Error Injection mode is also supported for FSM parity error check. Program the Error Injection enable for the respective clock domain denoted by [23:16] bits of MAC_FSM_Control Register.

72.15.2.2 FSM Timeout Protection

The FSM Timeout feature provides a mechanism to ensure that all FSMs in the module can complete a transaction and return to a known completion state (IDLE or any other state that indicates completion of a transaction/transfer) within the programmed timeout value.

Program the TMR field of MAC_FSM_ACT_Timer register with a value that indicates the number of CSR cycles required to generate a 1 microsecond tic. This microsecond tic is internally used to generate the programmed timeout duration. Two timeout tics (normal mode timeout and large mode timeouts) are generated to provide flexibility to choose one per clock domain, by using the bits [31:24] of MAC_FSM_Control Register. Supported values for Timeout duration are 1us, 1.024ms, 16.384ms, 65.5536ms, 262.144ms, 1048.576ms (~1sec), 4194.304ms (~4s), 8.388s, 16.777s, and 33.554s which is based on the programmable bits NTMRMD, LTMRMD fields of MAC_FSM_ACT_Timer register. Interface timeouts are based on the normal mode tic generation; only the FSM timeouts depend on either normal or large tick selection.

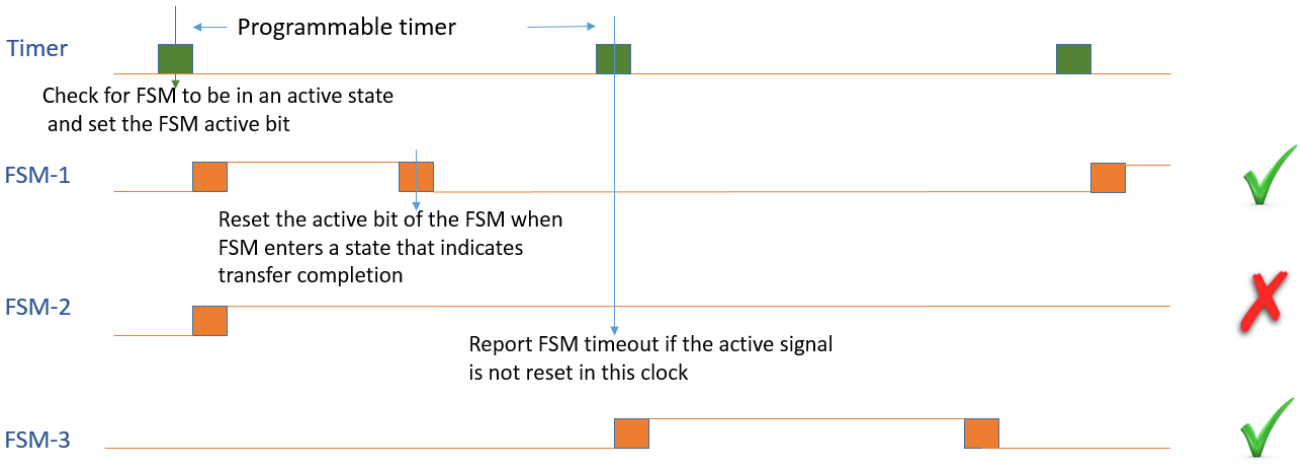

Figure 410. FSM Timeout Timing Diagram

In the above figure, the timer ticks are generated based on the programmable timeout value. The timer ticks are synchronized and made available in all the clock domains that have the FSMs.

At every timer tick, all the FSMs are monitored for being in active state (non-IDLE state, which indicates the FSM is actively processing transactions or hand-shakes) and an FSM active flag bit is set. The active flag bit is implemented for every FSM that is monitored for timeout. When the FSM reaches an IDLE or transaction completion state, the active flag bit of that FSM is reset. At the subsequent timer tick, all the FSMs' active flag bits are monitored and any flag that is set indicates a timeout for that FSM. This process of setting the flag and checking at subsequent timer tick is repeated at every tick.

Timeout Error Injection per clock domain is enabled by programming [15:8] fields of MAC_FSM_Control register. When Timeout error injection enable is set for a clock domain, the FSMs in that clock domain automatically timeout and generate an interrupt even without traffic. As error injection is a debug mode, TMR value need not indicate 1us, but can be programmed to a smaller value at which debug mode ticks are needed. FSM Timeout and Parity Error Injection modes can be used for testing at key-on/key-off.

The FSM timeout status is specified in the [15:8] field of MAC_DPP_FSM_Interrupt_Status register as per the respective clock domains. One FSM timeout status bit is made available per clock domain. The safety interrupt (sbd_sfty_ue_intr_o) is asserted when the timeout error is set for any of the clock domains. IP does not attempt to recover from a FSM timeout condition and relies on the application to take the corrective action (resetting IP).

72.15.2.3 Enabling FSM Parity and Timeout Protection

FSM timeout feature is enabled by setting the TMOUTEN field of MAC_FSM_Control register.

NOTE

See Programming guidelines for FSM parity and timeout

72.15.3 Application/CSR Interface Timeout Protection

This feature provides timeout protection to the application/CSR Interface. All the interfaces which has the handshake mechanism monitored for potential hangs due to the external agent (Master/Slave/Interconnect/Application client) not responding to the requests/transfers initiated by the QoS. After the request is initiated the response arrival interval is monitored. If the response does not arrive within a programmed time (TMR field of MAC_FSM_ACT_Timer) the timeout is triggered, using similar trigger generation as explained in the Section FSM protection.

The timeout is triggered when IP initiates SEQ, NON-SEQ and BUSY transfers on HTRANS[1:0]; and HREADY is not asserted by Slave within the programmed time.

The Timeout status for the AHB master interface is set in the MSTTES field of the MAC_DPP_FSM_Interrupt_Status register. The Safety interrupt (sbd_sfty_ue_intr_o) is asserted when application timeout status is set.

The hardware does not attempt to recover from Application/CSR Interface hangs and relies on software to take appropriate corrective action.

NOTE

- Protection is not needed for APB3 Slave interfaces because potential hangs can be only when IP does not respond to the requests. In such cases the IP internal protection logic (FSM timeout) detects such defects.
- Based on the time at which the transfer is initiated relative to the timer ticks, the timeout period could be any value between the programmed timeout and 2x times the programmed timeout.
- When an uncorrectable safety interrupt is issued and the read of the Interrupt status register returns all zeros, it implies that the CSR read is not functional. As soft reset of IP is not possible without the CSR access, and therefore, a hard reset of IP is recommended.
- See Programming guidelines for FSM parity and timeout .

72.16 Descriptors

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

72.16.1 Overview

The DMA in the Ethernet subsystem transfers data based on a linked list of descriptors. The application creates the descriptors in the system memory. The module supports the following two types of descriptors:

- Normal Descriptor: Normal descriptors are used for packet data and to provide control information applicable to the packets to be transmitted.
- Context Descriptor: Context descriptors are used to provide control information applicable to the packet to be transmitted.

Each normal descriptor contains two buffers and two address pointers. These buffers enable the adapter port to be compatible with various types of memory management schemes.

NOTE

There is no limit for the number of descriptors that can be used for a single packet.

72.16.2 Descriptor Structure

The module supports the ring structure for DMA descriptor as shown in the following figure.

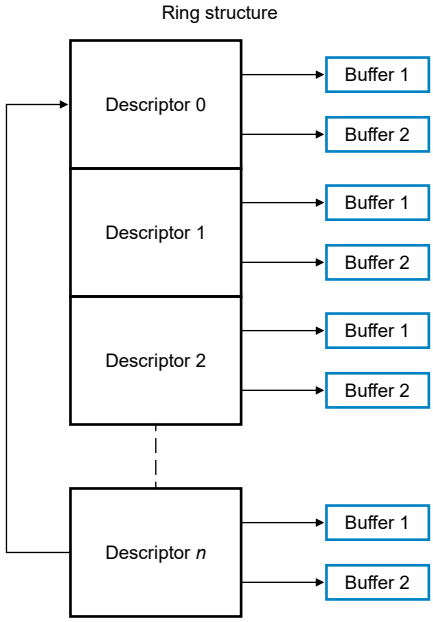

Figure 411. Descriptor Ring Structure

In Ring structure, descriptors are separated by the Word, DWord, or LWord number programmed in the DSL field of the DMA_CH#_Control register. The application needs to program the total ring length, that is, the total number of descriptors in ring span in the following registers of a DMA channel:

- Transmit Descriptor Ring Length Register (DMA_CH#_TxDesc_Ring_Length)
- Receive Descriptor Ring Length Register (DMA_CH#_RxDesc_Ring_Length)

The Descriptor Tail Pointer Register contains the pointer to the descriptor address (N). The base address and the current descriptor pointer decide the address of the current descriptor that the DMA can process. The descriptors up to one location less than the one indicated by the descriptor tail pointer (N – 1) are owned by the DMA. The DMA continues to process the descriptors until the following condition occurs:

Current Descriptor Pointer == Descriptor Tail Pointer;

The DMA goes into the Suspend mode when this condition occurs. The application must perform a write to the Descriptor Tail pointer register and update the tail pointer so that the following condition is true:

Current Descriptor Pointer < Descriptor Tail Pointer;

The DMA automatically wraps around the base address when the end of ring is reached, as shown in the following figure.

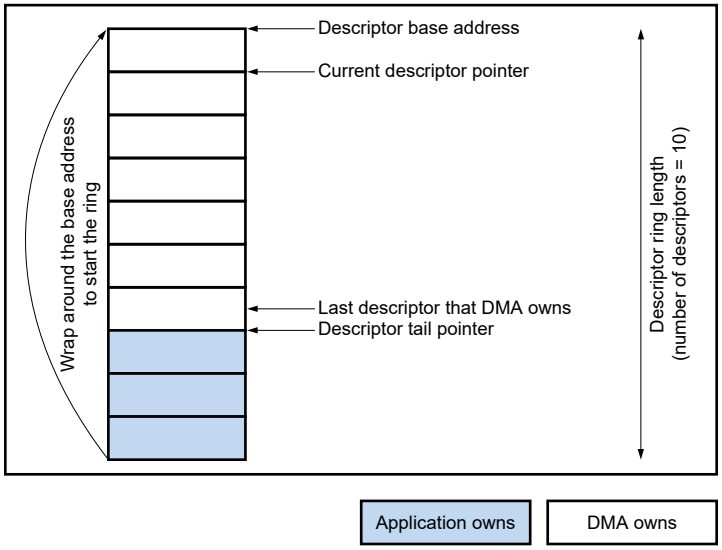

Figure 412. DMA Descriptor Ring

For descriptors owned by the application, the OWN bit of DES3 is reset to 0. For descriptors owned by the DMA, the OWN bit is set to 1. If the application has only one descriptor in the beginning, the application sets the last descriptor address (tail pointer) to Descriptor Base Address + 1. The DMA processes the first descriptor and then waits for the application to advance the tail pointer.

72.16.3 Transmit Descriptor

The DMA in the module requires at least one descriptor for a transmit packet. In addition to two buffers, two byte-count buffers, and two address pointers, the transmit descriptor has control fields which can be used to control the MAC operation on per-transmit packet basis. The Transmit Normal descriptor has two formats: Read format and Write-Back format

NOTE

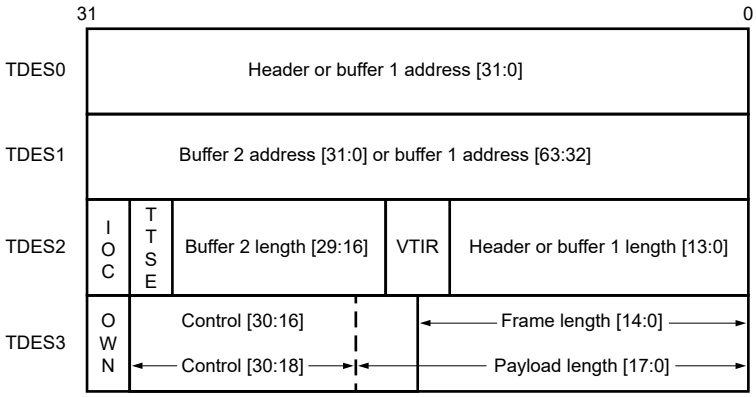
TSO Split header is not supported.

Software must not write same tail pointer addresses when DMA is in Suspended state before setting new descriptor(s) for further processing.

72.16.3.1 Transmit Normal Descriptor (Read Format)

Following figure shows the Read Format for a Transmit normal descriptor. Table: 'TDES0 Normal Descriptor (Read Format)' through Table: 'TDES3 Normal Descriptor (Read Format)' describe the read format for the Transmit Normal Descriptors: TDES0, TDES1, TDES2, and TDES3.

Figure 413. Transmit Descriptor Read Format



72.16.3.1.1 TDES0 Normal Descriptor (Read Format)

Table 500. TDES0 Normal Descriptor (Read Format)

Bit	Name	Description
31:0	BUF1AP	Buffer 1 Address Pointer or TSO Header Address Pointer These bits indicate the physical address of Buffer 1. These bits indicate the TSO Header Address pointer when the following bits are set: • TSE bit of TDES3 • FD bit of TDES3

72.16.3.1.2 TDES1 Normal Descriptor (Read Format)

Table 501. TDES1 Normal Descriptor (Read Format)

Bit	Name	Description
31:0	BUF2AP	Buffer 2 or Buffer 1 Address Pointer This bit indicates the physical address of Buffer 2 when a descriptor ring structure is used. There is no limitation for the buffer address alignment. In 40- or 48-bit addressing mode, these bits indicate the most-significant 8- or 16- bits of the Buffer 1 Address Pointer.

72.16.3.1.3 TDES2 Normal Descriptor (Read Format)

Table 502. TDES2 Normal Descriptor (Read Format)

31	30	29-16	15:14	13:0
IOC	TTSE/ TMWD	B2L	VTIR	HL or B1L

Table 503. TDES2 Normal Descriptor (Read Format)

Bits	Name	Description
31	IOC	Interrupt on Completion This bit controls the setting of TI and ETI status bits in the DMA_CH#_Status register. When ETIC = 1 and TDES2[LD] = 0, this bit sets the ETI bit. When TDES3[LD] = 1, this bit sets the TI status bit.
30	TTSE/ TMWD	Transmit Timestamp Enable or External TSO Memory Write Enable This bit enables the IEEE1588 time stamping for Transmit packet referenced by the descriptor, if TSE bit is not set. If TSE bit is set and external TSO memory is enabled, setting this bit disables external TSO memory writing for this packet.
29:16	B2L	Buffer 2 Length The driver sets this field. When set, this field indicates Buffer 2 length.
15:14	VTIR	VLAN Tag Insertion or Replacement These bits request the MAC to perform VLAN tagging or untagging before transmitting the packets. The application must set the CRC Pad Control bits appropriately when VLAN Tag Insertion, Replacement, or Deletion is enabled for the packet. The following list describes the values of these bits: • 2'b00: Do not add a VLAN tag. • 2'b01: Remove the VLAN tag from the packets before transmission. This option should be used only with the VLAN packets. • 2'b10: Insert a VLAN tag with the tag value programmed in the MAC_VLAN_Incl register or context descriptor. • 2'b11: Replace the VLAN tag in packets with the tag value programmed in the MAC_VLAN_Incl register or context descriptor. This option should be used only with the VLAN packets. These bits are valid when the Enable SA and VLAN Insertion on Tx option is selected while configuring the core.
13:0	HL or B1L	Header Length or Buffer 1 Length For Header length only bits [9:0] are taken. The size 13:0 is applicable only when interpreting buffer 1 length. If the TCP Segmentation Offload feature is enabled through the TSE bit of TDES3, this field is equal to the header length. When the TSE bit is set in TDES3, the header length includes the length in bytes from Ethernet Source address till the end of the TCP header. The maximum header length supported for TSO feature is 1023 bytes. The maximum header length supported for TSO feature is 1023 bytes. If the TCP Segmentation Offload feature is not enabled, this field is equal to Buffer 1 length.

72.16.3.1.4 TDES3 Normal Descriptor (Read Format)

Table 504. TDES2 Normal Descriptor (Read Format)

31	30	29	28	27:26	25:23	22:19	18	17:16	15	14:0
OWN	CTXT	FD	LD	CPC	SAIC	SLOTNUM or THL	TSE	CIC/TPL	TPL	FL/TPL

Table 505. TDES3 Normal Descriptor (Read Format)

Bits	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit after it completes the transfer of data given in the associated buffer(s).
30	CTXT	Context Type This bit should be set to 1'b0 for normal descriptor.
29	FD	First Descriptor When this bit is set, it indicates that the buffer contains the first segment of a packet.
28	LD	Last Descriptor When this bit is set, it indicates that the buffer contains the last segment of the packet. When this bit is set, the B1L or B2L field should have a non-zero value.
27:26	CPC	CRC Pad Control This field controls the CRC and Pad Insertion for Tx packet. This field is valid only when the first descriptor bit (TDES3[29]) is set. The following list describes the values of Bits[27:26]: • 2'b00: CRC and Pad Insertion The MAC appends the cyclic redundancy check (CRC) at the end of the transmitted packet of length greater than or equal to 60 bytes. The MAC automatically appends padding and CRC to a packet with length less than 60 bytes. • 2'b01: CRC Insertion (Disable Pad Insertion) The MAC appends the CRC at the end of the transmitted packet but it does not append padding. The application should ensure that the padding bytes are present in the packet being transferred from the Transmit Buffer, that is, the packet being transferred from the Transmit Buffer is of length greater than or equal to 60 bytes. • 2'b10: Disable CRC Insertion The MAC does not append the CRC at the end of the transmitted packet. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the Transmit Buffer. • 2'b11: CRC Replacement The MAC replaces the last four bytes of the transmitted packet with recalculated CRC bytes. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the Transmit Buffer. This field is valid only for the first descriptor. Note: When the TSE bit is set, the MAC ignores this field because the CRC and pad insertion is always done for segmentation.
25:23	SAIC	SA Insertion Control These bits request the MAC to add or replace the Source Address field in the Ethernet packet with the value given in the MAC Address 0 register. The application must set the CRC Pad Control bits appropriately when SA Insertion Control is enabled for the packet.

Table continues on the next page...

Table 505. TDES3 Normal Descriptor (Read Format) (continued)

Bits	Name	Description
		Bit 25 specifies the MAC Address Register (1 or 0) value that is used for Source Address insertion or replacement. The following list describes the values of Bits[24:23]: • 2'b00: Do not include the source address • 2'b01: Include or insert the source address. For reliable transmission, the application must provide frames without source addresses. • 2'b10: Replace the source address. For reliable transmission, the application must provide frames with source addresses. • 2'b11: Reserved These bits are valid in the EQOS-DMA, EQOS-AXI, and EQOS-AHB configurations when the Enable SA and VLAN Insertion on Tx option is selected while configuring the core and when the First Segment control bit (TDES3 [29]) is set. This field is valid only for the first descriptor.
22:19	SLOTNUM or THL	SLOTNUM: Slot Number Control Bits in AV Mode These bits indicate the slot interval in which the data should be fetched from the corresponding buffers addressed by TDES0 or TDES1. When the Transmit descriptor is fetched, the DMA compares the slot number value in this field with the slot interval maintained in the RSN field DMA_CH#_Slot_Function_Control_Status. It fetches the data from the buffers only if a value matches. These bits are valid only for the AV channels. THL: TCP/UDP Header Length If the TSE bit is set, this field contains the length of the TCP/UDP header. The minimum value of this field must be 5 for TCP header. The value must be equal to 2 for UDP header. This field is valid only for the first descriptor.
18	TSE	TSO Split header is not supported. The value of this bit is always zero.
17:16	CIC/TPL	Checksum Insertion Control or TCP Payload Length These bits control the checksum calculation and insertion. The following list describes the bit encoding: • 2'b00: Checksum Insertion Disabled. • 2'b01: Only IP header checksum calculation and insertion are enabled. • 2'b10: IP header checksum and payload checksum calculation and insertion are enabled, but pseudo-header checksum is not calculated in hardware. • 2'b11: IP Header checksum and payload checksum calculation and insertion are enabled, and pseudo-header checksum is calculated in hardware. This field is valid when the Enable Transmit TCP/IP Checksum Offload option is selected and the TSE bit is reset. When the TSE bit is set, this field contains the upper bits [17:16] of the TCP Payload (or IP Payload for UDP fragmentation). This allows the TCP/UDP packet length field to be spanned across TDES3[17:0] to provide 256 KB packet length support.

Table continues on the next page...

Table 505. TDES3 Normal Descriptor (Read Format) (continued)

Bits	Name	Description
		This field is valid only for the first descriptor.
15	TPL	Reserved or TCP Payload Length When the TSE bit is reset, this bit is reserved. When the TSE bit is set, this is Bit 15 of the TCP payload length [17:0]. This field is valid only when the Enable TCP Segmentation Offloading for TCP/IP Packets option is selected while configuring the core.
14:0	FL/TPL	Frame Length or TCP Payload Length This field is equal to the length of the packet to be transmitted in bytes. When the TSE bit is not set, this field is equal to the total length of the packet to be transmitted: Ethernet Header Length + TCP /IP Header Length – Preamble Length – SFD Length + Ethernet Payload Length When the TSE bit is set, this field is equal to the lower 15 bits of the TCP payload length in case of segmentation and IP payload in case of UDP fragmentation. In case of segmentation, this length does not include Ethernet header or TCP/UDP/IP header length. In case of fragmentation, this length does not include Ethernet header and IP header. When DWRR/WFQ algorithm is NOT enabled, value written into this field is not used when TSE = 0.

