.5 LC

DCM determines the LC of the chip by reading the LC slots from the Utest flash memory. This read operation is performed during the reset phase, with normal timings. The operating monitors and an ECC check protect the operation. Additionally, a set of sanity checks executed over the LC read data guarantee the integrity of the final LC value.

At the end of the reset phase, the LC contains one of the following values:

- OEM production (OEM_PROD)
- In field (IN_FIELD)
- Pre-FA
- FA

The DCM LC progresses in the direction shown in this figure:

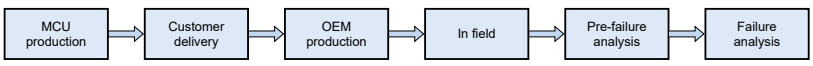

Figure 145. LC sequence

The LC is written into six slots, 128 bits each, and at fixed locations in the Utest flash memory blockblock. Each LC slot is read in a single atomic operation and is organized in two types of fields:

- Valid
- Invalid

Depending on the possible combinations of data programmed into these fields, each LC slot indicates one of the four possible statuses as shown in Table 193. To know more about LC slots, see Table 194.

Table 193. LC slot status

LC slots		LC slot value
Valid field (64 bits)	Invalid field (64 bits)	
Erased	Erased	Erased
Marked	Erased	Active
Marked	Marked	Inactive
Other values		Illegal

In this case, "Marked" refers to a value that is configured based on the bit pattern 55AA_50AF_55AA_50AFh, and "Erased" is detected using the bit pattern FFFF_FFFF_FFFF_FFFFh.

Table 194. LC slots

LC slot 0 MCU_PROD	LC slot 1 CUST_DEL	LC slot 2 OEM_PROD	LC slot 3 IN_FIELD	LC slot 4 Pre-FA	LC slot 5 FA	Resulting LC
Active	Erased	Erased	Erased	Erased	Erased	MCU_PROD
Inactive	Active	Erased	Erased	Erased	Erased	CUST_DEL
Inactive	Inactive	Active	Erased	Erased	Erased	OEM_PROD
Inactive	Inactive	Inactive	Active	Erased	Erased	IN_FIELD
Inactive	Inactive	Inactive	Inactive	Active	Erased	PFA
Inactive or Erased	Inactive	Inactive	Inactive	Inactive	Active	FA
Erased	Erased	Erased	Erased	Erased	Erased	System reset
Illegal[1]	Illegal	Illegal	Illegal	Erased	Erased	IN_FIELD

1. Values other than the ones specified in this table for Erased, Active, and Inactive are treated as illegal.

NOTE

When triggering DCM for rescanning the software, you must ensure that the flash memory program and erase fields are not set. Otherwise, DCM does not configure the chip and ignores all data returned from the flash memory. This results in LC becoming IN_FIELD. All DCF clients indicate their default values in this case.

38.3 DCM register descriptions

38.3.1 DCM memory map

DCM base address: 402A_C000h

Offset	Register	Width (In bits)	Access	Reset value

1. The value of this field is loaded from flash memory based on chip configuration.

Fields

Field	Function
31-19 —	Reserved
18-16 —	Reserved
15-12 —	Reserved
11 —	Reserved
10 DCMDBGPS	Debug Password Scanning Status Indicates the DCM debug password scanning status. 0b - Completed with errors 1b - Completed successfully
9 DCMOTAS	DCM OTA Scanning Status (valid only when the value of the DCMDONE field is 1) 0b - Completed with errors 1b - Completed successfully
8 DCMUTS	DCM Utest DCF Scanning Status (valid only if DCMDONE bit is set)

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This bit always returns 0 in In Field LC. 0b - DCM Utest DCF completed with errors. 1b - DCM Utest DCF completed successfully.
7-5 —	Reserved
4 DCMLCST	LC Scanning Status Indicates the DCM LC scanning status. This field is valid only if the value of the DCMDONE field is 1. Also, it always returns 0 in the IN_FIELD phase of the LC. For details, see LC. 0b - Completed with errors 1b - Completed successfully
3-2 —	Reserved
1 DCMERR	DCM completion with error status (valid only if DCMDONE bit is set) 0b - DCM completed with success. 1b - DCM completed with error.
0 DCMDONE	DCM Scanning Status Indicates whether the DCM scanning is in progress or complete. 0b - Running 1b - Completed

38.3.3 LC and LC Control (DCMLCC)

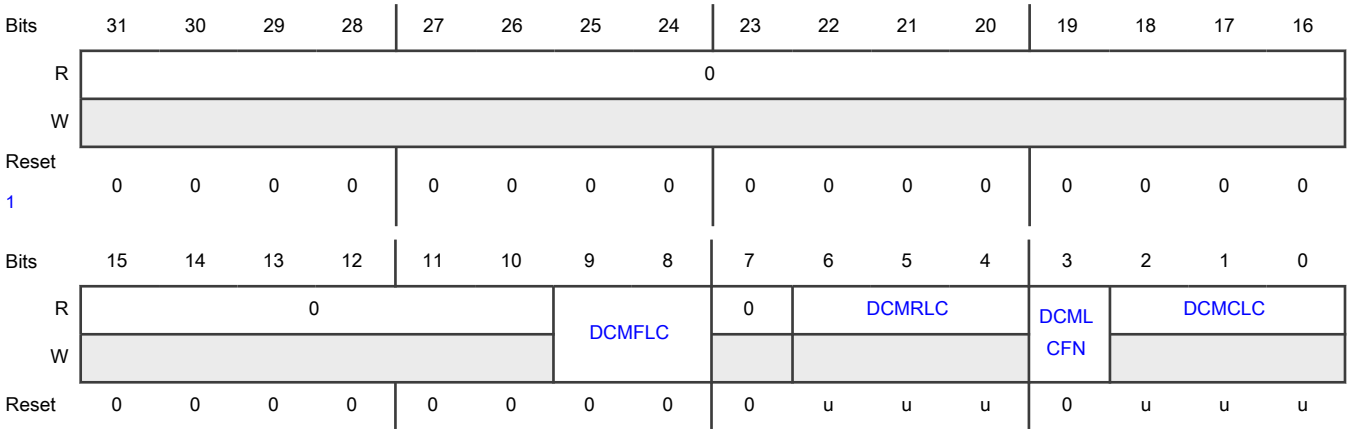
Offset

Register	Offset
DCMLCC	4h

Function
Resets on the functional reset.

NOTE
The DCMLCFN and DCMFLC fields of this register reset on destructive reset.

Diagram



1. Post reset, the reset value of this register is 0000_0077h, and after scanning, it changes according to the programmed value.

Fields

Field	Function
31-10 —	Reserved
9-8 DCMFLC	Force Next LC Provides provisions for a temporary LC update. LC can be temporarily forced as follows: • MCU_PROD => Force one => CUST_DEL (CD) • CUST_DEL => Force one => OEM_PROD • CUST_DEL => Force two => IN_FIELD • OEM_PROD => Force one => IN_FIELD • IN_FIELD => Force not allowed to move LC • Pre-FA => Force not allowed to move LC • FA => Force not allowed to move LC 00b - No force 01b - Force LC to one next 10b - Force LC to two next (only possible in CD) 11b - Reserved (no effect)
7 —	Reserved
6-4 DCMRLC	Real LC Projects the real LC of the chip.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	The LC can move in this sequence: (110 : MCU_PROD) > (011 : CUST_DEL) > (010 : OEM_PROD) > (111 : IN_FIELD) > (001 : Pre-FA) > (000 : FA) 000b - FA 001b - Pre-FA 010b - OEM_PROD 011b - CUST_DEL 100b - Reserved 101b - Reserved 110b - MCU_PROD 111b - IN_FIELD
3 DCMLCFN	Force LC Indicates if the LC is normal or forced on the current LC. If the value of this field is 1, the value configured according to the DCMLCF register is forced on the current LC whereas the real LC remains the same. 0b - Normal 1b - Forced on current LC
2-0 DCMCLC	Current LC Projects the current LC of the chip. The LC can move in this sequence: (110 : MCU_PROD) > (011 : CUST_DEL) > (010 : OEM_PROD) > (111 : IN_FIELD) > (001 : Pre-FA) > (000 : FA) 000b - FA 001b - Pre-FA 010b - OEM_PROD 011b - CUST_DEL 100b - Reserved 101b - Reserved 110b - MCU_PROD 111b - IN_FIELD

38.3.4 LC Scan Status (DCMLCS)

Offset

Register	Offset
DCMLCS	8h

Function

Stores the status of LC scanning. By default, the status of each LC is "not yet scanned."

This register:

- Resets on destructive reset.
- Always returns 0 in a valid IN_FIELD LC (in LC without an error).

This register captures the errors related to LC scanning on each of these resets: POR, destructive, and functional. If an error is captured, its status in this register is cleared by writing 1 to the corresponding field or to any of the destructive or POR events.

All LC slot errors are captured and cleared independently.

Diagram

Fields

Field	Function
31-30 —	Reserved
29 DCMLCFE5	Pre-FA Flash Memory Error Check Indicates the status of the Pre-FA flash memory error check. 0b - Successful 1b - Failed
28 DCMLCE5	Pre-FA ECC Errors Indicates if Pre-FA is successful or has ECC errors. 0b - No errors 1b - Marking error
27-25 DCMLCC5	Pre-FA Marking Status Indicates the Pre-FA marking status. These errors may cause this field to indicate the "not scanned yet" status:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• If the reading completes too early and DCM has not yet scanned the LC. • If there is an error in the flash memory after completion of the reading. 000b - Not scanned yet 001b - Marked as active 010b - Marked as inactive 011b - Region is erased/virgin 101b - Marked as inactive by an unknown pattern 110b - Scanning timed out
24 DCMLCSS5	Pre-FA Scan Status Indicates the status of the Pre-FA scan. 0b - Successful 1b - Errors exist
23 DCMLCFE4	IN_FIELD Flash Memory Error Check Indicates the status of IN_FIELD flash memory error check. 0b - Successful 1b - Failed
22 DCMLCE4	IN_FIELD ECC Errors Indicates if IN_FIELD has ECC errors. 0b - No errors 1b - Errors exist
21-19 DCMLCC4	IN_FIELD Marking Status Indicates the IN_FIELD marking status. These errors may cause this field to indicate the "not scanned yet" status: • If the reading completes too early and DCM has not yet scanned the LC. • If there is an error in the flash memory after completion of the reading. 000b - Not scanned yet 001b - Marked as active 010b - Marked as inactive 011b - Region is erased/virgin 101b - Marked as inactive by an unknown pattern 110b - Scanning timed out
18	IN_FIELD Scan Status

Table continues on the next page...

Table continued from the previous page...

Field	Function
DCMLCSS4	Indicates the status of the IN_FIELD scan. 0b - No errors 1b - Errors exist
17 DCMLCFE3	OEM_PROD Flash Memory Error Check Indicates the status of the OEM_PROD flash memory error check. 0b - Successful 1b - Failed
16 DCMLCE3	OEM_PROD ECC Errors Indicates if OEM_PROD has ECC errors. 0b - No errors 1b - Errors exist
15-13 DCMLCC3	OEM_PROD Marking Indicates the OEM_PROD marking status. These errors may cause this field to indicate the "not scanned yet" status: • If the reading completes too early and DCM has not yet scanned the LC. • If there is an error in the flash memory after completion of the reading. 000b - Not scanned yet 001b - Marked as active 010b - Marked as inactive 011b - Region is erased/virgin 101b - Marked as inactive by an unknown pattern 110b - Scanning timed out
12 DCMLCSS3	OEM_PROD Scan Status Indicates the status of OEM_PROD scan. 0b - No errors 1b - Errors exist
11 DCMLCFE2	CUST_DEL Flash Memory Error Check Indicates the status of CUST_DEL flash memory error check. 0b - Successful 1b - Failed
10 DCMLCE2	ECC Errors In CUST_DEL Indicates if CUST_DEL has ECC errors.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No errors 1b - Errors exist
9-7 DCMLCC2	CUST_DEL Marking Indicates the CUST_DEL marking status. These errors may cause this field to indicate the "not scanned yet" status: • If the reading completes too early and DCM has not yet scanned the LC. • If there is an error in the flash memory after completion of the reading. 000b - Not scanned yet 001b - Marked as active 010b - Marked as inactive 011b - Region is erased/virgin 101b - Marked as inactive by an unknown pattern 110b - Scanning timed out

Chapter 39
Messaging Unit (MU)

39.1 Chip-specific MU information

39.1.1 MU instances and configuration

This chip includes MUs for communication across the different cores. Each MU includes two interfaces, MUA and MUB. Two different processors control them for communication.

Table 195 indicates the MUs and their interfaces present in different parts of the MWCT chip family. The table also summarizes the implementation of this module in each chip of the MWCT product series.

NOTE

The HSE_B core controls the MUA interface of MU_0 and MU_1. Therefore, the application core cannot control the interface.

Table 195. MU instances

Instance	MWCT2D17S	MWCT2D16S	MWCT2016S	MWCT2015S	Use case
MU_0	Yes				Communication between HSE_B and application cores
MU_1	Yes				
MU_2	Yes	Yes	No		Communication between application cores

The base address of MU_1's MUB interface is different across the MWCT2xxxS product series because AIPS_2 is unavailable in MWCT2016S and MWCT2015S. Table 196 summarizes this difference.

Table 196. Base-address difference in MU_1's MUB interface across MWCT2xxxS product series

	MWCT2D17S	MWCT2D16S	MWCT2016S	MWCT2015S
Base address	404E_C000h		4039_0000h	

NOTE

For MWCT2D16S, reset value of MUA_VER and MUB_VER register is 0309_000Fh.

39.2 Overview

The Messaging Unit module (MU) enables two processors within the SoC to communicate and coordinate by passing messages (e.g. data, status and control) through the MU interface. The MU also provides the ability for one processor to signal the other processor using interrupts.

Because the MU manages the messaging between processors potentially using different clocks, the MU must synchronize the accesses from one side to the other. The MU accomplishes synchronization using two sets of matching registers (Processor A-facing, Processor B-facing).

39.2.1 Block Diagram

The following is the MU Block Diagram:

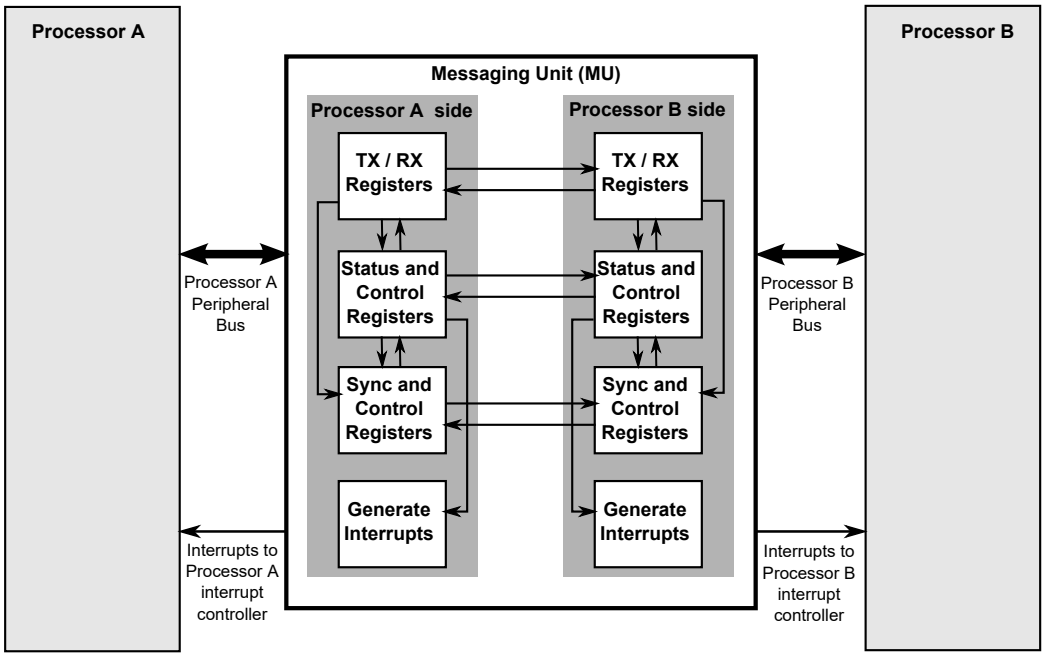

Figure 146. MU Block Diagram

39.2.2 Features

The MU includes the following features:

- Memory-Mapped Registers
  - The MU is connected as a peripheral under the Peripheral bus on Processor A-side and Processor B-side.
- Synchronized Message Transfers between Cores
  - For sending data or messages from one MU-side to the other MU-side, the MUA provides 4 transmit registers and 4 receive registers, the MUB provides 4 transmit registers and 4 receive registers.
  - The transfer of data messages between cores uses transmit empty and receive full flags provided on both sides of the MU.
  - The update of these transmit and receive flags is accomplished using a synchronization mechanism. There is inherent latency between updating the flag on one side and reflecting its status on other side.
  - The MU has a 3 bit Flag Data Register, which can be used to send flag data between two MU sides.
- Interprocessor Interrupts
  - The MU has 9 interrupt sources on each side (Processor A-side, Processor B-side) that are used for signaling the other processor. The interrupts can be used for notification of RX/TX events and general-purpose signaling between the processors. There are 1 general-purpose interrupt requests available and 8 RX/TX interrupt sources.
- MU Reset
  - Each Processor can issue a reset to the entire MU, using a control bit (MUR) in each Processor's Control Register (CR).
  - The MUR bit is a self-clearing bit.

39.3 Functional Description

The Messaging Unit (MU) enables two cores (Processor A or Processor B) to communicate with each other, by passing message/data information to each other, and by enabling one core to wake up the other core using interrupts.

The messaging, control, and status registers of the Processor A and Processor B-side for the MU are mapped to the Processor A and Processor B memory as a regular peripheral. The Peripheral data bus is 32 bits wide inside the MU module.

The messaging logic is used in conjunction with external memory. There are various messaging methods that can be used to implement a messaging protocol. Some of these messages could mean “A message of N words has been written starting at offset X in the memory,” or "The previous data block that was sent has been read." Having the messaging logic independent from the memory array is not restricted to a predefined hardware protocol. On the other hand, the software needed to manage the messaging is short and straightforward.

Most of the messaging mechanisms are symmetric. They are duplicated and are available on both the Processor A-side and the Processor B-side. The messaging mechanisms are:

- 4 32-bit transmit registers, which are each reflected in 4 read-only receive registers in the other processor’s side. You can use these registers to transfer 32-bit word messages or frame information of messages written to the shared memory (number of words, initial address, and message type code).
- A write to a transmit register on the transmitter side clears a “transmitter empty” bit in the Status Register on the transmitter side, and sets a “receiver full” bit in the Status Register on the receiver side. The setting of the bit at the receiver side can optionally trigger an interrupt at the receiver side (maskable receive interrupt).
- A read of one of the receive registers at the receiver side clears the “receiver full” bit in the Status Register at the receiver side, and sets the “transmitter empty” bit in the Status Register on the transmitter side. The setting of the “transmitter empty” bit can optionally trigger an interrupt at the transmitter side (maskable transmit interrupt).
- 1 general purpose interrupt request flags are reflected in the General Status Register(GSR) on the receiver side.
- 3-bit flag data is transmitted from FCR register to xFSR register with the SR[FUP] indicator bit.

A write to a transmit register signals the receiver side that data is ready for retrieval.

- Writing to the transmit register again without verifying that the data was retrieved is prohibited, because the transmitter side has no way of knowing the exact time that the receiver attempts to retrieve the data.
- Before attempting to write the transmit register again, the transmitter side should wait for a “Transmitter Empty” interrupt, or should poll the “Transmitter Empty” bit in the Transmit Status Register.

A read of a receive register signals the transmitter side that data can be written to that register. In the same way, the receiver processor should not read a receive register before receiving a “Receiver Full” interrupt or polling the “Receiver Full” bit in the Receive Status Register.

- Reading the receive register again without verifying that the data was written is prohibited, because the receiver side has no way of knowing the exact time that the transmitter attempts to write the data.
- Before attempting to read the receive register again, the receiver side should wait for a “Receiver Full” interrupt, or should poll the “Receiver Full” bit in the Receive Status Register.

39.3.1 Event Update Timing

Each processor’s MU messaging side (Processor A or Processor B) has a hardware mechanism to send “event update requests” to the other processor’s side. An “event” is considered when any information change should be reflected at the Status Register of the receiving processor. The event update latency is the delay between the event being ready at one processor and the resulting update at the Status Register of the other processor.

- The minimum event latency is “1 clock of the sending side” + “2 1/2 clocks of the receiving side”. The minimum case is if there is no event pending when the new event occurs.
- The maximum event latency is “6 clocks of the sending side” + “6 1/2 clocks of the receiving side.” The maximum case is if the event occurred just after a previous event was sent to the other side. The event update latency varies between the above-mentioned minimum and maximum latencies, depending on the time at which the subsequent event is triggered.

39.3.2 Interrupts

The MU controls one processor interrupt requests to the other processor. This section describes all the interrupts that the module generates.

Below interrupt sources can be generated individually from the MU to the Processors.

- 4 receive interrupts (asserted when the Processors receive full bits are set and enabled in the xRCR register) for each of the receive registers
- 4 transmit interrupts (asserted when the Processor transmit empty bits are set and enabled in the xTCR register) for each of the transmit registers
- 1 general purpose interrupts (asserted when the GIP bits are set and enabled in the xGIER register)
- Core Reset Assertion interrupts(asserted when Processor goes into of Reset state and enabled in RAIE register bit)
- MU Software/Hardware Reset assertion(asserted when MUR and HR bit are written and enabled in MURIE and HRIE register bit)

All the interrupts are maskable in the Processor Control Register (xTCR, xRCR, xGIER, xCR and xCIER). The MU does not assume any internal priority of these interrupts. Multiple interrupts (for example, Receive 0 and Receive 1 interrupts or any of the transmit and general purpose interrupts) can be asserted at one time. The priority of these interrupts should be resolved by the interrupt controller at the chip level.

Triggering any enabled interrupt wakes up the Processor before servicing the interrupt.

The General Purpose Interrupt Pending GIPn bits should be cleared by the software (as part of the interrupt service routine) to de-assert the request to the interrupt controller.

When a Processor writes to the General Interrupt bit (GIRn), the write event is synchronized to the other Processor to set the general interrupt request pending bit (GIPn). When the GIPn bit is set, and if the general purpose interrupt is enabled on the receiving Processor side (GIEn bit is set), then the transmitting Processor general purpose interrupt is issued to the receiving Processor. The receiving Processor clears this interrupt by writing a “1” on the GIPn bit. The interrupt is de-asserted as soon as the GIPn bit is written. The write event of the GIPn bit is synchronized to the other Processor. The synchronized signal clears the GIR bit. The software should not write the GIRn bit again until the GIRn bit is cleared.

Before setting a GIRn bit, you must verify that the GIRn bit is cleared, which means that a general interrupt is not pending. Generally, setting the GIRn bit while the bit has been set to “1” is ignored, but in some cases it may issue a second interrupt.

39.3.3 Resets

The MU has below reset sources, and each reset has a different function from the MU or system perspective.

- Asynchronous system reset:
  - The asynchronous system reset on one MU-side returns all registers on this MU side to their default state.
  - When the asynchronous system reset on any MU-side is asserted, the MURS bit in CR register is set to "1" until the asynchronous system reset ends. Check MURS bit is cleared before starting any access to MU.
- MU software reset:
  - Writing the CR[MUR] bit to "1" causes most of control and status registers to return to their default values and all internal states to be cleared.
  - The instruction immediately following assertion of the MUR bit should not write to MU registers. Such a write may be overwritten by the reset sequence and the register remains with the reset value. You should monitor the value of the SR[MURS] bit to know when the reset sequence on both processors has ended. After the reset sequence on both processors has ended, you can attemp a write to MU registers.

NOTE

MUR bit assertion is a delicate operation because it affects the other side's registers asynchronously. MUR bit assertion may cause unpredictable behavior if, for example, the other Processor is concurrently testing an MU register bit (TE bit in the other Processor TSR register). Before asserting the MUR bit, you should verify that the other Processor is not presently engaged in an MU signalling activity.

39.4 External Signals

There are no Messaging Unit signals directly available externally.

39.5 Application Information

The following are some messaging examples:

- **Passing short messages:** Transmit register(s) can be used to pass short messages from one to 4 words in length for Processor A and 4 for Processor B. For example, when a four-word message is desired, only one of the registers needs to have its corresponding interrupt enable bit set at the receiver side; the message's first three words are written to the registers whose interrupt is masked, and the fourth word is written to the other register (which triggers an interrupt at the receiver side).
- **Passing frame information:** Transmit registers can be used to pass frame information for long messages written to the shared system memory. Such frame information normally includes a start address, number of words, and perhaps a message type code.
- **Passing event notices and requests:** Events and requests that do not include data words can be signaled from the Processor B to the Processor A using the general interrupts, such as acknowledging that a long message was read from the shared system memory.
- **Passing fixed length data:** Formatted data with a fixed length can be written in predetermined locations in the shared memory. A processor can use a general interrupt to signal the other processor that the data is ready.
- **Passing announcements:** The 3 flags can be used by a processor to announce its current program state or other billboard messages to the other processor.

39.5.1 Messaging Protocols using Interrupts

The example below describes a four-word messaging sequence sent by the Processor to the other Processor.

In this example, the first, second, and third receive interrupts are disabled, and the fourth receive interrupt is enabled. We write registers sequentially for n = 0, 1, 2, 3. For n = 0, 1, 2, the interrupts are disabled, therefore no interrupt goes to the other core (although interrupt conditions occur). For n = 3, the interrupt is enabled, and the last Receive Interrupt request is generated.

1. Write Sequence
   - The Processor writes the message information sequentially to its Transmit Registers 0, 1, 2.
   - When the write to the Transmit Register 3 occurs, the RF3 bit of the xRSR is set after synchronization, and it immediately trigger the Receive Full 3 interrupt to the other Processor.
2. Read Sequence
   - The other Processor receives the Receive Full 3 interrupt and starts reading the message transferred from the receive registers.
   - After Receive Register 3 is read, the interrupt bit is cleared.

The following table and diagram describe the messaging model using transmit/receive registers and interrupt messaging protocol.

Table 197. Interrupt Messaging Protocol (Generalized)

Sequence	Action	Description
1	Processor A Data write	A data write to the TRn register by Processor A is immediately reflected in the Processor B RRn register.
2	Clear Tx Empty bit and Set Rx Full bit	The data write to the TRn register • Clears the transmitter empty bit (TEn) in the Processor A Transmit Status Register • Sets the receiver full bit (RFn) in the Processor B Receive Status Register
3	Generate Receive Interrupt request	The setting of the receiver full bit (RFn) in the Receive Status Register generates a Receive Interrupt request to Processor B.
4	Processor B Data read	After receiving the Receive Interrupt request, Processor B performs a data read of the RRn register.
5	Clear Rx Full bit and Set Tx Empty bit	Reading the data out of the RRn register • Clears the receiver full bit (RFn) in the Processor B Receive Status Register • Sets the transmitter empty bit (TEn) in the Processor A Transmit Status Register
6	Generate Transmit Interrupt request	The setting of the transmitter empty bit (TEn) in the Transmit Status Register generates a Transmit Interrupt request to Processor A.

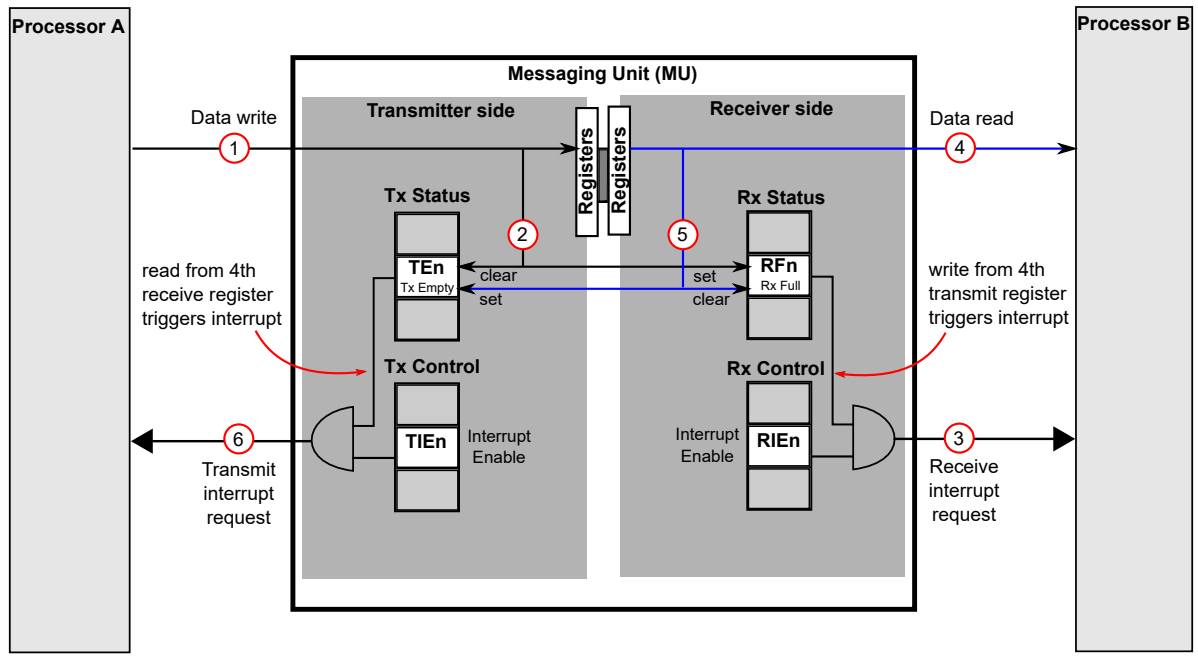

Figure 147. Messaging Model Using Transmit and Receive Registers

The messaging hardware can be used by software to implement messaging protocols for a wide array of message types. Full support is given for both interrupt and polling management schemes.

39.5.2 Messaging Protocols using Event Interrupts

Events and requests that do not include data words can be signaled from the Processor B to the Processor A using the two general interrupts.

Formatted data with a fixed length can be written in predetermined locations in the shared memory. A processor can use a general purpose interrupt to signal the other processor that the data is ready.

The 3 flags can be used by a processor to announce to the other processor the program state it is currently in, or to announce similar messages.

The following table and diagram describe the event sequence when the Processor triggers an interrupt.

Table 198. General Interrupt Messaging Protocol (Generalized)

Sequence	Action	Description
1	Processor A sets General Interrupt request bit	Processor A sets its associated General Interrupt request bit (GIRn = 1) in the General Control Register (GCR).
2	General Interrupt Request Pending status bit is set	The General Interrupt Request Pending status bit (GIPn) in the General Status Register (GSR) is set to "1".
3	General Interrupt request to Processor B is generated	Setting the GIPn bit generates the General Interrupt request to Processor B (Interrupt Request Enable bit, GIEn, must be set for Processor B).
4	Processor B reads status register	The Processor B reads the GIPn bit in the GSR register.
5	Processor B services the interrupt	-
6	Processor B sets GIPn bit to clear interrupt	The Processor B writes "1" to the corresponding GIPn bit to clear the interrupt.
7	GIRn bit is cleared	Setting the GIPn bit to "1" clears the General Interrupt request bit (GIRn) in the Processor A General Control Register (GCR).

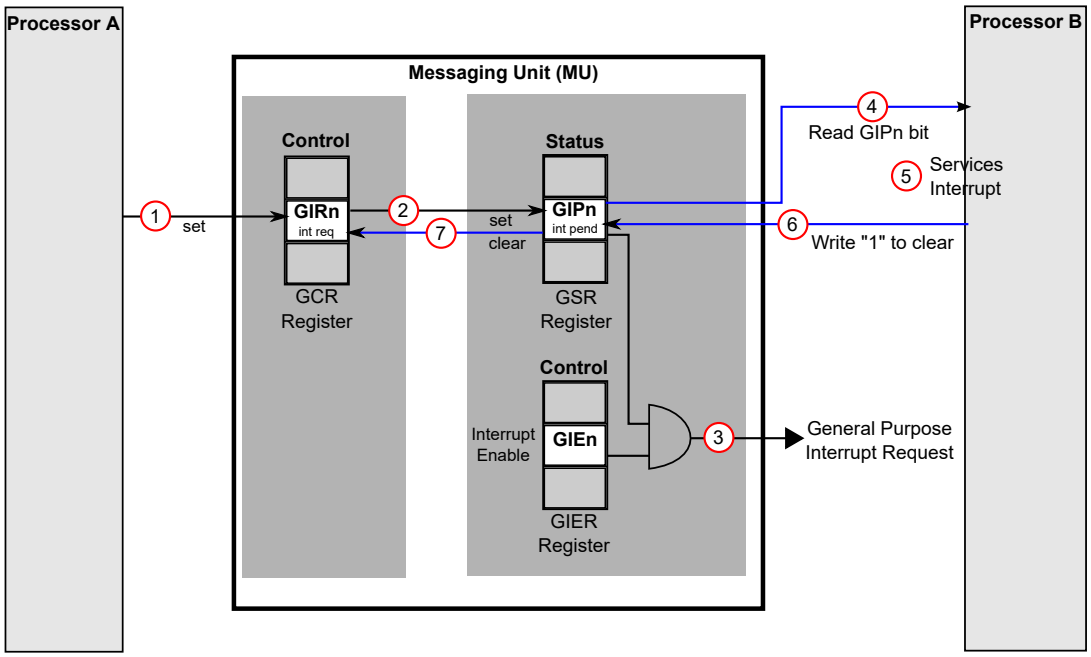

Figure 148. Messaging Model Using a General Purpose Interrupt

39.5.3 Exclusive Access to Shared Memory

MU can be used to signal one processor about its current access to the shared memory, so that the data is not overwritten by the other processor during the exclusive memory access period.

The following tables describe the signaling protocol that the Processor A uses to inform the Processor B about its current access (write) to the shared memory, assuming that the set of bits and registers (GIRn bit, RRn register, TRn register) are reserved to support exclusive access to the shared memory protocol.

Table 199. How the Processor A Performs an Exclusive Access to Shared Memory

Sequence	Action	Description
1	Processor A sends GIRn request to Processor B using Processor A control register	When the Processor A wants to perform an exclusive access to the shared memory, the Processor A sends an GIR0 request to the Processor B.
2	Processor A sends an exclusive-access request using a transmit data register (TRn)	The Processor A sends an exclusive-access request (command, location, and length of target access) to Processor B using a selected transmit data register (TR0).
3	Processor A waits for a dedicated interrupt from Processor B	The Processor A waits for a dedicated interrupt (as an acknowledgement) triggered by the Processor B before proceeding.
4	Processor A accesses shared memory	After receiving a dedicated interrupt from the Processor B, Processor A proceeds.

Table 200. How the Processor B Scans for Transaction Information

Sequence	Action	Description
1	Processor B receives an interrupt from a receive data register (RRn)	-
2	Processor B reads the receive data register (RRn)	-
3	Processor B scans the receive data register contents	For transaction information (whether Processor A has requested an exclusive-access).