72.16.3.1.5 Transmit normal descriptor (write-back format)

The transmit descriptor write-back format includes timestamp low, timestamp high, OWN, and Status bits.

The write-back format is applicable only for the last descriptor of the corresponding packet. Write 1 to the LD bit (TDES3[28]) in the descriptor where DMA writes back the status and timestamp information for the corresponding transmit packet.

Figure 414 shows the transmit descriptor write-back format.

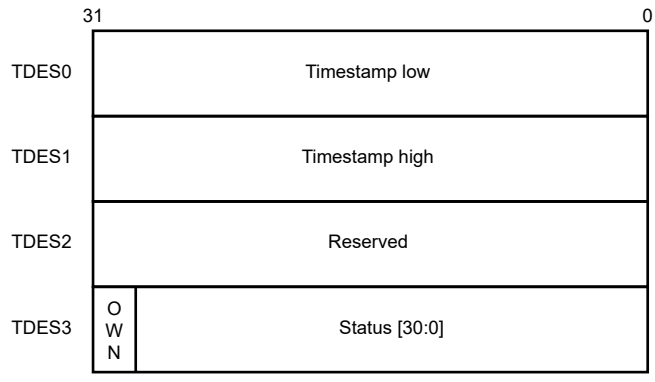


Figure 414. Transmit descriptor write-back format

TDES0 normal descriptor (write-back format)

Table 506 shows that this format is only applicable to the last descriptor of a packet.

Table 506. TDES0 normal descriptor (write-back format)TDES0 normal descriptor (write-back format)

Bit	Name	Description
31:0	TTSL	Transmit Packet Timestamp Low DMA updates this field with least significant 32 bits of the timestamp captured for the corresponding transmit packet. DMA writes the timestamp only if TTSE bit of TDES2 is 1 in the first descriptor of the packet. This field has the timestamp only if you write 1 to the Last Segment bit (LS) in the descriptor and the Timestamp status (TTSS) bit.

TDES1 normal descriptor (write-back format)

Table 507 shows that this format is only applicable to the last descriptor of a packet.

Table 507. TDES1 normal descriptor (write-back format)

Bit	Name	Description
31:0	TTSH	Transmit Packet Timestamp High DMA updates this field with the most significant 32 bits of the timestamp captured for a corresponding transmit packet. DMA writes the timestamp only if the TTSE bit of TDES2 is 1 in the first descriptor of the packet. This field has the timestamp only if you write 1 to the Last Segment bit (LS) in the descriptor and Timestamp status (TTSS) bit.

TDES2 Normal Descriptor (Write-Back Format)

This format is applicable only to the last descriptor of a packet.

Table 508. TDES2 normal descriptor (write-back format)

Bit	Description
31:0	Reserved

TDES3 Normal Descriptor (Write-Back Format)

This format is applicable only to the last descriptor of a packet.

Table 509. TDES3 normal descriptor (write-back format)

31	30	29	28	27:18	17	16	15	14	13	12	11	10	9	8	7:4	3	2	1	0
OWN	CTXT	FD	LD	Rsvd	TTSS	EUE	ES	JT	FF	PCE	LoC	NC	LC	EC	CC	ED	UF	DB	IHE

Table 510. TDES3 normal descriptor (write-back format)

Bit	Name	Description
31	OWN	Own Bit When this field is 1, it indicates that the module DMA owns the descriptor. DMA write 0 to this field when it completes the packet transmission. After the write-back is complete, this field is set to 'b0.
30	CTXT	Context Type

Table continues on the next page...

Table 510. TDES3 normal descriptor (write-back format) (continued)

Bit	Name	Description
		This field must be set to 'b0 for normal descriptor.
29	FD	First Descriptor This field indicates that the buffer contains the first segment of a packet.
28	LD	Last Descriptor This field is set to 'b1 for last descriptor of a packet. DMA writes the status fields only in the last descriptor of the packet.
27:24	Rsvd	Reserved
23	DE	Descriptor Error When this field is 1, it indicates that the descriptor content is incorrect. DMA writes 1 to this field during write-back when the descriptor is closed. Descriptor errors can be: • Incorrect sequence from the context descriptor. For example, a location after the first descriptor for a packet. • All 1s • CTXT is 1 along with LD or FD bits as 1. **NOTE** When a descriptor error occurs due to all ones or CTXT, LD, and FD bits are 1, the transmit DMA closes the transmit descriptor with DE and LD bits set to 1. When you write 1 to IOC bit in TDES2 of corresponding first descriptor, the transmit DMA write 1 to TI bit in the DMA_CH#_Status register **NOTE** Based on CTXT, LD, and FD bits of the transmit descriptor, the subsequent descriptor might consider as the first descriptor (even if FD bit is not 1) and partial packet is sent.
22:18	Rsvd	Reserved
17	TTSS	Tx Timestamp Status This field indicates that a timestamp has been captured for the corresponding transmit packet. When this field is 1, it indicates that TDES0 and TDES1 have timestamp values that were captured for the transmit packet. This field is valid only when the Last Segment control bit (TDES3 [28]) in a descriptor is 1. This field is valid only when IEEE1588 timestamping feature is enabled; otherwise, it is reserved.
16	EUE	ECC Uncorrectable Error Status Indicates the ECC uncorrectable error in the TSO memory. **NOTE** An uncorrectable error in the transmit FIFO memory is reported with (Bit 13) FF = 1. This is because the module flushes all such packets.

Table continues on the next page...

Table 510. TDES3 normal descriptor (write-back format) (continued)

Bit	Name	Description
15	ES	Error Summary This field indicates the logical OR of the following bits: • TDES3[0]: IP header error • TDES3[14]: Jabber timeout • TDES3[13]: Packet flush • TDES3[12]: Payload checksum error • TDES3[11]: Loss of carrier • TDES3[10]: No carrier • TDES3[9]: Late collision • TDES3[8]: Excessive collision • TDES3[3]: Excessive deferral • TDES3[2]: Underflow error This field is 1 when EUE (bit 16) = 1.
14	JT	Jabber Timeout This field indicates that the MAC transmitter experiences a jabber time-out. This field is 1 only when MAC_Configuration[JD] is not 1.
13	FF	Packet Flushed This field indicates that DMA or MTL flushes the packet because the CPU gives a software flush command.
12	PCE	Payload Checksum Error This field indicates that the checksum offload engine had a failure and does not insert any checksum into the encapsulated TCP, UDP, or ICMP payload. This failure can either because of insufficient bytes, as the payload length field of the IP header indicates or the MTL starting to forward the packet to the MAC transmitter in Store-and-forward mode without calculating the checksum. This second error condition only occurs when the transmit FIFO depth is less than the length of the Ethernet packet that is transmitted to avoid deadlock. The MTL starts forwarding the packet when the FIFO is full, even in the Store-and-forward mode. This error can also occur when you detects a bus error during packet transfer. When the full checksum offload engine is not enabled, this bit is reserved.
11	LoC	Loss of Carrier This field indicates that a loss of carrier occurred during packet transmission (that is, the gmii_crs_i signal was inactive for one or more transmit clock periods during packet transmission). This field is valid only for the packets transmitted without collision and when MAC operates in the Half-duplex mode.
10	NC	No Carrier This field indicates that the carrier sense signal from the PHY was not asserted during transmission.

Table continues on the next page...

Table 510. TDES3 normal descriptor (write-back format) (continued)

Bit	Name	Description
9	LC	Late Collision This bit indicates that packet transmission was aborted because a collision occurred after the collision window (64 byte times including Preamble in MII mode and 512 byte times including Preamble and Carrier Extension in GMII mode). This bit is not valid if Underflow Error is set.
8	EC	Excessive Collision This field indicates that the transmission was aborted after 16 successive collisions when you transmits the current packet. If MAC_Configuration[DR] = 1, this field is 1 after first collision and abort the packet transmission.
7:4	CC	Collision Count This 4-bit counter value indicates the number of collisions occurred before transmitting the packet. The count is not valid when the EC bit = 1.
3	ED	Excessive Deferral This field indicates that the transmission ends because of an excessive deferral of over 24,288 bit times (155,680 bits times in 1000 Mbit/s mode or Jumbo packet enabled mode) if MAC_Configuration[DC] = 1. When TBS is enabled in Full duplex mode and this field is 1, it indicates that the frame drops after the expiry time is reached.
2	UF	Underflow Error This field indicates that MAC aborts the packet because the data arrived late from the system memory. The underflow error can occur because of either of the following conditions: • DMA encounters an empty transmit buffer when it transmits the packet • The application filled the MTL Tx FIFO slower than the MAC transmit rate The transmission process enters the Suspended state and sets the underflow bit corresponding to a queue in MTL_Interrupt_Status.
1	DB	Deferred Bit This field indicates that MAC defers before transmitting because of presence of carrier. This field is valid only in the Half-Duplex mode.
0	IHE	IP Header Error When IP Header Error is 1, this field indicates that the checksum offload engine detects an IP header error. This field is valid only when transit checksum offload is enabled. Otherwise, it is reserved. If COE detects an IP header error, it inserts an IPv4 header checksum if the Ethernet type field indicates an IPv4 payload. In Full-Duplex mode, when EST/Qbv is enabled and this field is 1, it indicates the frame drop status due to the frame size error or schedule error.

72.16.3.2 Transmit context descriptor

The transmit context descriptor can provide any time before a packet descriptor. The context is valid for the current packet and subsequent packets. The context descriptor provide the timestamps for one-step timestamp correction and VLAN tag ID for VLAN insertion feature. Write back is done on a context descriptor only to write 0 to OWN bit.

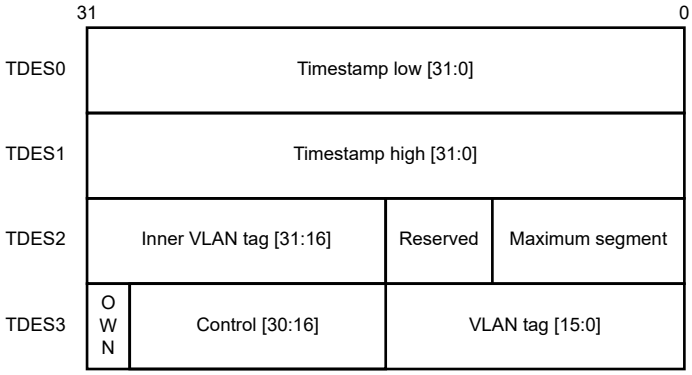
NOTE

DMA internally store the VLAN tag IDs and MSS values which the application provides in a context descriptor with their corresponding valid bits set. DMA always passes the last valid VLAN tag to the MTL, when the outer or inner VLAN tag is provided with the valid bit set. The application cannot invalidate the valid VLAN tag which DMA stores. The VLAN tag is inserted or replaced based on the control inputs provided for the packet.

The inner VLAN tag control input is used only for the next packet that immediately follows the context descriptor. The application must provide a context descriptor before the normal descriptor of each packet for which DMA must use the inner VLAN tag control input.

Figure 415 shows the transmit context descriptor format.

Figure 415. Transmit context descriptor format



72.16.3.2.1 TDES0 context descriptor

Table 511 describes the TDES0 context descriptor format.

Table 511. TDES0 context descriptor

Bit	Name	Description
31:0	TTSL	Transmit Packet Timestamp Low For one-step correction, the driver can provide the lower 32 bits of timestamp in this descriptor word. DMA uses this value as the low word for doing one-step timestamp correction. This field is valid only if the OSTC and TCMSSV bits of TDES3 context descriptor are 1.

72.16.3.2.2 TDES1 context descriptor

Table 512 describes the TDES1 context descriptor format.

Table 512. TDES1 context descriptor

Bit	Name	Description
31:0	TTSH	Transmit Packet Timestamp High For one-step correction, the driver can provide the upper 32 bits of timestamp in this descriptor. DMA uses this value as the high word for doing one-step timestamp correction. This field is valid only if the OSTC and TCMSSV bits of TDES3 context descriptor are 1.

72.16.3.2.3 TDES2 context descriptor

Table 513 shows the TDES2 context descriptor format.

Table 513. TDES2 context descriptor

Bit	Name	Description
31:16	IVT	Inner VLAN Tag When the IVLTV bit of TDES3 context descriptor is 1 and the TCMSSV and OSTC bits of TDES3 context descriptor becomes 0, it indicates that the TDES2[31:16] contains the inner VLAN tag to insert in the subsequent transmit packets.
15:14	Rsvd	Reserved
13:0	MSS	TSO split header is not supported. The value of this bit is always zero.

72.16.3.2.4 TDES3 context descriptor

Table 514. TDES3 context descriptor

31	30	29:28	27	26	25:24	23	22:18	17	16	15:0
OWN	CTXT	Rsvd	OSTC	TCMSSV	Rsvd	CDE	Rsvd	IVLTV	VLTV	VT

Table 515 shows the TDES3 context descriptor format.

Table 515. TDES3 context descriptor

Bit	Name	Description
31	OWN	Own Bit When this field is 1, it indicates that the module DMA owns the descriptor. When this field becomes 0, it indicates that the application owns the descriptor. DMA writes 0 to this field immediately after the read.
30	CTXT	Context Type This field must set to 1'b1 for context descriptor.
29:28	Rsvd	Reserved
27	OSTC	One-Step Timestamp Correction Enable When this field is 1, it indicates that DMA performs a one-step timestamp correction with reference to the timestamp values provided in TDES0 and TDES1.
26	TCMSSV	One-Step Timestamp Correction Input or MSS Valid When this field and the OSTC field are 1, it indicates that the timestamp correction input provided in TDES0 and TDES1 is valid. When the OSTC field becomes 0 and this field and the TSE bit of TDES3 are 1 in subsequent normal descriptor, it indicates that the MSS input in TDES2 is valid.
25:24	Rsvd	Reserved

Table continues on the next page...

Table 515. TDES3 context descriptor (continued)

Bit	Name	Description
23	DE	Descriptor Error When this field is 1, it indicates that the descriptor content is incorrect. DMA writes 1 to this field during write-back when it closes the context descriptor. Descriptor errors can be: • Incorrect sequence from the context descriptor. For example, a location before the first descriptor for a packet. • All ones. • CD, LD, and FD bits = 1. **NOTE** When a descriptor error occurs due to all ones or CTXT, LD, and FD bits are 1, the transmit DMA closes the transmit descriptor with DE and LD bits are 1. When you write 1 to IOC bit in TDES2 of corresponding first descriptor, the transmit DMA writes 1 to TI bit in the DMA_CH#_Status register **NOTE** On the basis of CTXT, LD, and FD bits of the transmit descriptor, the subsequent descriptor might considered as the first descriptor (even if FD bit is not 1) and partial packet is sent.
22:20	Rsvd	Reserved
19:18	IVTIR	Inner VLAN Tag Insert or Replace When this field is 1, it requests MAC to perform inner VLAN tagging or un-tagging before transmitting the packets. If the packet is modified for VLAN tags, MAC automatically recalculates and replaces the CRC bytes. The following list describes the values of these bits: • 2'b00: Do not add the inner VLAN tag. • 2'b01: Remove the inner VLAN tag from the packets before transmission. You must use this option only with the VLAN frames. • 2'b10: Insert an inner VLAN tag with the tag value programmed in MAC_Inner_VLAN_Incl or context descriptor. • 2'b11: Replace the inner VLAN tag in packets with the tag value programmed in MAC_Inner_VLAN_Incl or context descriptor. You must use this option only with the VLAN frames.. These fields are valid when you select the enable SA and VLAN insertion on transit and enable double VLAN processing options.
17	IVLTV	Inner VLAN Tag Valid When this field is 1, it indicates that IVT field of TDES2 is valid.
16	VLTV	VLAN Tag Valid When this field is 1, it indicates that VT field of TDES3 is valid.
15:0	VT	VLAN Tag

Table continues on the next page...

Table 515. TDES3 context descriptor (continued)

Bit	Name	Description
		Contains the VLAN tag to insert or replace in the packet. This field is used as VLAN tag only when MAC_VLAN_Incl[VLTI] becomes 0.

72.16.4 Receive descriptor

DMA in the module reads a descriptor only if the tail pointer is different from the base pointer or current pointer. It is recommended to have a descriptor ring with a length that accommodates at least two complete packets which MAC receives. Otherwise, the performance of DMA is impacted because of the unavailability of the descriptors. In such situations, the RxFIFO in MTL becomes full and starts dropping packets.

The following receive descriptors are present:

- Normal descriptors
- Context descriptors

You can prepare all the receive descriptors and give to DMA as normal descriptors with the content as shown in receive normal descriptor (read format). DMA reads this descriptor and the receive DMA closes the descriptor with the corresponding packet status after transferring a received packet (or part of) to the buffers indicated by the descriptor. The receive normal descriptor (write-back format) describes the format of this status.

For some packets, only the normal descriptor bits cannot write the complete status. For such packets, the receive DMA writes the extended status to the next descriptor (without processing or using the buffers or pointers embedded in that descriptor). Receive context descriptor describes the descriptor write back format and content.

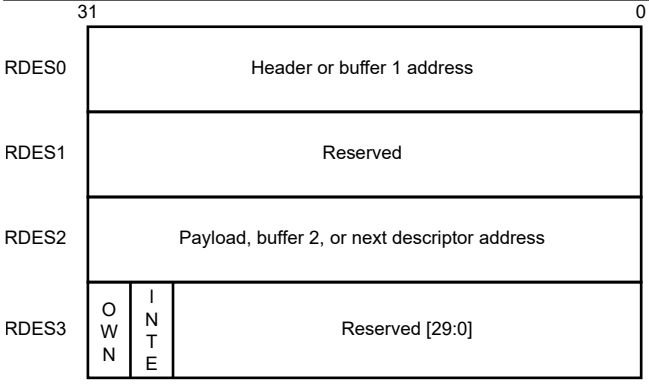
72.16.4.1 Receive normal descriptor (read format)

The read format for a receive normal descriptor is made up of the following:

- A header or buffer 1 address
- Reserved field
- Payload or buffer 2 or next descriptor address
- A 30-bit reserved field
- OWN bit
- An interrupt field

Figure 416 shows the read format for a receive normal descriptor.

Figure 416. Receive normal descriptor read format



NOTE

In the receive descriptor (read format), if the buffer address field is all zeros, the module does not transfer data to that buffer and skips to the next buffer or next descriptor.

72.16.4.1.1 RDES0 normal descriptor (read format)

Table 516 shows the RDES0 normal descriptor read format.

Table 516. RDES0 normal descriptor (read format)

Bit	Name	Description
31:0	BUF1AP	Header or Buffer 1 Address Pointer When the SPH field of control register of a channel becomes 0, these field indicates the physical address of buffer 1. When the SPH field is 1, these field indicates the physical address of header buffer where the receive DMA writes the L2/L3/L4 header bytes of the received packet. The application can program a byte-aligned address for this buffer which means that the LS bits of this field can be non-zero. However, DMA performs a write operation with RDES0[1:0] (or RDES0[2:0]/[3:0] in case of 64-/128-bit configuration) as zero, when the start of packet is transfered. However, the packet data shifts per the actual offset which the buffer address pointer provides. If the address pointer points to a buffer where the middle or last part of the packet is stored, DMA ignores the offset address and writes to the full location which the data-width indicates .

72.16.4.1.2 RDES1 normal descriptor (read format)

Table 517 shows the RDES1 normal descriptor read format.

Table 517. RDES1 normal descriptor (read format)

Bit	Name	Description
31:0	Reserved or BUF1AP	Contains the most-significant 32 bits of the buffer 1 address pointer in 64-bit Addressing mode. Otherwise, this field is reserved.

72.16.4.1.3 RDES2 normal descriptor (read format)

Table 518 shows the RDES2 normal descriptor read format.

Table 518. RDES2 normal descriptor (read format)

Bit	Name	Description
31:0	BUF2AP	Buffer 2 Address Pointer Indicates the physical address of buffer 2. When the SPH bit of the DMA_CH#_Control register = 1, it indicates that the buffer address pointer must be bus width-aligned, that is, RDES2[3:0, 2:0, or 1:0] = 0 corresponding to 128, 64, or 32 bus width. LSBs are ignored internally. When the SPH bit of the DMA_CH#_Control register becomes 0, it indicates that there is no limitations on the RDES2 value. However, the RxDMA uses the LS fields of the pointer address only when it transfers the start bytes of a packet. If the BUF2AP provides the address of a buffer in which the middle or last part of a packet is stored, DMA ignores BUF2AP[3:0 or 2:0 or 1:0] (corresponding to 128- or 64- or 32-bit data-bus) and writes to the complete location.

72.16.4.1.4 RDES3 normal descriptor (read format)

#unique_2917/unique_2917_Connect_42_id_1746ef2a-ecdf-425a-a0eb-74c5a5b90e21 describes the RDES3 normal descriptor read format.

31	30	19-26	25	24	23:0
OWN	IOC	Rsvd	BUF2V	BUF1V	Rsvd

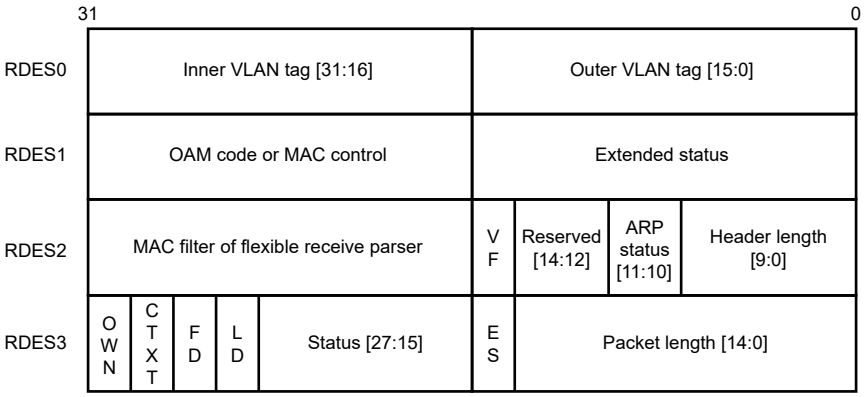
Table 519. RDES3 normal descriptor (read format)

Bit	Name	Description
31	OWN	Own Bit When this field is 1, it indicates that the module DMA owns the descriptor. When this field becomes 0, it indicates that the application owns the descriptor. DMA write 0 this field when either of the following conditions is true: • DMA completes the packet reception. • The buffers associated with the descriptor are full.
30	IOC	Interrupt Enabled on Completion When this field is 1, it indicates that an interrupt is issued to the application when DMA closes this descriptor.
29:26	Rsvd	Reserved
25	BUF2V	Buffer 2 Address Valid When this field is 1, it indicates to the DMA that the buffer 2 address specified in RDES2 is valid. The application must write 1 to this field so that DMA can use the address, to which the buffer 2 address in RDES2 points to write received packet data.
24	BUF1V	Buffer 1 Address Valid When this field is 1, it indicates to the DMA that the buffer 1 address specified in RDES1 is valid. The application must write 1 to this field, if DMA uses the address to which the buffer 1 address in RDES1 points to write the received packet data.
23:0	Rsvd	Reserved

72.16.4.1.5 Receive normal descriptor (write-back format)

Figure 417 shows the write-back format for a receive normal descriptor.

Figure 417. Receive normal descriptor (write-back format)



NOTE

When you enables the flexible receive parser, RDES2[31:16] indicates the parser status, and not the MAC filter status. The MAC filter status is not available when flexible receive parser is enabled.

72.16.4.1.5.1 RDES0 normal descriptor (write-back format)

Table 520 shows the write-back format for the RDES0 normal descriptor.

Table 520. RDES0 normal descriptor (write-back format)

Bit	Name	Description
31:16	IVT	Inner VLAN Tag Contains the inner VLAN tag of the received packet if the RS0V bit of RDES3 = 1. This field is valid only when you enables the double VLAN tag processing and VLAN tag stripping.
15:0	OVT	Outer VLAN Tag Contains the outer VLAN tag of the received packet if the RS0V bit of RDES3 = 1.

72.16.4.1.5.2 RDES1 normal descriptor (write-back format)

The status fields in the write-back format are valid only for the last descriptor (RDES3[28] = 1). #unique_2919/unique_2919_Connect_42_table_18e086e2-bda5-4002-b444-4d7ac47c01e8 provide the details of the write-back format for RDES1 normal descriptor.

31:16	15	14	13	12	11:8	7	6	5	4	3	2:0
OPC	TD	TSA	PV	PFT	PMT	IPCE	IPCB	IPV6	IPV4	IPHE	PT

Table 521. RDES1 normal descriptor (write-back format)

Bit	Name	Description
31:16	OPC	Indicates any one of the following: • OAM sub-type code: If bits [18:16] of RDES3 as described in RDES3 normal descriptor (read format) are 111b, this field contains the OAM sub-type and code fields.

Table continues on the next page...

Table 521. RDES1 normal descriptor (write-back format) (continued)

Bit	Name	Description
		• MAC control packet opcode: Bits 15:8 of RDES3 as described in RDES3 normal descriptor (read format) contain the subtype and bits 7:0 contain the code.
15	TD	Timestamp Dropped Indicates that the timestamp was captured for this packet but it dropped in the MTL Rx FIFO because of overflow. This field is available only when you select the timestamp feature. Otherwise, this field is reserved.
14	TSA	Timestamp Available Indicates that the timestamp value is available in a context descriptor word 2 (RDES2) and word 1(RDES1) when timestamp is present. This is valid only when the last descriptor field (RDES3 [28]) = 1 You can write the context descriptor in the next descriptor just after the last normal descriptor for a packet.
13	PV	PTP Version Indicates that the received PTP message has the IEEE 1588 version 2 format. When this field becomes 0, it indicates the IEEE 1588 version 1 format. This field is available only when you select the timestamp feature. Otherwise, this field is reserved.
12	PFT	PTP Packet Type Indicates that the PTP message is sent directly over Ethernet. This field is available only when you select the timestamp feature. Otherwise, this field is reserved.
11:8	PMT	PTP Message Type Encodes to give the type of the message received: • 0000: No PTP message received • 0001: SYNC (all clock types) • 0010: Follow_Up (all clock types) • 0011: Delay_Req (all clock types) • 0100: Delay_Resp (all clock types) • 0101: Pdelay_Req (in peer-to-peer transparent clock) • 0110: Pdelay_Resp (in peer-to-peer transparent clock) • 0111: Pdelay_Resp_Follow_Up (in peer-to-peer transparent clock) • 1000: Announce • 1001: Management • 1010: Signaling • 1011–1110: Reserved • 1111: PTP packet with reserved message type These fields are available only when you select the timestamp feature.

Table continues on the next page...

Table 521. RDES1 normal descriptor (write-back format) (continued)

Bit	Name	Description
7	IPCE	IP Payload Error When this field is 1, it indicates either of the following: • The 16-bit IP payload checksum (that is, the TCP, UDP, or ICMP checksum) which MAC calculates does not match the corresponding checksum field in the received segment. • The TCP, UDP, or ICMP segment length does not match the payload length value in the IP header field. • The TCP, UDP, or ICMP segment length is less than minimum allowed segment length for TCP, UDP, or ICMP. Bit 15 (ES) of RDES3 is not set when this field is 1.
6	IPCB	IP Checksum Bypassed Indicates that the checksum offload engine is bypassed. This field is available when you select the enable receive TCP/IP checksum check feature.
5	IPV6	IPv6 header Present Indicates that an IPV6 header is detected. When you select the enable split header feature option and the SPH bit of control register of a channel is 1, the IPV6 header is available in the header buffer area to which RDES0 points.
4	IPV4	IPV4 Header Present Indicates that an IPV4 header is detected. When the SPH bit of RDES3 is 1, the IPV4 header is available in the header buffer area to which RDES0 points.
3	IPHE	IP Header Error When this field is 1, it indicates either of the following: • The 16-bit IPv4 header checksum which MAC calculates does not match the received checksum bytes. • The IP datagram version is not consistent with the Ethernet type value. • Ethernet packet does not have the expected number of IP header bytes. This field is valid when either bit 5 or bit 4 is 1. This field is available when you select the enable receive TCP/IP checksum check feature.
2:0	PT	Payload Type Indicates the type of payload encapsulated in the IP datagram that the receive checksum offload engine (COE) process. • 3'b000: Unknown type or IP/AV payload not processed • 3'b001: UDP • 3'b010: TCP • 3'b011: ICMP • 3'b110: AV tagged data packet • 3'b111: AV tagged control packet

Table continues on the next page...

Table 521. RDES1 normal descriptor (write-back format) (continued)

Bit	Name	Description
		• 3'b101: AV untagged control packet • 3'b100: IGMP, if IPV4 header present field = 1, else DCB (LLDP) control packet If the COE does not process the payload of an IP datagram because there is an IP header error or fragmented IP, it sets these fields to 3'b000.

72.16.4.1.5.3 RDES2 normal descriptor (Write-back format)

31:29	28	27	26:19	18	17	16	15	14	13:11	10	9:0
L3L4FM	L4FM	L3FM	MADRM	HF	DAF	SAF	OTS	ITS	Rsvd	ARPNR	HL

Table 522. RDES2 normal descriptor (Write-back format)

Bit	Name	Description
31:29	L3L4FM	Layer 3 and Layer 4 Filter Number Matched Indicates the number of the layer 3 and layer 4 filter that matches the received packet: • 000: Filter 0 • 001: Filter 1 • 010: Filter 2 • 011: Filter 3 • 100: Filter 4 • 101: Filter 5 • 110: Filter 6 • 111: Filter 7 This field is valid only when bit 28 or bit 27 = 1. When more than one filter matches, these fields provide the number of lowest filter. **NOTE** This status is not available when Flexible RX Parser is enabled.
28	L4FM	Layer 4 Filter Match When this field is 1, it indicates that the received packet matches one of the enabled layer 4 port number fields. This status is given only when one of these conditions is true: • Layer 3 fields are not enabled and all enabled layer 4 fields match • All enabled layer 3 and layer 4 filter fields match When more than one filter matches, this bit gives the layer 4 filter status of filter indicated by Bits[31:29].

Table continues on the next page...

Table 522. RDES2 normal descriptor (Write-back format) (continued)

Bit	Name	Description
		NOTE This status is not available when the flexible receive parser is enabled.
27	L3FM	Layer 3 Filter Match When this field is 1, it indicates that the received packet matches one of the enabled layer 3 IP address fields. This status is given only when one of these conditions is true: • All enabled layer 3 fields match and bypasses all enabled layer 4 fields. • All enabled filter fields match. When more than one filter matches, this field gives the layer 3 filter status of filter which bits[31:29] indicate. **NOTE** This status is not available when the flexible receive parser is enabled.
26:19	MADRM	MAC Address Match or Hash Value When HF becomes 0, it indicates that this field contains the MAC address register number that matches the received packet destination address. This field is valid only if the DAF field becomes 0. When HF = 1, it indicates that this field contains the hash value that MAC computes. A packet passes the hash filter when the field corresponding to the hash value is 1 in the hash filter register. **NOTE** This status is not available when the flexible receive parser is enabled.
18	HF	Hash Filter Status When this field is 1, it indicates that the packet passes the MAC address hash filter. Bits[26:19] indicate the hash value. **NOTE** This status is not available when the flexible receive parser is enabled.
17	DAF/RXPI	Destination Address Filter Fail When flexible receive parser is disabled, and this field is 1, it indicates that the packet fails the DA filter in MAC. When flexible receive parser is enabled, and this field is 1, it indicates that the packet parsing is incomplete (RXPI) due to ECC error. **NOTE** When this field is 1, RDES3 ES field is also 1.
16	SAF/RXPD	SA Address Filter Fail When flexible receive parser is disabled, and this field is 1, it indicates that the packet fails the SA filter in MAC.

Table continues on the next page...

Table 522. RDES2 normal descriptor (Write-back format) (continued)

Bit	Name	Description
		When flexible receive parser is enabled and this field is 1, it indicates that the parser drops the RXPD packet. **NOTE** When this field is 1, RDES3 ES field is also 1.
15	OTS	VLAN Filter Status When this field is 1, it indicates that the received packet VLAN tag passes the VLAN filter. This field redefines as an outer VLAN tag filter status (OTS). This field is valid for both single and double VLAN tagged frames.
14	ITS	Inner VLAN Tag Filter Status (ITS) This field is valid only for double VLAN tagged frames, when double VLAN processing is enabled. See Filter status for more information.
13:11	Rsvd	Reserved
10	ARPNR	ARP Reply Not Generated When this field is 1, it indicates that MAC did not generate the ARP reply for the ARP request packet it receives.. This field is 1 when MAC is busy transmitting ARP reply to earlier ARP request (only one ARP request is processed at a time). This field is reserved when you do not select the enable IPv4 ARP offload option.
9:0	HL	L3/L4 Header Length Contains the length of the packet header which MAC splits at L3 or L4 header boundary which the MAC receiver identifies. This field is valid only when the first descriptor bit = 1 (FD = 1). You can write the header data to the buffer 1 address of corresponding descriptor. If the header length is zero, this field is not valid. It implies that MAC does not identify and split the header. This field is valid when you select the enable split header feature option.

72.16.4.1.5.4 RDES3 normal descriptor (Write-back format)

#unique_2921/unique_2921_Connect_42_id_9cde4392-a0c2-4731-bcb2-bf9dcd789aae describes the write-back format for the RDES3 normal descriptor.

31	30	29	28	27	26	25	24	23	22	21	20	19	18:16	15	14:0
OWN	CTXT	FD	LD	RS2V	RS1V	RS0V	CE	GP	RWT	OE	RE	DE	LT	ES	PL

Table 523. RDES3 normal descriptor (Write-back format)

Bit	Name	Description
31	OWN	Own Bit When this field is 1, it indicates that the module DMA owns the descriptor. If this field becomes 0, it indicates that the application owns the descriptor. DMA writes 0 to this field when either of these conditions is true: • DMA completes the packet reception. • The buffers associated with the descriptor are full.
30	CTXT	Receive Context Descriptor When this field is 1, it indicates that the current descriptor is a context type descriptor. DMA writes 1'b0 to this field for a normal receive descriptor. When CTXT and FD bits are used together, {CTXT, FD} • 2’b00: Intermediate descriptor • 2’b01: First descriptor • 2’b10: Reserved • 2’b11: Descriptor error (due to all 1s) **NOTE** When descriptor error occurs, the receive DMA closes the receive descriptor indicating a descriptor error. This receive descriptor is skipped and the buffer addresses are not used to write the packet data. Receive DMA will write 1 to the CDE bit in DMA_CH#_Status register but not to the RI bit even when IOC = 1, as this is not marked as the last receive descriptor for the packet. The subsequent valid receive descriptor writes the packet data.
29	FD	First Descriptor When this field is 1, it indicates that this descriptor contains the first buffer of the packet. If the size of the first buffer is 0, the second buffer contains the beginning of the packet and if the size of the second buffer is also 0, the next descriptor will contain the beginning of the packet. See the CTXT bit description for more information on how to use the CTXT bit and FD bit together.
28	LD	Last Descriptor When this field is 1, it indicates that this descriptor buffers points to the last buffers of the packet.
27	RS2V	Receive Status RDES2 Valid When this field is 1, it indicates that the status in RDES2 is valid and DMA writes it. This field is valid only when the LD bit of RDES3 = 1.
26	RS1V	Receive Status RDES1 Valid When this field is 1, it indicates that the status in RDES1 is valid and DMA writes it. This field is valid only when the LD bit of RDES3 = 1.
25	RS0V	Receive Status RDES0 Valid When this field is 1, it indicates that the status in RDES0 is valid and DMA writes it. This field is valid only when the LD bit of RDES3 = 1.

Table continues on the next page...

Table 523. RDES3 normal descriptor (Write-back format) (continued)

Bit	Name	Description
24	CE	CRC Error When this field is 1, it indicates that a cyclic redundancy check (CRC) error occurs on the received packet. This field is valid only when the LD bit of RDES3 = 1.
23	GP	Giant Packet When this field is 1, it indicates that the packet length exceeds the specified maximum Ethernet size of 1518, 1522, or 2000 bytes (9018 or 9022 bytes if jumbo packet enable = 1). **NOTE** Giant packet indicates only the packet length. It does not cause any packet truncation.
22	RWT	Receive Watchdog Timeout When this field is 1, it indicates that the receive watchdog timer expires when it receives the current packet. The current packet truncates after watchdog timeout.
21	OE	Overflow Error When this field is 1, it indicates that the received packet is damaged because of buffer overflow in receive FIFO. **NOTE** This field is 1 only when DMA transfers a partial packet to the application. This happens only when the receive FIFO operates in the Threshold mode. In the Store-and-Forward mode, all the partial packets drops completely in the receive FIFO.
20	RE	Receive Error When this field is 1, it indicates that the gmii_rxer_i signal asserts when the gmii_rxdv_i signal asserts during the packet reception. This error also includes carrier extension error in the GMII and Half-duplex mode. Error can be of less or no extension, or error (rxd!= 0f) during extension.
19	DE	Dribble Bit Error When this field is 1, it indicates that the received packet has a non-integer multiple of bytes (odd nibbles). This field is valid only in the MII mode.
18:16	LT	Length/Type Field Indicates if the packet received is a length packet or a type packet. The encoding of the 3 bits is as follows: • 3'b000: The packet is a length packet. • 3'b001: The packet is a type packet. • 3'b011: The packet is a ARP request packet type • 3'b100: The packet is a type packet with VLAN tag • 3'b101: The packet is a type packet with double VLAN tag • 3'b110: The packet is a MAC control packet type • 3'b111: The packet is a OAM packet type

Table continues on the next page...

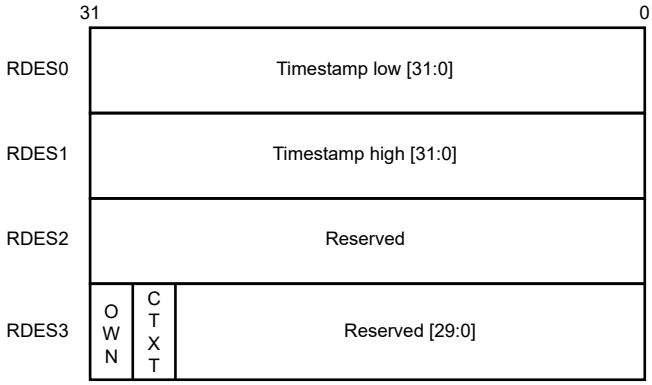
Table 523. RDES3 normal descriptor (Write-back format) (continued)

Bit	Name	Description
		• 3'b010: Reserved
15	ES	Error Summary When this field is 1, it indicates the logical OR of these bits, : • RDES3[24]: CRC error • RDES3[19]: Dribble error • RDES3[20]: Receive error • RDES3[22]: Watchdog timeout • RDES3[21]: Overflow error • RDES3[23]: Giant packet • RDES2[17]: Destination address filter fail, when the flexible receive parser is enabled • RDES2[16]: SA address filter fail, when flexible receive parser is enabled This field is valid only when the LD bit of RDES3 = 1.
14:0	PL	Packet Length Indicates the byte length of the received packet that was transferred to system memory (including CRC). This field is valid when the LD bit of RDES3 = 1 and overflow error bits becomes 0. The packet length also includes the two bytes that appends to the Ethernet packet when IP checksum calculation is enabled and the received packet is not a MAC control packet. This field is valid when the LD bit of RDES3 = 1. When the last descriptor and error summary bits are not 1, this field indicates the accumulated number of bytes that are transferred for the current packet.

72.16.4.1.6 Receive context descriptor

This descriptor is read-only for the application. Only DMA can write to this descriptor. The context descriptor provides information about the extended status related to the last received packet. Bit 30 of RDES3 indicates the context type descriptor.

Figure 418. Receive context descriptor format



72.16.4.1.6.1 RDES0 context descriptor

Table 524. RDES0 context descriptor

Bit	Name	Description
31:0	RTSL	Receive Packet Timestamp Low DMA updates this field with least significant 32-bits of the timestamp captured for the corresponding receive packet. When this field and the RTSH field of RDES1 show all-ones value, you must consider the timestamp as corrupt.

72.16.4.1.6.2 RDES1 context descriptor

Table 525. RDES1 context descriptor

Bit	Field	Description
31:0	RTSH	Receive Packet Timestamp High DMA updates this field with the most significant 32-bits of the timestamp captured for the corresponding receive packet. When this field and the RTSL field of RDES0 show all-ones value, you must consider the timestamp as corrupt.

Bit	Name	Description
31	OWN	Own Bit When this field is 1, it indicates that DMA owns the descriptor. When this field becomes 0, it indicates that the application owns the descriptor. DMA clears this field when either of these conditions is true: • DMA completes the packet reception. • The buffers associated with the descriptor are full.
30	CTXT	Receive Context Descriptor

Table continues on the next page...

Table 527. RDES3 context descriptor (continued)

Bit	Name	Description
		When this field is 1, it indicates that the current descriptor is a context descriptor. DMA writes 1'b1 to this field for context descriptor. DMA writes 2'b11 to indicate a descriptor error due to all = 1. When CTXT and DE bits are used together {CTXT, DE} • 2'b00: Reserved • 2'b01: Reserved • 2'b10: Context descriptor • 2'b11: Descriptor error Note: When descriptor error occurs, the receive DMA closes the receive descriptor indicating descriptor error. This receive descriptor is skipped and the buffer addresses does not write the packet data. The receive DMA writes 1 to the CDE bit in DMA_CH#_Status register but not to the RI bit even when IOC = 1, because this is not marked as last receive descriptor for the packet. The subsequent valid receive descriptor writes the packet data.
29	DE	Descriptor Error See the CTXT bit description for more information about how to use the DE bit along with CTXT bit.
28:0	Rsvd	Reserved

72.16.5 Enhanced descriptor for time-based scheduling

This feature needs 32 bytes enhanced descriptors to enable on all the DMA channels that uses this feature (write 1 to EDSE bit of DMA_CH(#i)_TX_Control register).