Table 201. How the Processor B Accepts Exclusive Access by Processor A

Sequence	Action	Description
1	Processor B triggers a dedicated interrupt	Processor B acknowledges the Processor A request by triggering a dedicated interrupt (ack) to the Processor A.
2	Processor B sends a code message to Processor A	Along with the acknowledge interrupt, the Processor B sends a code message to the Processor A through the selected transmit register (TRn). The message informs the Processor A that it can exclusively access the shared memory.

Table 202. How the Processor B Rejects Exclusive Access by Processor A

Sequence	Action	Description
1	Processor B ignores Processor A request for exclusive access	If the Processor B does not want to give go-ahead permission to the Processor A, Processor B ignores the exclusive access request.

39.5.4 Packet Data Transfers

The following example describes the packet transfer sequence between the Processor B and Processor A subsystems:

Table 203. Packet Data Transfer Sequence

Action	Sequence	Description
Processor B requests DMA	1	The Processor B sends a DMA request to initiate the packet data transfer.
DMA data transfer	2	DMA acknowledges.
	3	DMA starts transferring data from the specified Processor B location to the specified shared memory
	4	DMA interrupts the Processor B to signal that the packet transfer has finished.

Table continues on the next page...

Table 203. Packet Data Transfer Sequence (continued)

Action	Sequence	Description
Processor B informs Processor A that data is in shared memory	5	Using an MU Processor B-side transmit register, the Processor B sends a packet information message to the Processor A to inform the Processor A of the arrival of new packet data that is stored in shared memory. The message contains the command, location, and length of packet data information.
Processor A receives interrupt	6	The Processor A receives an interrupt (assuming its corresponding Processor A MU-side receive interrupt is enabled), and the pending processing task becomes active and processes packet data from memory.
Processor A reads data, writes data	7	The Processor A reads or processes packet data from shared memory.
	8	The Processor A writes the result from packet processing to a separate buffer.
Processor A informs Processor B that transfer is finished	9	After the processing of the packet data finishes, the Processor A informs the Processor B (using the MU Processor A-side transmit register, ATRn).
Processor A sends interrupt to Processor B (request for more data)	10	The Processor B receives the next interrupt from the Processor A, in which the Processor A requests more packet data.

39.5.5 Free the Processor from Deadlock

During normal operations, one processor may conclude that the other processor is not working or is deadlocked. Using the SR register, the following methods are available for the processor to use to identify and correct the problem.

Table 204. How to Free the Processor A/B from Deadlock

Processor Mode	Technique	Description
-	Processor issues an interrupt	The other Processor can interrupt the Processor by issuing any one of the 9 (general purpose, receive, and transmit) interrupts
-	Processor issues a hardware reset	If the above is not helpful, the Processor can issue a hardware reset strobe to the other Processor.

39.6 Register Definition

The MU provides transmit and receive data registers (xTR0-n, xRR0-n) for the communication between Processor A and Processor B. Some control and status registers (xCR, xSR) to the Processor A and Processor B sides for control operations (such as interrupts and reset), and for status checking of the other MU-side. Figure 149 shows the MU registers schematic.

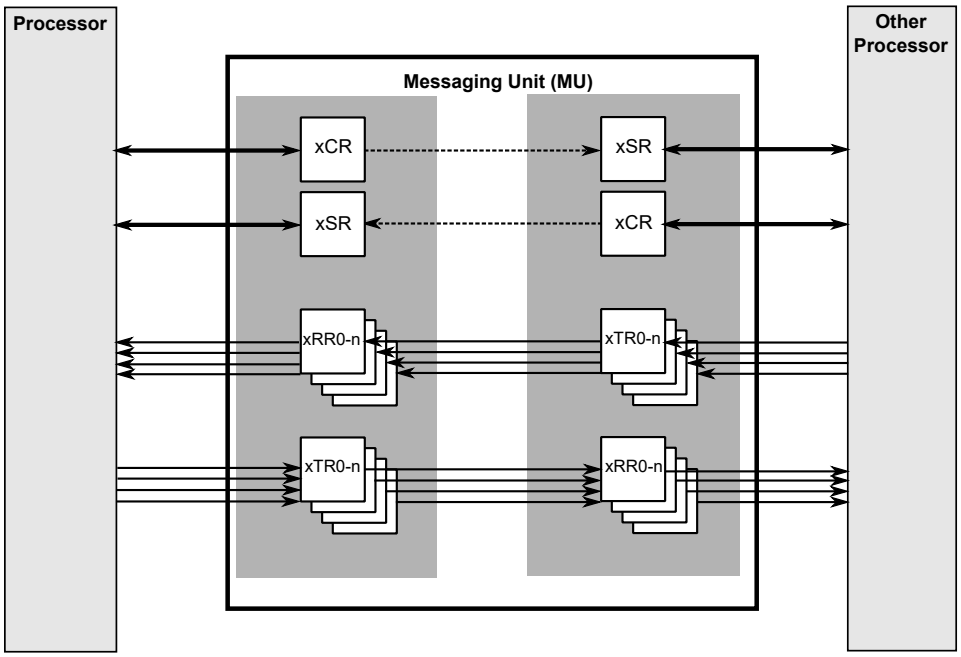

Figure 149. MU Registers

The detailed MU Register Definition can be found below.

39.6.1 MUA register descriptions

This section contains the detailed register descriptions for the MUA registers.

NOTE

A read/write access to any illegal location and a write to a read-only register on the Processor A-side or Processor B-side of the MU generates a module transfer error acknowledge to the Processor A or Processor B. The only exception to this is at address offsets 0x1C and 0x14 - no transfer error occurs when accessing these locations.

39.6.1.1 MUA memory map

MU_2.MUA base address: 400B_8000h

Offset	Register	Width (In bits)	Access	Reset value

39.6.1.2 Version ID Register (VER)

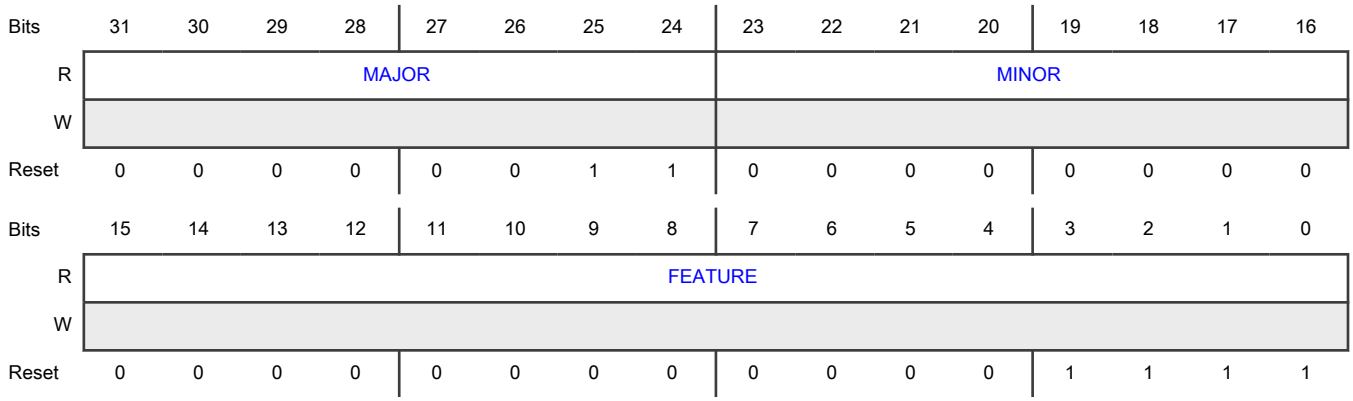
Offset

Register	Offset
VER	0h

Function

Use Version ID register to determine the version ID and feature set number of MUA.

Diagram



Fields

Field	Function
31-24 MAJOR	Major Version Number
23-16 MINOR	Minor Version Number
15-0 FEATURE	Feature Set Number Each bit of the Feature Set Number bitfield specifies a different feature: • If bit0 = 1: Standard features are implemented • If bit1 = 1: RAIP/RAIE register bits are implemented • If bit2 = 1: Core Control and Status Registers are implemented in both MUA and MUB • If bit3 = 1: Expand TRn/RRn registers number

39.6.1.3 Parameter Register (PAR)

Offset

Register	Offset
PAR	4h

Function

The PAR register defines the number of flags, transmit registers, receive registers, and the number of general interrupt requests available for the MU.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	FLAG_WIDTH								GIR_NUM							
W																
Reset	0	0	0	0	0	0	1	1	0	0	0	0	0	0	0	1

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RR_NUM								TR_NUM							
W																
Reset	0	0	0	0	0	1	0	0	0	0	0	0	0	1	0	0

Fields

Field	Function
31-24 FLAG_WIDTH	Flag Width This bitfield specifies the number of flag bits in the Flag Control Register (FCR) and Flag Status Register (FSR).
23-16 GIR_NUM	General Interrupt Request Number This bitfield specifies the number of general interrrupt requests available.
15-8 RR_NUM	RR Number This bitfield specifies the number of receive registers.
7-0 TR_NUM	Transmit Register Number This bitfield specifies the number of transmit registers.

39.6.1.4 Control Register (CR)

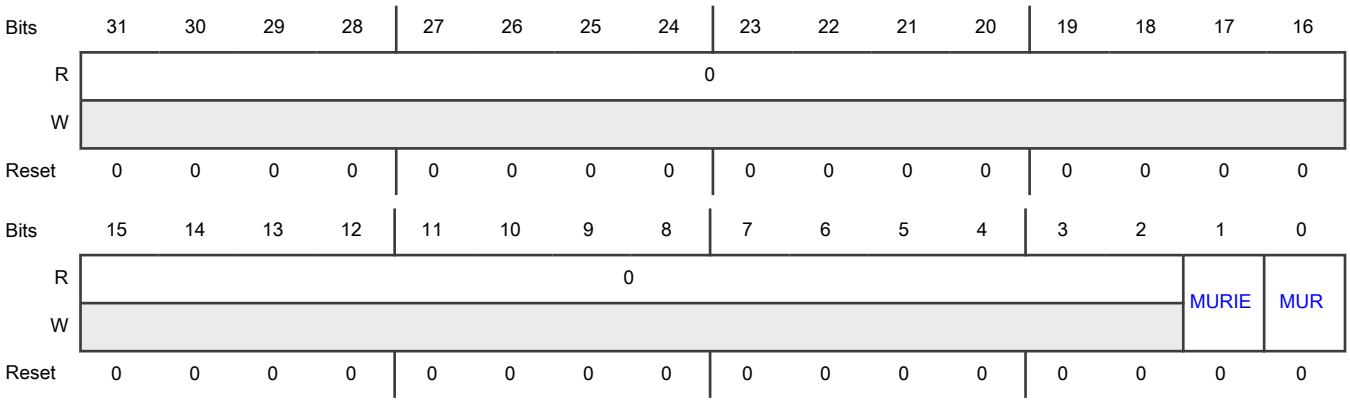
Offset

Register	Offset
CR	8h

Function

The CR register controls the MU reset and MU reset interrupt enable.

Diagram



Fields

Field	Function
31-2	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
1 MURIE	MUA Reset Interrupt Enable • If MURIE bit is set to "1", then MU reset interrupt request is issued to the Processor A when the MUA_SR[MURIP] bit is set to "1". • If MURIE is cleared, then the value of the MURIP bit is ignored and no MU reset interrupt request is issued. • Only system reset can reset MURIE, MU reset(MUR) cannot reset this bit. 0b - Disables Processor A-side MU Reset Interrupt request due to MU reset issued by MUB. 1b - Enables Processor A-side MU Reset Interrupt request due to MU reset issued by MUB.
0 MUR	MU Reset • Setting MUR bit to "1" resets both the MUA-side and MUB-side, forcing all control and status registers to return to their default values (except MURIE in MUA/B_CR registers, MURIP bit and MURS bit in MUA/B_SR registers), and all internal states to be cleared. • Before setting the MUR bit to "1", it is advisable to interrupt the Processor B, because setting the MUR bit may affect the ongoing Processor B program. • After setting the MUR bit, monitor the value of the MUA_SR[MURS] bit to know when the reset sequence on the Processor B-side has ended. • MUR bit is always read as "0". • MUR bit is cleared during the MU reset sequence. 0b - Self clearing bit. 1b - Asserts the MU reset.

39.6.1.5 Status Register (SR)

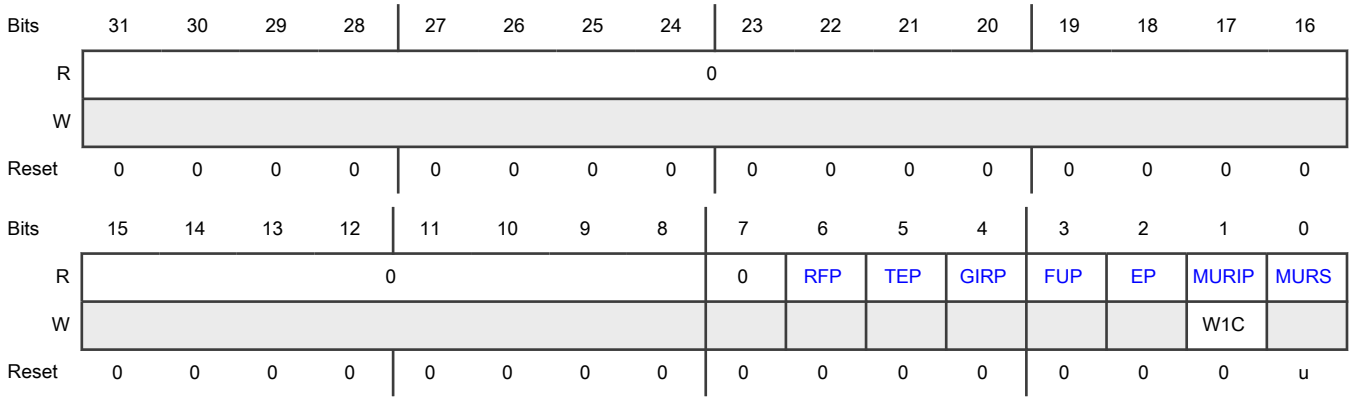
Offset

Register	Offset
SR	Ch

Function

The SR register shows the status of MU resets and the status of pending events/requests described below.

Diagram



Fields

Field	Function
31-8 —	Reserved
7 —	Reserved
6 RFP	MUA Receive Full Pending Flag • RFP bit is set to "1" when any TRn register is written by MUB to send data to MUA. • After the RFP bit is set to "1", checking the RSR[RFn] bit to decide the data in which RRn register is ready to be read by the MUA. • RFP bit is cleared when all MUA RRn registers are read, or when the MU is reset. 0b - No TRn register is written by MUB. 1b - Any TRn register is written by MUB.
5 TEP	MUA Transmit Empty Pending • TEP bit is set to "1" when TCR[TIEn] bit is set and the corresponding RRn register is read by MUB. • After the TEP bit is set to "1", checking the TSR[TEn] bit to decide the data in which TRn register is ready to be written by the MUA. • TEP bit is cleared when all MUA TRn register are written. • TEP bit is set to "0" when the MU resets. 0b - RRn register is not read by MUB. 1b - Any RRn register is read by MUB.
4 GIRP	MUA General Interrupt Pending • GIRP bit is set to "1" when any general interrupt request is sent from the MUB side to the MUA side. Reading the GSR[GIPn] bit can know which general interrupt request is received.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• GIRP bit is cleared when all GIPn bits in MUA_GSR register are cleared. • GIRP bit is cleared when the MU resets. 0b - No general interrupt request is sent from MUB. 1b - Any general interrupt request is sent from MUB.
3 FUP	MUA Flags Update Pending • FUP bit is set to "1" when the MUA side sends a Flags Update request to the MUB side. • A Flags Update request is generated when there is a change to the Fn[2:0] bits of the MUA_FCR register. No flag update changes are allowed while the FUP bit is set to "1". Any write to the Fn[2:0] bits of the MUA_FCR register, while the FUP bit is set to "1", does not generate a Flags Update event, and the Fn[2:0] bits stays unchanged. • Writing the FCR register doesn't set FUP bit immediately if there is any event pending(SR[EP] is "1"). • FUP bit is cleared when this Flags Update request is internally acknowledged (the flag is updated) from the MUB side, or during MU reset. 0b - No pending update flags(initiated by MUA) are in process 1b - Pending update flags(initiated by MUA) are in process
2 EP	MUA Side Event Pending • An "event" is any hardware message that is reflected in the status register on the MUB side (for example, "transmit register 0 written"). During normal operations, the update mechanism for the EP bit works automatically. • EP bit is set to "1" when the MUA side sends an event update request to the MUB side. • EP bit is cleared by hardware automatically when the event update acknowledge is received. • To ensure events have been posted to MUB, verify that the EP bit is cleared. If EP bit is set to "1", wait and continue to poll the EP bit. • The EP bit is cleared when the MU resets. 0b - The MUA side event is not pending. 1b - The MUA side event is pending.
1 MURIP	MU Reset Interrupt Pending • MURIP bit signals Processor A that Processor B initiated a MU reset by setting the MUB_CR[MUR] bit. • MURIP bit is set to "1" after Processor B initiated a MU reset. If the interrupt is enabled by the MURIE bit, the Processor A MU reset interrupt request is issued when the Processor B set MUR bit in MUB_CR. • Writing "1" to clear the MURIP bit, which also clears MU reset interrupt request. • Only system reset can reset MURIP. MU reset cannot reset this bit.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Processor B did not issue MU reset. 1b - Processor B issued MU reset.
0 MURS	MUA and MUB Reset State • The MURS bit is set to "1" during any system reset or any MU reset from MUA-side or MUB-side. • The MURS bit is cleared when the reset sequence on both MUA and MUB side ends. After issuing any of the reset events mentioned previously, **verify that the MURS bit is cleared before starting any access.** 0b - MUA and MUB are out of reset. 1b - MUA or MUB is in reset state.

39.6.1.6 Flag Control Register (FCR)

Offset

Register	Offset
FCR	100h

Function

The FCR register contains read-write flags that reflect the MUB_FSR[Fn] bits.

Fields

Field	Function
31-4 —	Reserved
3-0 TEn	MUA Transmit Register n Empty • There are 4 Transmit Registers (n = 0 to 3) • The TEn bit is set to "1" after the MUB RRn register is read on the MUB side. • After the TEn bit is set to "1", it signals the MUA side that the MUA TRn register is ready to be written on the MUA side, and a Transmit n interrupt is issued on the MUA side (if the MUA_TCR[TIEn] bit is set to "1"). • TEn bit is cleared after the MUA TRn register is written on the MUA side. • After TEn bit is cleared, the Transmit n interrupt(if the MUA_TCR[TIEn] bit is set to "1") is cleared on the MUA side. • TEn bit is set to "1" when the MU resets. 0b - MUA TRn register is not empty. 1b - MUA TRn register is empty.

39.6.1.13 Receive Control Register (RCR)

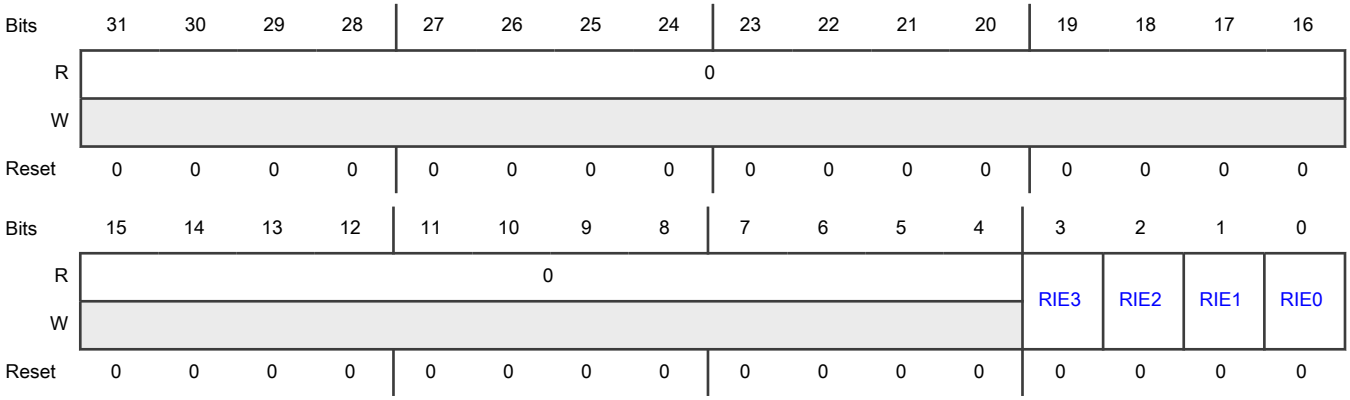
Offset

Register	Offset
RCR	128h

Function

The RCR register contains the MUA receive interrupt enables.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 RIEn	MUA Receive Interrupt Enable n • There are 4 Transmit Interrupts (n = 0 to 3) • If RIEn bit is set to "1", then an MUA Receive Interrupt n request is issued when the MUA_RSR[RFn] bit is set to "1". • If RIEn bit is cleared, then the value of the RFn bit is ignored and no MUA Receive Interrupt n request is issued. • RIEn bit is cleared when the MU resets. 0b - Disables MUA Receive Interrupt n. 1b - Enables MUA Receive Interrupt n.

39.6.1.14 Receive Status Register (RSR)

Offset

Register	Offset
RSR	12Ch

Function

The RSR register shows whether the MUA receive registers are full or not.

Diagram

Fields

Field	Function
31-4 —	Reserved
3-0 RFn	MUA Receive Register n Full • There are 4 Receive Registers (n = 0 to 3) • The RFn bit is set to "1" when the MUB TRn register is written on the MUB side. • After the RFn bit is set to "1", the RFn bit signals the MUA side that new data in the MUA RRn register is ready to be read by the MUA, and a Receive n interrupt is issued on the MUA side (if the MUA_RCR[RIEn] has been set to "1"). • RFn bit is cleared when the MUA RRn register is read, or when the MU is reset. • After RFn bit is cleared, the Receive n interrupt(if the MUA_RCR[RIEn] has been set to "1") is cleared on the MUA side. 0b - MUA RRn register is not full. 1b - MUA RRn register has received data from MUB TRn register and is ready to be read by the MUA.

39.6.1.15 Transmit Register (TR0 - TR3)

Offset

Register	Offset
TR0	200h
TR1	204h
TR2	208h
TR3	20Ch

Function
MUA Transmit Data.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	TR_DATA															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	TR_DATA															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 TR_DATA	MUA Transmit Data • Data written to the TRn register is reflected in the MUB Receive Register n (RRn). The TRn and RRn registers are not double-buffered, a write to the TRn register overrides the data readable at the RRn register. • A write to the transmit register clears the MUA_TSR[TEn] bit on the transmitter side, and sets the MUB_RSR[RFn] bit on the receiver side. • TRn register can be written only when the MUA_TSR[TEn] bit is set to "1". • Reading the TRn register returns all zeros.

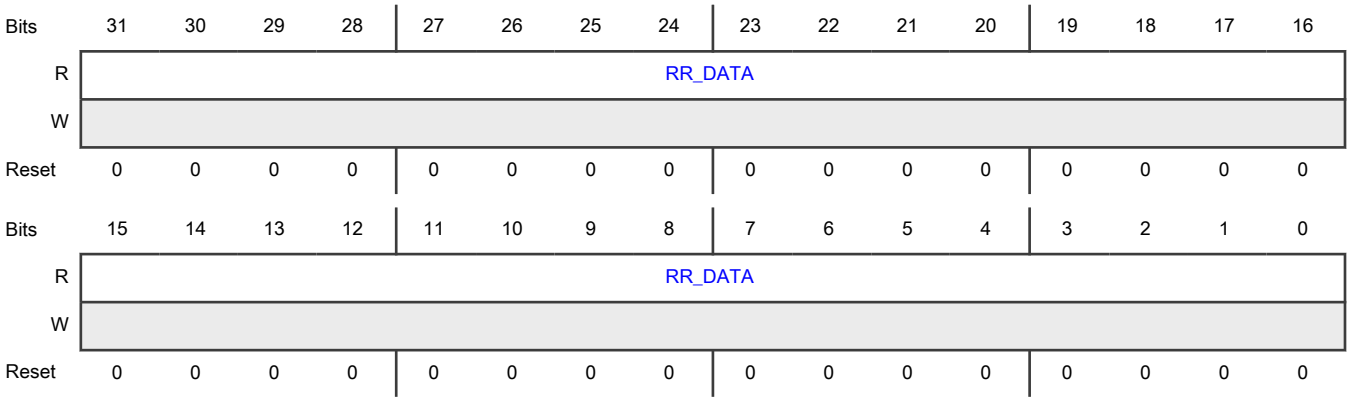
39.6.1.16 Receive Register (RR0 - RR3)

Offset

Register	Offset
RR0	280h
RR1	284h
RR2	288h
RR3	28Ch

Function
MUA Receive Data.

Diagram



Fields

Field	Function
31-0	MUA Receive Data

Table continues on the next page...

Field	Function
RR_DATA	• Reflects the data written to MUB Transmit Register (TRn). • Reading the RRn register clears the MUA_RSR[RFn] bit on the receiver side, and sets the MUB_TSR[TEn] bit on the transmitter side. • RRn register can be read only when the MUB_RSR[RFn] bit is set to "1". Reading before MUB_RSR[RFn]=1 may result in reading incorrect data. Therefore, polling the MUB_RSR[RFn] bit to confirm it is set to "1" before reading RRn is required. • Writing to the RRn register generates an error response to the MUA.

39.6.2 MUB register descriptions

This section contains the detailed register descriptions for the MUB registers.

NOTE

A read/write access to any illegal location and a write to a read-only register on the Processor A-side or Processor B-side of the MU generates a module transfer error acknowledge to the Processor A or Processor B. The only exception to this is at address offsets 0x1C and 0x14 - no transfer error occurs when accessing these locations.

39.6.2.1 MUB memory map

MU_0.MUB base address: 4038_C000h

MU_1.MUB base address: 404E_C000h

Reset	See Register reset values.															

Register reset values

Register	Reset value
PAR	MU_0.MUB,MU_1.MUB: 2020_0404h MU_2.MUB: 0301_0404h

Fields

Field	Function
31-24 FLAG_WIDTH	Flag Width This bitfield specifies the number of flag bits in the Flag Control Register (FCR) and Flag Status Register (FSR).
23-16 GIR_NUM	General Interrupt Request Number This bitfield specifies the number of general interrrupt requests available.
15-8 RR_NUM	RR Number This bitfield specifies the number of receive registers.
7-0 TR_NUM	Transmit Register Number This bitfield specifies the number of transmit registers.

39.6.2.4 Control Register (CR)

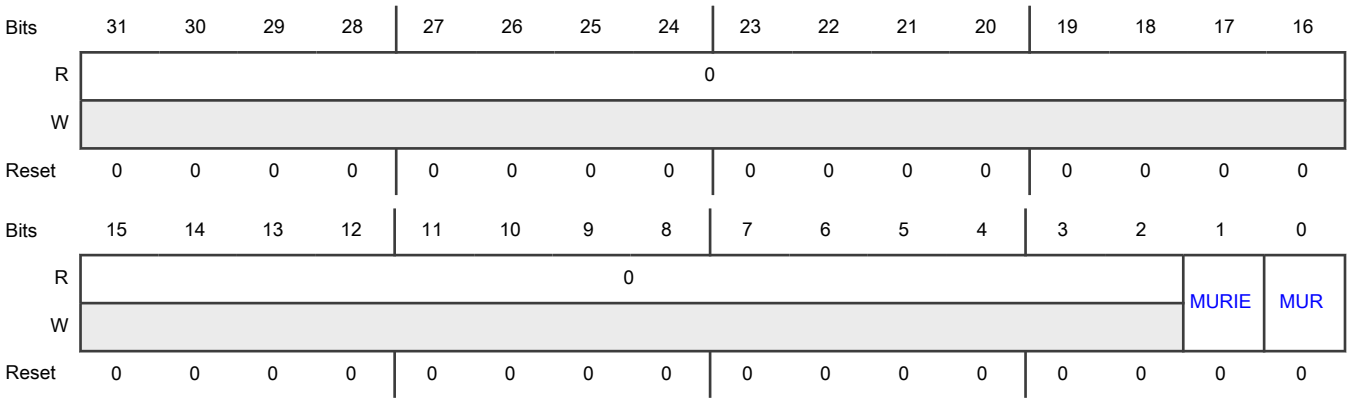
Offset

Register	Offset
CR	8h

Function

The CR register controls the MU reset and MU reset interrupt enable.

Diagram



Fields

Field	Function
31-2	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
1 MURIE	MUB Reset Interrupt Enable • If MURIE bit is set to "1", then MU reset interrupt request is issued to the Processor B when the MUB_SR[MURIP] bit is set to "1". • If MURIE is cleared, then the value of the MURIP bit is ignored and no MU reset interrupt request is issued. • Only system reset can reset MURIE, MU reset(MUR) cannot reset this bit. 0b - Disables Processor B-side MU Reset Interrupt request due to MU reset issued by MUA. 1b - Enables Processor B-side MU Reset Interrupt request due to MU reset issued by MUA.
0 MUR	MU Reset • Setting MUR bit to "1" resets both the MUB-side and MUA-side, forcing all control and status registers to return to their default values (except in MUB/A_CCR0 registers, MURIE in MUB/A_CR registers, MURIP bit and MURS bit in MUB/A_SR registers), and all internal states to be cleared. • Before setting the MUR bit to "1", it is advisable to interrupt the Processor A, because setting the MUR bit may affect the ongoing Processor A program. • After setting the MUR bit, monitor the value of the MUB_SR[MURS] bit to know when the reset sequence on the Processor A-side has ended. • MUR bit is always read as "0". • MUR bit is cleared during the MU reset sequence. 0b - Self clearing bit. 1b - Asserts the MU reset.

39.6.2.5 Status Register (SR)

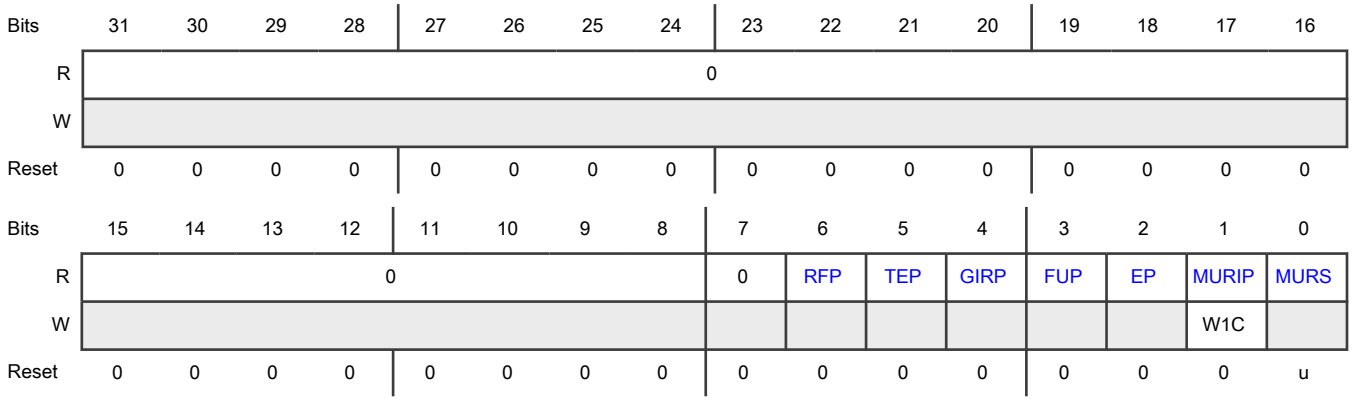
Offset

Register	Offset
SR	Ch

Function

The SR register shows the status of MU resets and the status of pending events/requests described below.

Diagram



Fields

Field	Function
31-8 —	Reserved
7 —	Reserved
6 RFP	MUB Receive Full Pending Flag • RFP bit is set to "1" when any TRn register is written by MUA to send data to MUB. • After the RFP bit is set to "1", checking the RSR[RFn] bit to decide the data in which RRn register is ready to be read by the MUB. • RFP bit is cleared when all MUB RRn registers are read, or when the MU is reset. 0b - No TRn register is written by MUA. 1b - Any TRn register is written by MUA.
5 TEP	MUB Transmit Empty Pending • TEP bit is set to "1" when TCR[TIEn] bit is set and the corresponding RRn register is read by MUA. • After the TEP bit is set to "1", checking the TSR[TEn] bit to decide the data in which TRn register is ready to be written by the MUB. • TEP bit is cleared when all MUB TRn register are written. • TEP bit is set to "0" when the MU resets. 0b - RRn register is not read by MUA. 1b - Any RRn register is read by MUA.
4 GIRP	MUB General Interrupt Pending • GIRP bit is set to "1" when any general interrupt request is sent from the MUA side to the MUB side. Reading the GSR[GIPn] bit can know which general interrupt request is received.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• GIRP bit is cleared when all GIPn bits in MUB_GSR register are cleared. • GIRP bit is cleared when the MU resets. 0b - No general interrupt request is sent from MUA. 1b - Any general interrupt request is sent from MUA.
3 FUP	MUB Flags Update Pending • FUP bit is set to "1" when the MUB side sends a Flags Update request to the MUA side. • A Flags Update request is generated when there is a change to the Fn[31:0] bits of the MUB_FCR register. No flag update changes are allowed while the FUP bit is set to "1". Any write to the Fn[31:0] bits of the MUB_FCR register, while the FUP bit is set to "1", does not generate a Flags Update event, and the Fn[31:0] bits stays unchanged. • Writing the FCR register doesn't set FUP bit immediately if there is any event pending(SR[EP] is "1"). • FUP bit is cleared when this Flags Update request is internally acknowledged (the flag is updated) from the MUA side, or during MU reset. 0b - No pending update flags(initiated by MUB) are in process 1b - Pending update flags(initiated by MUB) are in process
2 EP	MUB Side Event Pending • An "event" is any hardware message that is reflected in the status register on the MUA side (for example, "transmit register 0 written"). During normal operations, the update mechanism for the EP bit works automatically. • EP bit is set to "1" when the MUB side sends an event update request to the MUA side. • EP bit is cleared by hardware automatically when the event update acknowledge is received. • To ensure events have been posted to MUA, verify that the EP bit is cleared. If EP bit is set to "1", wait and continue to poll the EP bit. • The EP bit is cleared when the MU resets. 0b - The MUB side event is not pending. 1b - The MUB side event is pending.
1 MURIP	MU Reset Interrupt Pending • MURIP bit signals Processor B that Processor A initiated a MU reset by setting the MUA_CR[MUR] bit. • MURIP bit is set to "1" after Processor A initiated a MU reset. If the interrupt is enabled by the MURIE bit, the Processor B MU reset interrupt request is issued when the Processor A set MUR bit in MUA_CR. • Writing "1" to clear the MURIP bit, which also clears MU reset interrupt request. • Only system reset can reset MURIP. MU reset cannot reset this bit.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Processor A did not issue MU reset. 1b - Processor A issued MU reset.
0 MURS	MUA and MUB Reset State • The MURS bit is set to "1" during any system reset or any MU reset from MUA-side or MUB-side. • The MURS bit is cleared when the reset sequence on both MUA and MUB side ends. After issuing any of the reset events mentioned previously, **verify that the MURS bit is cleared before starting any access.** 0b - MUA and MUB are out of reset. 1b - MUA or MUB is in reset state.