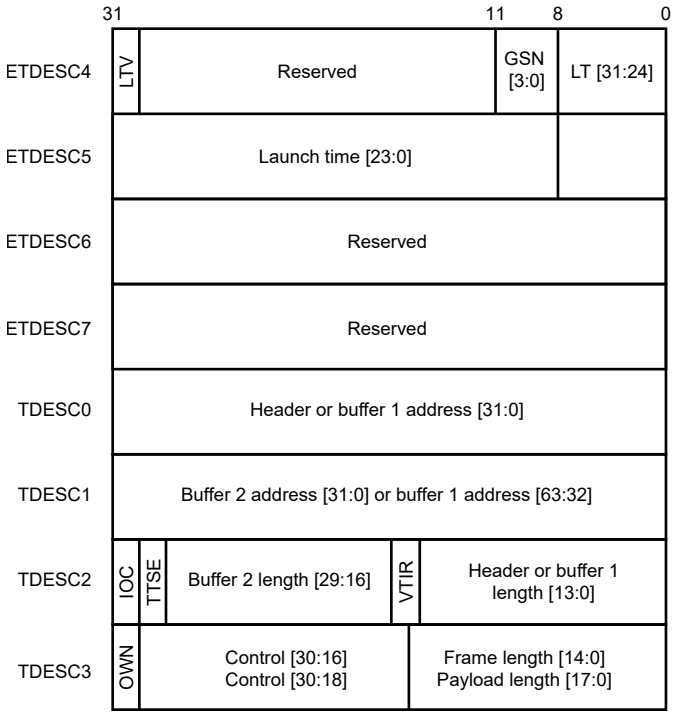
The structure of 32-byte descriptor for the context and the normal descriptor in read and write formats are described in the upcoming sections.

72.16.5.1 Enhanced normal descriptor - Read (32-bit mode)

These fields are present in the first 16 bytes of the enhanced descriptor format of normal descriptor:

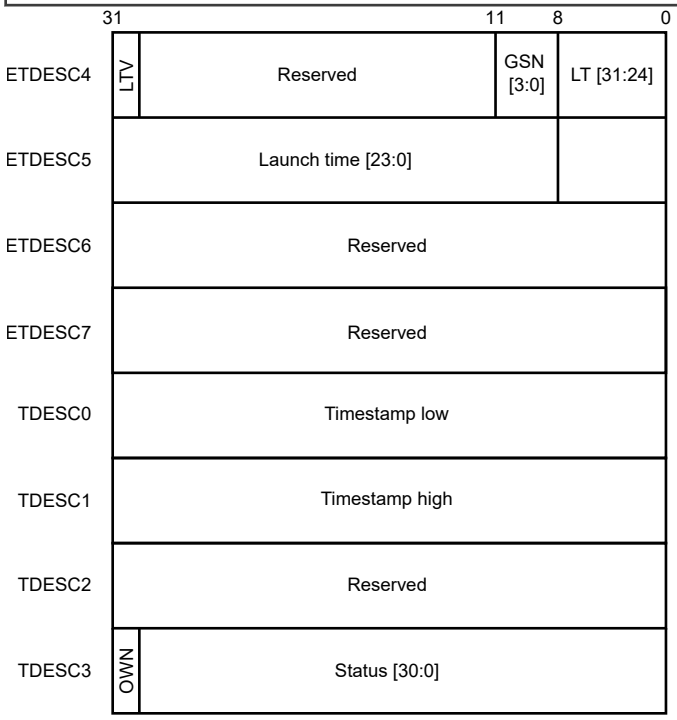
- LTV- Indicates that the launch time (LT) and GSN fields present in the descriptor are valid. The LTV must be = 1 only if the FD bit of the descriptor is not.
- GSN- Indicates the GCL slot number associated with the packet.
- LT- Indicates the launch time associated with the packet.

Figure 419. Enhanced normal descriptor - Read (32-bit mode)



72.16.5.2 Enhanced normal descriptor (Write, 32-bit mode)

Figure 420. Enhanced normal descriptor write (32-bit mode)



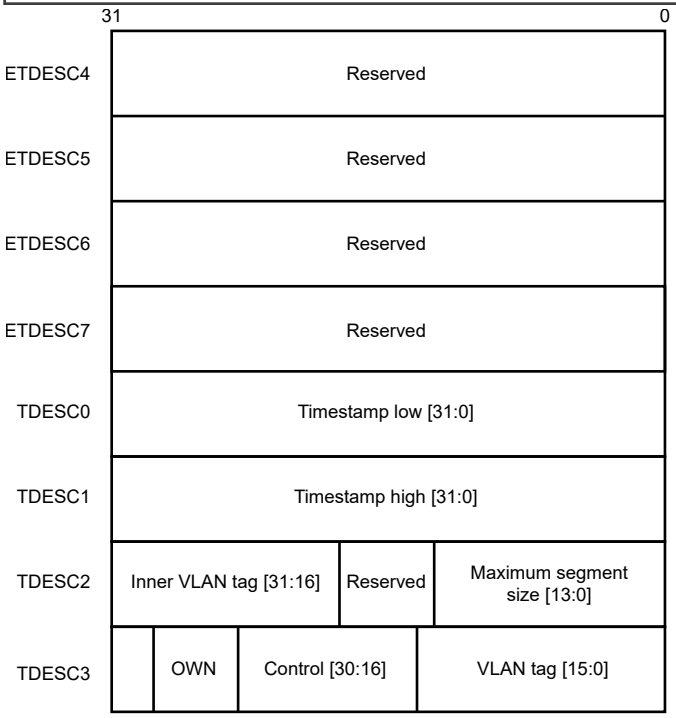
NOTE

- All the enhanced descriptors, example, assumes a 32-bit data width configurations. However, the same definitions are valid in 64-bit and 128-bit configurations.
- In both the write back formats, you cannot modify the extended 16 bytes. The remaining 16 bytes (TDESC0 to TDESC3) are written back per the previous 16 bytes descriptor format.
- When you enable the fetch time it overrides the AV slot function
- When an unaligned new GCL list (with a different CTR) is installed it is recommended not to have traffic during the installation of the new list. Any traffic during the switching of the lists might have unpredictable behavior regarding fetch, launch, and launch expiry because the CTR and BTR values get updated when the frame is processed

72.16.5.3 Enhanced context descriptor (Read, 32-bit mode)

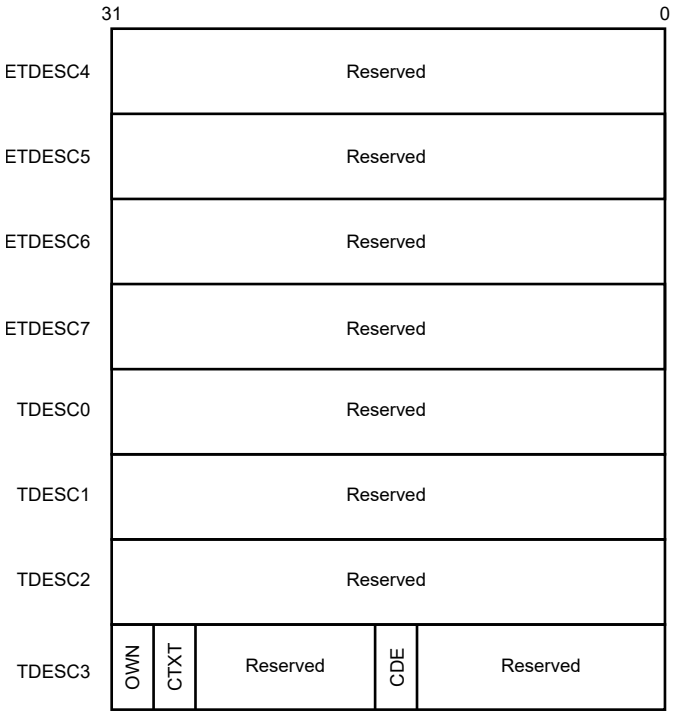
The first 16 bytes of the enhanced context descriptor (ETDESC4 to ETDESC7) are reserved and must be = 0. The fields present in the last bytes of the descriptor (TDESC0 to TDESC3) are same as the context descriptor (TDESC0 to TDESC3) in 16 byte format.

Figure 421. Enhanced context descriptor - Read



72.16.5.4 Enhanced context descriptor (Write, 32-bit mode)

Figure 422. Enhanced context descriptor - Write



72.17 Programming

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

This section provides the instructions for initializing the DMA or MAC registers in the proper sequence.

72.17.1 Initializing DMA

Perform these steps to initialize DMA:

1. Provide a software reset. This resets all the MAC internal registers and logic (bit-0 of DMA_Mode).
2. Wait for the reset process (poll bit 0 of DMA_Mode which is only clears after the reset operation completes) to complete.
3. Program these fields to initialize DMA_SysBus_Mode:
   a. DMA_SysBus_Mode[AAL]
   b. Fixed burst or undefined burst
   c. Burst mode values in case of AHB bus interface, OSR_LMT in case of AXI bus interface.
   d. Select the maximum burst length possible on the AXI bus (bits [7:1]), if fixed length value is enabled.
4. Create a descriptor list for a transmit and receive. Also, ensure that DMA (write 1 to bit 31 of descriptor TDES3/RDES3) owns the descriptors. See Descriptors for more information about descriptors.
5. Program the transmit and receive ring length registers (DMA_CH(#i)_TxDesc_Ring_Length (for i = 0; i <= 1) and DMA_CH(#i)_RxDesc_Ring_Length (for i = 0; i <= 1)). The programmed ring length must be at least 4.

   NOTE

   The descriptor address from the start to the end of the ring must not cross the 4 GB boundary.

6. Initialize the receive and transmit descriptor list address with the base address of the transmit and receive descriptor (DMA_CH(#i)_TxDesc_List_Address (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1), DMA_CH(#i)_RxDesc_List_Address (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1)). Also, program the transmit and receive tail pointer registers that indicates DMA about the available descriptors (DMA_CH(#i)_TxDesc_Tail_Pointer

(for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) and DMA_CH(#i)_RxDesc_Tail_Pointer (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1)).

NOTE

For 40-bit or 48-bit addressing mode, program the higher address List registers (DMA_CH[n]_TxDesc_List_HAddress, DMA_CH[n]_RxDesc_List_HAddress).

The tailpointer registers must advance to the location immediately after the descriptors that are set so that DMA is aware that the additional descriptors are available.

7. Program the settings of these registers for the parameters like maximum burst-length (PBL) which DMA initiates, descriptor skip lengths, OSP in case of TxDMA, RBSZ in case of RxDMA, and so on:
   - DMA_CH(#i)_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1)
   - DMA_CH(#i)_TX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1)
   - DMA_CH(#i)_RX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1)
8. Program the DMA_CH(#i)_Interrupt_Enable (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register to enable the interrupts.
9. Write 1 to SR (bit 0) of the DMA_CH(#i)_RX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1) and ST (bit 0) of the DMA_CH(#i)_TX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register to start the receive and transmit DMAs.
10. Repeat steps 4 to 9 for all the transit DMA and receive DMA channels selected in the hardware.

72.17.2 Initializing MTL registers

The transaction layer (MTL) registers must initialize to establish the transmit and receive operating modes and commands.

Perform these steps to initialize the MTL registers:

1. Program MTL_Operation_Mode[SCHALG] and MTL_Operation_Mode[RAA] to initialize the MTL operation in case of multiple transit and receive queues.
2. Program the receive queue to DMA mapping in MTL_RxQ_DMA_Map0.
3. Program these fields to initialize the mode of operation in MTL_TxQ0_Operation_Mode.
   a. MTL_TxQ0_Operation_Mode[TSF] or MTL_TxQ0_Operation_Mode[TTC] in case of Threshold mode.
   b. MTL_TxQ0_Operation_Mode[TXQEN] to value 2'b10 to enable transmit queue0.
   c. MTL_TxQ0_Operation_Mode[TQS]
4. Program these fields to initialize the mode of operation in MTL_RxQ0_Operation_Mode:
   a. MTL_RxQ0_Operation_Mode[RSF] or MTL_RxQ0_Operation_Mode[RTC] in case of Threshold mode.
   b. Flow control activation and de-activation thresholds for MTL receive FIFO (MTL_RxQ0_Operation_Mode[RFA] and MTL_RxQ0_Operation_Mode[RFD]).
   c. Error Packet and undersized good Packet forwarding enable (MTL_RxQ0_Operation_Mode[FEP] and MTL_RxQ0_Operation_Mode[FUP]).
   d. MTL_RxQ0_Operation_Mode[RQS]
5. Repeat previous two steps for all MTL transit and receive queues selected in the configuration.

72.17.3 Initializing MAC

The MAC configuration registers establish the operating mode of MAC. These registers must initialize before initializing DMA.

You can perform these MAC initialization operations after DMA initialization. If the MAC initialization completes before DMA is configured, enable the MAC receiver (last step in the following sequence) only after the DMA is active. Otherwise, the received frames fill the receive FIFO and overflow.

1. Provide the MAC address registers: MAC_Address0_High and MAC_Address0_Low. If more than one MAC address is enabled, , program the MAC addresses appropriately.

2. Program these fields to set the appropriate filters for the incoming frames in MAC_Packet_Filter:

a. Receive all

b. Promiscuous mode

c. Hash or perfect filter

d. Unicast, multicast, broadcast, and control frames filter settings

3. Program these fields for proper flow control in MAC_Q0_Tx_Flow_Ctrl:

a. Pause time and other Pause frame control bits

b. Transmit flow control bits

c. Flow control busy

4. Program MAC_Interrupt_Enable as required, and if applicable, for your configuration.

5. Program the appropriate fields in MAC_Configuration. For example Inter-packet gap when transmission and jabber disable.

6. Write 1 to MAC_Configuration[RE] and MAC_Configuration[TE] to start the MAC transmitter and receiver.

72.17.4 Performing normal receive and transmit operation

During normal operation of the module, read the normal and transmit interrupts, poll the descriptors, suspend the DMA (if it does not own descriptors), and read the values of the current host transmitter or receiver descriptor pointers for debugging.

For normal operation, perform these steps:

1. Read the interrupt status for normal transmit and receive interrupts. Then poll the descriptors, read the status of the descriptor which the host owns (either transmit or receive).

2. Set appropriate values for the descriptors, ensure that the DMA owns the transmit and receive descriptors to resume the data transmission and reception.

3. If DMA does not own the descriptors (or no descriptor is available), DMA enters into SUSPEND state. The transmission or reception can resume by freeing the descriptors and writing the descriptor tail pointer to Tx/Rx tail pointer register (DMA_CH[n]_TxDesc_Tail_Pointer and DMA_CH[n]_RxDesc_Tail_Pointer).

4. Read the current host transmitter or receiver descriptor address pointer values for the debug process (DMA_CH[n]_Current_App_TxDesc and DMA_CH[n]_Current_App_RxDesc regsiter).

5. Read the current host transmit buffer address pointer and receive buffer address pointer values for the debug process (Register DMA_CH[n]_Current_App_TxBuffer and DMA_CH[n]_Cur-rent_App_RxBuffer).

72.17.5 Stopping and starting transmission

Perform these steps to pause the transmission for some time. The steps are provided for channel 0.

1. Write 0 to bit 0 (ST) of DMA_CH(#i)_TX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register to disable the transmit DMA (if applicable) .

2. Wait for any previous frame transmissions to complete. Read the appropriate fields of MTL_TxQ0_Debug (MTL_TxQ0_Debug[TRCSTS] is not 01 and MTL_TxQ0_Debug[TXQSTS] = 0) to check this.

3. Write 0 to MAC_Configuration[RE] and MAC_Configuration[TE] to disable the MAC transmitter and MAC receiver.

4. Disable the receive DMA (if applicable), after you ensure that the data in the receive FIFO transfers to the system memory (read the appropriate fields MTL_RxQ0_Debug[PRXQ] = 0 and MTL_RxQ0_Debug[RXQSTS] = 00).

5. Ensure that both the transit queue and receive queue are empty (MTL_TxQ0_Debug[TXQSTS] = 0 and MTL_RxQ0_Debug[RXQSTS] = 0).

6. Restart the operation by first starting the DMAs, and then enable the MAC transmitter and receiver.

NOTE

- Do not change the configuration (such as duplex mode, speed, port, or loop back) when the MAC is actively transmitting or receiving. You can change these parameters only when the MAC transmitter and receiver are not active.
- Similarly, do not change the DMA related configuration when transmit and receive DMA are active.

72.17.6 Programming guidelines for switching to new descriptor list in RxDMA

Switching to a new descriptor list is different in the receive DMA as compared to the transit DMA. It is permitted when the RxDMA is in SUSPEND state as described below:

- RxDMA prepares the descriptors in advance.
- If the RxDMA goes to SUSPEND state because the descriptors are not available, a major failure occurs (you are not able to free the filled-up descriptors or buffers). If this issue does not rectify immediately, frames will be lost because of an RxFIFO overflow. Therefore, you can create a new descriptor list and program the RxDMA to start using it immediately, without going into STOP state.

72.17.7 Programming guidelines for multi-channel multi-queuing

72.17.7.1 Transmit

1. Program the transmit queue size in TQS field of MTL_TxQ[n]_Operation_Mode register. Based on the value programmed in TQS field, you can determine the queue size.

In the transmit operation, the number of channels is equal to the number of the queues, because of this reason, the channel-to-queue mapping is fixed.

2. Enable the queue in TXQEN in the corresponding MTL_TxQ[n]_Operation_Mode register to use the queue. In DMA configurations, enable the ST field of DMA_CH[n]_Tx_Con-trol register and corresponding TXQEN in MTL_TxQ[n]_Operation Mode register.

3. Program the scheduling method in MTL_Operation_Mode[SCHALG].

4. Program MTL_TxQ[n]_Quantum_Weight register for DCB queue per the selected algorithm. In case of CBS algorithm in AVB queues program the MTL_TxQ[n]_ETS_Control, MTL_TxQ[n]_SendSlopeCredit, MTL_TxQ[n]_HiCredit, and MTL_TxQ[n]_LoCredit registers as required.

5. Program the MAC_TxQ_Prty_Map0 register to assign a fixed priority to the queue, if DCB is enabled and PFC function is required. You can use this assigned priority to determine if the corresponding queue must stop transmitting packet on the basis of the received PFC packet.

72.17.7.2 Receive

1. Program the receive queue size in RQS field of MTL_RxQ[n]_Operation_Mode register. Determine the size of the queue, based on the value programmed in RQS field.
2. Enable the receive queues 0 to 7 in the fields RXQ0EN to RXQ7EN in MAC_RxQ_Ctrl0 for AV or DCB. In DMA configurations, SR bit of statically or dynamically map DMA_CH[n]_Rx_Control register and the corresponding RXQ[n]_EN in MAC_RxQ_Ctrl0 is enabled.
3. Based on these packet types MAC routes the receive packets to the receive queues :
    a. AV PTP packets: Based on the programming of MAC_RxQ_Ctrl1[PTPQ].
    b. AV untagged control packets: Based on the programming of MAC_RxQ_Ctrl1[AVCPQ].

c. Data center bridging (DCB) related link layer discovery protocol (LLDP) packets. Program DCBCPQ in MAC_RxQ_Ctrl1 to indicate MAC which queue should get the DCB packets.

d. VLAN tag priority field in VLAN tagged packets: Program PSRQ7-0 of the MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 register for routing the tagged packets based on the received packets USP (user priority) field to the receive queues 0 to 7.

e. Route the AV tagged control and data packets based on PSRQ field of MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers.

NOTE

The priorities set in PSRQ7-0 must be unique.

4. If multiple receive DMA channels are enabled, you must perform the following programming for proper arbitration and mapping:

a. Program MTL_Operation_Mode[RAA] to select the arbitration algorithm to decide which RxQ is read out from the RxFIFO memory.

b. Program the MTL_RxQ[n]_Control register to decide the weights and the packet arbitration for each RxQ.

c. If you program the static mapping in MTL_RxQ_DMA_Map[n] register (RXQ[n]DADMACH becomes 0), fields RXQx2DMA and others are programmed to select the channel to map each queue.

d. Write 1 to RXQ[n]DADMACH field in MTL_RxQ_DMA_Map0 to select the dynamic mapping of packets in each receive queue.

e. In dynamic channel mapping, the value of DCS field in the lowest MAC address registerthe decides the routing of a packet to a specific RxDMA channel.

72.17.7.2.1 Programming guidelines for recovering from DMA channel failure

When the DMA channel issues a bus error, follow these steps to recover from the failure.

Recovering from the receive DMA channel failure.

Perform these steps if you get bus error in the receive DMA channel:

1. Write 1 to DMA_CH0_Rx_Control[RPF]. This flushes all the packets one after the other.

This step is optional. However, writing 1 to this field prevents head-of-line blocking in the receive queues when packets sent to the RXDMA are stopped due to the bus error.

2. Re-program the specific registers of the DMA channel.

3. Start the DMA channel.

Recovering from the transmit DMA channel failure.

1. Stop the specific DMA channel, even if it is in active state.

2. Flush the corresponding MTL queue.

3. Re-program the specific registers of the DMA channel.

4. Start the DMA channel.

NOTE

Due to the known limitations in the design, reprogramming the DMA channel registers might not be always successful in recovering from a bus error. If the module is not fully functional after reprogramming the DMA, you can issue a soft reset to recover from the bus error.

72.17.8 Programming guidelines for GMII link state transitions

72.17.8.1 Transmit and receive clocks running when link down

Perform these steps when the link is down but the transmit and receive clocks are running:

NOTE

The steps are provided for channel 0.

1. Write 0 to bit 0 (ST) of DMA_CH(#i)_TX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register to disable the transmit DMA (if applicable).