39.6.2.6 Core Control Register 0 (CCR0)

Offset

Register	Offset
CCR0	10h

Function

The CCR0 enables the MUB to control the Processor on the MUA-side.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
MU_0.MUB	CCR0	—
MU_1.MUB	CCR0	—
MU_2.MUB	—	CCR0

Diagram

Field	Function
31-7 —	Reserved
6-5 —	Reserved
4 —	Reserved
3 —	Reserved
2 —	Reserved
1 —	Reserved
0 NMI	MUA Non-maskable Interrupt Request • When NMI bit is set to "1", it initiates a Non-Maskable Interrupt to the Processor A. • NMI bit is cleared after the MUA_CSSR0[NMIC] bit is written to "1". After the NMI bit is cleared, the MUB can initiate another non-maskable interrupt to the MUA. • The NMI bit is cleared when the MU resets. 0b - Non-maskable interrupt is not issued to the Processor A by the Processor B. 1b - Non-maskable interrupt is issued to the Processor A by the Processor B.

39.6.2.7 Core Sticky Status Register 0 (CSSR0)

Offset

Register	Offset
CSSR0	18h

Function

The CSSR0 register shows the status of interrupts pending (W1C).

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
MU_0.MUB	CSSR0	—
MU_1.MUB	CSSR0	—
MU_2.MUB	—	CSSR0

0 NMIC	Processor B Non-Maskable-Interrupt Clear • NMIC bit is used by the MUB-side Non-Maskable Interrupt service routine to clear the non-maskable interrupt from MUA-side. • Writing NMIC bit as "1" signals the MUA to clear the MUA_CCR0[NMI] bit, thus de-asserting the interrupt and enabling the NMI bit to receive another interrupt. • The NMIC bit is always read as "0", therefore NMIC bit cannot be polled. The NMIC bit can only be used as part of the interrupt service routine, in which the NMIC bit should only be written as "1" once. • The NMIC bit is cleared when the MU resets. 0b - Default 1b - Writing "1" clears the MUA_CCR0[NMI] bit.

39.6.2.8 Flag Control Register (FCR)

Offset

Register	Offset
FCR	100h

Function

The FCR register contains read-write flags that reflect the MUA_FSR[Fn] bits.

39.6.2.9 Flag Status Register (FSR)

Offset

Register	Offset
FSR	104h

Function

The FSR register contains flags that reflect the values written to the Fn bit of the MUA_FCR register.

Field	Function
	• If a 1 is read from an Fn bit - Fn bit in the MUA_FCR is 1. 0b - Fn bit in the MUA FCR register is written 0. 1b - Fn bit in the MUA FCR register is written 1.
0 F0	MUA to MUB Side Flag n • n = 0 to 31 • Fn bit is the MUB side flag that reflects the values written to the Fn bit in the MUA_FCR register. • Every time that the Fn bit in the MUA_FCR register is written, the Fn bit in the MUA FCR register write event updates the Fn bit in the MUB_FSR register after the event update latency. • If a 0 is read from an Fn bit - Fn bit in the MUA_FCR is 0. • If a 1 is read from an Fn bit - Fn bit in the MUA_FCR is 1. 0b - Fn bit in the MUA FCR register is written 0. 1b - Fn bit in the MUA FCR register is written 1.

39.6.2.10 General Interrupt Enable Register (GIER)

Offset

Register	Offset
GIER	110h

Function

The GIER register contains the MUB general purpose interrupt enables.

39.6.2.11 General Control Register (GCR)

Offset

Register	Offset
GCR	114h

Function

The GCR register contains the MUB general purpose interrupt requests.

Fields

Field	Function
31 GIR31	MUB General Purpose Interrupt Request n • There are 32 General Purpose Interrupts (n = 0 to 31) • Writing "1" to the GIRn bit sets the MUA_GSR[GIPn] bit on the MUA-side. If the MUA_GIER[GIEn] bit is set to "1" on the MUA-side, a General Purpose Interrupt n request is triggered to Processor A. • The GIRn bit is cleared if the MUA_GSR[GIPn] bit is cleared by writing "1", thereby signalling the MUB that the interrupt was accepted (cleared by the software).

Table continued from the previous page...

<table>
<tr><th>Field</th><th>Function</th></tr>
<tr><td></td><td>

Writing "0" to the GIRn bit is ignored.
To ensure proper operations, you must verify that the GIRn bit is cleared (meaning that there is no pending interrupt) before setting it (GIRn bit).
GIRn bit is cleared when the MU resets.

Chapter 40
Power Management

40.1 Introduction

The power management system generates, monitors, and controls power supplies and related resets. This chapter describes the system's interaction with other peripherals.

The power management system includes the following modules:

Table 205. Power management system modules and their functions

Part	Function
MC_ME	Initiates entry into Low-Power mode
MC_PCU	Controls entry into and exit from Low-Power mode
PMC	Regulates and monitors power supplies of the Run and the Standby domains
MC_RGM	Ensures a clean state and Run domain sanity by controlling the reset sequence
FIRC, WKPU, and other chip peripherals	Controls Standby mode wake-up and operations in Run and Standby modes

40.1.1 Power management system for MWCT2D16S and MWCT2D17S

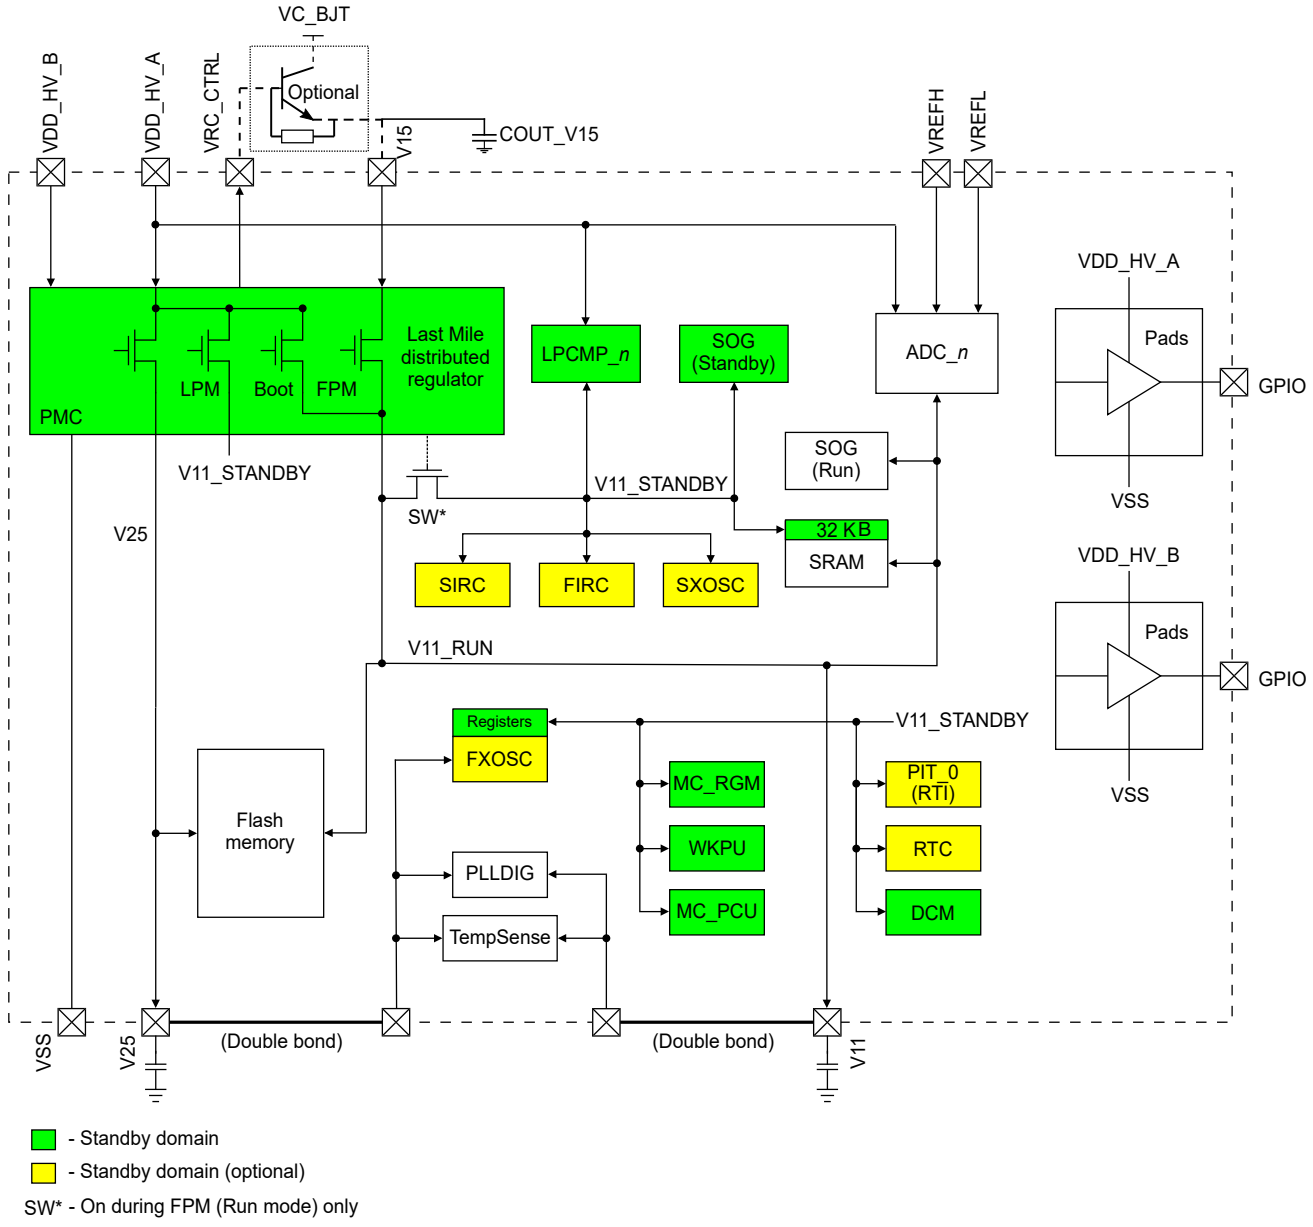

Figure 150. Power management system for MWCT2D16S and MWCT2D17S

40.1.2 Power management system for MWCT2016S and MWCT2015S

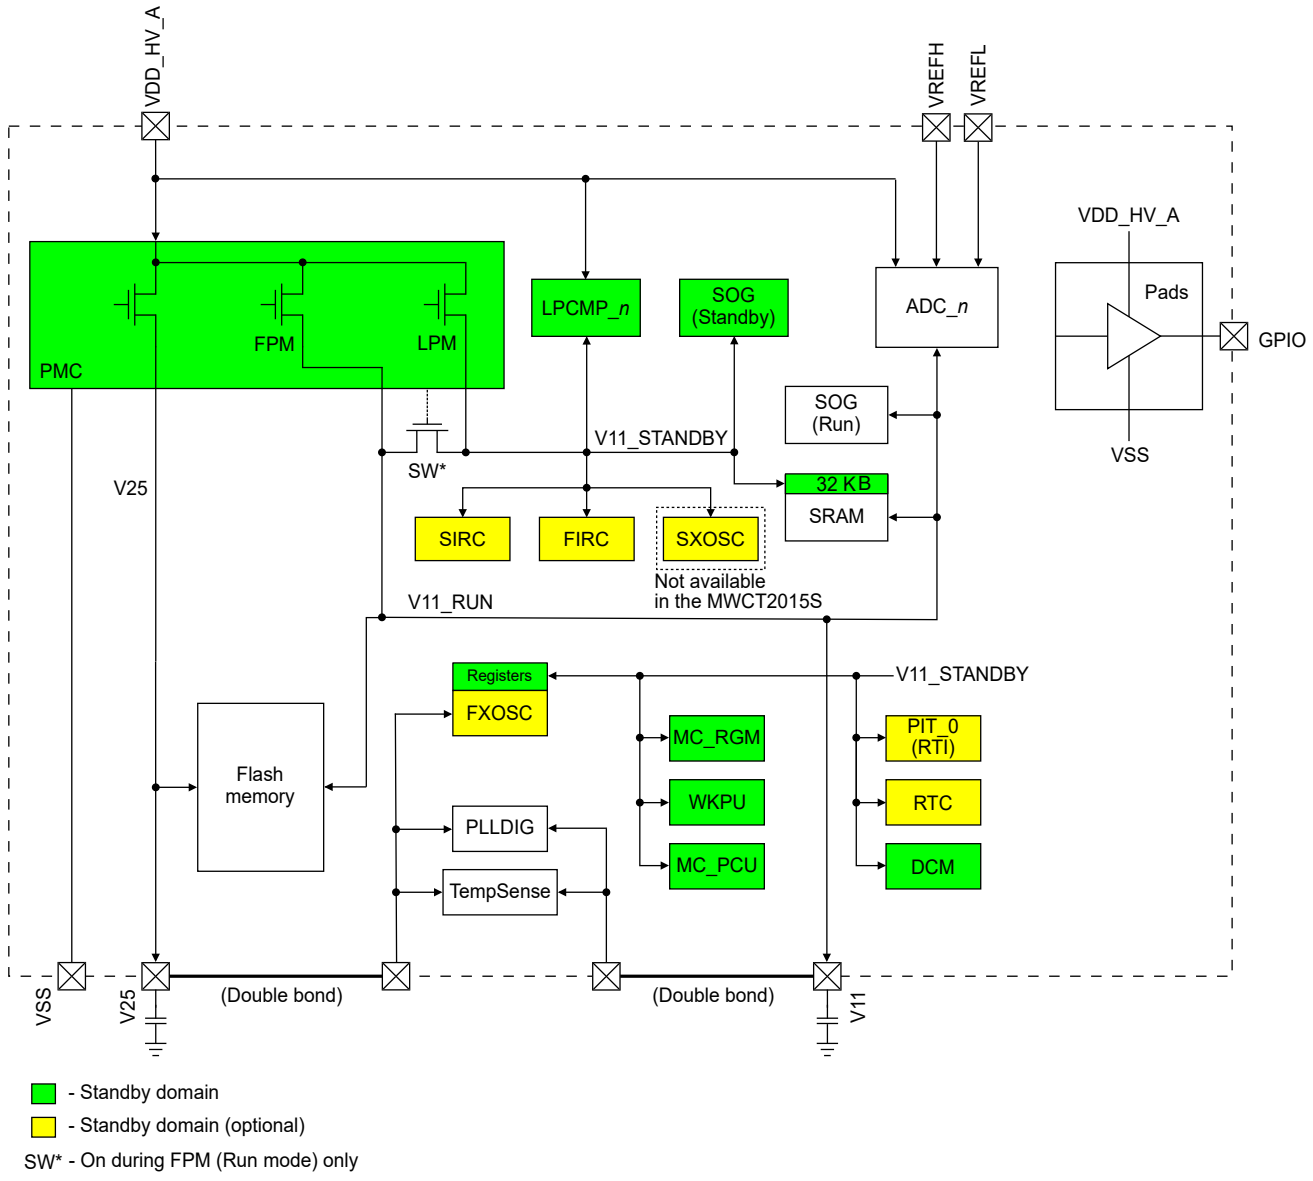

Figure 151. Power management system for MWCT2016S and MWCT2015S

40.1.3 Features

- Includes a linear regulator to use an optional external ballast (BJT) and VRC_CTRL output for 1.5 V generation. PMC uses 1.5 V supply and an internal regulator to generate 1.1 V (nominal) supply (V11_RUN) for the core logic
- Supports a low-power regulator (LPM) supplying core logic during Standby mode (V11_STANDBY)
- Includes two regulators for driving the logic in Run mode (both can be software-controlled):
  - Boot (Applicable for MWCT2D17S and MWCT2x16S)
  - Last-mile (FPM)
- Supports power switches to isolate voltage islands and configure the chip in Standby mode

- Includes a linear regulator that generates a 2.5 V supply (V25) from VDD_HV_A
- Supports voltage monitors ensuring transitions to a safe state (POR) when a supply is out of a valid range
- Controls power-mode transitions through an interaction with the digital interface
- Offers a padkeeping feature that retains I/O configuration after exiting Standby mode
- Separates ADC reference supplies (VREFH and VREFL)

40.1.4 Operational power modes

This chip uses two modes:

- Run mode (FPM): Main operation mode having full-chip performance and a higher current consumption as compared to Standby mode.
- Standby mode (LPM): Low-performance mode of the chip in which the Run domain is turned off. Most of the cores and peripherals turn off in this mode.

The boot regulator manages the chip during the booting process.

The last-mile regulator is the full-performance regulator, which you enable for running applications. The upcoming sections discuss the sequence to enable or disable the regulator.

The LPM regulator manages the chip in Standby mode.

40.1.5 External 1.5 V source

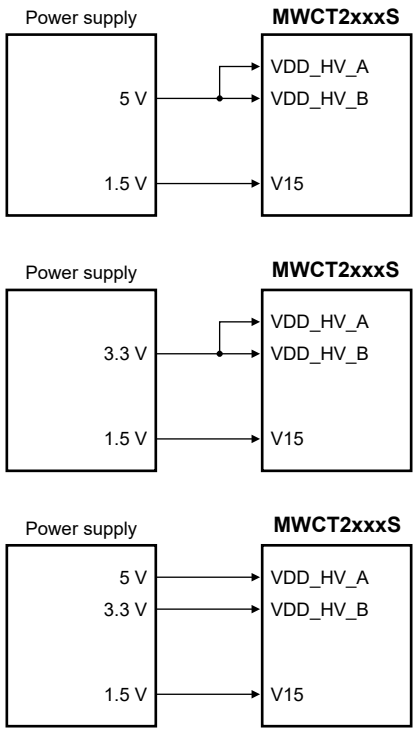

Figure 152. External 1.5 V source

40.1.6 Using a BJT for 1.5 V generation

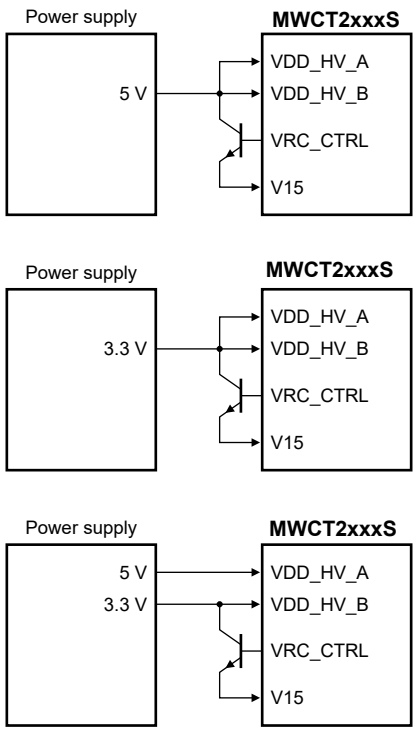

Figure 153. Using a BJT for 1.5 V generation

40.2 Power-up sequence

Figure 154 shows the reset sequence for a power-up or Standby mode event. This sequence starts from the POR phase. For the Run domain logic, Standby mode exit operation is same as power-up.

See the Reset Overview chapter for more information about the chip reset sequence.

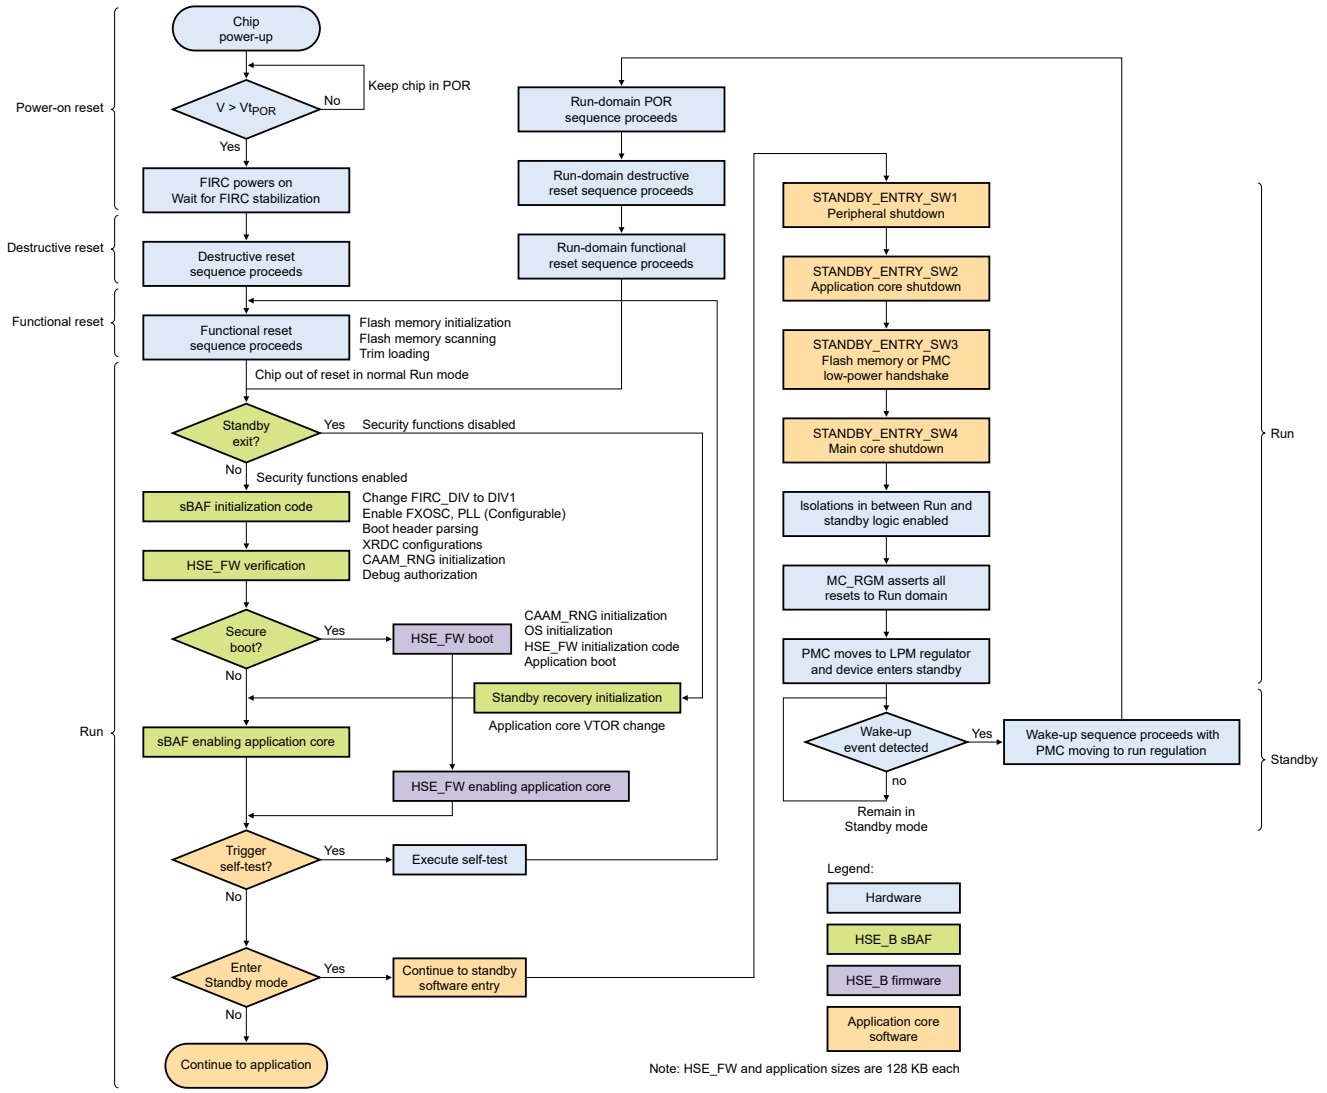

Figure 154. Power-up sequence

40.3 PMC last-mile regulator auto-enable feature

PMC includes an automatic last-mile auto-enable feature. After starting on boot regulator, this feature allows automatic switch over to last-mile regulator if 1.5 V is present during:

- Chip startup
- Standby mode recovery

You can control the PMC last-mile regulator by appropriately configuring:

- PMC's CONFIG[LMAUTOEN] field
- PMC's CONFIG[LM_EN] field

  For more information, see the descriptions of these fields in PMC's CONFIG register.

NOTE

You must write 1 to PMC's CONFIG[LM_EN] field before transtioning to faster clock frequencies irrespective of the setting of PMC's CONFIG[LMAUTOEN] field. This is because of the reduced clock speed when using the boot regulator.

40.3.1 Last-mile regulator with 1.5 V from an external source

Table 206. Last-mile regulator with 1.5 V from an external source

Operating condition	Last-mile regulator operation
After POR	Boots on boot regulator and then automatically switches to the last-mile regulator
After destructive reset	Remains on last-mile regulator **NOTE** If the destructive reset source is low voltage reset on 1.1 V then switchback happens from last-mile to boot regulator for boot.
After functional reset	Remains on last-mile regulator
After PMC's LVSC[LVD15S] field becomes 1	Switches, automatically, to the boot regulator to configure clocks for slow speed

40.3.2 Last-mile regulator using a BJT

Table 207. Last-mile regulator using a BJT

Operating condition	Last-mile regulator operation
After POR	Boots on boot regulator; switches to the last-mile regulator post reset when the Cortex-M7 core configures the software (post-secure boot) on FIRC (100 ms)
After destructive reset	Switches to boot regulator to check reset propagation delay
After functional reset	Remains on last-mile regulator
After PMC's LVSC[LVD15S] field becomes 1	Switches, automatically, to boot regulator to configure clocks for slow speed

40.4 Standby mode entry sequence

The Standby mode entry sequence includes three phases of operation:

- Standby mode entry configuration phase or software Standby mode entry sequence
- Standby mode entry handshake phase or hardware Standby mode entry sequence
- Standby mode entry or PMC Standby mode entry

NOTE

The Standby mode entry sequence described in this section is the only supported sequence. Contact NXP support if you require an alternate Standby mode entry sequence.

40.4.1 Software Standby mode entry sequence

The Standby mode entry sequence discusses chip configuration described in the sections that follow.

Before entering the software Standby mode sequence, the system clock source must be changed to FIRC at 48 MHz because PLLDIG is not available in Standby mode. In this mode, all clock sources can be optionally disabled (including FIRC, which results

in a no-clock, low-power consumption mode). You could use FXOSC, if enabled, when the 2.5 V supply is available by appropriate configuration of PMC's CONFIG[LPM25EN].

The software Standby mode entry sequence consists of four steps:

1. SW1: Module shutdown process
2. SW2: Application core shutdown process
3. SW3: Flash memory low-power handshake and PMC last-mile regulator control
4. SW4: Main core shutdown process

These processes are described in detail in the sections that follow. See Figure 154 that shows the relationship between these four steps in a flow diagram.

40.4.1.1 SW1: Module shutdown process

I/O and module configuration for Standby mode discusses the procedure to configure I/O and the chip modules for Standby mode.

The entry sequence for this mode includes module clock disabling steps (see the "Clocking" chapter for module clock turn on and turn off processes). You must use MC_ME's PRTN*n*_COFB*m*_CLKEN[REQ*p*] fields to enable or disable module clocks.

40.4.1.1.1 Disabling modules

Disable modules by configuring the appropriate fields in their registers for Standby mode operation. See specific module chapters for more information.

The Standby mode entry sequence includes the module clock disabling step, with which you can disable the modules that you do not need for Standby mode operation.

The sequence of disabling modules is shown in I/O and module configuration for Standby mode.

NOTE

While enabling or disabling the modules, you must verify that the module is disabled when you read MC_ME's PRTNn_COFBm_STAT register and the module disable field, if applicable. In case of a discrepancy, you must perform proper diagnostic steps.

You must clear the I/O controls for the pads that you do not require in Standby mode (OBE, IBE, and so on). This avoids any unwanted pad keeping settings. See Pad keeping for more information on the chip pad keeping process.

For any standby wake source, if an interrupt occurs it must be disabled before entering into standby and only the wake up event of that source must be enabled. This is to avoid any SW conflict in the interrupt handling for multi application core cases.

The MC_ME's PRTN*n*_COFB*m*_STAT register indicates the status of peripheral clock enable or disable. It may take up to three clock cycles for MC_ME's PRTN*n*_COFB*m*_STAT register to update after MC_ME's PRTN*n*_COFB*m*_CLKEN register is updated.

40.4.1.1.2 I/O and module configuration for Standby mode

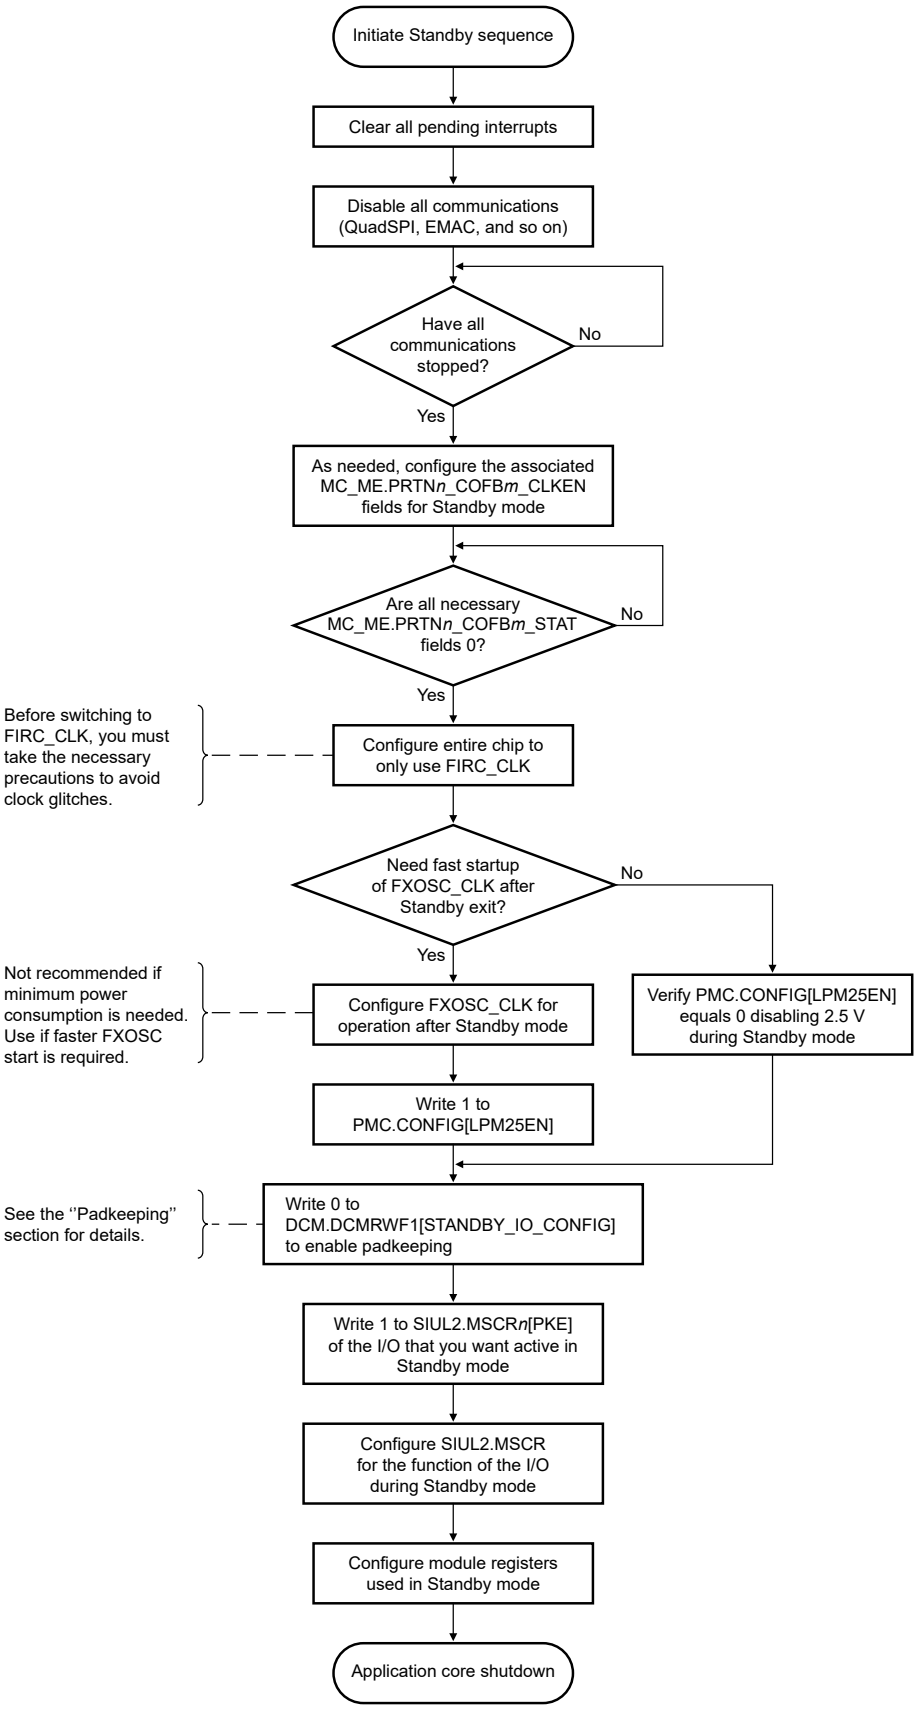

Figure 155. I/O and module configuration for Standby mode

40.4.1.2 SW2: Application core shutdown process

The application cores(s) execute a WFI (as opposed to the main core running the Standby mode entry sequence). See the section "Application core shutdown" in the MC_ME chapter for more information.

The main core configuration (programming valid core ID and enabling standby entry process) and wake-up source configuration must also be set in SW2, so that SW4 contains only the main core WFI execution.

40.4.1.3 SW3: Flash memory low-power handshake and PMC last-mile regulator

In this process, you execute a flash memory low-power handshake and disable the PMC last-mile regulator by executing the procedures indicated in Figure 156 and Figure 157 .