2. Write 0 to MAC_Configuration[RE] to disable the MAC receiver.

3. Wait for any previous frame transmissions to complete. You can check this by reading the appropriate fields of MTL_TxQ0_Debug (MTL_TxQ0_Debug[TRCSTS] is not 01) or, flush the Tx FIFO for faster empty operation.

4. Write 0 to MAC_Configuration[TE] to disable the MAC transmitter.

5. Make sure that both the transit queue and receive queue are empty (MTL_TxQ0_Debug[TXQSTS] and MTL_RxQ0_Debug[RXQSTS] are 0).

6. Read the PHY registers to know the latest configuration and accordingly program the MAC registers, after the link is up.

7. Start the transit DMA to restart the operation, and then enable the MAC transmitter and receiver.

You do not disable the receive DMA because the receiver is disabled and the FIFO does not get any data in the receive FIFO.

72.17.8.2 Transmit and receive clocks stopped when link down

Perform these steps when the link is down and the transmit and receive clocks are stopped:

NOTE

The steps are provided for channel 0.

1. Write 0 to MAC_Configuration[RE] and MAC_Configuration[TE] to disable the MAC transmitter and receiver. This does not take effect immediately as the clocks are absent.

2. Wait until the link is up and the clocks are restored.

3. Wait for the transfer of any partial frame, if any to complete at time of stopping of the transmit or receive clock. To check this, read MAC_Debug (should be all-zero). Some old packets may still remain in the TXFIFO because the MAC transmitter is stopped.

4. Read the PHY registers to know the latest operating mode and accordingly program the MAC registers.

5. Write 1 to MAC_Configuration[RE] and MAC_Configuration[TE] to restart the MAC transmitter and receiver.

72.17.9 Programming guidelines for IEEE 1588 timestamping

72.17.9.1 Initialization guidelines for system time generation

Write 1 MAC_Timestamp_Control[TSENA] to enable the timestamp feature. However, it is essential to initialize the timestamp counter after MAC_Timestamp_Control[TSENA] = 1. Perform these steps during the module initialization:

1. Write 0 to the bit 16 of MAC_Interrupt_Enable to mask the timestamp trigger interrupt.
2. Write 1 to MAC_Timestamp_Control[TSENA] to enable timestamping.
3. Program MAC_Sub_Second_Increment based on the PTP clock frequency.
4. Program MAC_Timestamp_Addend and write 1 to MAC_Timestamp_Control[TSADDREG], if you are using the fine correction approach.
5. Poll MAC_Timestamp_Control until MAC_Timestamp_Control[TSADDREG] = 0.
6. Program MAC_Timestamp_Control[TSCFUPDT] to select the fine update method (if required).

7. Program MAC_System_Time_Seconds_Update and MAC_System_Time_Nanoseconds_Update with the appropriate time value.
8. Write 1 to MAC_Timestamp_Control[TSINIT].
9. Initialize the timestamp counter with the value written in the timestamp update registers so that the timestamp counter can start operation. If one-step timestamping is enabled
    a. Program Bit 27 of the TDES3 context descriptor, to enable one-step timestamping.
    b. Program MAC_Timestamp_Ingress_Asym_Corr and MAC_Timestamp_Egress_Asym_Corr to update the correction field in PDelay_Req PTP messages.
10. Enable the MAC receiver and transmitter for proper timestamping.

NOTE

If the timestamp operation is disabled by writing 0 to MAC_Timestamp_Control[TSENA], repeat all these steps to restart the timestamp operation.

72.17.9.2 System time correction

72.17.9.2.1 Coarse correction method

Perform these steps to synchronize or update the system time in one process (coarse correction method):

1. Set the offset (positive or negative) in the timestamp registers that is MAC_System_Time_Seconds_Update and MAC_System_Time_Nanoseconds_Update.

2. Write 1 to MAC_Timestamp_Control[TSUPDT].

The value in the timestamp update registers is added to or subtracted from the system time when MAC_Timestamp_Control[TSUPDT] = 0.

72.17.9.2.2 Fine correction method

Perform these steps to synchronize or update the system time to reduce system-time jitter (fine correction method):

1. Calculate the rate by which you want to increment the system time slower or faster, with the help of the algorithm.

2. Update MAC_Timestamp_Addend with the new value and write 1 to MAC_Timestamp_Control[TSADDREG].

3. Wait for the time for which you want the new value of the addend register to be active. You can do this by enabling the timestamp trigger interrupt after the system time reaches the target value.

4. Program the required target time in MAC_PPS[n]_Target_Time_Seconds register and MAC_PPS[n]_Target_Time_Nanoseconds register.

5. Enable the timestamp interrupt in MAC_Interrupt_Enable[TSIE].

6. Write 1 to bit 4 in MAC_Timestamp_Control.

7. Read MAC_Interrupt_Status when this trigger causes an interrupt.

8. Reprogram MAC_Timestamp_Addend with the old value and write 1 to MAC_Timestamp_Control[TSADDREG] again.

72.17.10 Programming guidelines for AV feature

After you enable the AV feature in the module controller, follow these programming tasks:

- Initializing the DMA for QOS-AHB configurations only
- Enabling slot number checking
- Enabling average bits per slot reporting
- Disabling flow control for AV-enabled queues (transmit and receive flow control)

72.17.10.1 Initializing the DMA in audio video feature

The first step to program the AV feature in a QOS-AHB configuration is to initialize the DMA.

Use this initialization sequence for QOS-AHB/QOS-AXI/QOS-AXI4 configurations with AV feature.

1. Provide a software reset to reset all the QOS internal registers and logic (DMA_Mode[SWR]).

2. Wait for the reset process to complete. Poll DMA_Mode[SWR], which clears only after the reset operation completes.

3. Set the values in DMA_Mode to program the fields to initialize the DMA register.

4. Create a descriptor list for transmit and receive. In addition, ensure that the DMA owns the transmit and receive descriptors. When you use OSF mode, at least two transmit descriptors are required.

See Descriptors for more information about descriptors.

5. Ensure that you create three or more different transmit or receive descriptors in the list before reusing any descriptors.

6. Program the transmit and receive ring length registers (DMA_CH(#i)_TxDesc_Ring_Length (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) and DMA_CH(#i)_RxDesc_Ring_Length (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1)). The ring length programmed must be at least 4.

7. Initialize receive and transmit descriptor list address with the base address of the transmit and receive descriptor (DMA_CH(#i)_TxDesc_List_Address (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1), DMA_CH(#i)_TxDesc_List_Address (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1)). In addition, you must program the transmit and receive tail pointer registers to indicate the DMA about the available descriptors (DMA_CH(#i)_TxDesc_Tail_Pointer (for i = 0; i <= DWC_EQOS_NUM_D-MA_TX_CH-1) and DMA_CH(#i)_RxDesc_Tail_Pointer (for i = 0; i <= DWC_EQOS_NUM_D-MA_RX_CH-1)).

8. Program these fields to initialize the mode of operation in MTL_TxQ0_Operation_Mode:

a. MTL_TxQ0_Operation_Mode[TSF]

b. MTL_TxQ0_Operation_Mode[TTC]

c. MTL_TxQ0_Operation_Mode[TXQEN] to value 2'b10 to enable transmit queue0

d. MTL_TxQ0_Operation_Mode[TQS]

9. Enable the interrupts by programming DMA_CH(#i)_Interrupt_Enable (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register.

10. Repeat steps 4 through 9 for all the additional channels of AV feature.

11. Program the AV queues CBS control register, idleSlope, sendSlope, hiCredit, and loCredit registers.

12. Write 1 to bit 0 of DMA_CH(#i)_TX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) and DMA_CH(#i)_RX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1) register to start the receive and transmit DMA.

72.17.10.2 Enabling slot number checking

You can enable slot number checking feature if you specifies the intervals at which the DMA channels map to AV queues fetch the frames from the AHB/AXI system bus.

You must complete these steps after step 11 and before step 12 of Initializing the DMA in audio video feature .

You can use the slot number check feature to specify the intervals at which the DMA channels map to AV queues fetch the frames from the AHB/AXI system bus. This feature is useful for an uniform and periodic transfer of the AV traffic from the host memory and it is available only when you enable timestamping and programs MAC_Sub_Second_Increment. Perform these steps to enable the slot number checking:

1. Follow the steps described in Initialization guidelines for system time generation to enable timestamping.

2. Ensure that the SLOTNUM field (bits 22:19) of TDES3 normal descriptor (Read format) contains a valid slot number. You can read the current reference slot number from the DMA_CH(#i)_Slot_Func-tion_Control_Status (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register.

3. Write 1 to bit 0 (ESC) of the slot function control and status register of a channel to enable the slot number checking.

72.17.10.3 Enabling average bits per slot reporting

You can enable the reporting of average bits transmitted in a slot.

The CBS status register of the additional AV channels provide information about the average bits that are transmitted in a slot. You can asynchronously read this register to retrieve information about the average bits transmitted per slot. Perform these steps to enable average bits per slot reporting:

1. Follow the steps as described in the Initialization guidelines for system time generation to enable timestamping.

2. Program SLC bits [6:4], of the MTL_TxQ[n]_ETS_Control register of a channel with the number of slots over which the average transmitted bits per slot are computed.

3. Enable bit 9(ABPSSIE) of the MTL_Q[n]_Interrupt_Control_Status register of a channel to generate the average bits per slot interrupt.

NOTE

- The frequency of this interrupt depends on the value programmed in step 2. For example, when you program value 0 in the SLC field, the interrupt generates at every 125 microsecond.
- You can disable this interrupt to stop the interrupt flooding, when it is not required.

4. Read ABS bits [16:0], of the MTL_TxQ[n]_ETS_Status register of a channel on each interrupt.

NOTE

You can read the ABS fields in the polling mode even if ABPSIE bit is not enabled. When bit 1 (ABPSIS) of the MTL_TxQ[n]_ETS_Status register is 1, it indicates that a new value is updated in the ABS field.

72.17.10.4 Disabling flow control for AV enabled queues

72.17.10.4.1 Transmit flow

Program the EHFC (Enable Hardware Flow Control) field of the corresponding receive queue's MTL_RxQ[n]_Operation_Mode register to 0.

72.17.10.4.2 Receive flow control

Program PSTQ[n] field, corresponding to AV enabled transit queue in MAC_TxQ_Prty_Map0/1 register to 0.

72.17.10.5 Programming guidelines for flexible pulse-per-second output

After you enable the flexible pulse-per-second output feature in the module controller, you can perform these tasks:

- Generating single pulse on PPS
- Generating next pulse on PPS
- Generating a pulse train on PPS
- Generating an interrupt without affecting the PPS

72.17.10.5.1 Generating single pulse on PPS

Perform these steps to generate single pulse on PPS:

1. Program 11 or 10 (for interrupt) in TRGTMODSEL bits [6:5], of MAC_PPS_Control. This instructs MAC to use the target time registers (MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds) for a start time of the PPS signal output.
2. Program the start time value in the target time registers (MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds).
3. Program the PPS signal output width in MAC_PPS(#i)_Width (for i = 0; i <= 3) register.

4. Program PPSCMD bits [3:0], of MAC_PPS_Control to 0001. This instructs MAC to generate single pulse on the PPS signal output at the time programmed in the target time registers.

72.17.10.5.2 Generating next pulse on PPS

When the PPSCMD is executed (PPSCMD bits = 0), you can give the cancel start command (PPSCMD=0011) before the programmed start time elapses to cancel the pulse generation. You can also program the behavior of the next pulse in advance.

Follow these steps to program the next pulse:

1. Program the start time for the next pulse in the target time registers. This time must be more than the time at which the falling edge occurs for the previous pulse.

2. Program the next PPS signal output width in MAC_PPS(#i)_Width (for i = 0; i <= DWC_EQOS_PPS_OUT_NUM-1) register.

3. Program PPSCMD bits [3:0], of MAC_PPS_Control to generate a single pulse after the time at which the previous pulse is de-asserted. This instructs MAC to generate single pulse on the PPS signal output, at the time programmed in target time registers.

If you give this command before the previous pulse becomes low, then the new command overwrites the previous command and the QOS may generate only 1 extended pulse.

72.17.10.5.3 Generating a pulse train on PPS

Perform these steps to generate a pulse train on PPS:

1. Program 11 or 10 (for interrupt) in TRGTMODSEL bits [6:5] , of MAC_PPS_Control. This instructs MAC to use the target time registers for the start time of the PPS signal output.

2. Program the start time value in the target time registers.

3. Program the interval value between the train of pulses on the PPS signal output in MAC_PPS(#i)_Interval (for i = 0; i <= DWC_EQOS_PPS_OUT_NUM-1) register.

4. Program the PPS signal output width in MAC_PPS(#i)_Width (for i = 0; i <= DWC_EQOS_PPS_OUT_NUM-1) register.

5. Program PPSCMD bits [3:0], of MAC_PPS_Control to 0010. This instructs MAC to generate train of pulses on the PPS signal output with start time programmed in target time registers.

By default, the PPS pulse train is free-running unless the STOP pulse train at time or STOP pulse train immediately commands stop it.

6. Program the stop value in the target time registers. Ensure that bit 31 (TSTRBUSY) of MAC_PPS(#i)_Target_Time_Nanoseconds (for i = 0; i <= DWC_EQOS_PPS_OUT_NUM-1) register becomes 0 before programming the target time registers again.

7. Program PPSCMD field [bit 3:0] of MAC_PPS_Control to 0100. This stops the train of pulses on the PPS signal output after the programmed stop time specified in step 6 elapses.

You can program 0101 in PPSCMD field [bit 3:0] of MAC_PPS_Control to stop the pulse train at any time. Similarly, you can program 0110 in PPSCMD field [bit 3:0] of MAC_PPS_Control before the time (programmed in step 6) elapses to cancel the stop pulse train command (given in Step 7). Also, program 0011 in PPSCMD field [bit 3:0] of MAC_PPS_Control before the programmed start time (in Step 2) elapses to cancel the pulse train generation.

72.17.10.5.4 Generating an interrupt without affecting the PPS

MAC_PPS_Control TRGTMODSEL bits [6:5] enables you to program the target time registers to perform any one of these actions:

- Generate only interrupts.
- Generate interrupts and the PPS start and stop time.
- Generate only PPS start and stop time.

Perform these steps to program the target time registers to generate only interrupt event:

1. Program 00 (for interrupt) in MAC_PPS_Control TRGTMODSEL bits [6:5]. This instructs the MAC to use the target time registers for target time interrupt.

2. Program a target time value in the target time registers. This instructs the MAC to generate an interrupt when the target time elapses.

If TRGTMODSEL bits [6:5], are changed (for example, to control the PPS) then over-write the interrupt generation with the new mode and new programmed target time register value.

72.17.10.6 Programming guidelines for VLAN filtering on receive

Perform these steps to program VLAN filtering on receive:

1. Program MAC_VLAN_Tag register for the following fields to select the filtering method:

a. ETV: Enables 12-Bit VLAN tag comparison or 16-bit VLAN tag comparison.

b. VTHM: VLAN tag hash table match enable.

c. ERIVLT: Enables inner VLAN tag or outer VLAN Tag (to enable the inner or outer VLAN tag filtering, writing 1 to MAC_VLAN_Tag_Ctrl[EDVLP] enables the double VLAN processing).

d. ERSVLM: Enables receive S-VLAN match or C-VLAN match (write 1 to MAC_VLAN_Tag_Ctrl[ESVL] to enable S-VLAN processing).

e. DOVLTC: Ignores VLAN type for tag match

f. VTIM: Enables VLAN tag inverse match instead of the normal VLAN tag matching

2. Program VL of MAC_VLAN_Tag register for the 12-bit or 16-bit VLAN tag.

3. Program MAC_VLAN_Hash_Table, if hash filtering of VLAN tag is enabled. When MAC_VLAN_Tag_Ctrl[ETV] becomes 0, it indicates that the upper 4 bits of the calculated CRC-32 of VLAN tag are inverted and index the content of MAC_VLAN_Hash_Table. When MAC_VLAN_Tag_Ctrl[ETV] is 1, it indicates that the upper 4 bits of calculated CRC-32 of VLAN Tag index the content of MAC_VLAN_Hash_Table. For example, when MAC_VLAN_Tag_Ctrl[ETV] is 1, a hash value of 4b'1000 selects bit 8 of MAC_VLAN_Hash_Table. When MAC_VLAN_Tag_Ctrl[ETV] becomes 0 a hash value of 4'b1000 selects bit 7 of MAC_VLAN_Hash_Table.

72.17.10.7 Programming guidelines for extended VLAN filtering and routing on receive

Perform these steps, for the indirect access of the per VLAN tag registers:

- Write
  - Write the required data into MAC_VLAN_Tag_Data.
  - Program MAC_VLAN_Tag_Ctrl[OFS] with the required filter register's offset and command type to MAC_VLAN_Tag_Ctrl[CT]. For a write command, set this field to 0.
  - Write 1 to MAC_VLAN_Tag_Ctrl[OB] and wait till it becomes 0 to do the next write. This will guarantee that you have programmed the appropriate VLAN Tag Filter register.
- Read
  - Program MAC_VLAN_Tag_Ctrl[OFS] with the required register's offset and command type to MAC_VLAN_Tag_Ctrl[CT]. For a read command, set this field to 1.
  - Write 1 to MAC_VLAN_Tag_Ctrl[OB] and wait till it becomes 0. The appropriate value of the VLAN Tag Filter register is available in MAC_VLAN_Tag_Data.

72.17.10.8 Programming sequence for queue/channel based VLAN inclusion register

Perform these steps to program the queue/channel-based VLAN inclusion register:

NOTE

When MAC_VLAN_Incl[CBTI] = 1 you cannot access the indirect VLAN include registers.

1. Write 1 to MAC_VLAN_Incl[CBTI], to enable queue or channel based VLAN tag insertion on all the transmitted packets. This field must be 1 before any indirect access to the queue or channel specific MAC_VLAN_Incl(#i) register.

2. Program the VLAN tag and VLAN type to insert in packets from a particular queue or channel in MAC_VLAN_Incl[VLT] and MAC_VLAN_Incl[CSVL], corresponding offset address in ADDR field (0 for queue/channel 0, 1 for queue/channel 1, and so on) must be set. Write 0 to MAC_VLAN_Incl[RDWR] to indicate write access. The write to byte 0 (byte 3 in Big Endian mode) of MAC_VLAN_Incl initiates access to indirect access MAC_VLAN_Incl(#i) register.

3. Write 1 to MAC_VLAN_Incl[BUSY] via the module to indicate the progress of access to indirect access MAC_VLAN_Incl(#i) register. After the access completes, MAC_VLAN_Incl[BUSY] = 0. The application must not attempt subsequent access to MAC_VLAN_Incl(#i) register when the MAC_VLAN_Incl[BUSY] is 1.

4. Repeat step 2 and step 3 to program VLAN tag and VLAN type to insert in packets from the remaining queues or channels. The application must ensure that the required VLAN tag and VLAN type for all the queues or channels are programmed, otherwise an unintended VLAN tag and VLAN type might be inserted.

72.17.11 Programming guidelines for EST

Program the gate control values and time intervals in MTL_EST_Status[SWOL] along with the other EST related registers that are described in EMAC register descriptions to appropriate values. The upcoming sub-sections provide step by step details for programming the GCL and the other EST related registers.

72.17.11.1 Programming the GCL and GCL linked registers

Perform these steps to program the GCL and the four other registers implemented per GCL:

1. Access the GCL and the four other GCL-linked registers via indirect addressing using MTL_EST_GCL_Control and MTL_EST_GCL_Data. MTL_EST_Status[SWOL] indicates whether the software owns GCL0 or GCL1.
2. Write the 32-bit write data to MTL_EST_GCL_Data, to program the GCL. Then program MTL_EST_GCL_Control to write the write address and other control information.
3. In MTL_EST_GCL_Data, write data consists of up to 8 bits (configurable) of gate controls and up to 24 bits (configurable) of time interval. Programming a 0 indicates gate close and programming a 1 indicates gate open. For a 4-TC and 20-bit time interval configuration, the data width is 24-bits and the remaining 8-bits are reserved/read-only. You must write the data in the following format.

   {8'h0, TC3, TC2, TC1, TC0, 20-bit Time Interval} where TCx = 0 or 1.
4. Program MTL_EST_GCL_Control[SRWO] to 1 (to start a Write Op) and program the address and R/W fields appropriately.
5. Poll and check that the hardware clears MTL_EST_GCL_Control[SRWO] to indicate that the previous operation completes before initiating a new read-write operation via the same indirect addressing mode.
6. Repeat steps 3, 4, 5 until the programming of the GCL completes.
7. Program the BTR, CTR, TER and LLR registers, using the same indirect addressing method as described above. Write 1 to MTL_EST_GCL_Control[GCRR] appropriately. MTL_EST_GCL_Control[GCRR] interprets the address field as belonging to these registers (instead of the GCL).

After the GCL and the related registers are programmed, program MTL_EST_GCL_Control to allow hardware to own and process the GCL. When the list length (as indicated in LLR) is 1, the associated time interval must be smaller than the cycle time register value. Otherwise, an error is reported (as described in the Error handling section) as a single set of gate controls add no value in the TSN context.