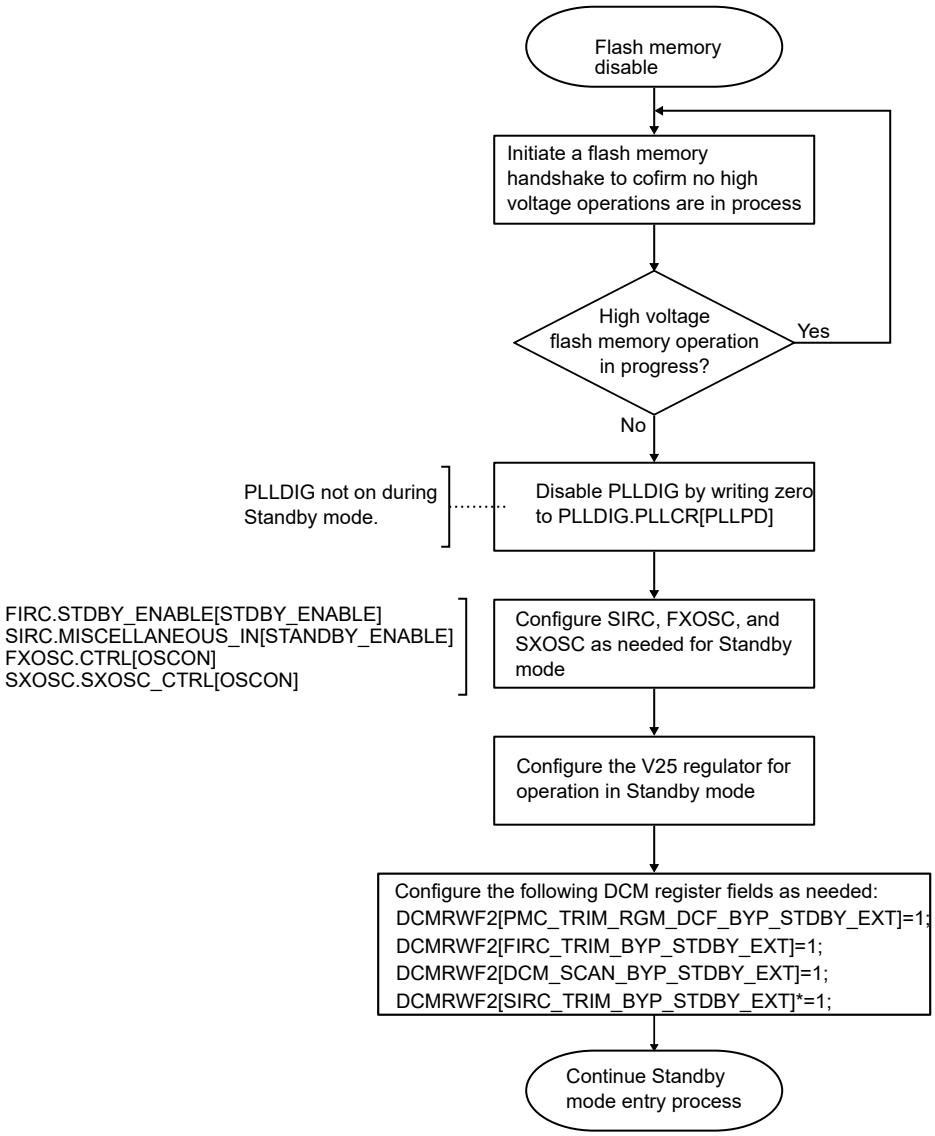

Figure 156. Flash memory Standby mode configuration

NOTE

Disable the last-mile regulator according to the Last-mile regulator disable sequence.

40.4.1.3.1 Last-mile regulator disable sequence

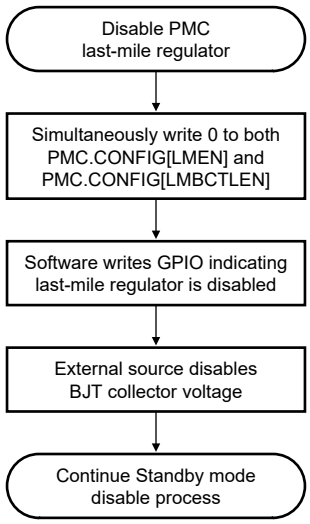

Figure 157. Last-mile regulator disable sequence

When exiting Standby mode, the 1.1 V capacitor is charging. You can charge the 1.5 V capacitor during or after the 1.1 V capacitor is charged. If you charge the 1.5 V capacitor sequentially after the 1.1 V capacitor, you will need additional time to complete the overall charging process.

Leaving PMCs CTRL[LMBCTLEN] = 1 saves time when exiting Standby mode and does not draw any additional current during this mode.

40.4.1.4 SW4: Main core shutdown process

For information on this process, see these in the "Mode Entry Module (MC_ME)" chapter:

- Figure "Standby entry sequence along with main core shutdown"
- Section "Main core shutdown and Standby mode entry"

You must configure WKPU before disabling interrupts to avoid missing any events as shown in the Standby entry sequence along with main core shutdown flowchart in the MC_ME chapter. You must program WKPU, disable interrupts, and configure MC_ME's Standby mode entry in SW1 (see SW1: Module shutdown process for more information). In SW4, you must perform only the main-core WFI execution.

40.4.2 Hardware Standby mode entry sequence

The hardware Standby mode entry sequence consists of handshaking between MC_PCU and MC_ME occuring after Software Standby mode entry sequence completes. The FSM in MC_PCU performs these steps automatically and does not require your intervention (see Power sequence FSM in the Power Control Unit (MC_PCU) chapter for more information).

40.4.2.1 PMC Standby mode entry

The PMC Standby mode entry sequence starts after Hardware Standby mode entry sequence completes, and consists of these phases:

1. Standby mode entry acknowledgment and initiation of an internal low-power process on receiving Standby mode entry request
2. Disabling of the boot regulator within the PMC low-power process. This point is only applicable for MWCT2D17S and MWCT2x16S.
3. Disabling of the V25 regulator and the FPM LVR monitors

4. Disabling of the V25 regulator (oscillator and flash memory supply) and the LPM monitor, unless it is enabled during Standby mode (see PMC's CONFIG[LPM25EN] field in the "Power management controller (PMC)" chapter for more information)
5. Disabling of the VDD_HV_B LPM monitors

40.5 Chip status at the end of Standby mode entry sequence

After PMC Standby mode entry completes, the chip completes Standby mode entry as follows:

1. Configures Standby domain peripherals according to SW1 (see SW1: Module shutdown process).
2. Enables pad keeping on pins as described in SW1 (see SW1: Module shutdown process). See Pad keeping for other details.
3. Powers down all memory types except Standby RAM (in SRAM0).
   - The V25 regulator can remain on during Standby mode. However, for maximum power savings, it must remain off in this mode.
4. Isolates Standby and Run domains from each other:
   - Standby domain is functional.
   - Run domain is held in reset.
5. Configures the system clock (FIRC_CLK or PLL_PHI*n*_CLK, depending on their configuration) and other clock sources according to SW3 (see Figure 156 for the procedure details).

   The cores are off and in the Standby domain.
6. Turns off the boot and FPM regulators.
7. Waits for a wake-up event to initiate recovery from Standby mode.

40.6 Chip operation in Standby mode

This chip supports the following functionalities in Standby mode:

- STANDBY_RAM content retention during Standby mode.
- Wake-up from up to 60 digital inputs (for details, see the signals WKUP[*n*] functions of WKPU module in the IOMUX file attached to this document). The section WKPU configuration on the chip in the "Wakeup Unit (WKPU)" chapter shows mapping of the wake-up sources.
- Wake-up from up to 16 analog inputs through the Trigger mode functionality (see the signals CMP*n*_IN*m* functions of CMP*n* modules in the IOMUX file attached to this document).
- Wake-up from on-chip timers:
  - RTI (function of PIT[0])
  - SWT0
  - RTC
- Ability to configure the chip clocking modules to optionally enable or disable in Standby mode (FIRC, SXOSC, FXOSC, and SIRC).

40.7 Standby mode exit

This chip supports Standby mode exit from a wake-up, functional reset, or destructive reset event. The sources that cause chip Standby mode exit are:

- MC_RGM functional reset event

- MC_RGM destructive reset event
- WKPU wake-up events, WKPU[0]–WKPU[63]. See the WKPU chapter for more information.

After Standby mode exit, the following events occur (for more information, see "Power sequence FSM" in the MC_PCU chapter for MC_PCU FSM transitions during entry into and exit from Standby mode):

1. A wake-up event arrives.
2. FIRC starts powering up (if disabled in Standby mode).
3. PMC starts the transition process to FPM (for example, enables the last-mile regulator and provides V11_RUN supply to the chip).
4. MC_PCU removes the isolation between Run and Standby domains.
5. Run domain reset deasserts (asserts on Standby mode entry) and the chip undergoes a functional reset exit sequence for this domain.
6. The chip enters Run mode of operation.

40.7.1 Faster Standby mode exit

The chip supports an optional configuration for faster recovery from Standby mode on the expense of a higher capacitor recharging current. See the CONFIG[FASTREC] field description in the PMC chapter for more information on faster PMC recovery from Standby mode.

This chip supports an optional feature that bypasses SIRC trimming, FIRC trimming, PMC trimming and DCM scanning, SIRC trimming is optionally bypassed or not, phases in case of Standby mode exit sequence by writing 1 to DCM's DCMRWF2[6], DCMRWF2[5], DCMRWF2[4], and DCMRWF2[3] fields respectively before Standby mode entry for bypass operation. Even if the FIRC trimming is bypass before entering to standbymode FIRC must be at 48MHz, this results in a considerable reduction in Standby mode exit duration. The trim values are retained across Standby mode and bypassing these values does not cause any impact.

Configure to achieve the tMODE_STDBYEXIT_FAST = 53us

DCMRWF2[PMC_TRIM_RGM_DCF__BYP_STDBY_EXT] = 1

DCMRWF2[FIRC_TRIM_BYP_STDBY_EXT] = 1

DCMRWF2[DCM_SCAN_BYP_STDBY_EXT] = 1

DCMRWF2[SIRC_TRIM_BYP_STDBY_EXT] = x

40.7.2 Last-mile regulator enable sequence

After Standby mode exit, you must re-enable the PMC last-mile regulator before transitioning to faster clock frequencies. Figure 158 shows the last-mile regulator enable sequence part of the Standby mode exit process.

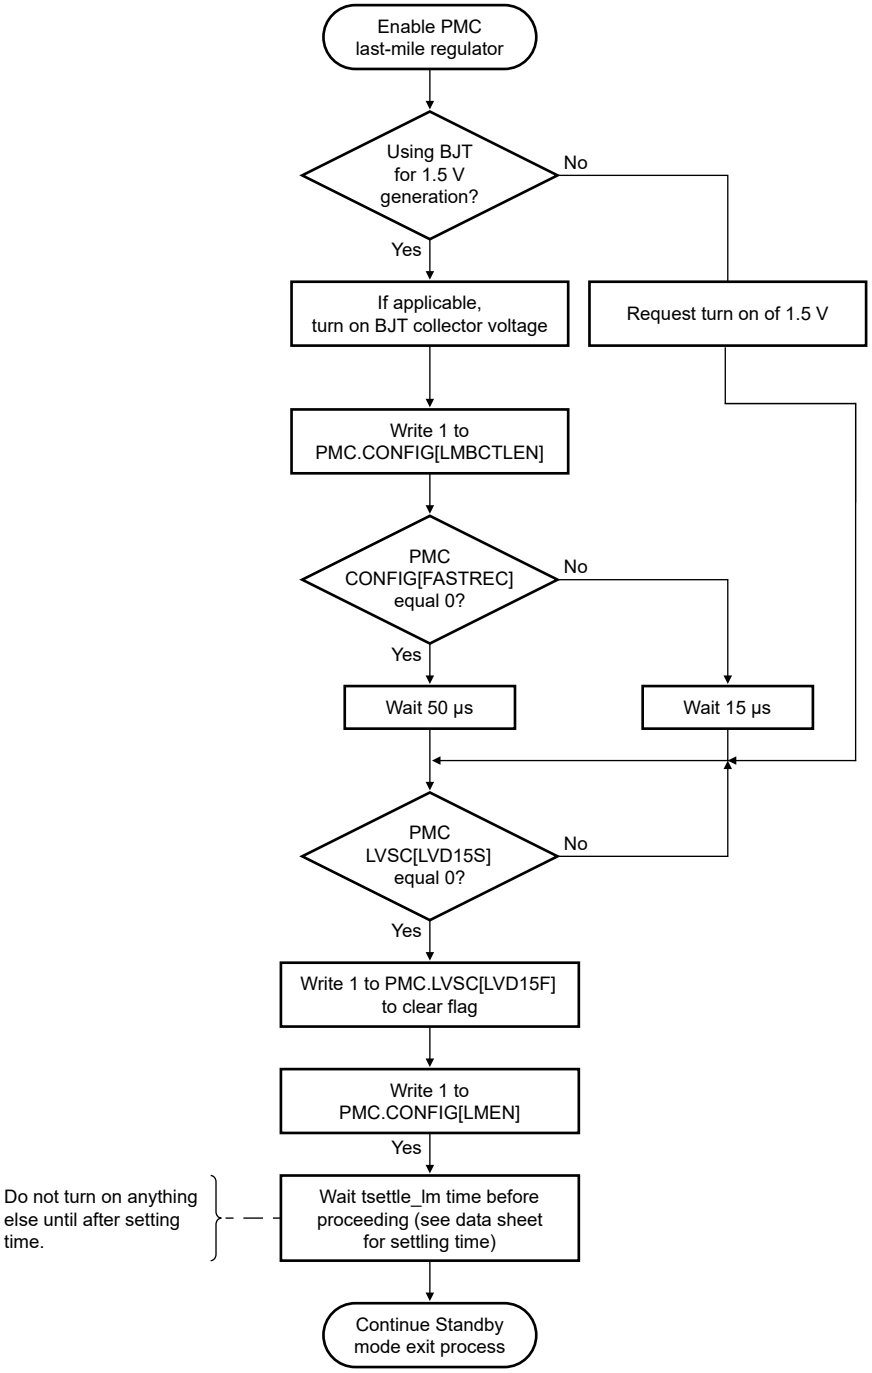

Figure 158. Last-mile regulator enable sequence

40.8 Chip power domain partitioning

These are the modules in the Standby domain. For more information, see "Peripheral reset status" in the "Reset Overview" chapter.

SRAM	32K	32K	32K	32K
PIT_RTI_0	Yes	Yes	Yes	Yes
DCM and DCF records	Yes	Yes	Yes	Yes
DCM Flash Interface	Yes	Yes	Yes	Yes

SWT0 (Cortex-M7_0) resides in the Standby domain and supports a configurable hardware-based timer operation during Standby mode depending on the configuration of SWTs.

All clock sources (excpet PLLDIG) are available in Standby mode. SIRC is present in the Standby domain for low-power wake-up, but can be enabled.

NOTE

This chip does not support Stop and Wait modes. The only low-power mode it supports is Standby.

40.9 Pad keeping

Pad keeping allows you to return to I/O Run mode configuration settings after using I/O during Standby mode. It eliminates I/O reconfiguration in Run mode.

40.9.1 Pad keeping on Run domain pins

The process of entering Standby mode ensures that the chip maintains the Run domain configuration settings. Software Standby mode entry sequence specifies that you must write 0 to DCM's DCMRWF1[STANDBY_IO_CONFIG] before configuring I/O pad keeping. You could consider DCM's DCMRWF1[STANDBY_IO_CONFIG] field as a global enable for all pad keeping purposes during Standby mode. If you are unable to write to this field as described, pad keeping works as explained in this chapter, during Standby mode.

After the chip exits Standby mode, you must write 1 to DCM's DCMRWF1[STANDBY_IO_CONFIG] field (see "Chip specific register descriptions" in the DCM chapter). Writing 1 to this field disables pad keeping and places chip I/O according to its Run mode configuration.

40.9.2 Pad keeping on Standby domain pins

The Standby domain pads can have pad keeping enabled or disabled based on pad availability in Standby mode. Writing to SIUL2's MSCR*n*[PKE] field configures Standby mode pad keeping on a selected I/O.

Ensure that DCM's DCMRWF1[STANDBY_IO_CONFIG] = 0 before Standby mode entry for pad keeping on Standby domain pads. Write 0 to the field in case its value is not 0 already.

If a pad is not required during Standby mode, the corresponding MSCR*n*[PKE] field in SIUL2 must be 0.

40.9.3 Pad keeping configuration procedure

This procedure specifies how to enable an I/O for pad keeping:

1. Configure SIUL2's MSCR*n* register to control the pad state prior to Standby mode entry (for example, writing 0 to SIUL2's MSCR*n*[OBE], MSCR*n*[IBE], and MSCR[PUE] fields tristates the corresponding I/O).
2. Configure SIUL2's MSCR*n*[PKE] field as needed for an I/O pad keeping state during Standby mode.
3. Write 0 to DCM's DCMRWF1[STANDBY_IO_CONFIG].

   The application core executes WFI, and Standby mode sequence starts.
4. Write 1 to DCM's DCMRWF1[STANDBY_IO_CONFIG] field on Standby mode exit to disable pad keeping. This configures SIUL2 according to its previous settings.

If you write 1 to DCM's DCMRWF1[STANDBY_IO_CONFIG] field before entering Standby mode, the isolation removal hardware removes pad keeping on Standby mode exit. This (writing 1 to DCM's DCMRWF1[STANDBY_IO_CONFIG] field before Standby mode entry) is useful in case of low-power debug because enabling pad keeping does not allow low-power debug protocol to work properly (because the TDO pad is padkept). For low-power debug, you must write 1 to DCM's DCMRWF1[STANDBY_IO_CONFIG] field prior to Standby mode entry.

In case of Standby mode exit by reset, the pad keeping of the reset pin is removed when the chip is reset on Standby mode wake up. See the "GPIO padkeeping enable" signal in Figure 160. The signal corresponds to wake-up via reset event case.

40.9.4 Pad keeping waveforms

40.9.4.1 Pad keeping when the chip wakes up from Standby mode via an interrupt event

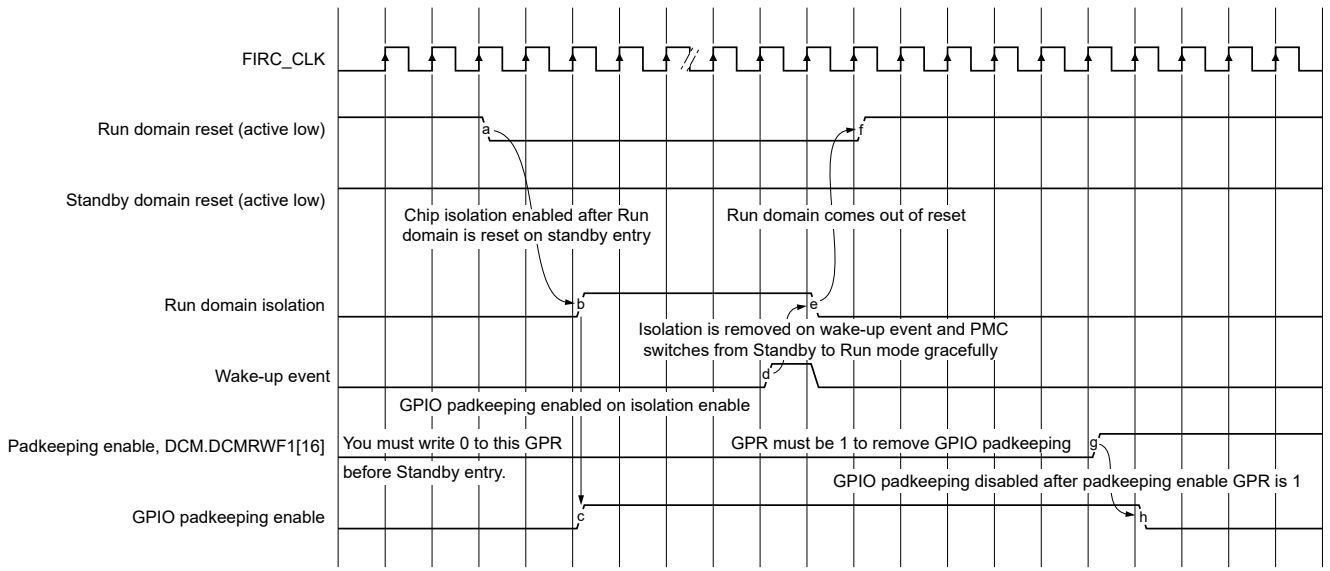

Figure 159. Pad keeping when the chip wakes up from Standby mode via an interrupt event

40.9.4.2 Pad keeping when the chip wakes up from Standby mode via reset

If the chip exits Standby mode via reset, the reset pad keeping is removed when the chip resets after Standby-mode wake-up. See the figure's "GPIO padkeeping enable" waveform corresponding to wake-up via a reset event.

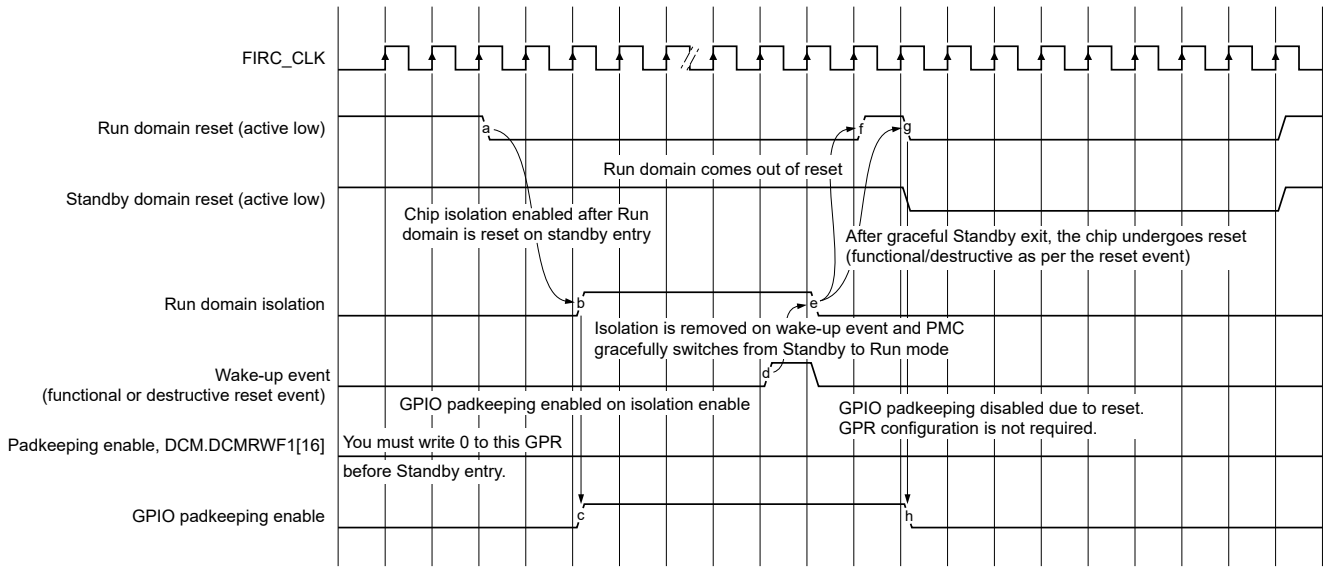

Figure 160. Pad keeping when the chip wakes up from Standby mode via reset

40.9.5 SIUL2's fields for actively-driven pins in Standby mode

If you use a WKPU pin as a wake-up input, perform these operations on SIUL2's fields:

1. Write 1 to MSCR*x*[IBE].

2. Program MSCR*x*[PUE] and MSCR*x*[PUS] according to the use case.
3. Write 0 to MSCR*x*[PKE].

For the GPIO pins that are driven to high impedance during Standby mode:

1. Write 0 to DCM's DCMRWF1[STANDBY_IO_CONFIG] field.
2. Write 0 to SIUL2's MSCR*x*[SSS] field (GPIO mode).
3. Write 0 to SIUL2's MSCR*x*[IBE] and MSCR*x*[OBE] fields.

Some of the pins are, by default, actively driven in Standby mode. If these pins retain a static value throughout the mode, program the corresponding MSCR*x*[PKE] bits individually.

This table shows the list of pins available in Standby mode along with the functions they perform.

Table 209. Active pins in Standby mode

Pin[1]	Function
GPIO_4	CMP0_OUT
GPIO_5	RESET_b
GPIO_9	CMP2_OUT
GPIO_11	CMP0_RRT
GPIO_12	CLKOUT_STANDBY; CMP1_OUT
GPIO_69	CMP2_RRT
GPIO_110	CMP0_RRT
GPIO_131	CMP0_OUT
GPIO_138	CLKOUT_STANDBY
GPIO_143	CMP1_RRT
GPIO_158	CMP1_OUT
GPIO_159	CMP1_RRT
GPIO_174	CMP0_OUT
GPIO_175	CMP0_RRT
GPIO_196	CMP2_OUT
GPIO_197	CMP2_RRT

40.10 Glossary

Application core Core apart from the main core

Boot regulator The on chip 1.1 V regulator that is active during startup and entry and exit from Standby mode

FSM Finite state machine

FPM Full-power mode (Run mode)—uses the last-mile regulator and 1.5 V source to generate the 1.1 V core logic supply during a full-power operation (V11_RUN)

LPM Low-power mode (Standby mode)—uses the low-power regulator to generate the 1.1 V core logic supply during low-power operation (V11_STANDBY)

LVR	Low voltage reset
Main core	Core initiating the chip Standby mode request (for example, the core corresponding to the "core index" in MC_ME's MAIN_COREID register)
Pad keeping	Maintains I/O pad configuration during Standby mode, if enabled
V11_STANDBY	Core logic and clock sources, low-voltage supply to Standby domain
V11_RUN	Low-voltage supply to Run domain
V15	High-current input for core or logic supply from either an external BJT or from direct 1.5 V external supply
V25	Flash memory, FXOSC, and PLLDIG high-voltage supply
VDDA_ADC	ADC supply voltage
VREFH	ADC high-voltage reference supply
VREFL	ADC low-voltage reference supply
VSS	Core logic ground supply
VDD_HV_A	Main I/O voltage supply (5 V or 3.3 V)
VDD_HV_B	Other I/O domain voltage supply (5 V or 3.3 V)
VRC_CTRL	PMC voltage regulator control output using the BJT option to generate a 1.5 V supply
WFI	Wait for interrupt software instruction

Chapter 41
Power Management Controller (PMC for MWCT2D17S and MWCT2D16S)

41.1 Introduction

PMC is the power management controller for the MWCT2S family of microcontrollers. It provides multiple power options to allow you to optimize power consumption for the level of functionality needed. It includes internal voltage regulators, POR, and the integrated low/high voltage detect system with reset (brown-out) capability. The voltage regulator requires a 3.3 V or 5 V input to generate all the required secondary supplies.

41.2 Features

PMC includes the following features:

- Combination of internal and external voltage regulator options, offering RUN and Standby modes
- Active POR providing brown-out detect
- LVR for all system-relevant power domains
- LVD and HVD as indication for software

41.3 Modes of operation

PMC provides two basic modes of operation for the voltage regualtors and monitors:

- FPM, which is used on chip-level in RUN modes: For high-current consumption
- LPM, which is used on chip-level for Standby modes: For low-current consumption

41.4 Block diagram

The following figure shows the block diagram for this module.

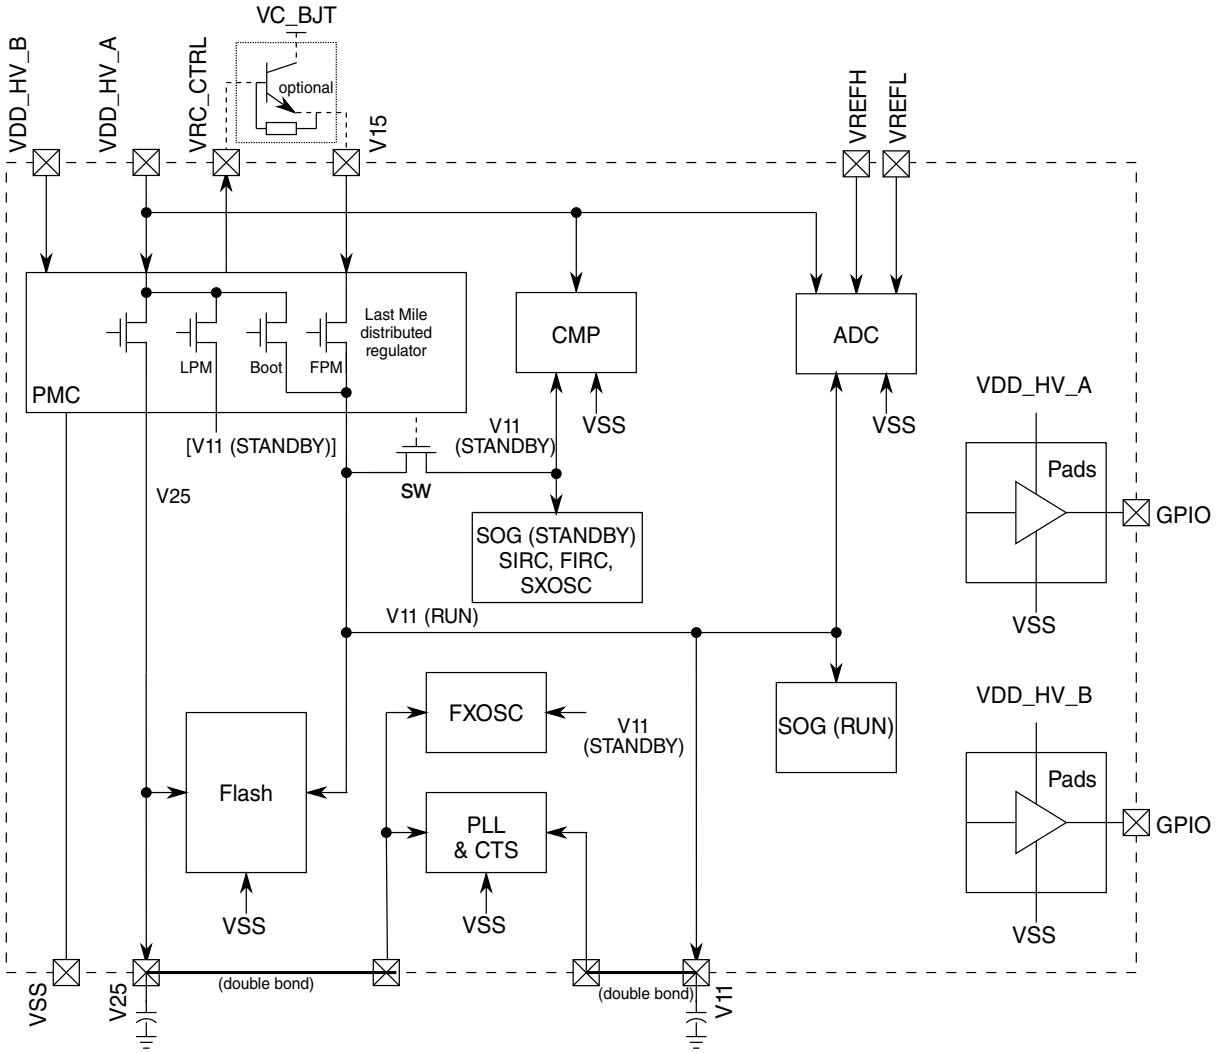

Figure 161. PMC block diagram

41.5 Signals

This table describes the PMC module signals.

Table 210. Signal Description

Signal	I/O	Description
VDD_HV_A	Supply input	This is the primary high-voltage supply input to PMC. VDD_HV_A is used for the PMC internal precision references. After the VDD_HV_A domain is powered up, it must be kept powered at all times of operation (FPM and LPM).
VDD_HV_B[1]	Supply input	This is the secondary high-voltage supply input supervised by the PMC. After the VDD_HV_B domain is powered up, it must be kept powered at all times of operation (FPM and LPM).

Table continues on the next page...

Table 210. Signal Description (continued)

Signal	I/O	Description
V25	Supply output	V25 power supply domain is driven by a fully integrated low-dropout linear voltage regulator. It supplies the Flash memory and (via a double bond) the clock modules.
V15[1]	Supply input	This is the high-current input for core/logic supply that can be fed by an external BJT or another source.
VRC_CTRL	Output	VRC_CTRL connects to the base of external BJT, if this option is used to generate V15.
V11	Supply output	V11 is the core/logic supply. It is driven by a fully integrated low-dropout linear voltage regulator.
VSS	Ground	VSS must be grounded. All VSS Pins need to be externally connected to the same ground node.

1. VDD_HV_B and V15 not present in MWCT2015S and MWCT2016S.

41.6 Functional description

The following sections describe functional details of the PMC.

41.6.1 Reset

The POR and all LVRs are combined into one single MCU POR.

After an MCU POR event, it can be determined which power domain caused it, by reading in the PMC_LVSC register, the POR flag, and LVR flags.

After an initial power ramp up of the MCU in the PMC_LVSC register, the POR flag and the LVR flags are all set to 1. The Go/Nogo flags have an arbitrary value.

NOTE

After an initial power ramp up, all flags in the LVSC register must be cleared (by writing 0xFFFFFFFF to the LVSC register).

Because the flags are sticky bits, it is required to clear them before usage. So, in case of an unxepected MCU POR, the source of the problem can be tracked and debugged by reading the flags in the LVSC register.

41.6.2 Interrupts

PMC includes two interrupt sources:

- HVD interrupt: It combines all HVD monitors into one interrupt source. Interrupt enable is the HVDIE field in the CONFIG register. See the PMC Configuration Register (CONFIG) and Low Voltage Status and Control Register (LVSC) registers for details.
- LVD interrupt: It combines the LVD15 and LVD5A monitors into one interrupt source. Interrupt enable is the LVDIE field in the CONFIG register. See the CONFIG and LVSC registers for details.

41.7 PMC register descriptions

41.7.1 PMC memory map

This section includes the PMC module memory map and detailed descriptions for all the registers.

DEFAULT_NICKNAME base address: 0h

Offset	Register	Width (In bits)	Access	Reset value
0h	Low Voltage Status and Control Register (LVSC)	32	W1C	See description
4h	PMC Configuration Register (CONFIG)	32	RW	See description
Ch	Version ID register (VERID)	32	RO	0200_0001h

41.7.2 Low Voltage Status and Control Register (LVSC)

Offset

Register	Offset
LVSC	0h

Function

This register contains status and control bits to support the low-voltage reset and low- or high-voltage detect function. When the PMC is in LPM, the low- or high-voltage detect systems are disabled.

NOTE

For all flags that are not affected by reset (POR flag, all LVR flags, all GNG flags), in case a reset occurs at the same time while trying to clear the flags (by writing 1), the flag value is not defined appropriately. In this case, you need to clear the flag again after exit from reset.