NOTE

The time unit in all the GCL related registers is seconds and nanoseconds. In cases where internally generated PTP system time is used, you must program the nanoseconds field to use the Digital Rollover mode. (The value of MAC_Timestamp_Control[TSCTRLSSR]must be 1)

72.17.11.2 Programming the EST registers

After the steps mentioned in "Programming the GCL and GCL Linked Registers" completes, program MTL_EST_Control

1. Write 1 to MTL_EST_Control[CTOV] and MTL_EST_Control[TILS]. Also, write 1 to MTL_EST_Control[EEST] and MTL_EST_Control[SWOL].

   NOTE

   The CTOV recommendations for GMII for SPRAM configurations are:

   - 96 * Tx clock period, for 32 and 64 bit data width configurations.
   - 128 * Tx clock period for 128 bit data width configurations.

   The CTOV recommendations for GMII for non-SPRAM configurations are:

   - 30 * Tx clock period, when SA/VLAN insertion is enabled.
   - 22 * Tx clock period, when SA/VLAN insertion is not enabled.

2. Enables the hardware to own and process the new GCL and make a switch to the new GCL at the BTR value. The hardware provides an interrupt (if enabled) when the switch to the new list happens.
3. Performs an appropriate action to address any other interrupts (explained in the Inter-rupts section) received during the hardware execution of the GCL.

Write 1 to MTL_EST_Control[SSWL] to handoff to hardware. Software is not allowed to write to the GCL and GCL linked registers when MTL_EST_Control[SSWL] = 1, because the hardware might be using the new GCL.

The hardware resets or clears MTL_EST_Control[SSWL] when it successfully switches to the new list. The hardware also flips MTL_EST_Status[SWOL] to indicate the new GCL that the software owns.

Program the GCL that software owns (MTL_EST_Status[SWOL] indicates) as described in "Programming the GCL and GCL Linked Registers" and then program MTL_EST_Control as described above, to install a new GCL. Ensure that the new BTR is set to an appropriate value to avoid BTR Error that may require software intervention in some cases.

The packet length (frame size) information must be available at all times, to avoid transmission overruns. Therefore, in the DMA configurations, program the packet length in the first descriptor of every transmit frame. Similarly, in the MTL configuration, provide the packet length in the control word.

NOTE

The packet length provided in the transmit descriptor must account for the SA and VLAN insertion, to avoid transmission overruns, if applicable, that is, packet length must represent the actual packet length on the Ethernet line.

72.17.12 Programming the launch time in time-based scheduling

Configure the launch time in the enhanced normal transmit descriptors in DMA configurations and is driven as a control word in MTL configurations as follows:

The OSTC and launch time features are mutually exclusive and must not be used together. In case of a conflict (if OSTC = LTV = 1 in MTL configuration), give priority to OSTC and ignore the launch time.

In DMA configuration, if a context descriptor is received with a valid OSTC values immediately before receiving a first normal descriptor with LTV = 1, then the LTV is ignored.

72.17.13 Programming guidelines for media clock generation and recovery

72.17.13.1 Programming guidelines for media clock generation

These are the guidelines for the media clock generation:

1. Program the appropriate presentation time control (supported generation modes "1001-1011") to PPSCTRL_PPSCMD (for 0th instance)/PPSCMD#i (for 1,2,3 instances) of MAC_PPS_Control, to define the PPS instance in Media clock generation mode.

2. Based on the selected PPS instance, application must drive the appropriate trigger signal to the corresponding mcg_pst_trig_i[#i].

3. Based on the programmed mode, DUT captures the timestamp and programs it in the MAC_PPS(#i)_Target_Time_Seconds register. Then, mcgr_dma_req_o[#i] is set.

4. For every request which DUT generates, the module reads the corresponding MAC_PPS(#i)_Target_Time_Seconds register and asserts the corresponding mcgr_d-ma_ack_i[#i] to acknowledge the read request.

72.17.13.2 Programming guidelines for media clock recovery

These are the guidelines for the media clock recovery:

- Writing 1 to MAC_Timestamp_Control[PTGE] enables the CPT counter. In addition to configuring the initialization values for the system time, update MAC_Presn_Time_Updt with the equivalent presentation time initialization value, then MAC_Timestamp_Control[TSINIT] = 1.
- Use the increment values for the system time and also for the CPT because the increment value is in sub-seconds and sub-nanoseconds.
- Update MAC_Presn_Time_Updt with the equivalent presentation time update value (32 bit ns), when an update is requred, and also configure the updated values for the system time. Finally, MAC_Timestamp_Control[TSUPDT] must be 1 for the update.
- Program the MCGREN#i field of MAC_PPS_Control to enable the PPS instance to operate in MCGR mode.
- Program the appropriate presentation time control (supported recovery modes "0001 - 0011") to PPSCTRL_PPSCMD (for 0th instance) or PPSCMD#i (for 1,2,3 instances) of MAC_PPS_Control register, to set the PPS instance in Media clock recovery mode.
- After the PPS instance is set in Recovery mode, DUT sets the corresponding mcgr_dma_req_o[#i]. For every request which DUT generates, program the target presentation time into the MAC_PPS(#i)_Target_Time_Seconds register and assert the corresponding mcgr_dma_ack_i[#i] to acknowledge the request. Acknowledgment can be given before/after programming the Target presentation time.
- Observe the recovered media clock on the corresponding ptp_pps_o[#i].

72.17.14 Programming guidelines for ECC protection for memories

These are the guidelines for the ECC protection for memories:

- Write 1 to the appropriate field of MTL_ECC_Control to enable the ECC features for the respective memory.
- Generate a correctable interrupt (sbd_sfty_ce_intr_o) or an uncorrectable interrupt (sbd_sfty_ue_intr_o) to indicate the application, if any correctable, uncorrectable, or address errors are detected. DMA_Interrupt_Status or MTL_ECC_Interrupt_Status indicates an appropriate status.
- Provide debug mode for each memory to specify errors.

NOTE

Enable the ECC feature before the traffic is online (or after the reset), otherwise the false interrupts may trigger.

72.17.14.1 Programming guidelines for ECC hardware error injection (Debug mode)

Follow these steps for ECC hardware error injection:

- Write 1 to the appropriate field in MTL_DBG_CTL to enable the ECC error injection feature for MTL TX/RX and DMA TSO.
- Write 1 to the appropriate field in MTL_EST_GCL_Control to enable the ECC error injection feature for the EST memory.
- Write 1 to the appropriate field in MTL_RXP_Indirect_Acc_Control_Status to enable the ECC error injection for the receive parser memory. To access the receive parser memory in Debug mode, write 0 to MTL_RXP_Indirect_Acc_Control_Status[FRPE] to disable the receive parser feature.
- Ensure that all the CSR writes corresponding to one memory write must have the same value for the error injection control word, where multiple CSR writes are required for writing single data word into the memory.

72.17.15 Programming guidelines for on-chip datapath parity protection

Follow these steps for on-chip datapath parity protection:

- Writing 1 to MTL_DPP_Control[EDPP] enables the parity generation and parity detection mismatch on datapath.
- Generates an uncorrectable interrupt (sbd_sfty_ue_intr_o) to indicate the application if any parity mismatch is detected. DMA_Safety_Interrupt_Status or MTL_Safety_Interrupt_Status and MAC_DPP_FSM_Interrupt_Status indicates the appropriate status.
- Supports Debug mode for each parity generator to insert an error.

NOTE

Enable the datapath parity protection before the receive or transit traffic starts, to avoid the false safety interrupts.

72.17.16 Programming guidelines for FSM parity and timeout

Follow these steps to configure the FSM parity and timeout:

- Write 1 to MAC_FSM_Control[PRTYEN] and MAC_FSM_Control[TMOUTEN] to enable the FSM parity and timeout feature respectively.
- Force the FSMs to enter into a state with even number of 1s and wait for the safety uncorrectable interrupt to define with MAC_DPP_FSM_Interrupt_Status[FSMPES] for a parity error detection.
- Write 1 to the parity error injection using the [23:16] bits of MAC_FSM_Control to select the appropriate clock domain, for Error injection mode in FSM parity. Wait for the safety uncorrectable interrupt to be defined with MAC_DPP_FSM_Interrupt_Status[FSMPES].
- Configure the large and normal mode values which MAC_FSM_ACT_Timer[LTMRMD] and MAC_FSM_ACT_Timer[NTMRMD] indicates , for FSM timeouts.
- Use the [31:24] bits of MAC_FSM_Control to select the large or normal mode tic generation per clock domain.
- Write 1 to MAC_FSM_ACT_Timer[TMR] with the appropriate number of CSR clock cycles to generate 1us tic.
- Force the FSM in a particular clock domain to remain in an active state for timeout duration (for example, T-2T). You can check the safety interrupt and the status field for the corresponding clock domain that sets in the [15:8] bits of the MAC_DPP_FSM_Interrupt_Status .
- Select the appropriate clock domain for which timeout error injection must be set using the [15:8] bits of MAC_FSM_Control, for Error injection mode in FSM timeout. Wait for the safety uncorrectable interrupt to define with the corresponding error status in the MAC_DPP_FSM_Interrupt_Status .
- Use only normal mode tic generation, for application or CSR interface timeout. On the basis of the time-outs of configured interface, appropriate fields (MSTTES, SLVTES) of MAC_DPP_FSM_Interrupt_Status is defined with the safety interrupt.

72.18 EMAC register descriptions

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

NOTE

This chip has 16 KB allocated per Ethernet controller for configuration space. EMAC uses only 8 KB of this memory and the remaining 8 KB is reserved for future use. Writing to the reserved memory may lead to unintended behavior.

72.18.1 EMAC memory map

EMAC base address: 4048_0000h

Fields

Field	Function
31 —	Reserved
30-28 SARC	Source Address Insertion Or Replacement Control Controls the source address insertion or replacement for all the transmitted packets. Bit 30 of this field specifies which MAC Address register (0 or 1) is used for source address insertion or replacement based on the values of bits [29:28]: • 2'b0x: The mti_sa_ctrl_i and ati_sa_ctrl_i input signals control the SA field generation. • 2'b10: If bit 30 = 0, MAC inserts the content of the MAC Address 0 registers in the SA field of all the transmitted packets. If bit 30 = 1 and the Enable MAC Address Register 1 option is selected while configuring the core, MAC inserts the content of the MAC Address 1 registers in the SA field of all the transmitted packets. • 2'b11: If bit 30 = 0, MAC replaces the content of the MAC Address 0 registers in the SA field of all the transmitted packets. If bit 30 = 1 and the MAC Address Register 1 is enabled, MAC replaces the content of the MAC Address 1 registers in the SA field of all the transmitted packets. **NOTE** Changes to this field take effect only on the start of a packet. If you write to the field when a packet is being transmitted, only the subsequent packet can use the updated value. This means that the current packet does not use the updated value. 000b - mti_sa_ctrl_i and ati_sa_ctrl_i input signals control the SA field generation 010b - Contents of are inserted in the SA field 011b - Contents of replace the SA field 110b - Contents of are inserted in the SA field 111b - Contents of replace the SA field
27 IPC	Checksum Offload Indicates the status of IP header or payload checksum checking. If this field is 1, the field enables IPv4 header checksum checking and IPv4 or IPv6 TCP, UDP, or ICMP payload checksum checking. When the field becomes 0, the COE function in the receiver is disabled. The Layer 3 and Layer 4 packet filter and enable split header features automatically select the IPC full checksum offload engine on the receive side. When any of these features are enabled, you must write 1 to this field. 0b - Disabled 1b - Enabled
26-24 IPG	Inter-Packet Gap Controls the minimum IPG between packets during transmission. The range of minimum IPG is valid in Full-Duplex mode, and in this mode, the minimum IPG can be configured only for 64-bit times (IPG = 100). Lower values are not considered.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When a JAM pattern is being transmitted because of backpressure activation, MAC does not consider the minimum IPG. This function (IPG less than 96-bit times) is valid only when MAC_Ext_Configuration[EIPGEN] is 0. If this field is 1, the minimum IPG (greater than 96-bit times) is controlled according to the field's description. 000b - 96-bit times IPG 001b - 88-bit times IPG 010b - 80-bit times IPG 011b - 72-bit times IPG 100b - 64-bit times IPG 101b - 56-bit times IPG 110b - 48-bit times IPG 111b - 40-bit times IPG
23 GPSLCE	Giant Packet Size Limit Control Enable Enables and disables giant packet size limit control. If this field = 1, MAC considers the value of MAC_Ext_Configuration[GPSL] to declare a received packet as a giant packet. This field must be programmed to have a size of more than 1,518 bytes. Otherwise, MAC considers 1,518 bytes as the giant packet limit. When this field becomes 0, MAC considers the received packet as a giant packet if its size is greater than 1,518 bytes (1522 bytes for a tagged packet). The WD, JE, and S2KP fields have a higher precedence over this field, which means MAC considers a received packet as a giant packet when its size is greater than 9,018 bytes (9,022 bytes for a tagged packet) with JE = 1 and the size of the jumbo packet greater than 2,000 bytes and S2KP = 1. If the WD field is 1, the field terminates the received packet if it reaches the watchdog limit. Therefore, the programmed giant packet limit must be less than the watchdog limit to get the giant packet status. 0b - Disabled 1b - Enabled
22 S2KP	IEEE 802.3 Support For 2K Packets Indicates the status of IEEE 802.3 support for 2K packets. If this field is 1, MAC considers all the packets with up to 2,000-byte length as normal. When the JE field is not 1, MAC considers all the received packets of size more than 2K bytes as giant packets. When this field becomes 0 and the JE field is not 1, MAC considers all the received packets of size more than 1,518 bytes (1,522 bytes for tagged) as giant packets. For more information about how the setting of this field and the JE field impacts the giant packet status, see this status based on the S2KP and JE fields. If the JE field is 1, writing 1 to the S2KP field has no effect on the giant packet status. 0b - Disabled 1b - Enabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
21 CST	CRC Stripping For Type Packets Indicates the status of CRC stripping for Type packets. If this field is 1, the last four bytes (FCS) of all the Ether-type packets are stripped and dropped before forwarding the packet to the application. This field is valid only when the receive packet size is more than or equal to 1536 bytes. For information about how the settings of this field and the ACS field impact the packet length, see MAC Configuration (MAC_Configuration). 0b - Disabled 1b - Enabled
20 ACS	Automatic Pad Or CRC Stripping Indicates the status of automatic pad or CRC stripping. If this field is 1, MAC strips the pad or the FCS field on the incoming packets only if the size of the packets is less than 1,536 bytes. All the received packets with a size greater than or equal to 1,536 bytes are passed to the application without stripping the pad or the FCS field. When this field becomes 0, MAC passes all the incoming packets to the application, without any modification. For information about how the settings of this field and the CST field impact the packet length, see MAC Configuration (MAC_Configuration). 0b - Disabled 1b - Enabled
19 WD	Watchdog Disable Indicates the status of watchdog. If this field is 1, MAC disables the watchdog timer on the receiver. MAC can receive packets of up to 16,383 bytes. When this field becomes 0, MAC does not allow more than 2,048 bytes (10,240 if the JE field = 1) of the packet being received. MAC cuts off bytes received after 2,048. 0b - Enabled 1b - Disabled
18 —	Reserved
17 JD	Jabber Disable Indicates the status of jabber. If this field is 1, MAC disables the jabber timer on the transmitter. It can transfer packets of up to 16,383 bytes.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If this field is 0 and the application sends more than 2,048 bytes of data (10,240 if the JE field = 1) during transmission, MAC does not send the rest of the bytes in that packet. 0b - Enabled 1b - Disabled
16 JE	Jumbo Packet Enable Indicates the status of jumbo packets. If this field is 1, MAC allows jumbo packets of 9,018 bytes (9,022 bytes for VLAN-tagged packets) without reporting a giant packet error in the receive packet status. 0b - Disabled 1b - Enabled
15 PS	Port Select Selects the Ethernet line speed. This field, along with the FES field, selects the exact line speed. In the 10/100 Mbit/s-only (always 1) or 1000 Mbit/s-only (always 0) configurations, this field is read-only (RO) with an appropriate value. By default, with 10/100/1000 Mbit/s configurations, this field is read-write (R/W). The mac_speed_o[1] signal reflects the value of this field. 0b - For 1000 or 2500 Mbit/s operations 1b - For 10 or 100 Mbit/s operations
14 FES	Speed Indicates the speed. This field selects the speed mode. The mac_speed_o[0] signal indicates the value of this field. 0b - 10 Mbit/s if PS = 1 and 1 Gbps if PS = 0 1b - 100 Mbit/s if PS = 1 and 2.5 Gbps if PS = 0
13 DM	Duplex Mode Indicates the mode in which MAC operates. If this field is 1, MAC operates in Full-Duplex mode in which it can transmit and receive simultaneously. The field can only be read, with 1 as its default value, in full-duplex-only configurations. 0b - Half-duplex mode 1b - Full-duplex mode
12 LM	Loopback Mode Indicates the status of Loopback mode If this field is 1, MAC operates in Loopback mode at GMII or MII. This mode requires the (G)MII Rx clock input (clk_rx_i) signal to function properly because the transmit clock is not internally looped back.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disabled 1b - Enabled
11 ECRSFD	Enable Carrier Sense In Full-Duplex Mode Indicates whether ECRSFD is enabled or disabled. If this field is 1, the MAC transmitter checks the CRS signal before packet transmission in Full-Duplex mode. MAC starts transmitting only when the CRS signal is low. If this field becomes 0, the MAC transmitter ignores the status of the CRS signal. 0b - Disabled 1b - Enabled
10 DO	Disable Receive Own Enables or disables receive own. If this field is 1, MAC disables the reception of packets when the gmii_txen_o signal asserts in Half-Duplex mode. When the field is 0, MAC receives all the packets that PHY sent. This field is not applicable in Full-Duplex mode. 0b - Enabled 1b - Disabled
9 DCRS	Disable Carrier Sense During Transmission Enables or disables carrier sense during transmission. If this field is 1, the MAC transmitter ignores the (G)MII CRS signal during packet transmission in Half-Duplex mode. As a result, no errors generate because of loss of carrier or no carrier during transmission. When this field becomes 0, the MAC transmitter generates errors because of carrier sense. MAC can even abort the transmission. 0b - Enabled 1b - Disabled
8 DR	Disable Retry Enables or disables retry attempts. If this field is 1, MAC attempts only one transmission. When a collision occurs on GMII or MII, MAC ignores the current packet transmission and reports a packet abort with excessive collision errors in the transmit packet status. If this field becomes 0, MAC retries based on the settings of the BL field of this register. The settings of this field apply only in Half-Duplex mode. 0b - Enabled 1b - Disabled
7	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
6-5 BL	Back-Off Limit Determines the random integer number (r) of slot time delays (4,096 bit times for 1000/2500 Mbit/s; 512 bit times for 10/100 Mbit/s) for which MAC waits before rescheduling a transmission attempt during retry attempts after a collision. • *n* = retransmission attempt • *r* = random integer that takes the value in the range 0 <= r < 2^k This field is applicable only in Half-Duplex mode. 00b - k = min(n,10) 01b - k = min(n,8) 10b - k = min(n,4) 11b - k = min(n,1)
4 DC	Deferral Check Indicates the status of the deferral check function. If this field is 1, the deferral check function is enabled in MAC, which issues a packet abort status, with Tx_Excessive_Deferral_Error[TXEXSDEF] = 1 in the transmit packet status, when the transmit state machine is deferred for more than 24,288 bit times in 10 Mbit/s or 100 Mbit/s mode. If MAC is configured for a 1000/2500 Mbit/s operation, the threshold for deferral is 155,680 bit times. Deferral begins when the transmitter is ready to transmit, but it is prevented because of an active carrier sense signal (CRS) on GMII or MII. The defer time is not cumulative. For example, if the transmitter defers for 10,000 bit times because the CRS signal is active, and then the CRS signal becomes inactive, the transmitter transmits and collision happens. Because of this collision, the transmitter needs to back off and then defer again after back off completion. In such a scenario, the deferral timer resets to 0 and restarts. When this field becomes 0, the deferral check function disables and MAC defers until the CRS signal becomes inactive. This field is applicable only in Half-Duplex mode. 0b - Disabled 1b - Enabled
3-2 PRELEN	Preamble Length for Transmit Packets Controls the number of preamble bytes that are added to the beginning of every transmit packet. Preamble reduction occurs only when MAC operates in Full-Duplex mode. 00b - 7 bytes 01b - 5 bytes 10b - 3 bytes 11b - Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
1 TE	Transmitter Enable Indicates the status of the transmitter. • If this field is 1, the MAC transmit state machine is enabled for transmission on GMII or MII. • When the field becomes 0, the MAC transmit state machine is disabled after it completes the transmission of the current packet. The transmit state machine does not transmit any more packets. 0b - Disabled 1b - Enabled
0 RE	Receiver Enable Indicates the status of the receiver. If this field is 1, MAC's receive state machine is enabled for receiving packets from GMII or MII. When this field becomes 0, the MAC receive state machine is disabled after it completes the reception of the current packet. The receive state machine does not receive any more packets from GMII or MII. 0b - Disabled 1b - Enabled