Fields

Field	Function
31	POR flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
PORF	Indicates that a power-on reset event has occurred. Writing 1 to this field clears it, and other reset sources have no effect. 0b - No power-on reset event has occurred 1b - Power-on reset event has occurred
30-26 —	Reserved
25 GNG11OSCF	Go/NoGo detect flag on Osc part of V11 domain Indicates that the Go/NoGo sensor has detected a low voltage on the V11 domain in FPM. This applies to only that part of the domain which supplies the 1.1V clocking modules (for example, PLL). Writing 1 to the field clears it, and other reset sources have no effect. 0b - No event has occurred 1b - NoGo event has occurred
24 GNG25OSCF	GO/NoGo detect flag on Osc part of V25 domain Indicates that the Go/NoGo sensor has detected a low voltage on the V25 domain in FPM. This applies to only that part of the domain which supplies the 2.5V clocking modules (for example, XOSC and IRC). Writing 1 to the field clears it, and other reset sources have no effect. 0b - No event has occurred 1b - NoGo event has occurred
23 LVR11LPF	LVR11LP flag on V11 domain Indicates that a low-voltage reset event has occurred on the 1.1V V11 power domain (FPM or LPM). Writing 1 to the field clears it, and other reset sources have no effect. 0b - No low-voltage reset event has occurred 1b - Low-voltage reset event has occurred
22 LVR11F	LVR11 flag on V11 domain in FPM Indicates that a low-voltage reset event has occurred on the 1.1V V11 power domain in the FPM. Writing 1 to this field clears it, and other reset sources have no effect. 0b - No low-voltage reset event has occurred 1b - Low-voltage reset event has occurred
21 LVR25LPF	LVR25LP flag on V25 domain Indicates that a low-voltage reset event has occurred on the V25 power domain (FPM or LPM). Writing 1 to this field clears it, and other reset sources have no effect. 0b - No low-voltage reset event has occurred 1b - Low-voltage reset event has occurred
20	LVR25 flag on V25 domain in FPM

Table continues on the next page...

Table continued from the previous page...

Field	Function
LVR25F	Indicates that a low-voltage reset event has occurred on the V25 power domain in FPM. Writing 1 to this field clears it, and other reset sources have no effect. 0b - No low-voltage reset event has occurred 1b - Low-voltage reset event has occurred
19 LVRBLPF	LVRBLP flag on VDD_HV_B domain Indicates that a low-voltage reset event has occurred on the VDD_HV_B power domain (FPM or LPM). Writing 1 to this field clears it, and other reset sources have no effect. 0b - No low-voltage reset event has occurred 1b - Low-voltage reset event has occurred
18 LVRBF	LVRB flag on VDD_HV_B domain in FPM Indicates that a low-voltage reset event has occurred on the VDD_HV_B power domain in FPM. Writing 1 to this field clears it, and other reset sources have no effect. 0b - No low-voltage reset event has occurred 1b - Low-voltage reset event has occurred
17 LVRALPF	LVRALP flag on VDD_HV_A domain Indicates that a low-voltage reset event has occurred on the VDD_HV_A power domain (FPM or LPM). Writing 1 to this field clears it, and other reset sources have no effect. 0b - No low-voltage reset event has occurred 1b - Low-voltage reset event has occurred
16 LVRAF	LVRA flag on VDD_HV_A domain in FPM Indicates that a low-voltage reset event has occurred on the VDD_HV_A power domain in FPM. Writing 1 to this field clears it, and other reset sources have no effect. 0b - No low-voltage reset event has occurred 1b - Low-voltage reset event has occurred
15-14 —	Reserved
13 LVD15S	LVD15 status on V15 domain in FPM Shows the status of the 1.5V low-voltage detect, LVD15, on the V15 power domain. This monitor indicates when the V15 voltage level generated from external is on target. This feature is available only in FPM and disabled in LPM. After a reset or wakeup from LPM, the software should clear the LVD15F flag and check the status bit LVD15S to determine voltage level on V15 supply. 0b - Voltage on V15 is above low-voltage detect threshold or LPM. 1b - Voltage on V15 is below low-voltage detect threshold and FPM.
12	LVD5A status on VDD_HV_A domain in FPM

Table continues on the next page...

Table continued from the previous page...

Field	Function
LVD5AS	Shows the status of the 5V low-voltage detect, LVD5A, on the VDD_HV_A power domain. This monitor indicates if the voltage is below a certain threshold, which is set slightly below 4.5V (see Datasheet for exact value). The feature is only available in FPM and disabled in LPM. After a reset or wakeup from LPM, the software should clear the LVD5AF flag and check the status bit LVD5AS to determine voltage level on VDD_HV_A supply. 0b - Voltage on VDD_HV_A is above low-voltage detect threshold 1b - Voltage on VDD_HV_A is below low-voltage detect threshold
11 HVD11S	HVD11 status on V11 domain in FPM Shows the status of the high-voltage detect, HVD11, on the V11 power domain. This feature is only available in FPM and disabled in LPM. 0b - Voltage on V11 is below high-voltage detect threshold or LPM. 1b - Voltage on V11 is above high-voltage detect threshold and FPM.
10 HVD25S	HVD25 status on V25 domain in FPM Shows the status of the high-voltage detect, HVD25, on the V25 power domain. The feature is only available in FPM and disabled in LPM. 0b - Voltage on V25 is below high-voltage detect threshold or LPM. 1b - Voltage on V25 is above high-voltage detect threshold and FPM.
9 HVDBS	HVDB status on VDD_HV_B domain in FPM Shows the status of the high-voltage detect, HVDB, on the VDD_HV_B power domain. The feature is only available in FPM and disabled in LPM. 0b - Voltage on VDD_HV_B is below high-voltage detect threshold or LPM. 1b - Voltage on VDD_HV_B is above high-voltage detect threshold and FPM.
8 HVDAS	HVDA status on VDD_HV_A domain in FPM Shows the status of the high-voltage detect HVDA on the VDD_HV_A power domain. The feature is only available in FPM and disabled in LPM. 0b - Voltage on VDD_HV_A is below high-voltage detect threshold or LPM. 1b - Voltage on VDD_HV_A is above high-voltage detect threshold and FPM.
7-6 —	Reserved
5 LVD15F	LVD15 flag on V15 domain in FPM PMC writes 1 to the LVD15F field when the LVD15S status field changes. To clear LVD15F, write 1 to it. If enabled, LVD15F causes an interrupt request. 0b - LVD15S has not changed. 1b - LVD15S has changed.

Table continues on the next page...

Table continued from the previous page...

Field	Function
4 LVD5AF	LVD5A flag on VDD_HV_A domain in FPM PMC writes 1 to this field when LVD5AS status field changes. To clear LVD5AF, write 1 to it. If enabled, LVD5AF causes an interrupt request. 0b - LVD5AS has not changed. 1b - LVD5AS has changed.
3 HVD11F	HVD11 flag on V11 domain in FPM PMC writes 1 to this field when the HVD11S status field changes. To clear HVD11F, write 1 to it. If enabled, HVD11F causes an interrupt request. 0b - HVD11S has not changed. 1b - HVD11S has changed.
2 HVD25F	HVD25 flag on V25 domain in FPM PMC writes 1 to the HVD25F field when HVD25S status field changes. To clear HVD25F, write 1 to it. If enabled, HVD25F causes an interrupt request. 0b - HVD25S has not changed. 1b - HVD25S has changed.
1 HVDBF	HVDB flag on VDD_HV_B domain in FPM PMC writes 1 to the HVDBF field when HVDBS status field changes. To clear HVDBF, write 1 to it. If enabled, HVDBF causes an interrupt request. 0b - HVDBS has not changed. 1b - HVDBS has changed.
0 HVDAF	HVDA flag on VDD_HV_A domain in FPM PMC writes 1 to the HVDAF field when HVDAS status field changes. To clear HVDAF, write 1 to it. If enabled, HVDAF causes an interrupt request. 0b - HVDAS has not changed. 1b - HVDAS has changed.

41.7.3 PMC Configuration Register (CONFIG)

Offset

Register	Offset
CONFIG	4h

Function

If the Last Mile Regulator option is not available on your device (Version ID register (VERID) register: LMFEAT=0), then the bits LMEN, LMBCTLEN, LMAUTOEN and LMSTAT fields can not be written and read always 0.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0														LMSTAT	LMAUTOEN

R	0						LVDIE	HVDIE	0			LVRBLPEN	LPM25EN	FASTREC	LMBCTLEN	LMEN
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-18 —	Reserved
17 LMSTAT	Last Mile regulator status bit This bits reflects the current status of the Last Mile regulator. This information is required as when auto turn over feature is enabled (LMAUTOEN=1) the PMC will switch automatically between Boot regulator and Last Mile regulator debending on the V15 status (LVD15S). 0b - Last Mile Regulator is off 1b - Last Mile Regulator is on
16 LMAUTOEN	Last Mile regulator auto turn over bit Enables to turn over automatically from Boot Regulator Mode to Last Mile regulator mode and vice versa depending on the V15 voltage status (LVD15S). As long as LMEN=0 software must make sure that the system clock is on FIRC clock or slower. To use higher clock speed software must set LMEN=1. 0b - Auto turnover disabled 1b - Auto turnover enabled
15-10 —	Reserved
9 LVDIE	Low voltage detect interrupt enable Enables hardware interrupt requests if any of the following flags is set: LVD5AF, LVD15F. LVD interrupt must be disabled before going into LPM. 0b - LVD hardware interrupt is disabled (use polling). 1b - Request an LVD hardware interrupt when LVDA5F=1 or LVD15F=1.
8 HVDIE	High voltage detect interrupt enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Enables hardware interrupt requests if any of the following flags is set: HVDAF, HVDBF, HVD25F, HVD11F. 0b - HVD hardware interrupt is disabled (use polling). 1b - Request an HVD hardware interrupt when HVDAF=1, HVDBF=1, HVD25F=1, or HVD11F=1.
7-5 —	Reserved
4 LVRBLPEN	LVRBLP enable bit during LPM Controls whether the low-voltage reset detection (LVRBLP) on the VDD_HV_B power domain is active or inactive in LPM 0b - Low-voltage reset detection is disabled in LPM. 1b - Low-voltage reset detection is enabled in LPM.
3 LPM25EN	V25 domain enable bit during LPM Controls whether the V25 regulator and low-voltage reset detection (LVR25LP) are active or inactive in LPM 0b - V25 regulator and LVR25LP are disabled in LPM. 1b - V25 regulator and LVR25LP are enabled in LPM.
2 FASTREC	Fast recovery from LPM enable bit Controls the recovery time from LPM to FPM. At recovery from LPM, all the tank capacitors from the secondary supplies have to be recharged. This causes a high-current demand, which might not be met by the supply driving the VDD_HV_A primary domain. When selecting the fast recovery time, the current for recharging is approximately three times higher than that for FASTREC=0. The application must determine from the drive capability of the external VDD_HV_A regulator, the size of tank caps on the secondary supply pins and the selected recovery time if this is sufficient to start up from LPM in time. 0b - Normal recovery time from LPM 1b - Fast recovery time from LPM
1 LMBCTLEN	Last Mile regulator base control enable bit This field must be set to 1 if external BJT between VDD_HV_A and V15 is used on the PCB. The base of this BJT must be connected to the VRC_CTRL pin and is controlled by the PMC to regulate a voltage of 1.5V on V15 pin. After setting LMBCTLEN=1 the software has to wait for 15us (FASTREC=1) respectively 50us (FASTREC=0) before polling LVD15S=0 and then setting LMEN=1. This respects the softstart time of the V15 regulator. If LMAUTOEN=1 then LMBCTLEN can be left enabled when going into LPM, the hardware will turn the regulator off and back on automatically after recovery from LPM. 0b - External BCTL regulator for V15 disabled 1b - External BCTL regulator for V15 enabled
0 LMEN	Last Mile regulator enable bit

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Enables the Last Mile regulator, which regulates an external 1.5V voltage on V15 down to the core and logic supply (V11 power domain), which is typically 1.1V. Setting LMEN=1 hands over the V11 voltage generation from the Boot regulator to the Last Mile regulator. The software must ensure that before enabling the Last Mile regulator, the voltage on V15 is sufficiently high as indicated by the LVD15S status field (LVD15S=0). To use external BJT between VDD_HV_A and V15, the LMBCTLEN field must be set before the LMEN field, and the software must wait until 1.5V is up (LVD15S=0). If LMAUTOEN=0 then to disable the Last Mile regulator, LMEN and LMBCTLEN must be cleared simultaneously (single register write). The software must disable (LMEN=0) the Last Mile regulator before going into LPM. After setting LMEN=1, software must wait a minimum time of 1.5us before changing clock rate. 0b - Last Mile regulator is disabled. 1b - Last Mile regulator is enabled.

41.7.4 Version ID register (VERID)

Offset

Register	Offset
VERID	Ch

Function

This register returns the major and minor version numbers of hardware implementation.

Chapter 42
Power Management Controller (PMC for MWCT2016S)

42.1 Introduction

PMC provides multiple power options to allow you to optimize power consumption for the appropriate level of functionality. It includes:

- Internal voltage regulators
- POR
- Integrated low and high voltage detection system with reset (brownout) capability

The voltage regulator requires a 3.3 V or 5 V input to generate all the required secondary supplies.

42.2 Features

- A combination of internal and external voltage regulator options, offering Run and Standby modes
- Active POR, providing brownout detect
- LVR for all system-relevant power domains
- Software-readable Low Voltage Status and Control register that contains flags that indicate low- or high-voltage conditions

42.3 Modes of operation

PMC provides two basic modes of operation for voltage regulators and monitors:

- FPM supports chip run modes that have high current consumption.
- LPM supports chip standby modes that have low current consumption.

42.4 Block diagram

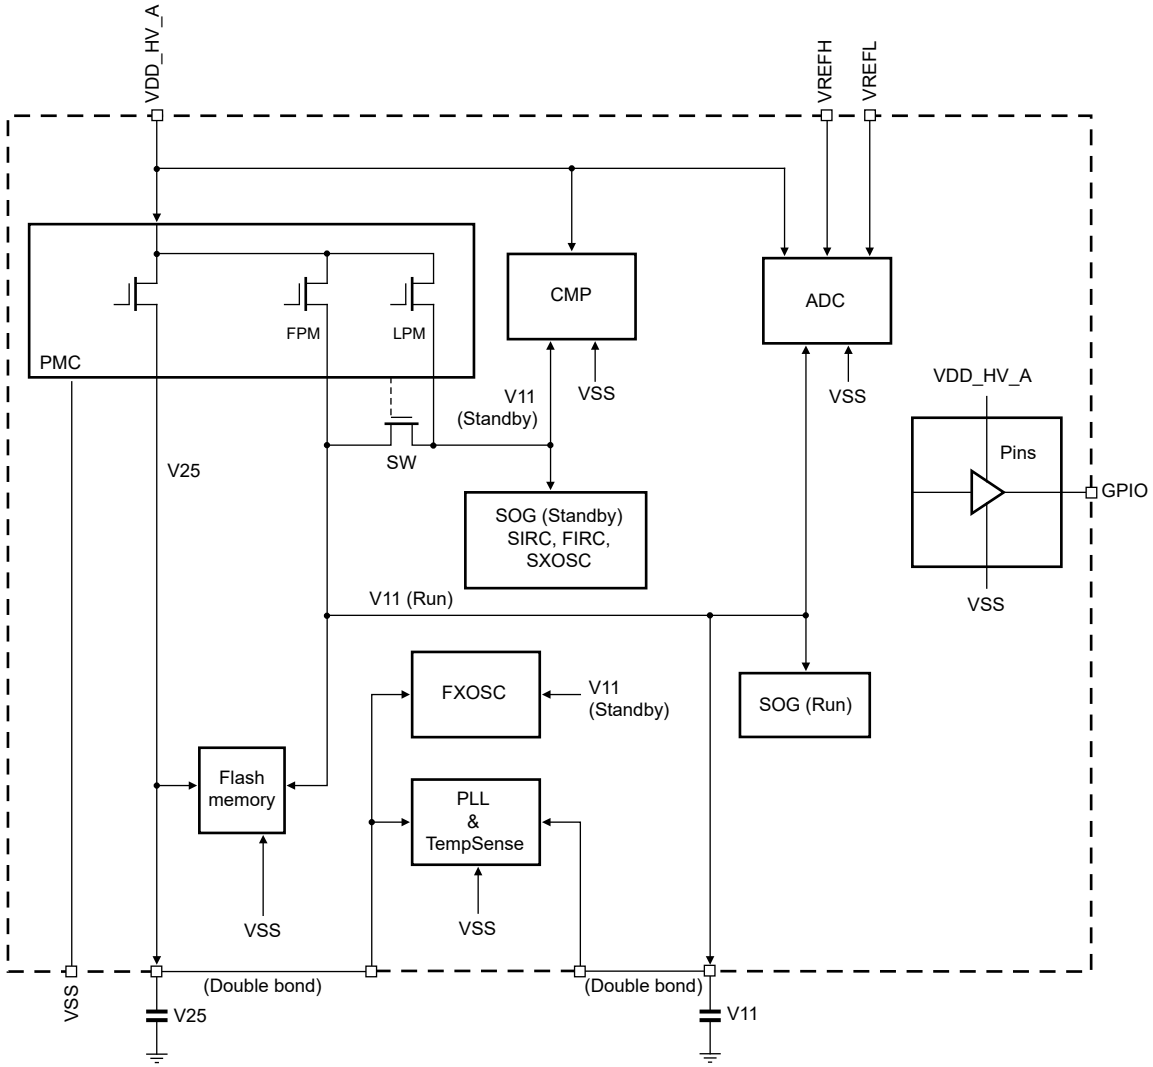

Figure 162. Block diagram

42.5 Signals

Table 211. Signals

Signal	Type	Description
VDD_HV_A	Supply input	The primary high-voltage supply input to PMC. VDD_HV_A is used for the PMC internal precision references. After the VDD_HV_A power domain is powered up, it must always be kept powered for both FPM and LPM.
V25	Supply output	A fully integrated low-dropout linear voltage regulator drives the V25 power supply domain. V25 supplies the flash memory and (via a double bond) the clock modules.

Table continues on the next page...

Table 211. Signals (continued)

Signal	Type	Description
V11	Supply output	V11 is the core and logic supply. A fully integrated low-dropout linear voltage regulator drives V11.
VSS	Ground	VSS must be grounded. You must connect all VSS pins externally to the same ground node.

42.6 Functional description

42.6.1 Reset

[BLG_PMC_RESET]The POR and all LVRs combine into one single chip POR.[end]

After a chip POR event, you can determine which power domain caused it by reading the PORF and LVR*x* flags in Low Voltage Status And Control (LVSC).

After an initial power ramp-up of the chip in LVSC, PMC sets the POR and LVR*x* flags. The go/no go flags have an arbitrary value.

NOTE

After an initial power ramp-up, you must clear all flags in LVSC by writing FFFF_FFFFh to that register.

Because the flags are sticky bits, you must clear them before using them. That way, if an unexpected chip POR occurs you can track and debug the source of the problem by reading the flags in LVSC.

42.6.2 Interrupts

PMC includes two interrupt sources:

- HVD interrupt: Combines all HVD monitors into one interrupt source. CONFIG[HVDIE] enables this interrupt. See PMC Configuration (CONFIG) and Low Voltage Status And Control (LVSC) for details.
- LVD interrupt: The LVD5A monitor is the only interrupt source. CONFIG[LVDIE] enables this interrupt. See PMC Configuration (CONFIG) and Low Voltage Status And Control (LVSC) for details.

Offset

Register	Offset
LVSC	0h

Function

Contains status and control fields that support the low-voltage reset and low- or high-voltage detect functions. When PMC is in LPM, the low- or high-voltage detect systems are disabled.

NOTE

For all flags that are not affected by reset (POR flag, all LVR flags, all GNG flags), if a reset occurs while trying to clear the flags (by writing 1), the flag value is not defined appropriately. In this case, you must clear the flag again after exiting from reset.

22 LVR11F	LVR11 Flag On V11 Power Domain In FPM [BLG_PMC_LVR11F] Indicates that a low-voltage reset event has occurred in the 1.1 V V11 power domain in FPM. Other reset sources have no effect. [end] **NOTE** This field behaves differently for read and write operations. When reading 0b - Event did not occur 1b - Event occurred When writing 0b - No effect 1b - Clear the flag
21 LVR25LPF	LVR25LP Flag On V25 Power Domain [BLG_PMC_LVR25LPF] Indicates that a low-voltage reset event has occurred in the V25 power domain (FPM or LPM). Other reset sources have no effect. [end] **NOTE** This field behaves differently for read and write operations. When reading 0b - Event did not occur 1b - Event occurred When writing 0b - No effect 1b - Clear the flag
20 LVR25F	LVR25 Flag On V25 Power Domain In FPM [BLG_PMC_LVR25F] Indicates that a low-voltage reset event has occurred in the V25 power domain in FPM. Other reset sources have no effect. [end] **NOTE** This field behaves differently for read and write operations.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When reading 0b - Event did not occur 1b - Event occurred When writing 0b - No effect 1b - Clear the flag
19-18 —	Reserved
17 LVRALPF	LVRALP Flag On VDD_HV_A Power Domain [BLG_PMC_LVRALPF] Indicates that a low-voltage reset event has occurred in the VDD_HV_A power domain (FPM or LPM). Other reset sources have no effect. [end] **NOTE** This field behaves differently for read and write operations. When reading 0b - Event did not occur 1b - Event occurred When writing 0b - No effect 1b - Clear the flag
16 LVRAF	LVRA Flag On VDD_HV_A Power Domain In FPM [BLG_PMC_LVRAF] Indicates that a low-voltage reset event has occurred in the VDD_HV_A power domain in FPM. Other reset sources have no effect. [end] **NOTE** This field behaves differently for read and write operations. When reading 0b - Event did not occur 1b - Event occurred When writing 0b - No effect 1b - Clear the flag
15-13 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
12 LVD5AS	LVD5A Status On VDD_HV_A Power Domain In FPM [BLG_PMC_LVD5AS] Indicates whether the voltage on VDD_HV_A is above or below the low-voltage detect threshold. This monitor reflects the status of the 5 V low-voltage detect, LVD5A, and indicates if the voltage is below a certain threshold, which is set slightly below 4.5 V (see the chip data sheet for the exact value). The feature is only available in FPM and is disabled in LPM. After a reset or wake-up from LPM, you must clear the LVD5AF flag and check LVD5AS to determine the voltage level on the VDD_HV_A supply. [end] 0b - Above 1b - Below
11 HVD11S	HVD11 Status On V11 Power Domain In FPM [BLG_PMC_HVD11S] Indicates whether the voltage on V11 is above or below the high-voltage detect threshold. This field reflects the status of the high-voltage detect, HVD11, on the V11 power domain. This feature is only available in FPM and is disabled in LPM. [end] 0b - Voltage is below threshold or chip is in LPM 1b - Voltage is above threshold and chip is in FPM
10 HVD25S	HVD25 Status On V25 Power Domain In FPM [BLG_PMC_HVD25S] Indicates whether the voltage on V25 is above or below the high-voltage detect threshold. This field reflects the status of the high-voltage detect, HVD25, on the V25 power domain. The feature is only available in FPM and is disabled in LPM. [end] 0b - Voltage is below threshold or chip is in LPM 1b - Voltage is above threshold and chip is in FPM
9 —	Reserved
8 HVDAS	HVDA Status On VDD_HV_A Power Domain In FPM [BLG_PMC_HVDAS] Indicates whether the voltage on VDD_HV_A is above or below the high-voltage detect threshold. This field reflects the status of the high-voltage detect, HVDA, on the V25 power domain. The feature is only available in FPM and is disabled in LPM. [end] 0b - Voltage is below threshold or chip is in LPM 1b - Voltage is above threshold and chip is in FPM
7-5 —	Reserved
4 LVD5AF	LVD5A Flag On VDD_HV_A Power Domain In FPM [BLG_PMC_LVD5AF] Indicates whether LVD5AS has changed. When LVD5AS changes, PMC changes LVD5AF to 1. [end]

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for read and write operations. When reading 0b - Did not change 1b - Changed When writing 0b - No effect 1b - Clear the flag
3 HVD11F	HVD11 Flag On V11 Power Domain In FPM [BLG_PMC_HVD11F] Indicates whether HVD11S has changed. When HVD11S changes, PMC changes HVD11F to 1. [end] **NOTE** This field behaves differently for read and write operations. When reading 0b - Did not change 1b - Changed When writing 0b - No effect 1b - Clear the flag
2 HVD25F	HVD25 Flag On V25 Power Domain In FPM [BLG_PMC_HVD25F] Indicates whether HVD25S has changed. When HVD25S changes, PMC changes HVD25F to 1. [end] **NOTE** This field behaves differently for read and write operations. When reading 0b - Did not change 1b - Changed When writing 0b - No effect 1b - Clear the flag
1 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
0 HVDAF	HVDA Flag On VDD_HV_A Power Domain In FPM [BLG_PMC_HVDAF] Indicates whether HVDAS has changed. When HVDAS changes, PMC changes HVDAF to 1. [end] **NOTE** This field behaves differently for read and write operations. When reading 0b - Did not change 1b - Changed When writing 0b - No effect 1b - Clear the flag

42.7.3 PMC Configuration (CONFIG)

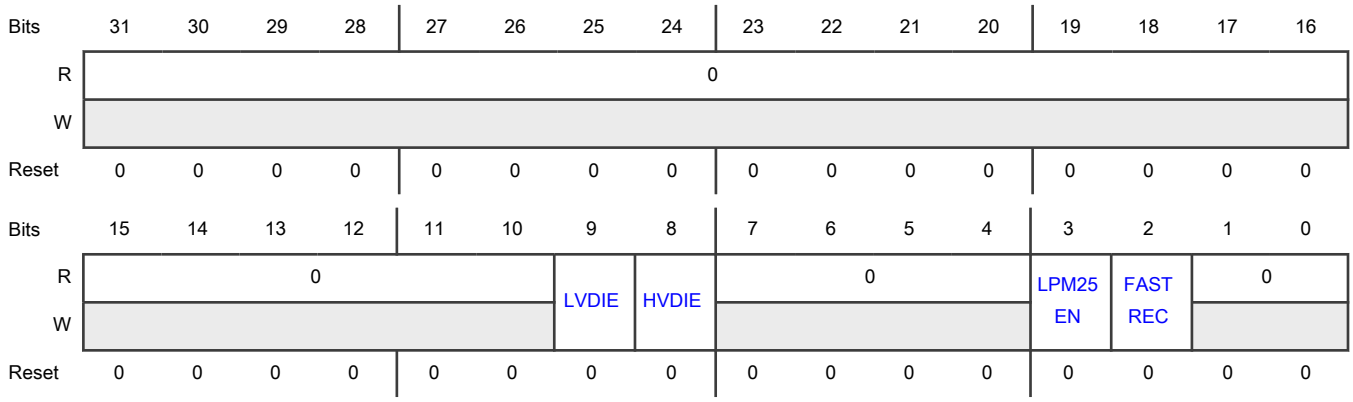
Offset

Register	Offset
CONFIG	4h

Function

Configures PMC.

Diagram



Fields

Field	Function
31-10 —	Reserved
9 LVDIE	Low Voltage Detect Interrupt Enable [BLG_PMC_LVDIE] Enables hardware interrupt requests if LVSC[LVD5AF] = 1. You must disable the LVD interrupt before entering LPM. [end] 0b - LVD hardware interrupt is disabled (use polling) 1b - Request an LVD hardware interrupt when LVDA5F = 1
8 HVDIE	High Voltage Detect Interrupt Enable [BLG_PMC_HVDIE] Enables hardware interrupt requests if any of the following flags in Low Voltage Status And Control (LVSC) are set: • HVDAF • HVDBF • HVD25F • HVD11F [end] 0b - HVD hardware interrupt is disabled (use polling) 1b - Request an HVD hardware interrupt when HVDAF=1, HVDBF=1, HVD25F=1, or HVD11F=1
7-4 —	Reserved
3 LPM25EN	V25 Power Domain Enable During LPM [BLG_PMC_LPM25EN] Controls whether the V25 regulator and low-voltage reset detection (LVR25LP) are enabled or disabled in LPM [end] 0b - Disabled 1b - Enabled
2 FASTREC	Fast Recovery From LPM Enable [BLG_PMC_FASTREC] Controls the recovery time from LPM to FPM. At recovery from LPM, all the tank capacitors from the secondary supplies must be recharged. This causes a high-current demand, which the supply driving the VDD_HV_A primary power domain might not meet. When you select the fast recovery time, the current for recharging is approximately three times higher than that for normal recovery time. You must determine whether this current is sufficient to start up from LPM in time, using these criteria: • Drive capability of the external VDD_HV_A regulator • Size of the tank caps on the secondary supply pin • Selected recovery time

LPM	Low Power mode
LVD	Low voltage detect
LVR	Low voltage reset
POR	Power-on reset

Chapter 43
Mode Entry Module (MC_ME)

43.1 Chip-specific MC_ME information

43.1.1 MC_ME modes

This chip implements these modes:

- Reset
- Run
- Standby

The chip always enters Run mode after exiting Reset mode wherein you can configure the chip to perform its computational and communication functions. In Run mode:

- The chip remains fully powered. The boot core is the only core enabled on Run entry.
- You can enable and disable application cores and peripherals as needed, based on functional and power requirements.
- You can configure the pins and self-test as needed. See "Self-Test programming sequence" section in the STCU2 chapter for the self-test programming sequence to be followed before initiating self-test, in which:
  - Pins are safe-stated.
  - No computational or communication activities are possible.
- The chip automatically enters Reset mode after self-test (BIST) is complete.

43.1.2 Core operation modes

The Cortex-M7 cores in the chip support these two modes of operation:

- Decoupled/independent operation
- Coupled/lockstep operation

The device configuration clients (utest_misc DCF client) control these modes of operation. See the DCF clients file attached to this document for details.

43.1.3 MC_ME partition mapping of cores and peripherals

MC_ME provides registers and interface signals to support multiple partitions. These MC_ME partitions are different from the chip's LBIST partitions described in the "Safety Overview" chapter. This chip has three MC_ME partitions:

- Partition 0: Contains application cores and the on/off-platform slots on AIPS_0 bridge
- Partition 1: Contains the on/off-platform slots on AIPS_1 bridge
- Partition 2: Contains the on/off-platform slots on AIPS_2 bridge

Table 212 and Table 213 specify the core and peripheral mapping on MC_ME partitions and their associated clock gating possiblities.

MC_ME also provides provisions to control the booting address for application cores, which can be configured to start from a nondefault address location by appropriately configuring PRTN*x*_CORE*n*_ADDR[ADDR].

43.1.4 Core clock gating

MC_ME has individual core-clock enable fields that gate the application core clocks, which can also be clock gated by executing Waiting for Interrupt (WFI).

You can enable the application cores by configuring the respective CCE fields. See Application core initialization process and Application core shutdown process for proper initialization and shutdown of application cores. There is no clock control for the HSE_B core. It needs to be only put into WFI if required to be shutdown (for example, in Standby mode).

Table 212. MC_ME partition core mapping

Core	MC_ME partition	MC_ME clock enable register field
Cortex-M7_0	0	MC_ME.PRTN0_CORE0_PCONF[CCE]
Cortex-M7_1 [1]	0	MC_ME.PRTN0_CORE1_PCONF[CCE]

1. Not present on MWCT2016S and MWCT2015S

43.1.5 Peripheral clock gating

See Peripheral initialization process and Peripheral shutdown process for proper initialization and shutdown of peripherals. See Table 213 for peripheral clock gating possibilities.

The application core can program the reserved configurations.

NOTE

Before accessing the registers of a peripheral to start using it, its clock must be turned on, otherwise, a Hard-Fault event will occur.

1. See the memory-map sheet attached to this document for details on available peripherals in different chips.
2. While accessing SELFTEST_GPR space, software must ensure that the STCU2 block has its clock enabled. i.e., MC_ME.PRTN1_COFB3_CLKEN[REQ104] configured as 1'b1. Not ensuring this might result in unpredictable device behaviour.

43.1.6 Application core initialization process

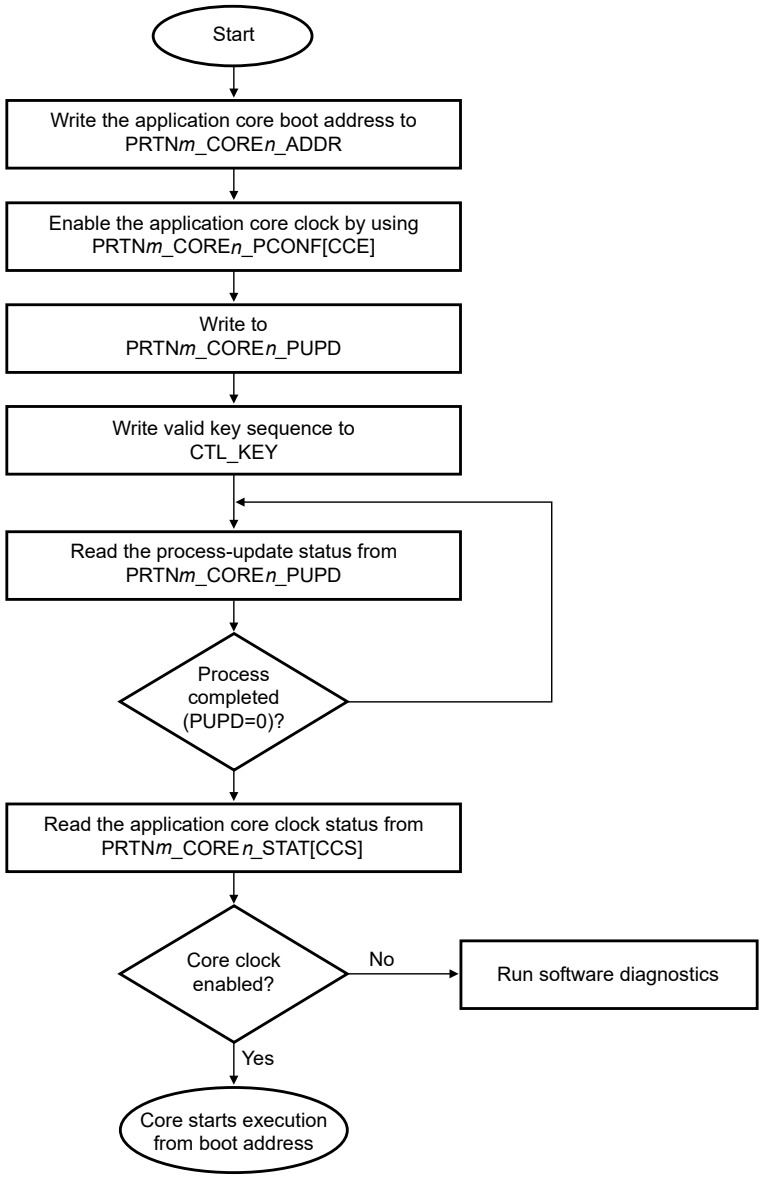

Figure 163. Application core initialization process

43.1.7 Application core shutdown process

If a debugger is attached to the chip and application debug is enabled, the application core continues running if you write 0 to MDM_AP.MDMAPCT[CM7_*n*_CORE_ACCESS].

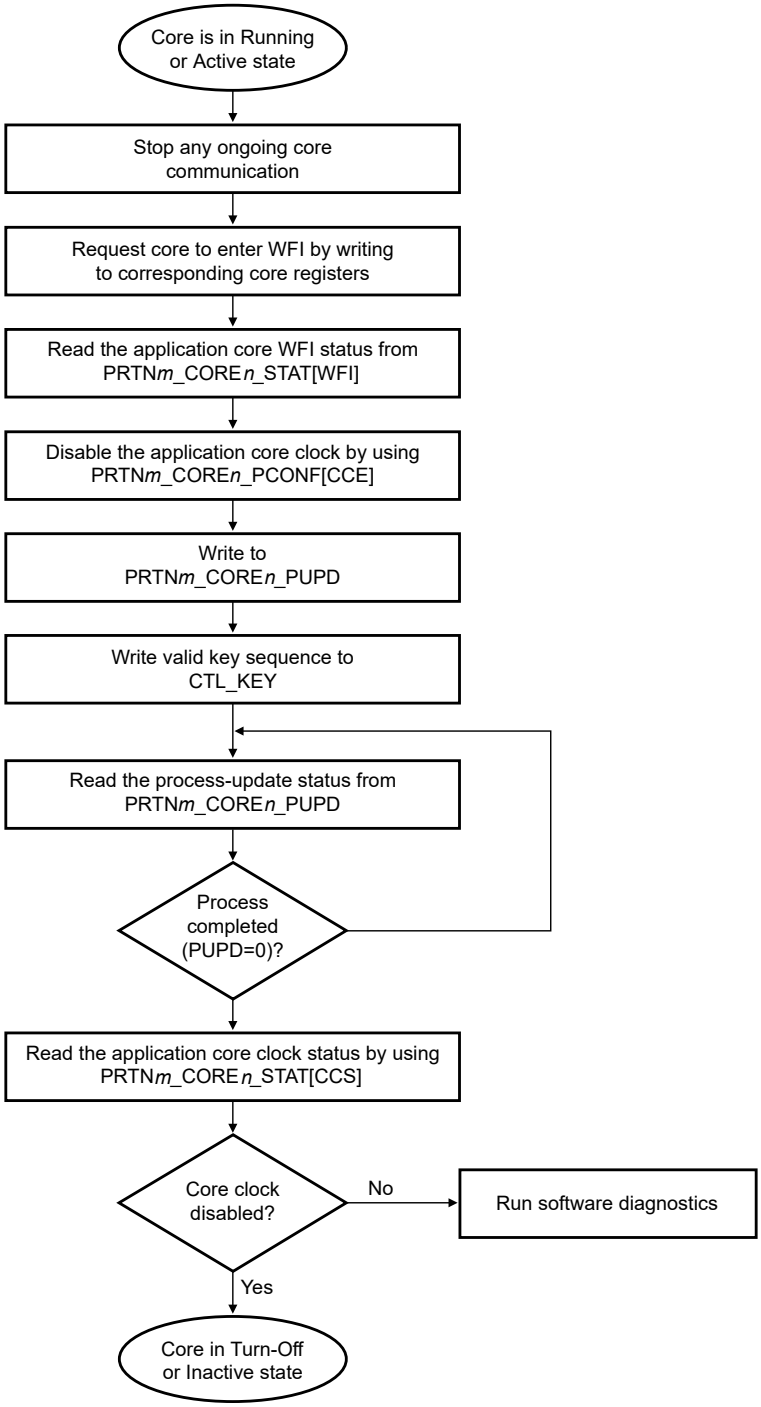

Figure 164. Application core shutdown process

43.1.8 Peripheral initialization process

You cannot control all the peripherals. For example, you cannot turn on and turn off the peripherals required for chip functionality across reset or power-up. They always remain on.

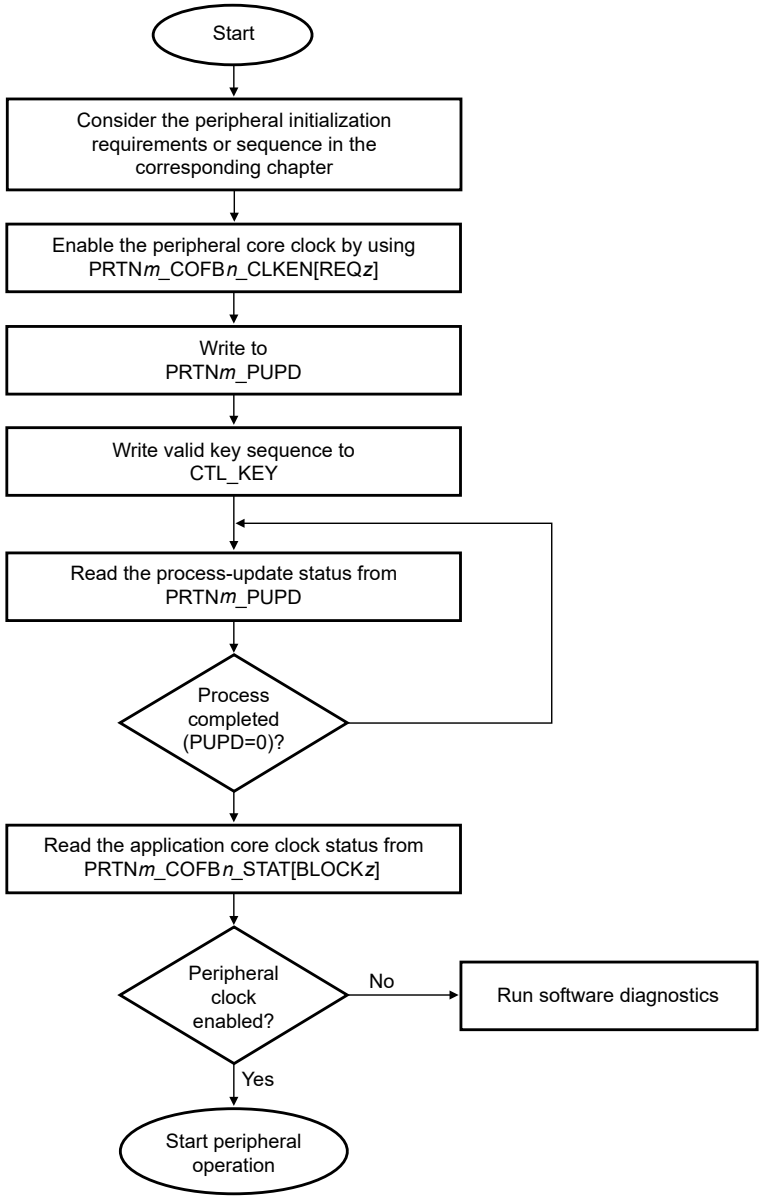

Figure 165. Peripheral initialization process

43.1.9 Peripheral shutdown process

You cannot control all the peripherals. For example, you cannot turn on and turn off the peripherals required for chip functionality across reset or power-up. They always remain on.

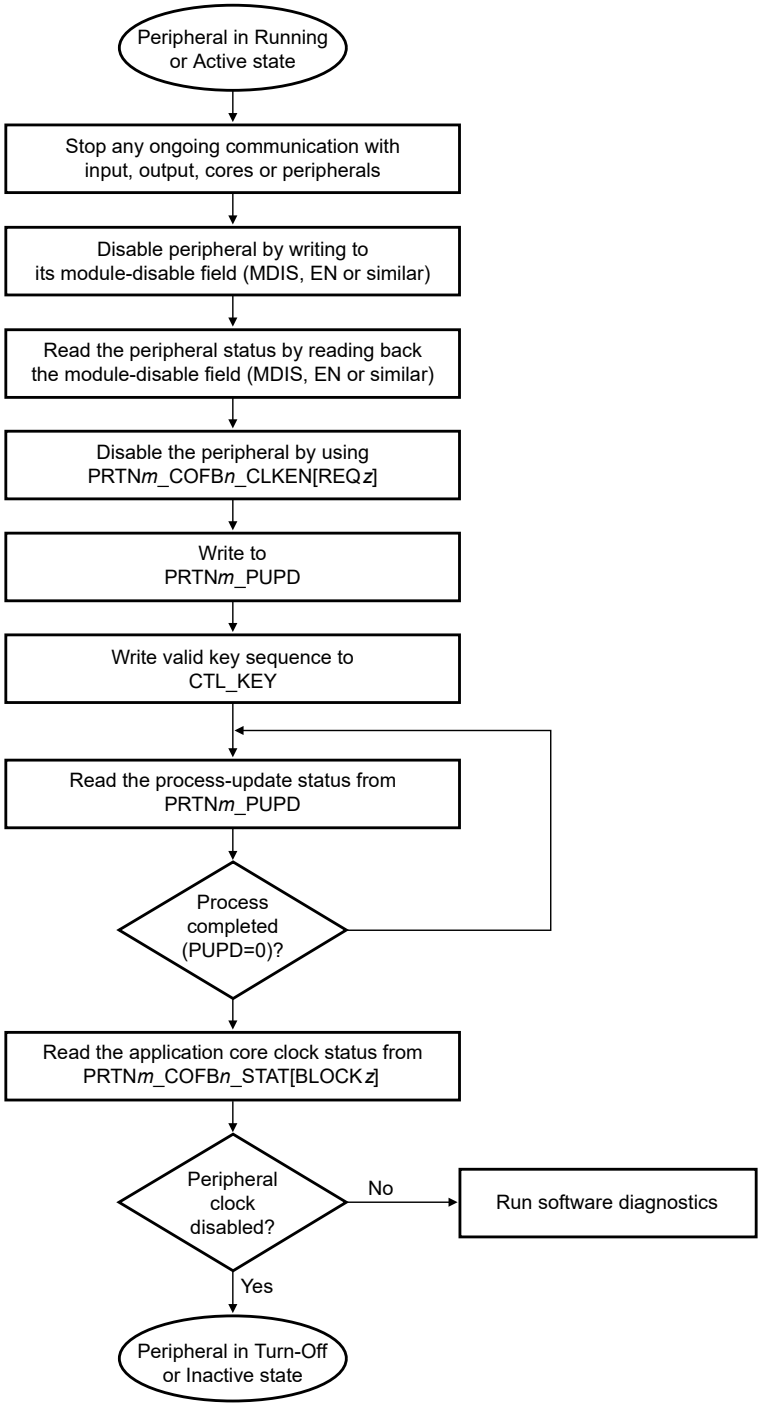

Figure 166. Peripheral shutdown process

43.2 Introduction

The MC_ME module generates control signals for a set of modules of the SoC. The set of signals are defined in corresponding 'Partition Configuration Registers'. It also implements a software-based mechanism for initiating a functional and destructive reset sequence and standby entry handshake with power management of SoC. See Figure 167 for the MC_ME block diagram.

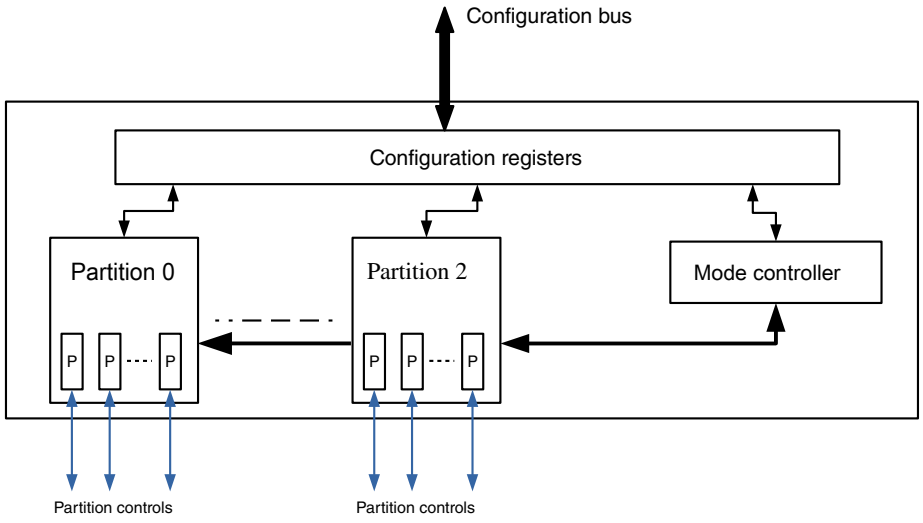

Figure 167. MC_ME block diagram

43.3 Features

MC_ME includes the following features:

- 3 logic partitions implementation and their controls
- Core clock controls
- Partition clock control
- Control mechanism for initiating a destructive or functional reset sequence to MC_RGM
- Control mechanism for initiating standby mode entry for SoC

The logic partition inside MC_ME refers to a certain group of on-chip resources (or IP blocks) that are clubbed together to represent a single 'Partition' inside MC_ME. The MC_ME partition can be the same or different than an LBIST partition. Each of the MC_ME partitions implements a certain number of hardware processes. These hardware processes provide a mechanism to regulate various control signals provided to or received from the IP blocks. The corresponding status signals can also be monitored from MC_ME register(s). Each of the hardware processes is bound to finish in 512 cycles of the MC_ME register configuration clocks. Therefore, the hardware processes are non blocking in nature. Mismatch in the expected versus actual status of any hardware process is controlled by a pre-defined software.

43.4 Partition processes

Each of the processes inside the partition controls register space and corresponds to a control signal provided to that partition. A partition can include a core, or COFBs, or both. The MC_ME hardware processes provide control and status via signals provided to partitions. Each partition can be assigned a signal for control and a signal for status. Each of the control signals implements functionality for the partition. For example, clock gating and peripheral control.

The hardware process can be triggered and monitored using a set of three registers:

- Configuration register; for example, Partition n Process Configuration register
- Update register; for example, Partition n Process Update register
- Status register; for example, Partition n Status register

Similar registers exist for cores inside the partition.

The process setup and triggering procedure is shown in Figure 168. Each of the processes is independent of others and can be triggered or retriggered in parallel or sequential to other processes. The triggering or retriggering mechanism remains the same.

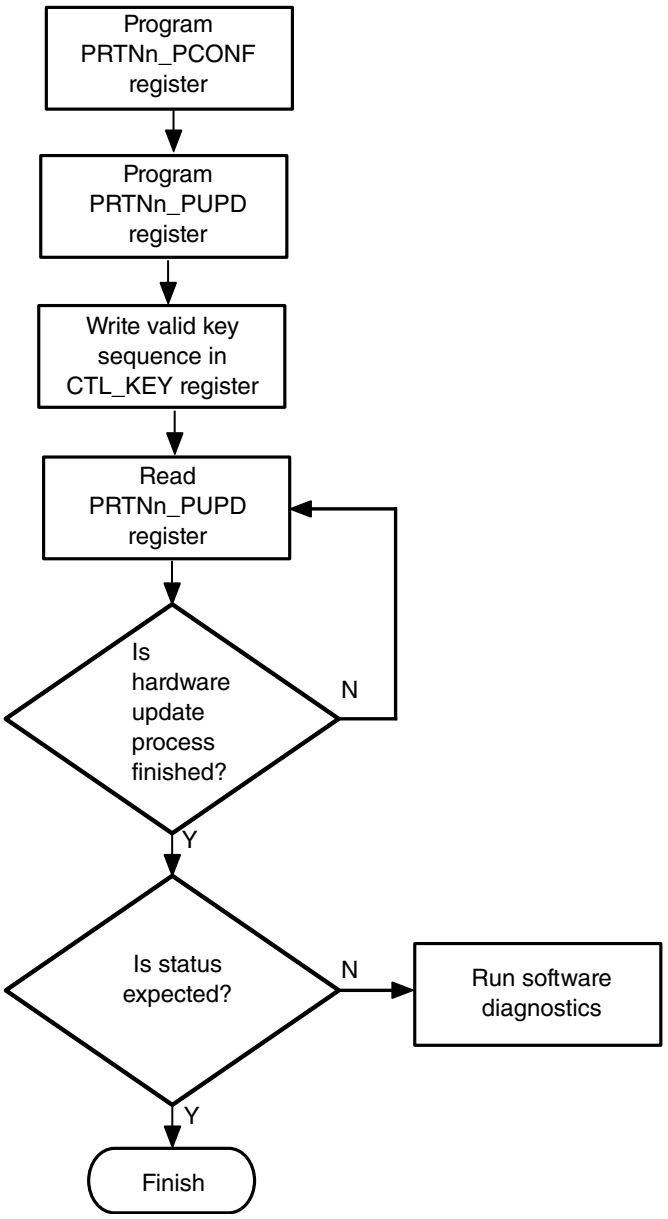

Figure 168. Partition process setup procedure

All the hardware processes are bound to finish in 512 cycles of the MC_ME configuration clock. If the actual and the expected status for a process does not match, then the diagnostics is left as a software responsibility. The software diagnostic can include further wait cycles for the status to match.

43.5 Mode transition

MC_ME implements a mode transition mechanism, whereby the mode of operation for SoC can be changed. Then module implements a mechanism that can lead to:

- Destructive reset
- Functional reset
- Standby mode entry

Destructive reset and functional reset requests from MC_ME are non-retractable transitions. After it is initiated, the other MC_ME functionality is rendered unusable and bus errors are provided for upcoming access to the MC_ME register until a reset sequence is executed by MC_RGM. Hence, it is vital that MC_RGM should never ignore or gate the reset requests from MC_ME.

For transition into the standby mode, the software should ensure that required IP blocks such as clock sources and I/O communication are in their respective inactive states before initiating a standby mode transition to MC_ME. After MC_ME initiates a power down sequence request, it cannot be retracted. The SoC enters a standby power down sequence and then reenter power-up sequence even for cases where the standby wakeup happens right at the time of initiating a power-down sequence request.

Steps for initiating the MC_ME mode transition:

1. Setup the MODE_CONF register with the corresponding target mode bit set to logic-1.
2. Perform the same update as done in the MODE_CONF register on the CONF_UPD register.
3. Write the valid control key (0x5AF0) on the CTL_KEY register.
4. Write the valid invert control key (0xA50F) on the CTL_KEY register.

Mode transition to MC_ME is initiated, after the sequence mentioned above is completed.

In step 1, if both FUNC_RST and DEST_RST in Mode Configuration Register (MODE_CONF) are 1:

- After step 4 is complete, MC_ME initiates a mode transition to a destructive (not functional) reset.
- After the chip exits reset, MC_RGM records that both MC_ME's destructive reset and MC_ME's functional reset were the reset source.

NOTE

Any hardware partition processes setup, along with mode transition, is executed in parallel to the mode transition of MC_ME.

43.6 Standby entry

MC_ME provides hardware processes that implement shutdown sequencing of on-chip resources, such as cores and COFBs. The standby entry sequencing can be achieved or implemented using these hardware processes. The order of the hardware process is determined by the software and MC_ME. It requires no restriction in sequencing of the operation. Following is an example sequence for initiating a power-down sequence for entering the standby mode for SoC. The standby entry sequence should include (but not limited to) the following steps:

1. Setting up wakeup lines
2. Shutting down cores and COFBs
3. Switching all MC_CGM muxes to FIRC with PCFS
4. Powering down all clock sources except FIRC
5. Setting up MC_ME using the main core and initiating a standby mode transition
6. Executing WFI instruction on the main core (per Arm specification)

43.6.1 Application core shutdown

This section describes a mechanism for shutting down an application core. The sequence proposed here is extendible with the housekeeping tasks required for other IPs. Each of the tasks mentioned in the following sequence, can be further integrated with an SoC-specific task.

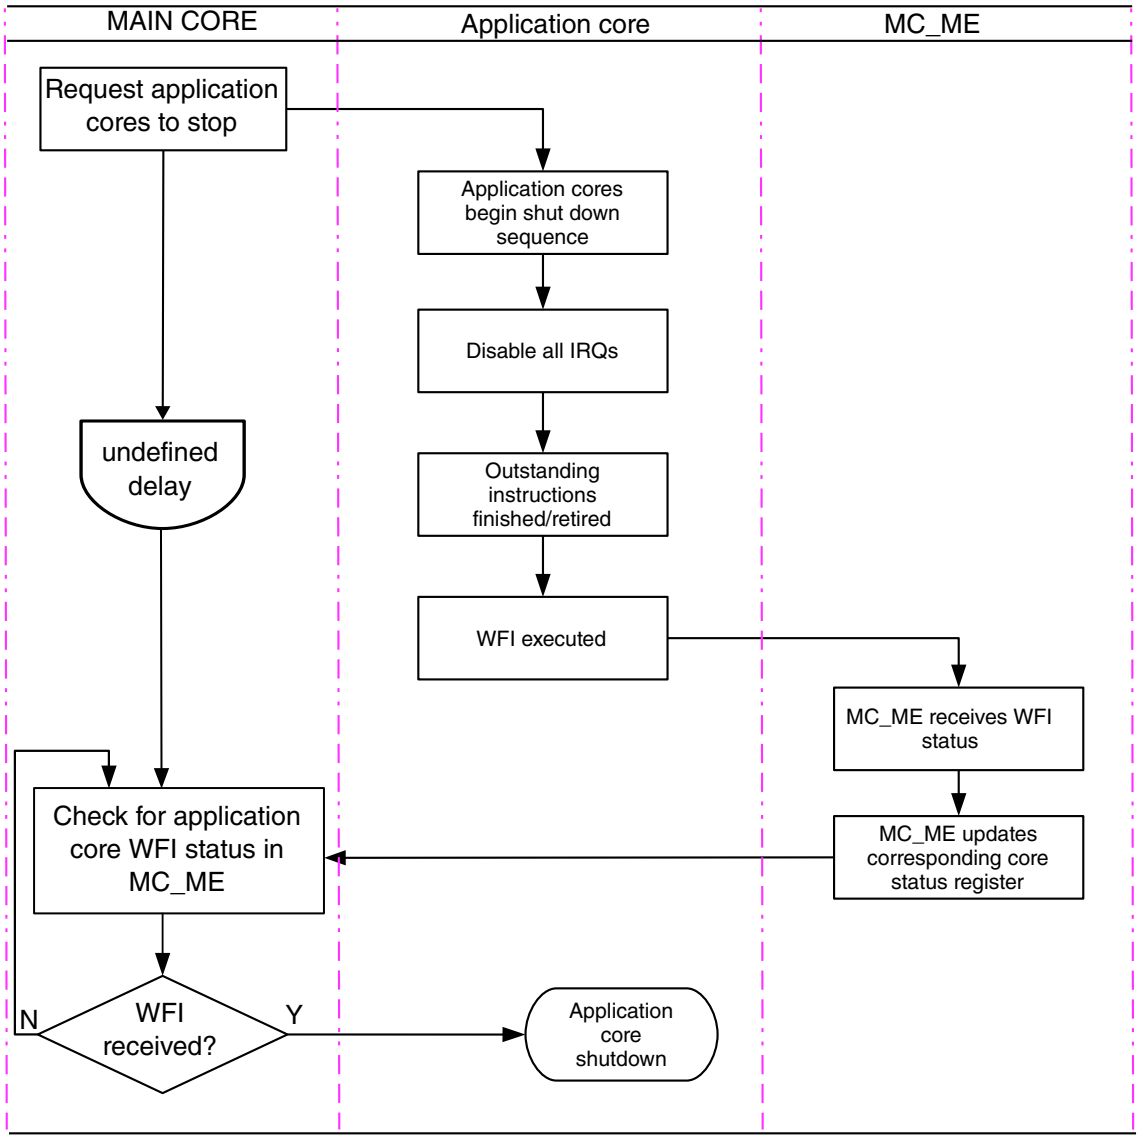

Figure 169. Application core shutdown

After the application core is shutdown, the main core can optionally decide to gate the respective core clock using the corresponding core clock hardware process.

43.6.2 Main core shutdown and standby entry

This section describes standby entry sequence along with the main core shutdown. This sequence should only be initiated after SoC is ready for entering standby and has completed all the housekeeping activities. It is necessary that the main core has completed all the operations pertaining to other (application cores) and is the last active core before initiating the standby entry sequence. See Figure 170.

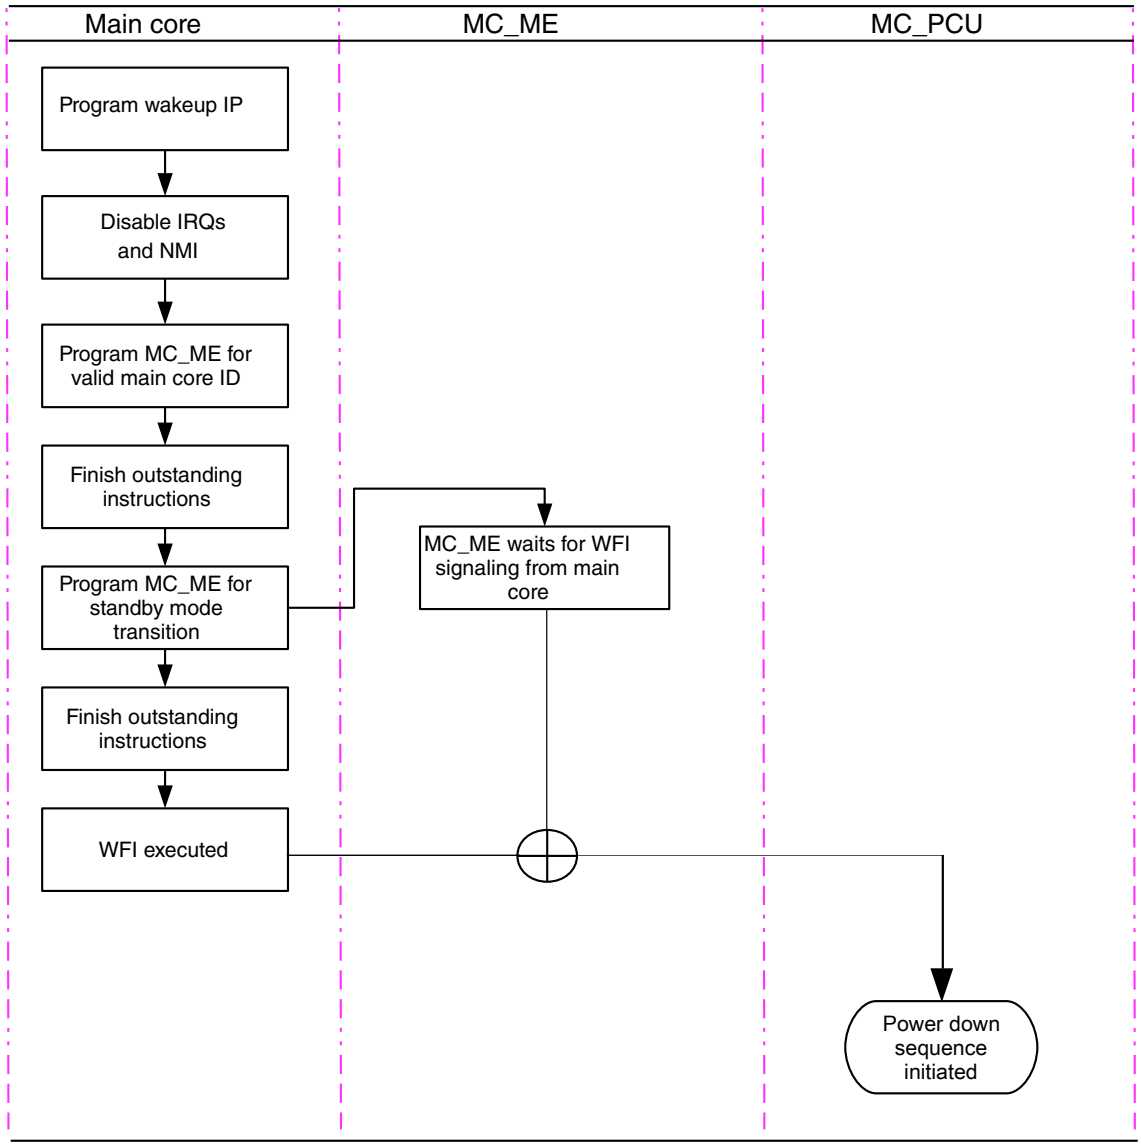

Figure 170. Standby entry sequence along with main core shutdown

NOTE

- MC_ME initiates the power sequence to MC_PCU. This enables the main core to remain inactive (WFI state) until it is reset and power-up again at standby exit.

43.7 MC_ME register descriptions

MC_ME implements set hardware processes that can be used by the software for changing the mode of operation for a partition. Following are the features of MC_ME registers:

- All registers are 32-bit wide.
- Only 32-bit read and write accesses are supported.
- Read/write accesses of less than 32 bits terminate with an error.
- Writes to read-only register fields in writable registers are ignored and do not provide an error message.

- Writes to read-only registers are aborted with an error message.

43.7.2 Control Key Register (CTL_KEY)

Offset

Register	Offset
CTL_KEY	0h

Function

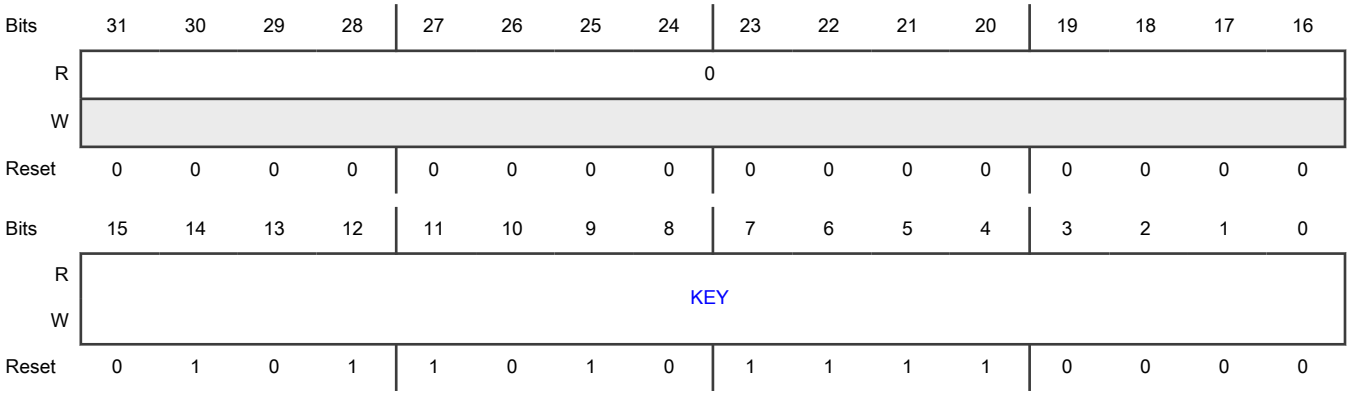
This register provides the mechanism to MC_ME for starting the hardware processes for the partition(s) and standby entry sequence. The hardware processes for partitions are triggered through the corresponding PRTNn_PCONF register. The mechanism to trigger the hardware processes of the respective partitions require two write operations: first time with key and second time with inverted key. The hexadecimal value of key is 0x5AF0 whereas for inverted key is 0xA50F.

For initiating a standby entry sequence, the MODE_CONF register is used for providing a standby entry request along with a valid key combination.

NOTE

Reads from this register return a valid key value to be written next.

Diagram



Fields

Field	Function
31-16 —	Reserved This field is reserved and read returns zeros.
15-0 KEY	Control key Key for starting the hardware processes. Writes with a value other than key or inverted key are ignored. Reads return bit inverted value corresponding to last write.

43.7.3 Mode Configuration Register (MODE_CONF)

Offset

Register	Offset
MODE_CONF	4h

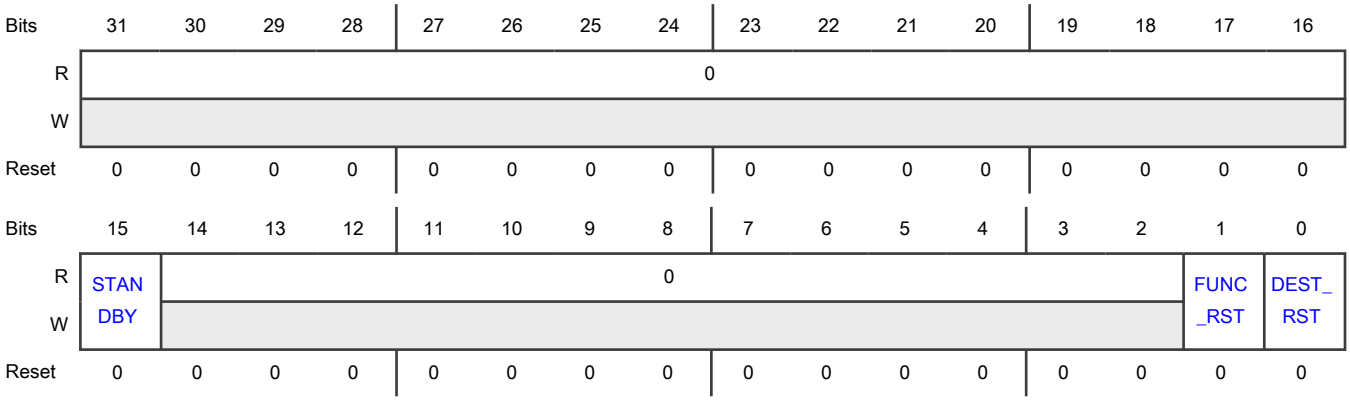
Function

This register is used for initiating a standby request or a reset event (destructive or functional) for the chip. The functional or destructive events are signaled to MC_RGM for further handling.

NOTE

Software must not enable mode entry if the value of multiple fields is 1 in the MODE_CONF register.

Diagram



Fields

Field	Function
31-16 —	Reserved This field is reserved and read returns zeros.
15 STANDBY	Standby request Writing a logic-1 to this bit along with the MODE_UPD register configuration and followed with a valid key combination makes a standby entry sequence request to MC_ME.
14-2 —	Reserved This field is reserved and read returns zeros.
1 FUNC_RST	Functional reset request Writing a logic-1 to this bit along with the MODE_UPD register configuration and followed with a valid key combination makes a functional reset event signaling to MC_RGM.
0 DEST_RST	Destructive reset request Writing a logic-1 to this bit along with the MODE_UPD register configuration and followed with a valid key combination makes a destructive reset event signaling to MC_RGM.

43.7.4 Mode Update Register (MODE_UPD)

Offset

Register	Offset
MODE_UPD	8h

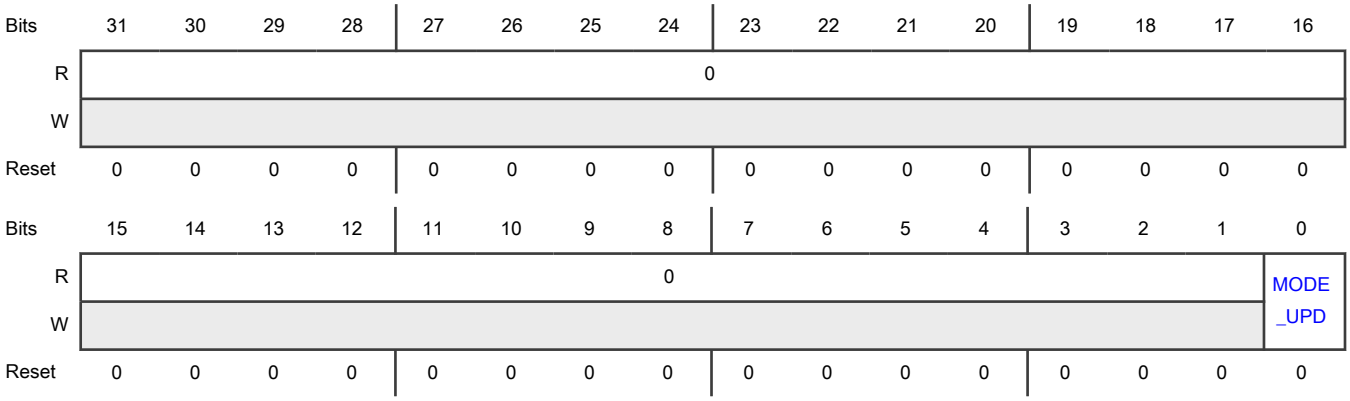
Function

This register is used for initiating a mode change. Mode change refers to initiating a standby request, or generating a destructive or functional reset event to MC_RGM. Setting mode update field to logic-1, along with programming MODE_CONF registers and then followed by a valid key combination will generate a mode transition request.