72.18.3 MAC Extended Configuration (MAC_Ext_Configuration)

Offset

Register	Offset
MAC_Ext_Configuration	4h

Function

Establishes MAC's operating mode.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31 —	Reserved
30 —	Reserved
29-25 EIPG	Extended Inter-Packet Gap Indicates the value of the extended inter-packet gap. The value of this field is applicable when EIPGEN = 1. The most-significant bits of this field, along with those of MAC_Configuration[IPG], render the minimum IPG greater than 96-bit times in steps of 8-bit times. 8'h00: 104-bit times 8'h01: 112-bit times 8'h02: 120-bit times ---------- 8'hFF: 2144-bit times
24 EIPGEN	Extended Inter-Packet Gap Enable Indicates the status of the extended inter-packet gap. • If this field is 1, MAC interprets the EIPG field of this register and the IPG field of MAC Configuration (MAC_Configuration) together as minimum IPG greater than 96-bit times in steps of 8-bit times. • If this field is 0, MAC ignores the EIPG field of this regsiter and interprets the IPG field of MAC Configuration (MAC_Configuration) as minimum IPG less than or equal to 96-bit times in steps of 8-bit times. **NOTE** You must enable the extended inter-packet gap feature when operating in Full-Duplex mode only. There could be undesirable effects on the back-pressure function and frame transmission if the feature is enabled in Half-Duplex mode. 0b - Disabled 1b - Enabled
23 —	Reserved
22-20 —	Reserved
19 PDC	Packet Duplication Control Indicates the packet duplication control status.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• If this field is 1, the received packet with multicast or broadcast destination address is routed to multiple receive DMA channels. MAC_Address0_High[DCS] identifies the receive DMA channels (corresponding to the MAC Address register) that match the multicast or broadcast destination addresses in the received packet. The DCS field is interpreted to be a one-hot value, each bit corresponding to the receive DMA channel. • If this field is 0, the received packet routes to a single receive DMA channel. MAC_Address0_High[DCS] identifies the receive DMA channel corresponding to the MAC Address register that matches the destination address in the received packet. The DCS field is interpreted as a binary value. 0b - Disabled 1b - Enabled
18 USP	Unicast Slow Protocol Packet Detect Indicates the status of unicast slow-protocol packet detection. • If this field is 1, MAC detects the slow-protocol packets with unicast address of the station specified in MAC Address 0 High (MAC_Address0_High) and MAC Address 0 Low (MAC_Address0_Low). MAC also detects the slow-protocol packets with the slow-protocol multicast address (01-80-C2-00-00-02). • If this field is 0, MAC detects only slow-protocol packets with the slow protocol multicast address specified in IEEE 802.3-2015, section 5. 0b - Disabled 1b - Enabled
17 SPEN	Slow Protocol Detection Enable Enables or disables slow protocol detection. • If this field is 0, EMAC forwards all error-free, slow-protocol packets to the application. EMAC considers such packets as normal-type packets. • If this field is 1, EMAC processes the slow-protocol packets (Ether type 8809h) and provides the slow protocol sub-type and code fields in receive status. 0b - Disabled 1b - Enabled
16 DCRCC	Disable CRC Checking For Received Packets Indicates the status of CRC checking. If this field is 1, MAC receiver does not check the CRC field in the received packets. When this field becomes 0, the MAC receiver always checks the CRC field in the received packets. 0b - Enabled 1b - Disabled
15-14	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
13-0 GPSL	Giant Packet Size Limit Declares the status of a packet based on its size. If the received packet size (in bytes) is greater than the value programmed in this field, MAC declares the received packet as a giant packet. The value programmed in this field must be greater than or equal to 1,518 bytes. Also, any other programmed value is considered as 1,518 bytes. For VLAN-tagged packets, MAC adds 4 bytes to the programmed value. If MAC_VLAN_Tag_Ctrl[EDVLP] = 1, MAC adds 8 bytes to the programmed value for double VLAN-tagged packets. The value of GPSL is valid if MAC_Configuration[GPSLCE] = 1.

72.18.4 MAC Packet Filter (MAC_Packet_Filter)

Offset

Register	Offset
MAC_Packet_Filter	8h

Function

Contains the filter controls for receiving packets.

Some of the controls from this register go to MAC's address check block that performs the first level of address filtering. The second level of filtering is performed on the incoming packet based on other controls such as pass bad packets and pass control packets.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31 RA	Receive All Indicates whether the received packets are enabled or disabled. • If this field is 1, the MAC Receiver module passes all the received packets to the application, irrespective of their passing the address filter. The result (pass or fail) of the SA or DA filtering is updated in the corresponding field of the receive status word. • If this field is 0, the module passes only those packets to the application that pass the SA or DA address filter. 0b - Receive All is disabled 1b - Receive All is enabled
30-22 —	Reserved
21 DNTU	Drop Non-TCP/UDP Over IP Packets Indicates whether MAC drops or forwards non-TCP/UDP protocols over IP packets. • If this field is 1, MAC drops these protocols over IP packets. MAC forwards only those packets that the layer 4 filter processes. • If this field is 0, MAC forwards all these protocols over IP packets. 0b - Forwards 1b - Drops
20 IPFE	Layer 3 and Layer 4 Filter Enable Indicates the status of layer 3 and layer 4 filters. • If this field is 1, MAC drops packets that do not match the enabled layer 3 and layer 4 filters. If these two filters are not enabled for matching, this field does not have any effect. • If this field is 0, MAC forwards all the packets irrespective of the match status of the layer 3 and layer 4 fields. 0b - Disabled 1b - Enabled
19-17 —	Reserved
16 VTFE	VLAN Tag Filter Enable Indicates the status of VLAN tag filter. • If this field is 1, MAC drops the VLAN-tagged packets that do not match the VLAN tag. • If this field is 0, MAC forwards all the packets irrespective of the match status of the VLAN tag. 0b - Disabled 1b - Enabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-11 —	Reserved
10 HPF	Hash Or Perfect Filter Indicates the status of hash or perfect filter. • If this field is 1, the address filter passes a packet if it matches either perfect filtering or hash filtering as defined by the HMC or HUC fields of this register. • If this field is 0 and HUC = 1 or HMC = 1, the packet passes only if it matches the hash filter. 0b - Disabled 1b - Enabled
9 SAF	Source Address Filter Enable Indicates the status of SA filtering. • If this field is 1, MAC compares the SA field of the received packets with the values programmed in the enabled SA registers. If the comparison fails, MAC drops the packet. • When this field becomes 0, MAC forwards the received packet to the application with an updated field value, depending on the SA address comparison. **NOTE** According to the IEEE specification, bit 47 of the SA field is reserved. However, MAC compares all the 48 bits. You must consider this when programming the MAC address registers for SA. 0b - Disabled 1b - Enabled
8 SAIF	SA Inverse Filtering Indicates the status of SA inverse filtering. • If this field is 1, the address check block operates in the inverse filtering mode for SA address comparison. If the SA of a packet matches the values programmed in the SA registers, it is marked as failing the SA address filter. • If this field becomes 0 and the SA of a packet does not match the values programmed in the SA registers, the SA is marked as failing the SA address filter. 0b - Disabled 1b - Enabled
7-6 PCF	Pass Control Packets Controls the forwarding of all the control packets (including unicast and multicast pause packets). 00b - MAC filters all the control packets from reaching the application 01b - MAC forwards all the control packets, except pause packets, to the application even if they fail the address filter

Table continues on the next page...

Table continued from the previous page...

Field	Function
	10b - MAC forwards all the control packets to the application even if they fail the address filter 11b - MAC forwards all the control packets that pass the address filter
5 DBF	Disable Broadcast Packets Enables or disables broadcast packets. • If this field is 1, AFM blocks all the incoming broadcast packets. In addition, it overrides all the other filter settings. • If this field is 0, AFM passes all the received broadcast packets. 0b - Enabled 1b - Disabled
4 PM	Pass All Multicast Enables or disables the passing of received packets. • If this field is 1, it indicates that all the received packets with a multicast destination address (first bit in the destination address field is 1) are passed. • If this field is 0, filtering of multicast packets depends on the settings of the HMC field. 0b - Disabled 1b - Enabled
3 DAIF	DA Inverse Filtering Indicates the status of DA inverse filtering. • If this field is 1, the Address Check block operates in Inverse Filtering mode for the DA address comparison of both unicast and multicast packets. • If this field is 0, normal filtering of packets is performed. 0b - Disabled 1b - Enabled
2 HMC	Hash Multicast Indicates the status of hast multicast. • If this field is 1, MAC performs the destination address filtering of received multicast packets according to the hash table. • If this field is 0, MAC performs the perfect destination address filtering for multicast packets, that is, it compares the DA field with the values programmed in DA registers. 0b - Disabled 1b - Enabled
1 HUC	Hash Unicast Indicates the status of hash unicast.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• If this field is 1, MAC performs the destination address filtering of unicast packets according to the hash table. • When this field becomes 0, MAC performs a perfect destination address filtering for unicast packets, that is, it compares the DA field with the values you program in the MAC Address registers. 0b - Disabled 1b - Enabled
0 PR	Promiscuous Mode Indicates the status of Promiscuous mode. If this field is 1, the address filtering module passes all the incoming packets irrespective of the destination or source address. MAC clears the SA or DA filter fail status fields of the receive status word when PR = 1. 0b - Disabled 1b - Enabled

72.18.5 MAC Watchdog Timeout (MAC_Watchdog_Timeout)

Offset

Register	Offset
MAC_Watchdog_Timeout	Ch

Function

Controls the watchdog timeout for received packets.

72.18.6 MAC Hash Table First 32 Bits (MAC_Hash_Table_Reg0)

Offset

Register	Offset
MAC_Hash_Table_Reg0	10h

Function

Contains the first 32 bits of the hash table, when the total width of the hash table is 128 bits or 256 bits.

The hash table is used for group address filtering, for which the content of the destination address in the incoming packet is passed through the CRC logic and the bits of Receive CRC Error Packets (Rx_CRC_Error_Packets) are used to index the contents of the hash table as follows:

- 6 bits when you have a 64-bit hash
- 7 bits when you have a 128-bit hash
- 8 bits when you have a 256-bit hash

The most-significant bits determine the Hash Table register to be used, and the least-significant 5 bits determine the bit within the register. For example, a hash value of 10_0000b (in 64-bit hash) selects bit 0 of MAC Hash Table Second 32 Bits (MAC_Hash_Table_Reg1).

Perform these steps to calculate the hash value of the destination address:

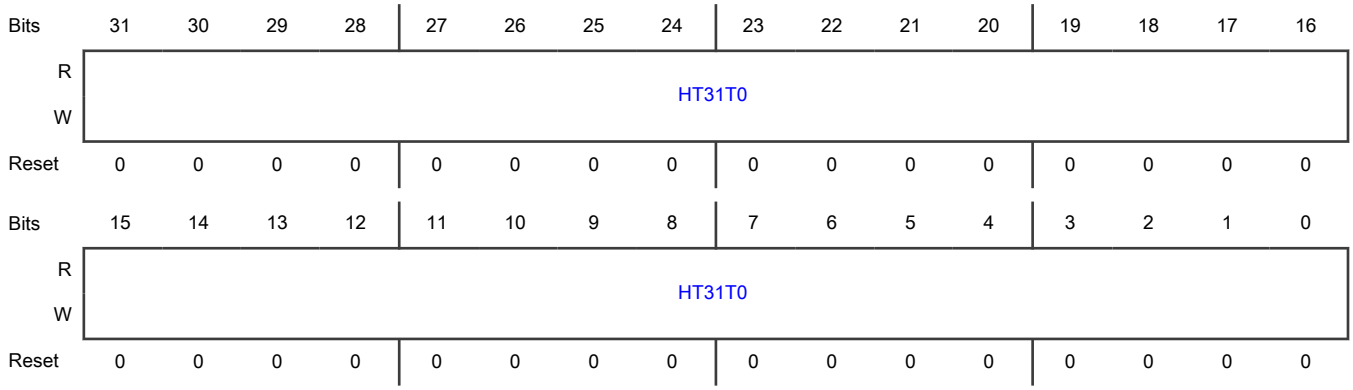
1. Calculate the 32-bit CRC for DA (see section 3.2.8 in IEEE 802.3 for the steps to calculate CRC32).
2. Perform bit-wise reversal for the value obtained in step 1.
3. Use the upper 6, 7, or 8 bits from the value obtained in step 2.

If this field is 1, the packet is accepted. Otherwise, it is rejected. If MAC_Packet_Filter[PM] = 1, all multicast packets are accepted regardless of the multicast hash values.

If this register is configured to be double-synchronized with the (G)MII clock domain, the synchronization is triggered only when bits [31:24] (in Little-Endian mode) or bits [7:0] (in Big-Endian mode) of the Hash Table registers are written to.

If double-synchronization is enabled, consecutive writes to this register must be performed after at least four clock cycles in the destination clock domain.

Diagram



Fields

Field	Function
31-0 HT31T0	MAC Hash Table First 32 Bits Contains the first 32 bits [31:0] of the hash table.

72.18.7 MAC Hash Table Second 32 Bits (MAC_Hash_Table_Reg1)

Offset

Register	Offset
MAC_Hash_Table_Reg1	14h

Function

Contains the second 32 bits of the hash table, when the width of the hash table is 128 or 256 bits.

The hash table is used for group address filtering, for which the content of the destination address in the incoming packet is passed through the CRC logic and the bits of Receive CRC Error Packets (Rx_CRC_Error_Packets) are used to index the contents of the hash table as follows:

- 6 bits when you have a 64-bit hash
- 7 bits when you have a 128-bit hash
- 8 bits when you have a 256-bit hash

The most-significant bits determine the Hash Table register to be used, and the least-significant 5 bits determine the bit within the register. For example, a hash value of 10_0000b (in 64-bit hash) selects bit 0 of MAC Hash Table Second 32 Bits (MAC_Hash_Table_Reg1).

Perform these steps to calculate the hash value of the destination address:

1. Calculate the 32-bit CRC for DA (see section 3.2.8 in IEEE 802.3 for the steps to calculate CRC32).
2. Perform bit-wise reversal for the value obtained in step 1.
3. Take the upper 6, 7, or 8 bits from the value obtained in step 2.

If the corresponding bit value of this register is 1'b1, the packet is accepted. Otherwise, it is rejected. If MAC_Packet_Filter[PM] = 1, all multicast packets are accepted regardless of the multicast hash values.

If this register is configured to be double-synchronized with the (G)MII clock domain, the synchronization is triggered only when bits [31:24] (in Little-Endian mode) or bits [7:0] (in Big-Endian mode) of the Hash Table registers are written to.

If double-synchronization is enabled, consecutive writes to this register must be performed after at least four clock cycles in the destination clock domain.

Fields

Field	Function
31 EIVLRXS	Enable Inner VLAN Tag In Receive Status Indicates whether the inner VLAN tag in receive status is enabled or disabled. • If this field is 1, MAC provides the inner VLAN tag in the receive status. • If this field is 0, MAC does not provide the inner VLAN tag in the receive status. 0b - Disabled 1b - Enabled
30 —	Reserved
29-28 EIVLS	Enable Inner VLAN Tag Stripping Indicates the stripping operation on the inner VLAN tag in a received packet. The field enables or disables inner VLAN tag stripping on receive. 00b - Do not strip 01b - Strip if VLAN filter passes 10b - Strip if VLAN filter fails 11b - Always strip
27 ERIVLT	Enable Inner VLAN Tag Comparison Enables or disables the inner VLAN tag. • If ERIVLT = VTHM = EDVLP = 1, the EMAC receiver enables the VLAN hash filtering operation on the inner VLAN tag (if present). • If ERIVLT = 0 and VTHM = 1, the EMAC receiver enables the VLAN hash filtering operation on the outer VLAN tag (if present). ERSVLM and DOVLTC determine which VLAN type is enabled for filtering. 0b - Disabled 1b - Enabled
26 EDVLP	Enable Double VLAN Processing Enables or disables double VLAN processing. • If this field is 1, MAC enables processing of up to two VLAN tags on transmit and receive (if present). • If this field is 0, MAC enables processing of up to one VLAN tag on transmit and receive (if present). 0b - Disabled 1b - Enabled
25 VTHM	VLAN Tag Hash Table Match Indicates the status of VLAN tag hash table match.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• If this field is 1, the most-significant four bits of CRC-32 of VLAN tag are used to index the content of MAC VLAN Hash Table (MAC_VLAN_Hash_Table). See VLAN filtering for details. • If MAC_VLAN_Hash_Table[VLHT] = 1, corresponding to the index, it indicates that the Ethernet packet matches the VLAN hash table. See VLAN filtering for details. • If ETV = 1, the CRC of the 12-bit VLAN identifier (VID) is used for comparison. When the ETV field becomes 0, the CRC of the 16-bit VLAN tag is used for comparison. • If VTHM = 1, the VLAN hash match operation is not performed. 0b - Disabled 1b - Enabled
24 EVLRXS	Enable VLAN Tag In Receive Status Indicates whether the VLAN tag in receive status is enabled. • If this field is 1, MAC provides the outer VLAN tag in the receive status. • If this field is 0, MAC does not provide the outer VLAN tag in receive status. 0b - Disabled 1b - Enabled
23 —	Reserved
22-21 EVLS	Enable VLAN Tag Stripping Indicates the stripping operation on the outer VLAN tag in received packets. The field enables or disables VLAN tag stripping on receive. 00b - Do not strip 01b - Strip if VLAN filter passes 10b - Strip if VLAN filter fails 11b - Always strip
20 DOVLTC	Disable VLAN Type Check Enables or disables VLAN type check for VLAN hash filtering. • If this field is 1, the MAC VLAN hash filter matches or filters the VLAN tag that the ERIVLT field specifies only when the VLAN tag type is similar to the one that the ERSVLM field specifies. • If this field is 0, the MAC VLAN hash filter does not check whether the VLAN tag that the ERIVLT field specifies is of type S-VLAN or C-VLAN. 0b - Enabled 1b - Disabled
19 ERSVLM	Enable Receive S-VLAN Match Enables or disables receive S-VLAN match for VLAN hash filtering.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• If this field is 1, the MAC receiver enables VLAN hash filtering or S-VLAN matching (type = 88A8h) packets. • If this field is 0, the MAC receiver enables VLAN hash filtering or matching for C-VLAN (type = 8100h) packets. The ERIVLT field determines the VLAN tag position considered for VLAN hash filtering or matching. 0b - Disabled 1b - Enabled
18 ESVL	Enable S-VLAN Enables or disables S-VLAN. If this field is 1, the MAC transmitter and receiver consider the S-VLAN packets (type = 88A8h) as valid VLAN-tagged packets. 0b - Disabled 1b - Enabled
17 VTIM	VLAN Tag Inverse Match Enable Enables or disables VLAN tag inverse matching. • If this field is 1, it enables the VLAN tag inverse matching. The packets without matching VLAN tag are marked as matched. • If this field is 0, it enables the VLAN tag perfect matching. The packets with matched VLAN tag are marked as matched. 0b - Disabled 1b - Enabled
16 ETV	Enable Tag For VLAN Enables or disables 12-bit VLAN tag comparison for VLAN hash filtering. • If this field is 1, a 12-bit VLAN identifier is used for VLAN hash filtering instead of the complete 16-bit VLAN tag. Bits [11:0] of the VLAN tag in the received VLAN-tagged packet are used for hash-based VLAN filtering. • When this field becomes 0, all 16 bits of the 15th and 16th bytes of the received VLAN packet are used for VLAN hash filtering. 0b - Disabled 1b - Enabled
15-0 VL	VLAN Tag Identifier for Receive Packets Contains the 802.1Q VLAN tag to identify the VLAN packets. This VLAN tag identifier is compared to the 15th and 16th bytes of the packets being received for VLAN packets. The following list describes the bits of this field:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• 15:13 — User priority • 12 — Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI) • 11:0 — VID field of VLAN tag When ETV = 1, only the VID is used for comparison. When VL = 0, and ETV = 1, MAC does not check the 15th and 16th bytes for VLAN tag comparison and declares all packets with Type field value of 8100h or 88a8h as VLAN packets.

72.18.9 MAC VLAN Tag Control (MAC_VLAN_Tag_Ctrl)

Offset

Register	Offset
MAC_VLAN_Tag_Ctrl	50h

Function

Is the redefined version of the MAC_VLAN_Tag register.

This register provides the control and addressing fields required for indirect access to the MAC_VLAN_Tag_Filter registers. It also contains the address offset, command type, and busy bit for CSR access of the MAC VLAN Hash Filter registers.