NOTE

The MODE_UPD register is implemented to make mode transition programming model the same as partition programming model. This is for future expansion inside MC_ME.

Diagram



Fields

Field	Function
31-1 —	Reserved This field is reserved and read returns zeros.
0 MODE_UPD	Mode update Writing a logic-1 to this bit, followed by a valid key combination initiates a mode change as per the MODE_CONF register.

43.7.5 Mode Status Register (MODE_STAT)

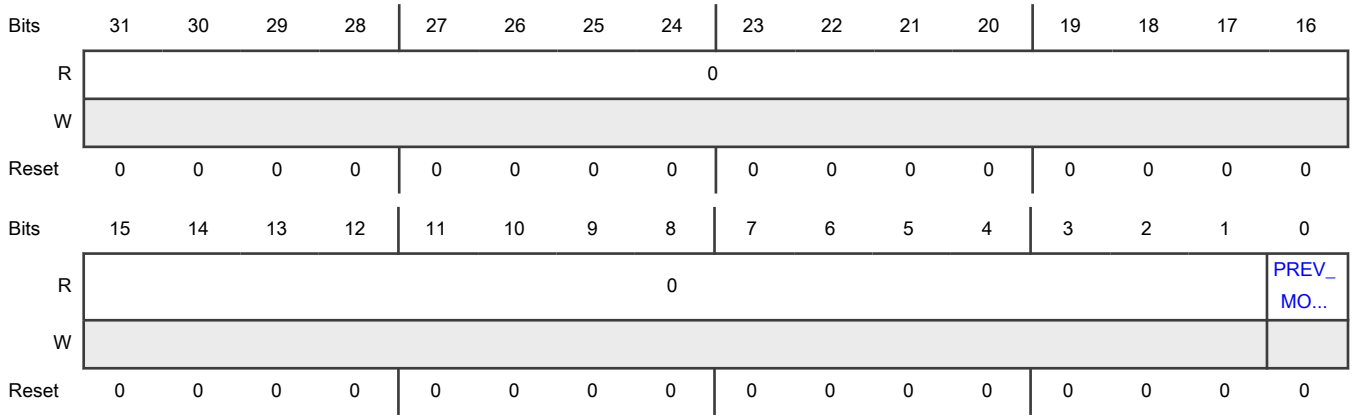
Offset

Register	Offset
MODE_STAT	Ch

Function

This register provides the status of the previous mode. In case of standby exit, if the reset event status register of MC_RGM are set, then contents of this register should be ignored.

Diagram



Fields

Field	Function
31-1 —	Reserved This field is reserved and read returns zeros.
0 PREV_MODE	Previous mode This bit shows the status of the previous mode. 0b - The previous mode was reset (any reset). 1b - The previous mode was standby.

43.7.6 Main Core ID Register (MAIN_COREID)

Offset

Register	Offset
MAIN_COREID	10h

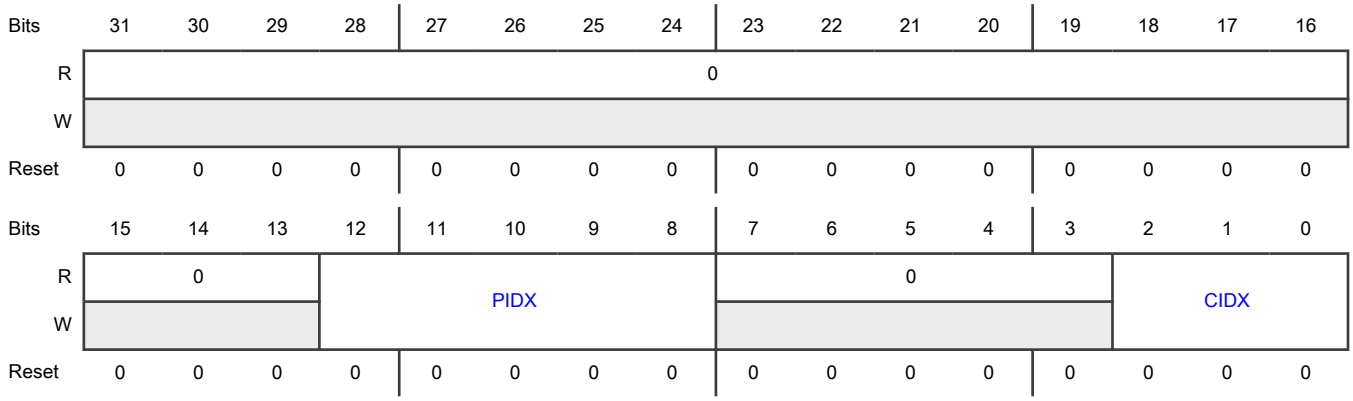
Function

This register provides the ID of the main core sequencing the operation for the standby sequence. Core ID is required for entering in the standby mode, and using this MC_ME locates the WFI instruction execution of the main core. The core ID in this register is specified by the partition index along with the core index.

NOTE

Before initiating a standby entry sequence, the contents of this register should point to the correct main core. Providing non-existing or incorrect core ID leads to unpredictable hardware behavior.

Diagram



Fields

Field	Function
31-13 —	Reserved This field is reserved and read returns zeros.
12-8 PIDX	Partition index Provides the partition index of the main core. Only values 0 - 2 can be written.
7-3 —	Reserved This field is reserved and read returns zeros.
2-0 CIDX	Core index Provides the core index of the main core inside the partition.

43.7.7 Partition 0 Process Configuration Register (PRTN0_PCONF)

Offset

Register	Offset
PRTN0_PCONF	100h

Function

This register provides a configuration for the hardware processes corresponding to partition 0. Each of the configuration bit corresponds to the 'nature' of the processes; for example, enabling/disabling and the trigger is controlled by the corresponding field in the PRTN0_PUPD register. When valid KEY combinations are written onto the CTL_KEY register, the PRTN0_PCONF and PRTN0_PUPD registers are used to determine the hardware processes to be executed. These are triggered in parallel and independent of each other. All dependent processes should be requested one after another from the software.

NOTE

The partition clock enable/disable and output safe stating enable/disable are not standalone and must be done coherently in a fixed sequence. For details, see Software Reset Partition Turn-On Flow Chart and Software reset partition turn-off flowchart in Reset chapter.

1 —	Reserved This field is reserved and read returns zeros.
0 PCE	Partition clock enable This bit controls whether the clock to IPs (other than core(s)) in the partition should be enabled or disabled. 0b - Disable the clock to IPs 1b - Enable the clock to IPs

43.7.8 Partition 0 Process Update Register (PRTN0_PUPD)

Offset

Register	Offset
PRTN0_PUPD	104h

Function

This register provides trigger signaling for the hardware processes corresponding to partition 0. Each of the control bit acts as a trigger for the corresponding hardware processes. When valid KEY combinations are written onto the CTL_KEY register, the hardware checks the bit fields that are programmed as logic-1 in this register, and then triggers the hardware process per the value in the corresponding bit field in the PRTN0_PCONF register. When the hardware process is finished the corresponding bit in this register is auto-cleared to logic-0.

43.7.11 Partition 0 COFB Set 1 Clock Enable Register (PRTN0_COFB1_CLKEN)

Offset

Register	Offset
PRTN0_COFB1_CLKEN	134h

Function

This register provides clock control signaling to the individual COFBs in set 1 inside partition 0. Whenever a partition clock enable (non-core) hardware process is initiated, the value of logic-1 in the corresponding bit locations of this register enables the clock to the corresponding block in the partition.

NOTE

The reset value of this register is not defined and is as per the availability of the clock source. See Chip-specific MC_ME information for clock source availability.

43.7.12 Partition 0 Core 0 Process Configuration Register (PRTN0_CORE0_PCONF)

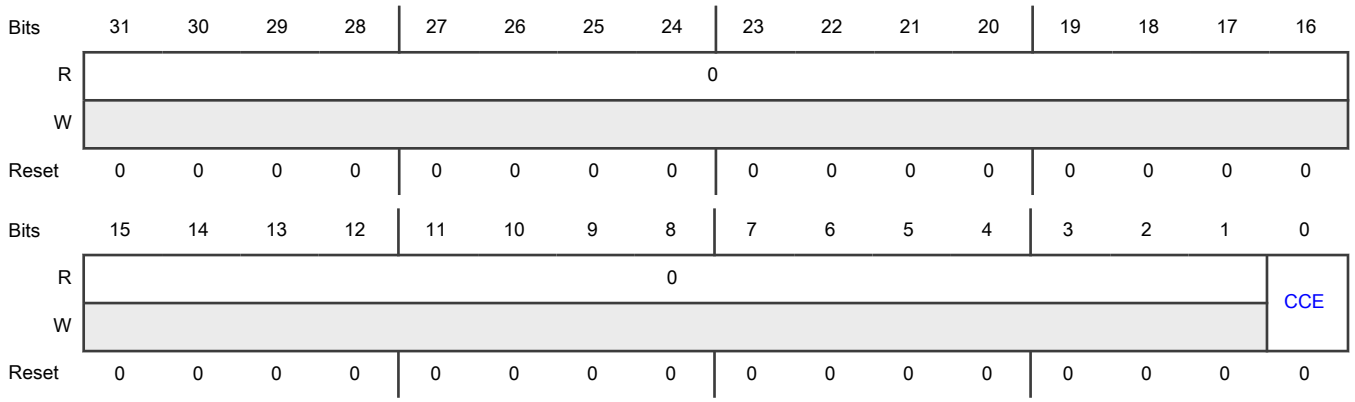
Offset

Register	Offset
PRTN0_CORE0_PCONF	140h

Function

This register provides configurations for the Core 0 hardware processes corresponding to partition 0. Each of the configuration bit corresponds to the 'nature' of the processes; for example, enabling/disabling and the trigger is controlled by the corresponding field in the PRTN0_CORE0_PUPD register. When valid KEY combinations are written onto the CTL_KEY register, the PRTN0_CORE0_PUPD and PRTN0_CORE0_PCONF registers are used to determine the hardware processes to be executed. These processes are triggered in parallel and are independent of each other. All dependent processes should be requested one after another from the software.

Diagram



Fields

Field	Function
31-1 —	Reserved This field is reserved and read returns zeros.
0 CCE	Core 0 clock enable This bit controls whether the clock to Core 0 in partition 0 should be enabled or disabled. 0b - Disable the core clock 1b - Enable the core clock

43.7.13 Partition 0 Core 0 Process Update Register (PRTN0_CORE0_PUPD)

Offset

Register	Offset
PRTN0_CORE0_PUPD	144h

Function

This register provides trigger signaling for the core hardware processes corresponding to partition 0. Each of the control bit acts as a trigger for the corresponding hardware processes. When valid KEY combinations are written onto the CTL_KEY register, the hardware checks the bit fields that are programmed as logic-1 in this register, and then triggers the hardware process per the value in the corresponding bit field in the PRTN0_CORE0_PCONF register. When the hardware process is finished, the corresponding bit in this register is auto-cleared to logic-0.

Field	Function
—	This field is reserved and read returns zeros.
0 CCUPD	Core 0 clock update This bit controls whether the hardware processes for enabling/disabling the clock to Core 0 in the partition 0 should be triggered or not. 0b - Do not trigger the hardware process 1b - Trigger the hardware process

43.7.14 Partition 0 Core 0 Status Register (PRTN0_CORE0_STAT)

Offset

Register	Offset
PRTN0_CORE0_STAT	148h

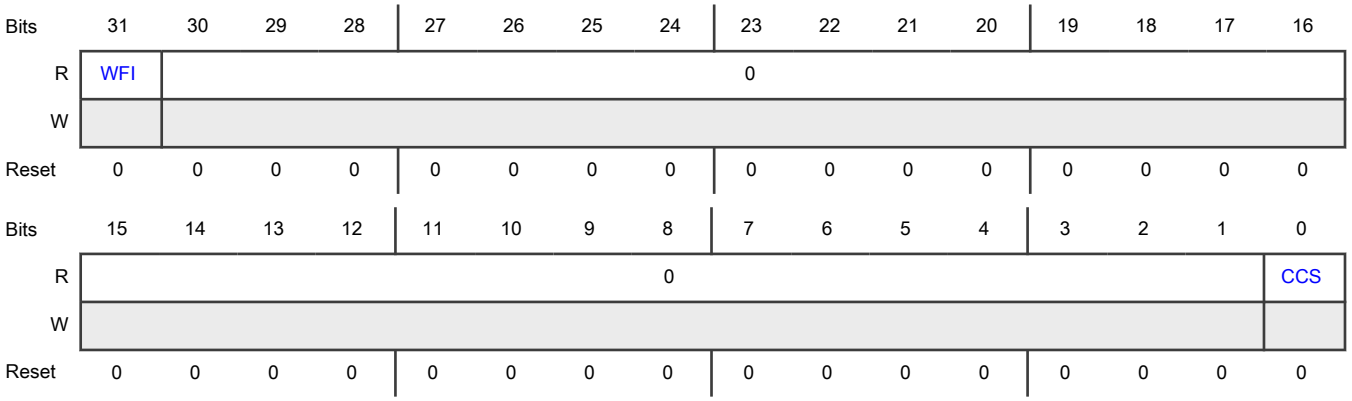
Function

This register provides the status corresponding to Core 0 in partition 0. The status signal corresponds to clock states and the WFI signal included from Core 0.

NOTE

The value held in WFI field of this STATUS register is "current" value of the WFISTANDBY signal from the core. Hence out-of-reset, the reset value of this field will depend on the status of the core (core is running or in low power mode). So, simple reset read sweep will always return current value (different than other register reads such as on control registers).

Diagram



Fields

Field	Function
31 WFI	Wait for interrupt status This bit provides the WFI status approaching from Core 0 in partition 0. 0b - No WFI executed 1b - WFI executed
30-1 —	Reserved This field is reserved and read returns zeros.
0 CCS	Core 0 clock process status This bit provides the status of the clock corresponding to core clock enablement/disablement. 0b - Clock is inactive. 1b - Clock is active.

43.7.15 Partition 0 Core 0 Address Register (PRTN0_CORE0_ADDR)

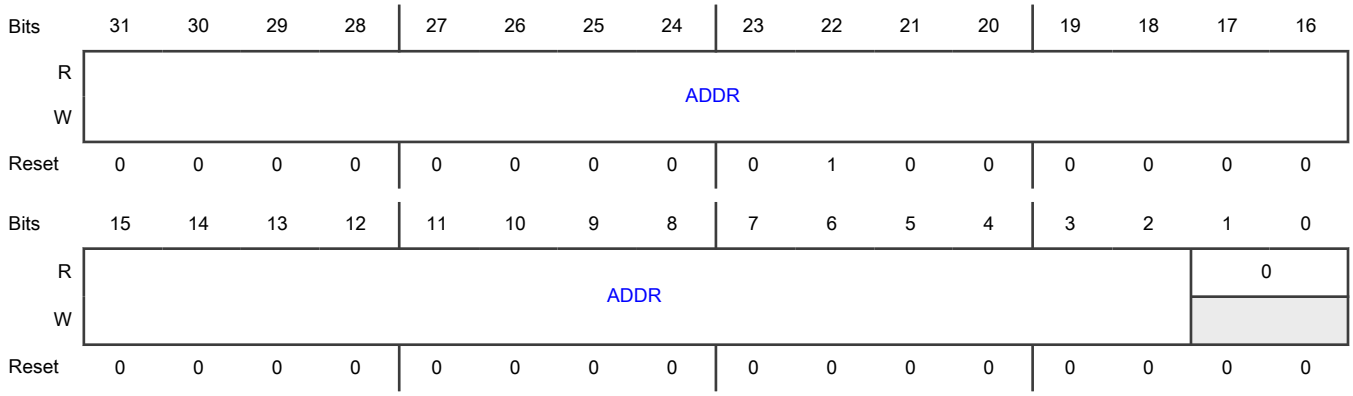
Offset

Register	Offset
PRTN0_CORE0_ADDR	14Ch

Function

This register contains the boot address for Core 0 in partition 0.

Diagram



Fields

Field	Function
31-2 ADDR	Address Core 0 boot address
1-0 —	Reserved This field is reserved and read returns zeros.

43.7.16 Partition 0 Core 1 Process Configuration Register (PRTN0_CORE1_PCONF)

Offset

Register	Offset
PRTN0_CORE1_PCONF	160h

Function

This register provides configurations for the Core 1 hardware processes corresponding to partition 0. Each of the configuration bit corresponds to the 'nature' of the processes; for example, enabling/disabling and the trigger is controlled by the corresponding field in the PRTN0_CORE1_PUPD register. When valid KEY combinations are written onto the CTL_KEY register, the PRTN0_CORE1_PUPD and PRTN0_CORE1_PCONF registers are used to determine the hardware processes to be executed. These processes are triggered in parallel and are independent of each other. All dependent processes should be requested one after another from the software.

1-0 —	Reserved This field is reserved and read returns zeros.

43.7.22 Partition 1 Process Configuration Register (PRTN1_PCONF)

Offset

Register	Offset
PRTN1_PCONF	300h

Function

This register provides a configuration for the hardware processes corresponding to partition 1. Each of the configuration bit corresponds to the 'nature' of the processes; for example, enabling/disabling and the trigger is controlled by the corresponding field in the PRTN1_PUPD register. When valid KEY combinations are written onto the CTL_KEY register, the PRTN1_PCONF and PRTN1_PUPD registers are used to determine the hardware processes to be executed. These are triggered in parallel and independent of each other. All dependent processes should be requested one after another from the software.

NOTE

The partition clock enable/disable and output safe stating enable/disable are not standalone and must be done coherently in a fixed sequence. For details, see Software Reset Partition Turn-On Flow Chart and Software reset partition turn-off flowchart in Reset chapter.

43.7.28 Partition 1 COFB Set 3 Clock Status Register (PRTN1_COFB3_STAT)

Offset

Register	Offset
PRTN1_COFB3_STAT	31Ch

Function

This register provides the status of set 3 of COFBs inside partition 1.

NOTE

The reset value of this register can vary depending on the availability of active clock pulses inside partition 1.

43.7.29 Partition 1 COFB Set 0 Clock Enable Register (PRTN1_COFB0_CLKEN)

Offset

Register	Offset
PRTN1_COFB0_CLKEN	330h

Function

This register provides clock control signaling to the individual COFBs in set 0 inside partition 1. Whenever a partition clock enable (non-core) hardware process is initiated, the value of logic-1 in the corresponding bit locations of this register enables the clock to the corresponding block in the partition.

NOTE

The reset value of this register is not defined and is as per the availability of the clock source. See Chip-specific MC_ME information for clock source availability.

1 —	Reserved This field is reserved and read returns zeros.
0 REQ96	Clock enable This bit provides the clock enable control for CRC in partition 1. 0b - Clock is turned off. 1b - Clock is turned on.

43.7.33 Partition 2 Process Configuration Register (PRTN2_PCONF)

Offset

Register	Offset
PRTN2_PCONF	500h

Function

This register provides a configuration for the hardware processes corresponding to partition 2. Each of the configuration bit corresponds to the 'nature' of the processes; for example, enabling/disabling and the trigger is controlled by the corresponding field in the PRTN2_PUPD register. When valid KEY combinations are written onto the CTL_KEY register, the PRTN2_PCONF and PRTN2_PUPD registers are used to determine the hardware processes to be executed. These are triggered in parallel and independent of each other. All dependent processes should be requested one after another from the software.

NOTE

The partition clock enable/disable and output safe stating enable/disable are not standalone and must be done coherently in a fixed sequence. For details, see Software Reset Partition Turn-On Flow Chart and Software reset partition turn-off flowchart in Reset chapter.

Field	Function
1 —	Reserved This field is reserved and read returns zeros.
0 PCE	Partition clock enable This bit controls whether the clock to IPs (other than core(s)) in the partition should be enabled or disabled. 0b - Disable the clock to IPs 1b - Enable the clock to IPs

43.7.34 Partition 2 Process Update Register (PRTN2_PUPD)

Offset

Register	Offset
PRTN2_PUPD	504h

Function

This register provides trigger signaling for the hardware processes corresponding to partition 2. Each of the control bit acts as a trigger for the corresponding hardware processes. When valid KEY combinations are written onto the CTL_KEY register, the hardware checks the bit fields that are programmed as logic-1 in this register, and then triggers the hardware process per the value in the corresponding bit field in the PRTN2_PCONF register. When the hardware process is finished the corresponding bit in this register is auto-cleared to logic-0.

43.7.38 Partition 2 COFB Set 0 Clock Enable Register (PRTN2_COFB0_CLKEN)

Offset

Register	Offset
PRTN2_COFB0_CLKEN	530h

Function

This register provides clock control signaling to the individual COFBs in set 0 inside partition 2. Whenever a partition clock enable (non-core) hardware process is initiated, the value of logic-1 in the corresponding bit locations of this register enables the clock to the corresponding block in the partition.

NOTE

The reset value of this register is not defined and is as per the availability of the clock source. See Chip-specific MC_ME information for clock source availability.

Chapter 44
Power Control Unit (MC_PCU)

44.1 Introduction

The power control unit (MC_PCU) is used for initiating a Standby mode entry that reduces the overall chip power consumption. Power can be saved by disconnecting parts of the chip from the power supply. The blocks inside the chip are grouped into multiple parts having this capability, which are called "power domains".

When a power domain is disconnected from the supply, the power consumption is reduced to zero in that domain. Any status information, such as, power domain is lost. When you reconnect a power domain to the supply voltage, the domain draws an increased current until the power domain reaches its operational voltage. Maximum power saving is achieved by entering the Standby mode.

After the MC_ME asserts a standby entry request, MC_PCU initiates the power sequence, which is non-retractable and includes the handshake with the chip power management controller. The power-up/down sequences are handled by FSMs to ensure a smooth and safe transition into and out of the Standby mode. Exiting the Standby mode can only be done through a system wakeup event, power-on reset, destructive reset, or a functional reset.

44.2 Power sequence FSM

MC_PCU implements an FSM to initiate the power sequencing of the Standby mode entry/exit sequence for the chip.

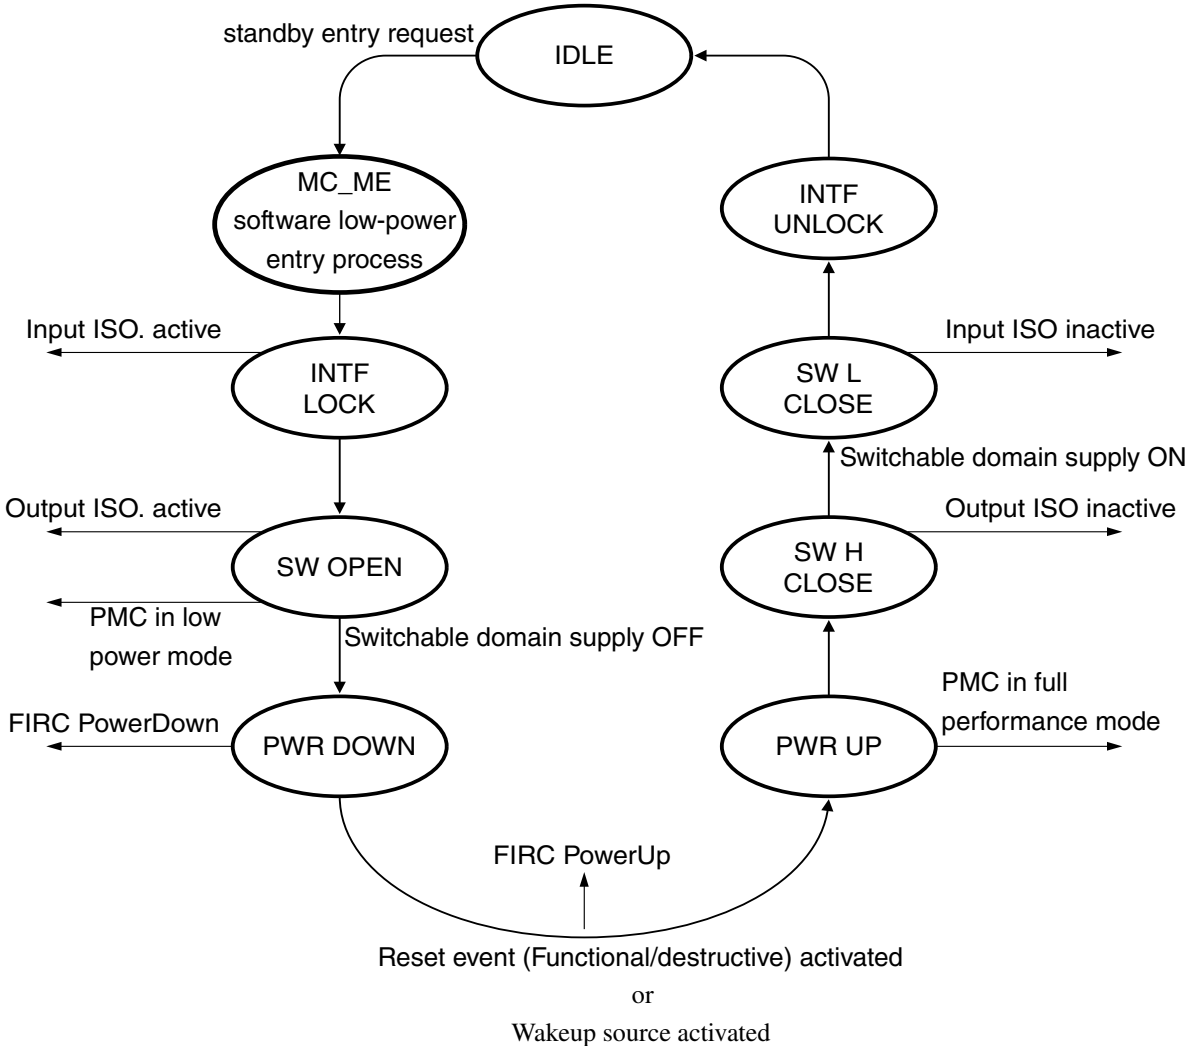

Figure 171. MC_PCU FSM

NOTE

When destructive reset is asserted from MC_RGM, MC_PCU FSM moves to the IDLE state immediately. Indication of this is not shown in the above figure.

Table 214. MC_PCU FSM transition description

State	Name	Exit condition	Signal controlled	Signal monitored
IDLE	Idle state	Standby request received from MC_ME	-	-
MC_ME software low power entry process	MC_ME software low power entry process	Software entry sequence completed (SW4 process completed)	-	-

Table continues on the next page...

Table 214. MC_PCU FSM transition description (continued)

44.3 Glossary

FSM Finite state machine

Chapter 45
Wakeup Unit (WKPU)

45.1 Chip-specific WKPU information

45.1.1 WKPU configuration on the chip

WKPU provides the following features:

- A configurable, low-power wake-up capability to the chip from multiple configurable asynchronous wake-up events.
- Support for four internal and minimum 59 external source depending on the chip, that can generate interrupts or wake-up events.
- Support for an NMI input.

Table 215. WKPU configuration on the chip

Number of sources, interrupts, and vectors	MWCT2D17S/ MWCT2D16S/ MWCT2016S/ MWCT2015S/ MWCT2014S	Description
NMI sources	1	Single NMI pin routed to all application cores
Internal wake-up sources	4	• SWT_0 wake-up, RTC-API wake-up • RTC timeout • Analog comparator round robin wake-up (from LPCMP_0, 1, and 2 round robin wake-up)[1] • RTI wake-up
External wake-up sources	60	Minimum 59 GPIO pins (WKPU[0]-WKPU[59])[2] support the wake-up functionality. See the IOMUX file attached to this document for details.
Glitch filters for external interrupts	60	Glitch filter on each external wake-up source
External interrupt vectors	8	—

1. Both wake-up sources 0 (RTC-API) and 2 (CMP_*x* trigger mode wake-up) use RTC-API wake-up, with Trigger mode having a higher priority. This means, if you configure LPCMP_*x*.RRCR0[ERR_EN] for either of the comparators, the RTC_API wake-up is used only for the CMP_*x* trigger mode operation. The RTC-API wake-up does not cause wake-up from Standby mode in this scenario.
2. For MWCT2016S, WKPU[34] is reserved.

All of the aforementioned wake-up sources can be enabled or disabled. Also, you can configure these wake-up sources, by using WKPU configuration registers, to provide wake-up on rising or falling events. See the WKPU register memory map for details.

NOTE

You must use SIUL2 to perform WKPU pin configurations (PUE, PUS, and IBE). For this, you must first configure SIUL2.MSCR[IBE] for the corresponding pin. This chip does not support WKPU-provided pin configurations; it supports only bypass control.

45.1.2 WKPU register fields and their applicability

Table 216. WKPU register fields and applicability

Register	Field	Chips where applicable
NSR	NIF1	MWCT2D17S, MWCT2D16S
NSR	NOVF1	MWCT2D17S, MWCT2D16S
NCR	NLOCK1	MWCT2D17S, MWCT2D17S
NCR	NDSS1	MWCT2D17S, MWCT2D17S
NCR	NWRE1	MWCT2D17S, MWCT2D17S
NCR	NREE1	MWCT2D17S, MWCT2D17S
NCR	NFEE1	MWCT2D17S, MWCT2D17S
NCR	NFE1	MWCT2D17S, MWCT2D17S

45.1.3 WKPU NMI configuration

WKPU supports one external source that can cause non-maskable interrupts to on-chip cores and wake-up events to the system.

The following figure shows applicable cores, some family chips may not have cores Cortex-M7_1 or Cortex-M7_2. In case of a wake-up event (internal or external), WKPU initiates the recovery of the chip and feeds an interrupt to the core(s) depending on the configuration. The sections that follow provide details related to the associated configurations.

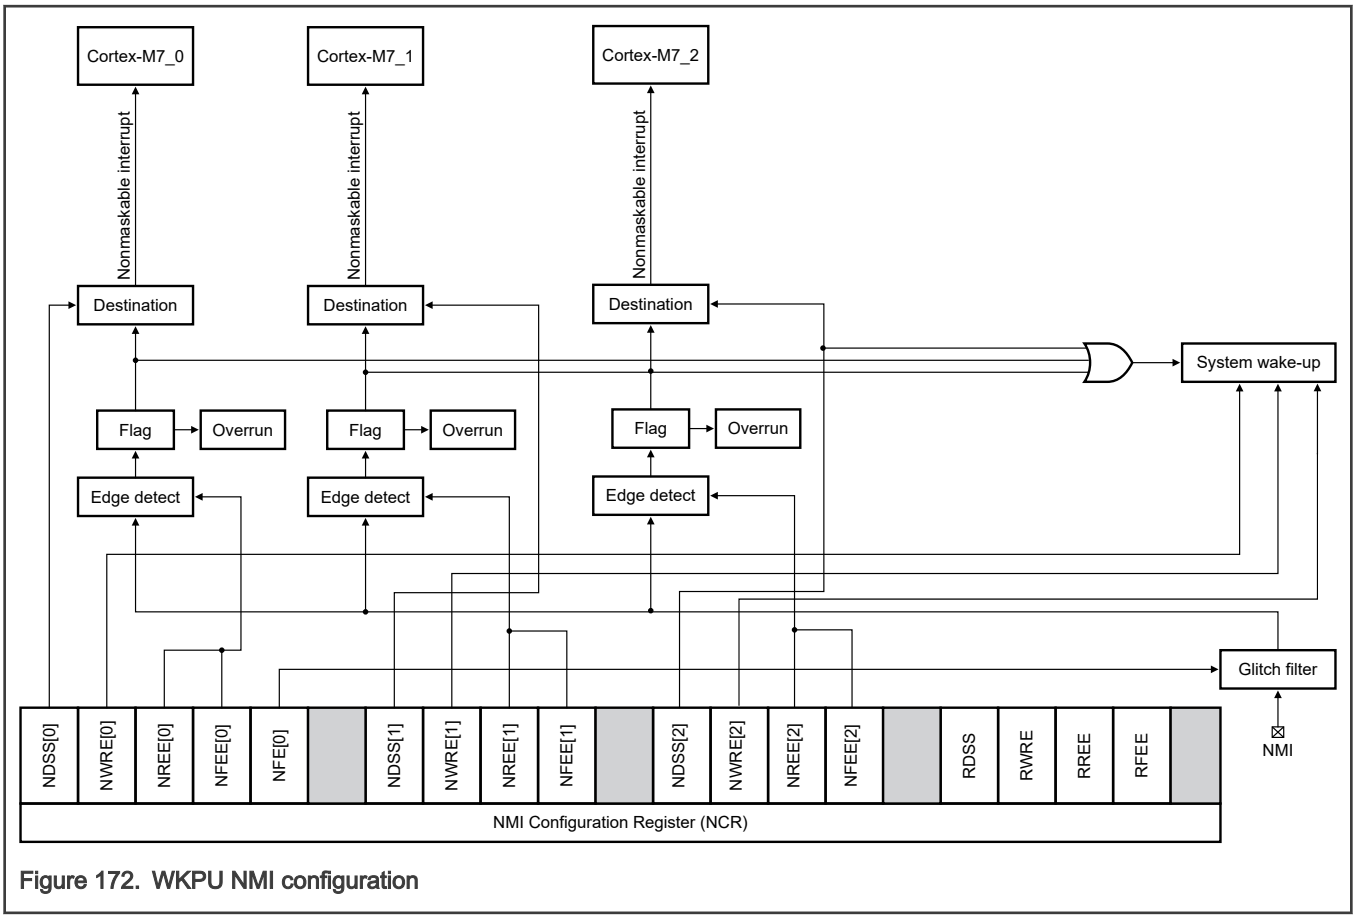

Figure 172. WKPU NMI configuration

45.1.4 WKPU wake-up source connectivity

WKPU allows the external NMI pin to assert the core NMIs on the chip. NMI supports NSR's status and overrun flags. This is what you could do using NCR:

- Control the NMI destination interrupt by configuring NCR[NDSS].
- Control the rising edge, falling edge, or either of the edge reactions to the NMI pin by using bits 2:0 of NCR[NFEE] and NCR[NREE]. The enabling of these edge reactions to the NMI pin is independent of each core.

WKPU supports the capturing of a second event per NMI input before the interrupt is cleared, thus reducing the chance of losing an NMI event.

The following figure shows routing of external wake-up events or interrupts with WKPU and the system interrupt controller.

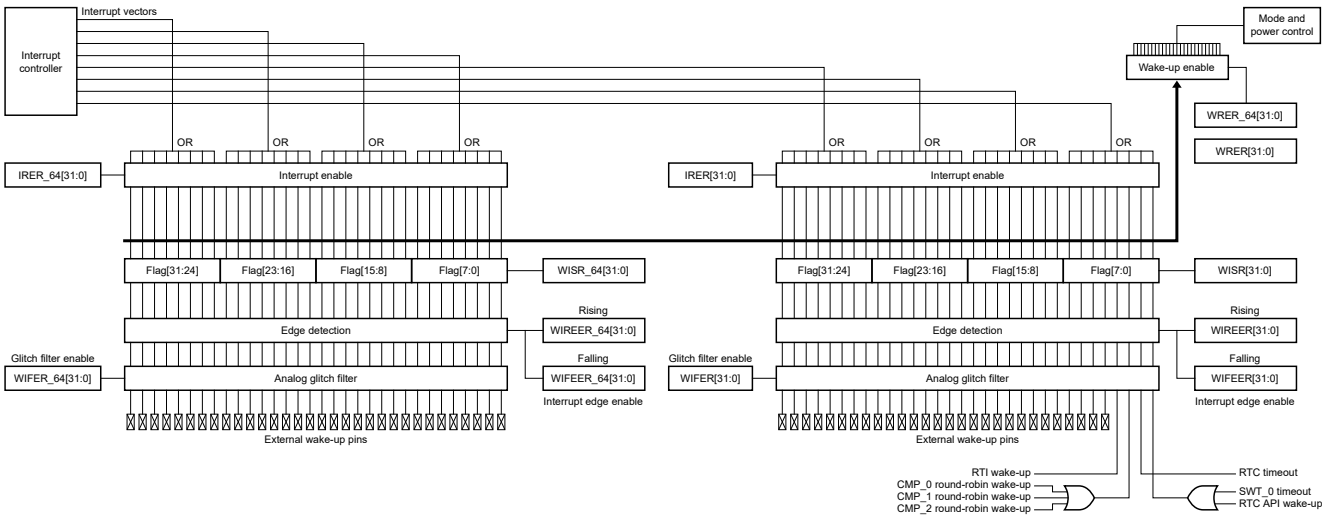

Figure 173. WKPU wake-up source connectivity

This is the wake-up source mapping to WKPU:

- Wake-up source 0 : SWT_0 timeout, RTC-API API wake-up
- Wake-up source 1 : RTC-API RTC timeout
- Wake-up source 2 : Round robin wake-up interrupt (Trigger mode interrupt) from LPCMP_0, LPCMP_1, or LPCMP_2
- Wake-up source 3 : RTI wake-up
- Wake-up source 4 : Wake-up source minimum 59-external pin wake-up sources, WKPU[0]-WKPU[59]

If you configure any or all of the LPCMP_*x*.RRCR0[RR_EN] fields to be active, the corresponding CMP_*x* pins must be dedicated for the CMP_*x* operation. In case you are not using any of the CMPs, you can use SIUL2.MSCR*x*[SSS] to configure the pins for digital functionalities.

NOTE

You must enable WKPU (by using MC_ME.PRTN*x*_COFB*y*_CLKEN) before entering any of the chip's low-power modes.

45.2 Introduction

The WKPU supports 64 external sources that can generate interrupts or wakeup events and 2 external source(s) that can cause non-maskable interrupt request(s) or wakeup event(s). In addition, it combines its wakeup events with those generated from other wakeup sources to supply a single wakeup to the system. The block diagram of WKPU and its interfaces to other system components is shown below.

NOTE

The signal widths in the following diagram might not depict this device's particular configuration. See chip-specific WKPU for more information.

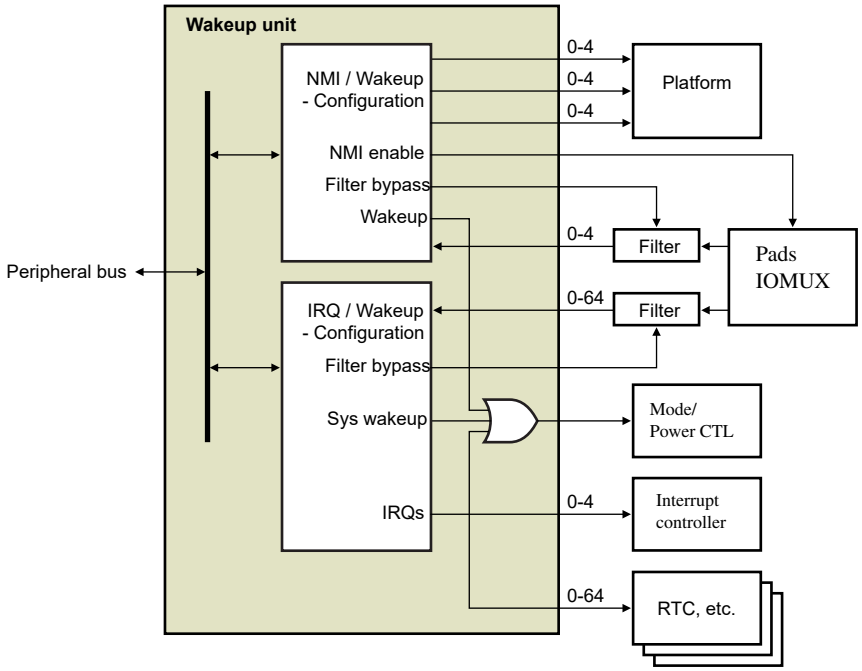

Figure 174. WKPU and connected system components

45.3 Features

The WKPU supports these features:

- Non-maskable interrupt support with:
  - 2 NMI sources
  - 2 analog glitch filters
  - Independent interrupt destination for each core:
    - Non-maskable interrupt
    - Critical interrupt
  - Active (rise/fall) edge selection control for events
  - Configurable system wakeup triggering from NMI sources
- External wakeup/interrupt support with:
  - One System interrupt vector for interrupt sources
  - 64 analog glitch filters
  - Independent interrupt mask
  - Edge detection
  - Configurable system wakeup triggering from all interrupt sources

45.4 Functional description

This section provides functional description of WKPU.

45.4.1 Non-maskable interrupts

The WKPU supports the capturing of a second event per NMI input before the interrupt is cleared, thus reducing the chance of losing an NMI event, although it creates an overrun condition.

Each NMI passes through a bypassable analog glitch filter.

NOTE

Glitch filter control and pad configuration should be performed when NMI is disabled, to avoid erroneous triggering by glitches caused by the configuration process itself.

NOTE

The figure below represents a generic configuration and might not represent this particular device's configuration. See the chip-specific information for details on this chip's WKPU.

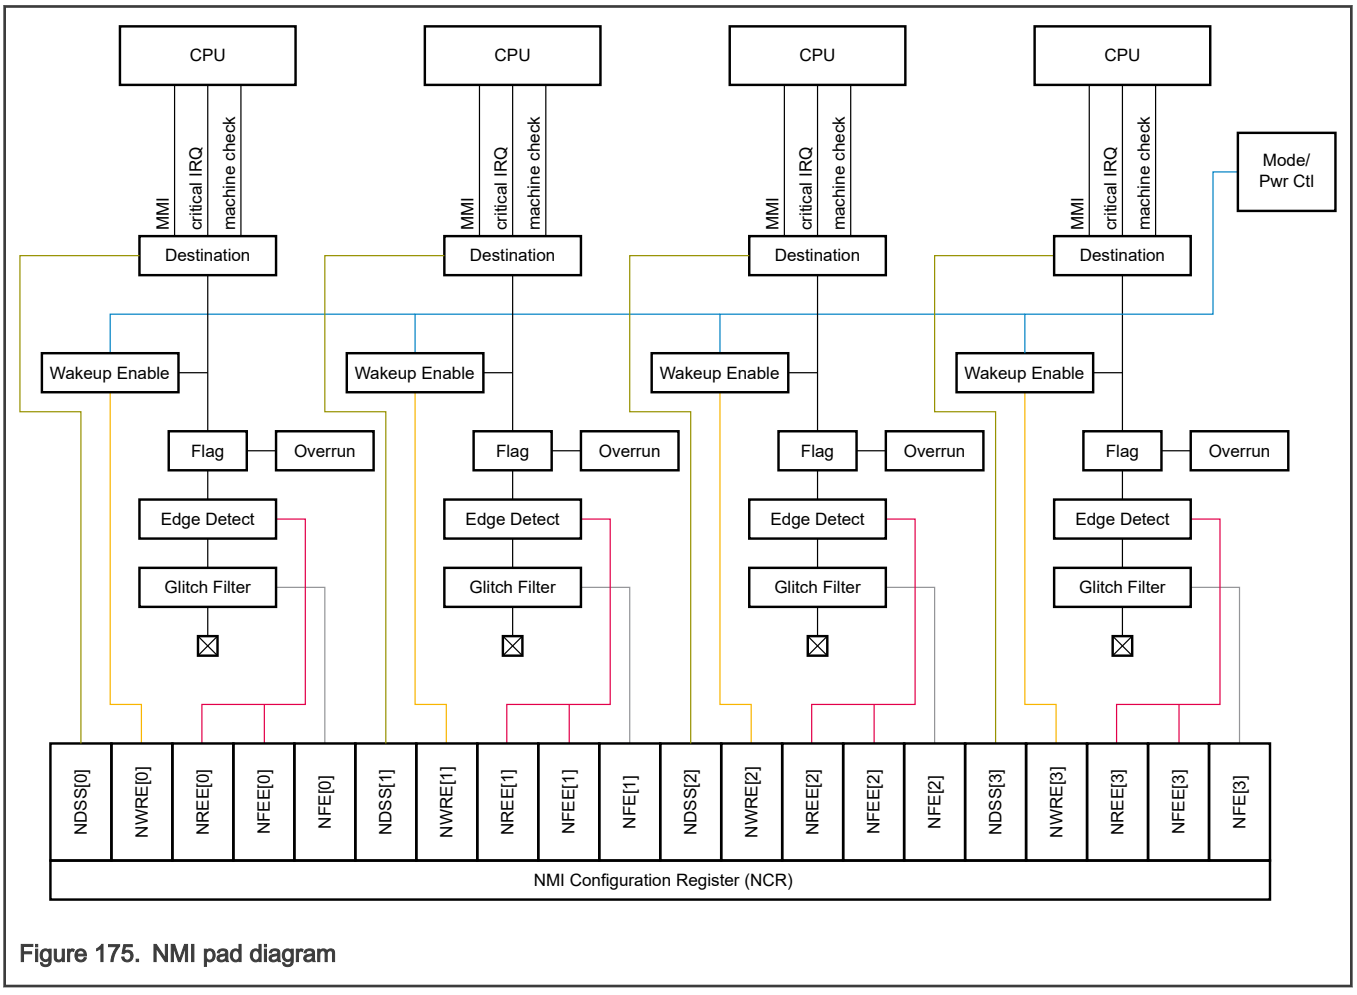

Figure 175. NMI pad diagram

45.4.1.1 NMI management

Each NMI can be enabled or disabled independently. This can be performed using the single NCR register laid out to contain all configuration bits for a given NMI in a single byte (see NMI Configuration Register (NCR)). A pad defined as an NMI can be configured by the user to recognize interrupts with an active rising edge, an active falling edge, or both edges being active. A setting of having both edge events disabled results in no interrupt being detected and should not be configured.

The active NMI edge is controlled by the user through the configuration of the NCR[NREEn] and NCR[NFEEn] bits.

NOTE

After reset, NREE and NFEE are set to '0'; therefore, the NMI functionality is disabled after reset and must be enabled explicitly by software.

After a pad's NMI functionality is enabled, the pad cannot be reconfigured to override or disable the NMI. See the chip-specific WKPU information for details of NMI implementation.

The NMI destination interrupt is controlled by the user through the configuration of the NCR[NDSSn] bits. See NMI Configuration Register (NCR) for details.

Each NMI supports a status flag and an overrun flag, which are located in the NSR register (see NMI Status Flag Register (NSR)). This register is a clear-by-write-1 register type, preventing inadvertent overwriting of other flags in the same register. The status flag is set whenever an NMI event is detected. The overrun flag is set whenever an NMI event is detected and the status flag is set (that is, status flag has not been cleared).

NOTE

The overrun flag is cleared by writing a '1' to the appropriate overrun bit in the NSR register. If the status bit is cleared and the overrun bit is still set, the pending interrupt is not cleared.

During an NMI ISR, on wakeup of the chip from an NMI, any writes to the ECC-protected memory must have the correct ECC.

45.5 External wakeups/interrupts

The WKPU supports 2 interrupt vectors to the interrupt controller of the chip. Each interrupt vector can support up to the number of external interrupt sources from the device pads, with the total across all vectors being equal to the number of external interrupt sources. Each external interrupt source is assigned to exactly one interrupt vector. The interrupt vector assignment is sequential so that one interrupt vector is for external interrupt sources 0 through N-1, the next is for N through N+M-1, and so forth.

See the following figure for an overview of the external interrupt implementation, showing an example of four interrupt vectors with eight external interrupt sources each.

NOTE

The figure below shows a generic representation of WKPU. See the chip-specific WKPU information for details on how this device's configuration might differ from this figure.

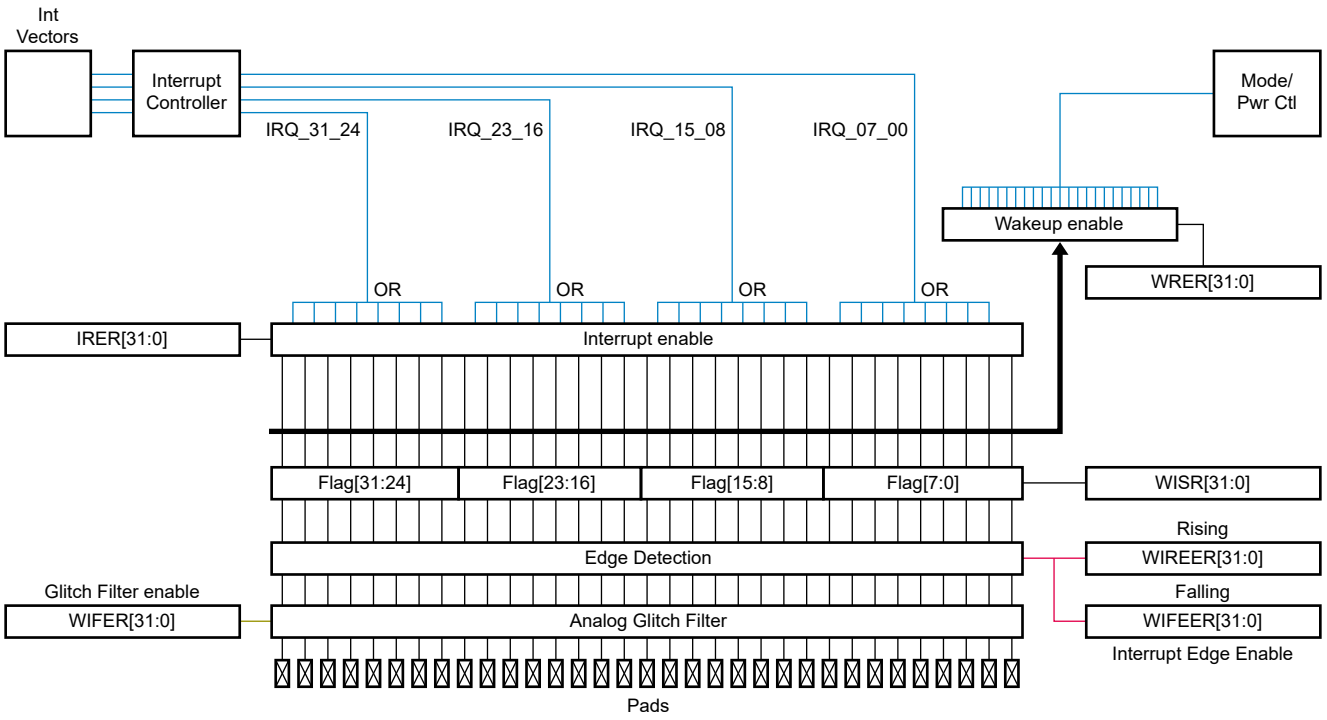

Figure 176. External interrupt pad diagram

All of the external interrupt pads within a single group have equal priority. It is the responsibility of the user software to search through the group of sources in the most appropriate way for their application.

The priority of the vectors used by the external interrupt pads is set based on the platform and the interrupt controller's priority levels, but the allocation of pads to each group of interrupts can be independently configured by the chip.

External interrupt lines have a digital glitch filter applied to them.

45.5.1 External interrupt management

Each interrupt can be enabled or disabled independently. This can be performed using a single rolled-up register (Interrupt Request Enable Register (IRER)). A pad defined as an external interrupt can be configured by the user to recognize interrupts with an active rising edge, an active falling edge, or both edges being active.

NOTE

Writing a '0' to both IREE[x] and IFEE[x] disables the external interrupt functionality for that pad completely (that is, no system wakeup or interrupt is generated on any activity of that pad).

The active IRQ edge is controlled by users through the configuration of the registers WIREER and WIFEER.

Each external interrupt supports an individual flag, which is held in the flag register, WISR. This register is a clear-by-write-1 register type, preventing inadvertent overwriting of other flags in the same register.

45.6 Initialization information

This section discusses initialization for the following features:

- Glitch filter and pad configuration
- Non-maskable interrupts

45.6.1 Glitch filter and pad configuration

Glitch filter control and pad configuration should be performed when the NMI is disabled. This is to avoid erroneous triggering by glitches caused by the configuration process.

When enabling the glitch filter, do not enable the rising-/falling-edge events bits, i.e., the NCR[NREE], NCR[NFEE], NCR[RREE], and NCR[RFEE] bits in the same register write.

45.6.2 Non-maskable interrupts

If the IBE of NMI is controlled by the NFEE or NREE fields of NMI Configuration Register (NCR) when an NMI interrupt pin is first enabled, it is possible to get a false interrupt flag. You must follow the following sequence to enable the NMI interrupt on a rising edge event on the NMI pin:

1. Write 1 to NCR[NFEE0] , NCR[NFEE1]
2. Write 1 to NCR[NREE0] , NCR[NREE1]
3. Write 0 to NCR[NFEE0] , NCR[NFEE1]

If the IBE of NMI is tied off to 1, no false interrupt is expected.

45.7 WKPU memory map and registers

45.7.1 WKPU register descriptions

This section provides a detailed description of all the registers accessible in the WKPU module.

NOTE

Reserved registers read as zero and writes have no effect. A transfer error is generated when trying to access a completely reserved register space. The field length of external pad control registers depends on the number of WKPU channels implemented in a chip.

45.7.1.1 WKPU memory map

WKPU base address: 402B_4000h

Offset

Register	Offset
WISR_64	54h

Function

This register holds the wakeup/interrupt flags.

NOTE

- This register is accessible only by 32-bit read/write operations.
- Status bits associated with on-chip wakeup sources are located to the left of the external wakeup/interrupt status bits and are read-only. The wakeup for these sources must be configured and cleared at the on-chip wakeup source. Also, the configuration registers for the external interrupts/wakeups do not have corresponding bits.

Access: User read/write

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	EIF_1															
W	W1C															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	EIF_1															
W	W1C															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 EIF_1	External Wakeup/Interrupt Status Flag x This flag can be cleared only by writing 1. Writing 0 has no effect. If enabled (IRER[x]), EIF[x] causes an interrupt request. 0b - No event has occurred on the pad 1b - An event as defined by WIREER and WIFEER has occurred

45.7.1.11 Interrupt Request Enable Register (IRER_64)

Offset

Register	Offset
IRER_64	58h

Function

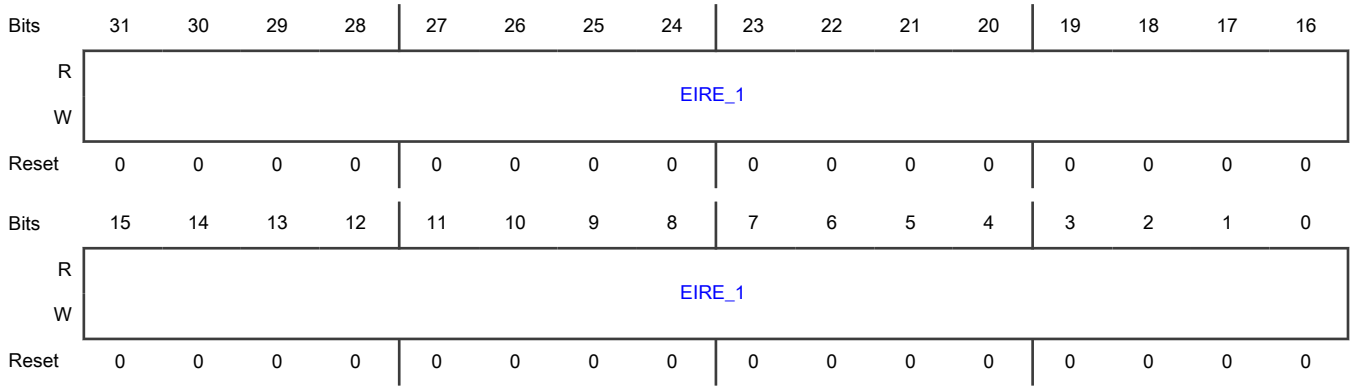
This register is used to enable interrupt messaging from the wakeup/interrupt pads to the interrupt controller.

NOTE

This register is accessible only by 32-bit read/write operations.

Access: User read/write

Diagram



Fields

Field	Function
31-0 EIRE_1	External Interrupt Request Enable x 0b - Interrupt requests from the corresponding EIF[x] bit are disabled 1b - A set EIF[x] bit causes an interrupt request

45.7.1.12 Wakeup Request Enable Register (WRER_64)

Offset

Register	Offset
WRER_64	5Ch

Function

This register is used to enable system wakeup messaging from the wakeup/interrupt pads to the mode entry and power control modules.

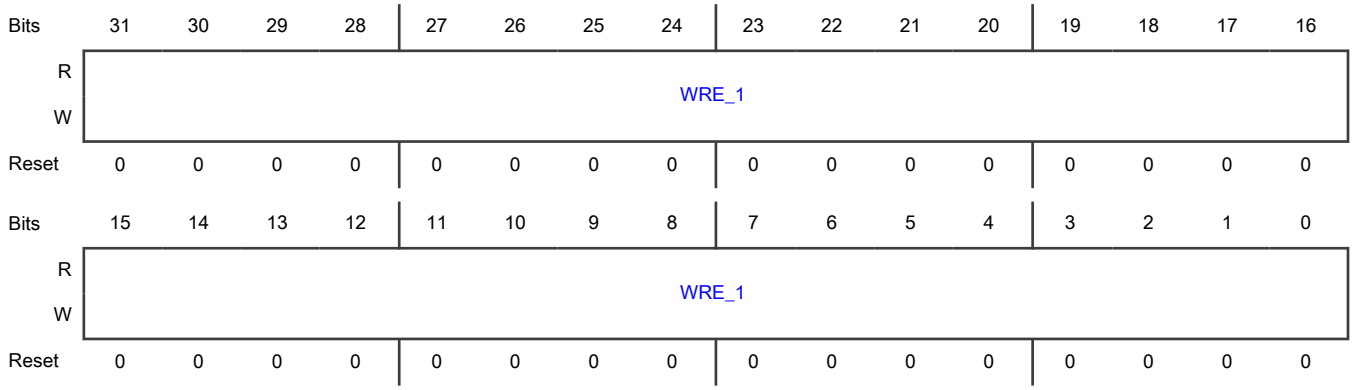
NOTE

This register is accessible only by 32-bit read/write operations.

If a pin is disabled through this register, the corresponding bits in the WIFEER and WIREER registers must be written to 0 to ensure that the pin does not respond to any change.

Access: User read/write

Diagram



Fields

Field	Function
31-0 WRE_1	External Wakeup Request Enable x 0b - System wakeup requests from corresponding EIF[x] bit are disabled 1b - A set EIF[x] bit causes a system wakeup request

45.7.1.13 Wakeup/Interrupt Rising-Edge Event Enable Register (WIREER_64)

Offset

Register	Offset
WIREER_64	68h

Function

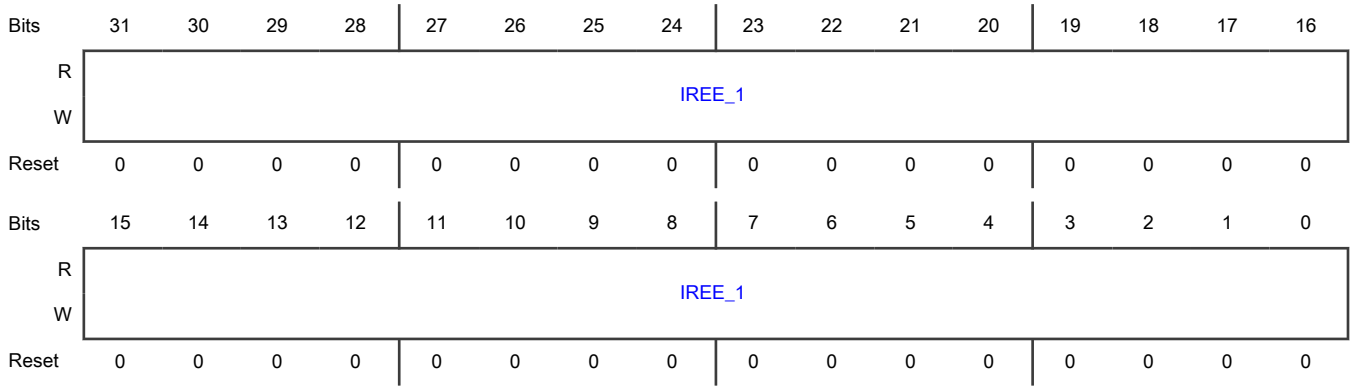
This register is used to enable rising-edge triggered events on the corresponding wakeup/interrupt pads.

NOTE

This register is accessible only by 32-bit read/write operations.

Access: User read/write

Diagram



Fields

Field	Function
31-0 IREE_1	External Interrupt Rising-edge Events Enable x 0b - Rising-edge event is disabled 1b - Rising-edge event is enabled

45.7.1.14 Wakeup/Interrupt Falling-Edge Event Enable Register (WIFEER_64)

Offset

Register	Offset
WIFEER_64	6Ch

Function

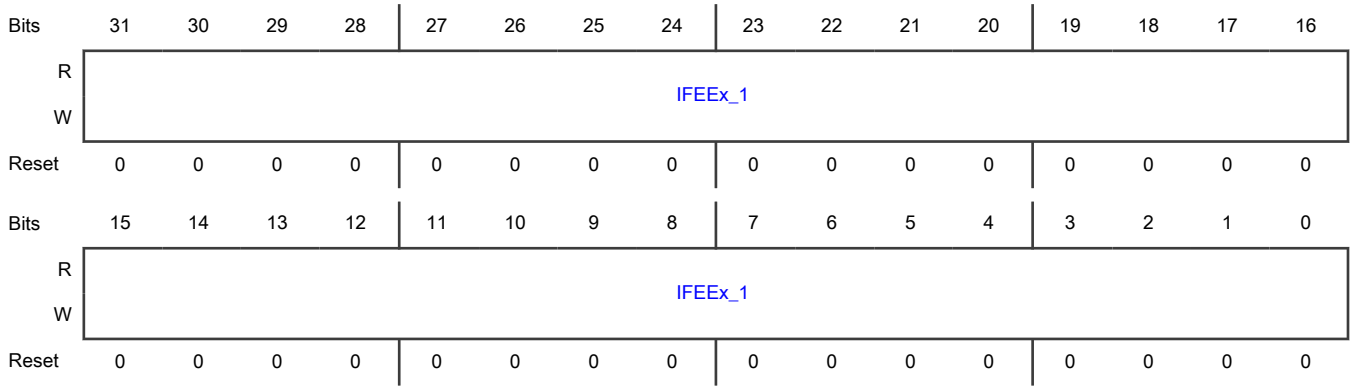
This register is used to enable falling-edge triggered events on the corresponding wakeup/interrupt pads.

NOTE

This register is accessible only by 32-bit read/write operations.

Access: User read/write

Diagram



Fields

Field	Function
31-0 IFEEx_1	External Interrupt Falling-edge Events Enable x 0b - Falling-edge event is disabled 1b - Falling-edge event is enabled

45.7.1.15 Wakeup/Interrupt Filter Enable Register (WIFER_64)

Offset

Register	Offset
WIFER_64	70h

Function

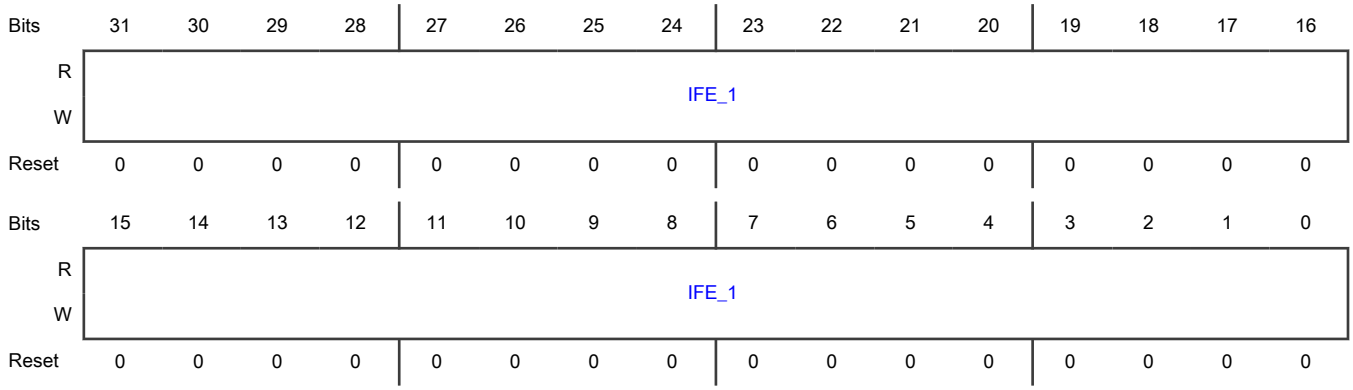
This register is used to enable an analog filter on the corresponding interrupt pads to filter out glitches on the inputs.

NOTE

This register is accessible only by 32-bit read/write operations.

Access: User read/write

Diagram



Fields

Field	Function
31-0 IFE_1	External Interrupt Filter Enable x Enable analog glitch filter on the external interrupt pad input. 0b - Filter is disabled 1b - Filter is enabled

45.8 Glossary

NMI Non-maskable interrupts

Chapter 46
Safety Overview

46.1 Introduction

This chip family is developed following the ISO 26262 standards, with derivatives targeting the chips that are operable in a system that fulfills the requirements of the ASIL D or ASIL B safety integrity levels.

Table 217. ASIL levels

Chip	ASIL level
MWCT2D17S, MWCT2D16S, MWCT2016S, MWCT2015S, MWCT2014S	B

The ASIL level targets the safety processing, which means the software functions are executed as intended:

1. Read instructions from memory.
2. Execute instructions.
3. Read data from memory.
4. Process data.
5. Write back the result data into memory.

Some elements of the safety concept are based on the assumption that the chip is connected to an external SBC or PMIC. The SBC or PMIC performs observations and control functionalities that are essential to fulfill some related functional safety requirements. If you do not use an SBC or PMIC, you must ensure that your MWCT-family chip provides an equivalent functionality that properly manages the corresponding interface(s).

The following figure illustrates the safety interface between the chip and the SBC or PMIC.

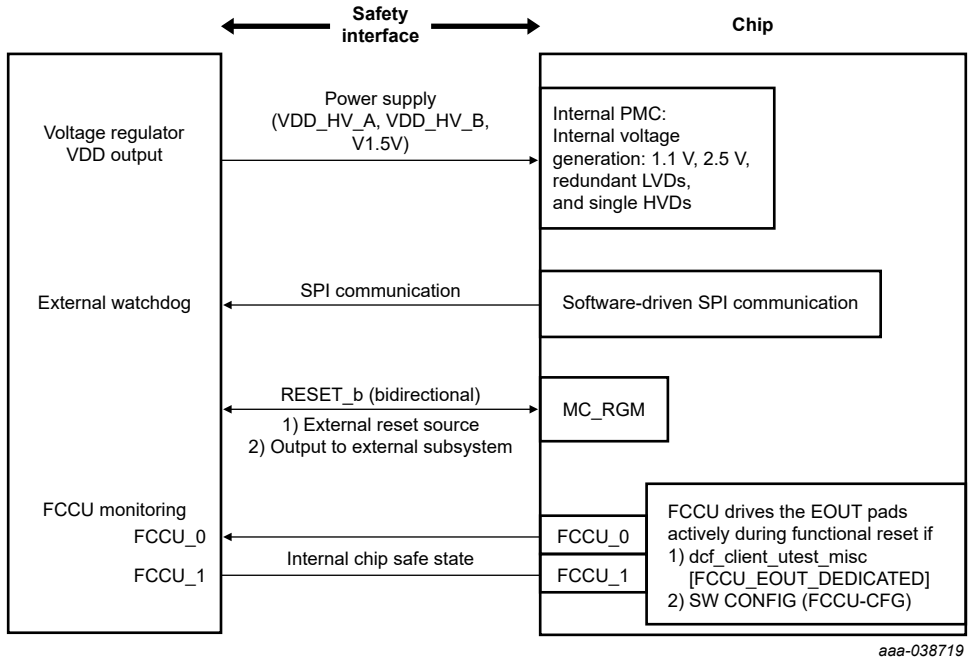


Figure 177. Safety interface between the chip and the SBC or PMIC

In the safety context, the chip interfaces can be classified into the groups shown in the table.

Table 218. Chip interface groups

Interface	Description
Power supply	This interface is between the SBC and the chip. It ensures that the supply to the chip is in the correct range. In case of any low-voltage event, the chip has POR, LVR, and LVD circuits in place and in case of any HVD event, the chip raises an interrupt. The SBC must ensure that the voltage regulator outputs never exceed the allowed range (more specifically for HVD range).
Communication	Responsible for communication between the SBC and the chip. Though the chip supports multiple communication protocols (UART, LIN, SPI, I2C, FlexCAN, and so on), SPI is the preferred communication with SBC. This is relevant to initialize an external watchdog when the chip is inoperative for a considerably long time (this is indicated by the pin states of the communication interface).
Reset	The chip consists of a reset bidirectional pin interfaced with SBC. The SBC can initiate a chip reset via this pin as a safety reaction in case of: • Extreme critical faults • An inoperative chip • Stuck cases based on the criticality and the application requirements The SBC also samples the reset pin state to identify the chip condition (whether in running state or in reset).
FCCU	The chip indicates the chip faults to the SBC via FCCU EOUT pins through this interface.

The interfaces in Table 218 ensure the chip's operational safety and integrity.

46.2 Safety architecture elements

The chip safety architecture consists of following elements that operate in an interconnected way to meet the ASIL requirements:

- Cortex-M7 core complex (including the cache controllers) operating in delayed lockstep (ASIL D only)
- eDMA controller
- Structural core self-test
- Internal windowed watchdogs with independent clock sources