Field	Function
	• If ETV = 1, the CRC of the 12-bit VLAN identifier (VID) is used for comparison. When the ETV field becomes 0, the CRC of the 16-bit VLAN tag is used for comparison. • If VTHM = 1, the VLAN hash match operation is not performed. 0b - Disabled 1b - Enabled
24 EVLRXS	Enable VLAN Tag In Receive Status Indicates whether the VLAN tag in receive status is enabled. • If this field is 1, MAC provides the outer VLAN tag in the receive status. • If this field is 0, MAC does not provide the outer VLAN tag in receive status. 0b - Disabled 1b - Enabled
23 —	Reserved
22-21 EVLS	Enable VLAN Tag Stripping Indicates the stripping operation on the outer VLAN tag in received packets. The field enables or disables VLAN tag stripping on receive. 00b - Do not strip 01b - Strip if VLAN filter passes 10b - Strip if VLAN filter fails 11b - Always strip
20 DOVLTC	Disable VLAN Type Check Enables or disables VLAN type check for VLAN hash filtering. • If this field is 1, the MAC VLAN hash filter matches or filters the VLAN tag that the ERIVLT field specifies only when the VLAN tag type is similar to the one that the ERSVLM field specifies. • If this field is 0, the MAC VLAN hash filter does not check whether the VLAN tag that the ERIVLT field specifies is of type S-VLAN or C-VLAN. 0b - Enabled 1b - Disabled
19 ERSVLM	Enable Receive S-VLAN Match Enables or disables receive S-VLAN match for VLAN hash filtering. • If this field is 1, the MAC receiver enables VLAN hash filtering or S-VLAN matching (type = 88A8h) packets. • If this field is 0, the MAC receiver enables VLAN hash filtering or matching for C-VLAN (type = 8100h) packets.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	The ERIVLT field determines the VLAN tag position considered for VLAN hash filtering or matching. 0b - Disabled 1b - Enabled
18 ESVL	Enable S-VLAN Enables or disables S-VLAN. If this field is 1, the MAC transmitter and receiver consider the S-VLAN packets (type = 88A8h) as valid VLAN-tagged packets. 0b - Disabled 1b - Enabled
17 VTIM	VLAN Tag Inverse Match Enable Enables or disables VLAN tag inverse matching. • If this field is 1, it enables the VLAN tag inverse matching. The packets without matching VLAN tag are marked as matched. • If this field is 0, it enables the VLAN tag perfect matching. The packets with matched VLAN tag are marked as matched. 0b - Disabled 1b - Enabled
16 ETV	Enable Tag For VLAN Enables or disables 12-bit VLAN tag comparison for VLAN hash filtering. • If this field is 1, a 12-bit VLAN identifier is used for VLAN hash filtering instead of the complete 16-bit VLAN tag. Bits [11:0] of the VLAN tag in the received VLAN-tagged packet are used for hash-based VLAN filtering. • When this field becomes 0, all 16 bits of the 15th and 16th bytes of the received VLAN packet are used for VLAN hash filtering. 0b - Disabled 1b - Enabled
15-4 —	Reserved
3-2 OFS	Offset Holds the address offset of the MAC VLAN Tag Filter register that the application tries to access. The width of this field depends on the number of enabled MAC VLAN Tag registers.
1 CT	Command Type Specifies whether the current register access indicates a read or a write operation. It indicates a read operation if this field is 1 and a write operation when the field is 0.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Write operation 1b - Read operation
0 OB	Operation Busy Indicates the operation busy status. • This field becomes 1 to initiate a read or write command for an indirect access to the Per VLAN Tag Filter register. • The field becomes 0 when the read or write command to Per VLAN Tag Filter indirect access register completes. The next indirect register access can be initiated only after the field resets. During a write operation, the field becomes 0 only after the data is written into a MAC_VLAN_Tag_Filter register. During a read operation, the data must be read from MAC VLAN Tag Data (MAC_VLAN_Tag_Data) only after this field becomes 0. 0b - Disabled 1b - Enabled

72.18.10 MAC VLAN Tag Data (MAC_VLAN_Tag_Data)

Offset

Register	Offset
MAC_VLAN_Tag_Data	54h

Function

Holds the read and write data for indirect access to the Per VLAN Tag registers.

- During read access, this register contains valid read data only after MAC_VLAN_Tag_Ctrl[OB] becomes 0.
- During write access, this register must become valid before you write 1 to MAC_VLAN_Tag_Ctrl[OB].

Fields

Field	Function
31-26 —	Reserved
25 DMACHN	DMA Channel Number Indicates the DMA channel number to which the VLAN-tagged frame is to be routed if it passes the VLAN tag filter programmed using this field.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If the routing based on VLAN tag filter is not necessary, this field does not need to be programmed.
24 DMACHEN	DMA Channel Number Enable Enables or disables the DMA channel number value programmed using the DMACHN field. If this field is 0, the routing does not occur based on the VLAN filter result. The frame is routed on the basis of DA-based DMA channel routing. 0b - Disabled 1b - Enabled
23-21 —	Reserved
20 ERIVLT	Enable Inner VLAN Tag Enables or disables inner VLAN tag comparison. • This field is valid only when the double VLAN tag enable of the filter is set. • If this field and the EDVLP field is 1, the MAC receiver enables operation on the inner VLAN tag (if present). • If this field is 0, the MAC receiver enables operation on the outer VLAN tag (if present). 0b - Disabled 1b - Enabled
19 ERSVLM	Enable S-VLAN Match Enables or disables S-VLAN match for received frames. This field is valid only when the VLAN tag enable of the filter is set. • If this field is 1, the MAC receiver enables filtering or matching for S-VLAN (type = 88A8h) packets. • If this field is 0, the MAC receiver enables filtering or matching for C-VLAN (type = 8100h) packets. 0b - Disabled 1b - Enabled
18 DOVLTC	Disable VLAN Type Comparison Enables or disables VLAN type comparison. This field is valid only when the VEN field is 1. • If this field is 1, MAC does not check whether the VLAN tag that ERIVLT specifies is of type S-VLAN or C-VLAN. • If this field is 0, MAC filters or matches the VLAN tag that the ERIVLT field specifies only when the VLAN tag type is similar to the one that the ERSVLM field specifies. 0b - Enabled 1b - Disabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
17 ETV	VLAN Comparison Indicates 12-bit or 16-bit VLAN comparison. • This field is valid only when the VEN field is 1. • When the value of this field is 1, a 12-bit VLAN identifier is used for filter and comparison instead of the complete 16-bit VLAN tag. Bits [11:0] of the VLAN tag are compared with the corresponding field in the received VLAN-tagged packet. 0b - 16-bit VLAN comparison 1b - 12-bit VLAN comparison
16 VEN	VLAN Tag Enable Enables or disables the VLAN tag. • If this field is 1, MAC compares the VLAN tag of the received packet with the VLAN tag ID. • If this field is 0, no comparison is performed irrespective of the programming of the other fields. 0b - Disabled 1b - Enabled
15-0 VID	VLAN Tag ID Holds the VLAN tag value that MAC uses for perfect comparison. The field is valid when VEN = 1.

72.18.14 MAC VLAN Tag Filter 3 (MAC_VLAN_Tag_Filter3)

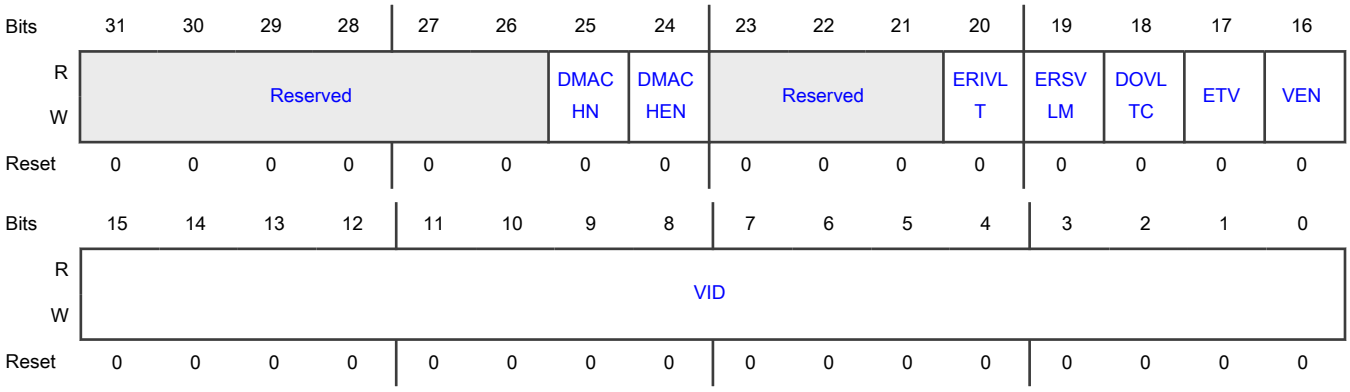
Offset

Register	Offset
MAC_VLAN_Tag_Filter3	54h

Function

Contains VLAN tag filter 3 control information.

Diagram



Fields

Field	Function
31-26 —	Reserved
25 DMACHN	DMA Channel Number Indicates the DMA channel number to which the VLAN-tagged frame is to be routed if it passes the VLAN tag filter programmed using this field. If the routing based on VLAN tag filter is not necessary, this field does not need to be programmed.
24 DMACHEN	DMA Channel Number Enable Enables or disables the DMA channel number value programmed using the DMACHN field. If this field is 0, the routing does not occur based on the VLAN filter result. The frame is routed on the basis of DA-based DMA channel routing. 0b - Disabled 1b - Enabled
23-21 —	Reserved
20 ERIVLT	Enable Inner VLAN Tag Enables or disables inner VLAN tag comparison. • This field is valid only when the double VLAN tag enable of the filter is set. • If this field and the EDVLP field is 1, the MAC receiver enables operation on the inner VLAN tag (if present). • If this field is 0, the MAC receiver enables operation on the outer VLAN tag (if present). 0b - Disabled 1b - Enabled
19 ERSVLM	Enable S-VLAN Match Enables or disables S-VLAN match for received frames. This field is valid only when the VLAN tag enable of the filter is set. • If this field is 1, the MAC receiver enables filtering or matching for S-VLAN (type = 88A8h) packets. • If this field is 0, the MAC receiver enables filtering or matching for C-VLAN (type = 8100h) packets. 0b - Disabled 1b - Enabled
18 DOVLTC	Disable VLAN Type Comparison Enables or disables VLAN type comparison. This field is valid only when the VEN field is 1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• If this field is 1, MAC does not check whether the VLAN tag that ERIVLT specifies is of type S-VLAN or C-VLAN. • If this field is 0, MAC filters or matches the VLAN tag that the ERIVLT field specifies only when the VLAN tag type is similar to the one that the ERSVLM field specifies. 0b - Enabled 1b - Disabled
17 ETV	VLAN Comparison Indicates 12-bit or 16-bit VLAN comparison. • This field is valid only when the VEN field is 1. • When the value of this field is 1, a 12-bit VLAN identifier is used for filter and comparison instead of the complete 16-bit VLAN tag. Bits [11:0] of the VLAN tag are compared with the corresponding field in the received VLAN-tagged packet. 0b - 16-bit VLAN comparison 1b - 12-bit VLAN comparison
16 VEN	VLAN Tag Enable Enables or disables the VLAN tag. • If this field is 1, MAC compares the VLAN tag of the received packet with the VLAN tag ID. • If this field is 0, no comparison is performed irrespective of the programming of the other fields. 0b - Disabled 1b - Enabled
15-0 VID	VLAN Tag ID Holds the VLAN tag value that MAC uses for perfect comparison. The field is valid when VEN = 1.

72.18.15 MAC VLAN Hash Table (MAC_VLAN_Hash_Table)

Offset

Register	Offset
MAC_VLAN_Hash_Table	58h

Function

If MAC_VLAN_Tag_Ctrl[VTHM] = 1, the 16-bit VLAN hash table register is used for group address filtering based on the VLAN tag. For hash filtering, the content of the 16-bit VLAN tag or 12-bit VLAN ID (based on MAC_VLAN_Tag_Ctrl[ETV]) in the incoming packet is passed through the CRC logic. The upper four bits of the calculated hash value are used to index the contents of the VLAN hash table. For example, hash value of 1000b selects bit 8 of the VLAN hash table.

Perform these steps to calculate the hash value of the destination address:

1. Calculate the 32-bit CRC for DA (see section 3.2.8 of IEEE 802.3 for steps to calculate CRC32).

2. Perform bit-wise reversal for the value obtained in step 1.
3. Take the upper 4 bits from the value obtained in step 2.

If this register is configured to be double-synchronized with the (G)MII clock domain, the synchronization is triggered only when bits [15:8] (in Little-Endian mode) or bits [7:0] (in Big-Endian mode) of the register are written to.

If double-synchronization is enabled, consecutive writes to this register must be performed after at least four clock cycles in the destination clock domain.

72.18.16 MAC VLAN Inclusion Or Replacement (MAC_VLAN_Incl)

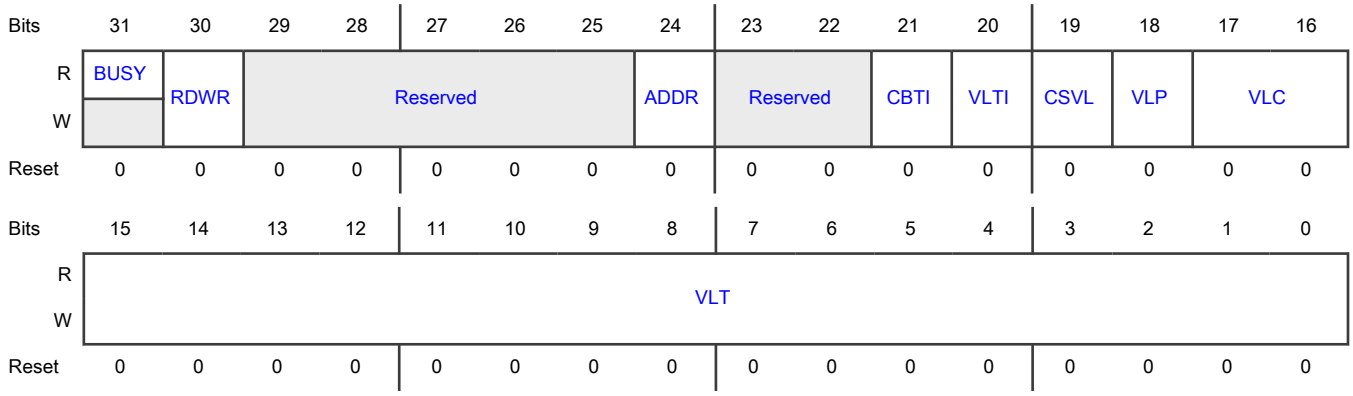
Offset

Register	Offset
MAC_VLAN_Incl	60h

Function

Contains the VLAN tag for insertion or replacement in the transmit packets and the VLAN tag insertion controls.

Diagram



Fields

Field	Function
31 BUSY	Busy Indicates the status of the read or write operation of indirect access to the queue- or channel-specific VLAN inclusion register. The write operation to a register completes when this field becomes 0. For a read operation, the read data is valid when the field becomes 0. The application must make sure that this field becomes 0 before attempting subsequent accesses to this register. 0b - Busy status not detected 1b - Busy status detected
30 RDWR	Read Write Control Controls the read or write operation for indirectly accessing the queue- or channel-specific VLAN inclusion register. • If this field is 1, it indicates the write operation. • If this field is 0, it indicates the read operation. The value of this field is not impacted when the CBTI field becomes 0. 0b - Read operation of indirect access 1b - Write operation of indirect access
29-25 —	Reserved
24 ADDR	Address Selects one of the queue- or channel-specific VLAN inclusion registers for read or write access. The value of this field is not impacted when the CBTI field is 0.
23-22	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
21 CBTI	Channel-Based Tag Insertion Indicates the status of channel-based tag insertion. If this field is 1: • The outer VLAN tag is inserted for all the packets that MAC transmits. • The tag value is taken from the queue- or channel-specific VLAN tag register. Also, the VLTI, VLP, VLC, and VLT fields of the register are ignored. • A write operation to byte 3 of this register initiates the read or write access to the indirect register. If this field is 0, the outer VLAN operation is based on the settings of the VLTI, VLP, VLC, and VLT fields of this register. 0b - Disabled 1b - Enabled
20 VLTI	VLAN Tag Input Indicates the status of the VLAN tag input. The value of this field being 1 indicates that the VLAN tag to be inserted or replaced in the transmit packet must be taken from the transmit descriptor. 0b - Disabled 1b - Enabled
19 CSVL	C-VLAN Or S-VLAN Indicates whether C-VLAN or S-VLAN is inserted or replaced in the transmitted packets. • If this field is 1, S-VLAN type (88A8h) is inserted or replaced in the 13th and 14th bytes of the transmitted packets. • If this field is 0, C-VLAN type (8100h) is inserted or replaced in the 13th and 14th bytes of the transmitted packets. 0b - C-VLAN 1b - S-VLAN
18 VLP	VLAN Priority Control Indicates the status of VLAN priority control. • If this field is 1, the control bits [17:16] are used for VLAN deletion, insertion, or replacement. • If this field is 0, the mti_vlan_ctrl_i control input is used and bits [17:16] are ignored. 0b - Disabled 1b - Enabled
17-16	VLAN Tag Control Contains values for VLAN tag control in transmit packets.

Table continues on the next page...

Table continued from the previous page...

Field	Function
VLC	MAC: • Removes the VLAN type (bytes 13 and 14) and VLAN tag (bytes 15 and 16) of all the transmitted packets with VLAN tags. • Replaces VLT in bytes 15 and 16 of all the VLAN-type transmitted packets (bytes 13 and 14 are 8100h or 88a8h). MAC inserts the following into the packet in the order shown: 1. Type value (8100h or 88A8h) into bytes 13 and 14 2. MAC_VLAN_Tag_Data[VLT] into bytes 15 and 16 This operation is performed on all the transmitted packets, irrespective of whether they already have a VLAN tag. **NOTE** Changes to this field take effect only on the start of a packet. If you write to this field when a packet is being transmitted, only the subsequent packets can use the updated value. That is, the current packet does not use the updated value. 00b - No VLAN tag deletion, insertion, or replacement 01b - VLAN tag deletion 10b - VLAN tag insertion 11b - VLAN tag replacement
15-0 VLT	VLAN Tag For Transmit Packets Contains the value of the VLAN tag to be inserted or replaced. This value must only be changed during the initialization phase or when the transmit lines are inactive. The following list describes the bits of this field: • Bits [15:13]: User priority • Bit 12: Canonical format indicator (CFI) or drop eligible indicator (DEI) • Bits [11:0]: MAC_VLAN_Tag_Data[VID]

72.18.17 MAC VLAN Inclusion 0 (MAC_VLAN_Incl0)

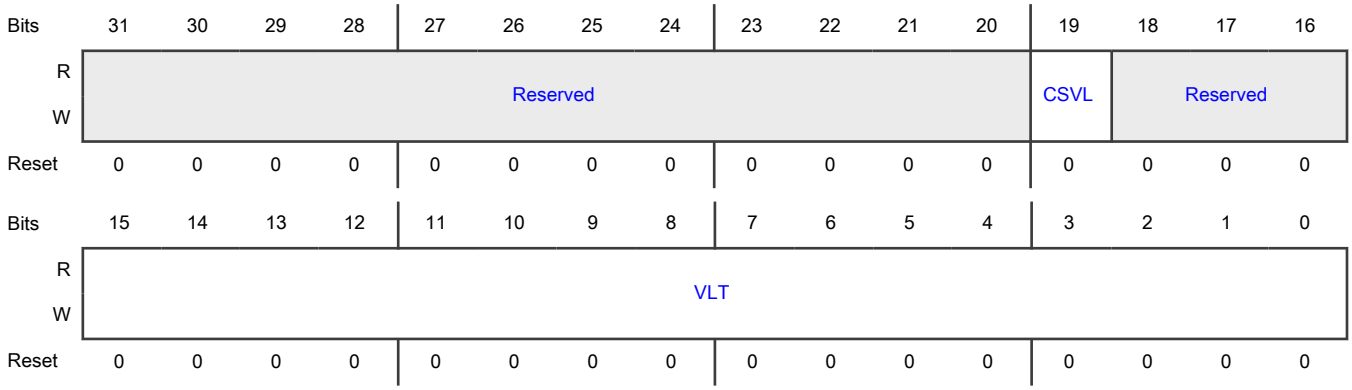
Offset

Register	Offset
MAC_VLAN_Incl0	60h

Function

Contains the VLAN tag for insertion in the transmit packets from transmit queue 0. The register also contains the VLAN tag insertion controls.

Diagram



Fields

Field	Function
31-20 —	Reserved
19 CSVL	C-VLAN or S-VLAN When this field is 1, S-VLAN type (0x88A8) is inserted in the 13th and 14th bytes of transmitted packets. When this field is reset, C-VLAN type (0x8100) is inserted in the 13th and 14th bytes of transmitted packets. 0b - C-VLAN type (0x8100) is inserted 1b - S-VLAN type (0x88A8) is inserted
18-16 —	Reserved
15-0 VLT	VLAN Tag for Transmit Packets Contains the value of the VLAN tag to be inserted. The value of this field must only be changed when the transmit lines are inactive or during the initialization phase. The following list describes the bits of this field: • Bits[15:13]: User Priority • Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI) • Bits[11:0]: VLAN Identifier (VID) field of VLAN tag

Fields

Field	Function
31-21 —	Reserved
20 VLTI	VLAN Tag Input Indicates the status of VLAN tag input. If this field is 1, it indicates that the VLAN tag to be inserted or replaced in the transmit packet must be taken from the transmit descriptor.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disabled 1b - Enabled
19 CSVL	C-VLAN Or S-VLAN Controls the insertion or replacement type in the 17th and 18th bytes of the transmitted packets. 0b - C-VLAN type (8100h) 1b - S-VLAN type (88A8h)
18 VLP	VLAN Priority Control Indicates the status of VLAN priority control. • If this field is 1, it's used for VLAN deletion, insertion, or replacement. • If this field is 0, the mti_vlan_ctrl_i control input is used and MAC_VLAN_Incl[VLC] is ignored. 0b - Disabled 1b - Enabled
17-16 VLC	VLAN Tag Control in Transmit Packets Indicates the value of VLAN tag control in transmit packets. The following list specifies these values: • 2'b00: No VLAN tag deletion, insertion, or replacement • 2'b01: VLAN tag deletion • 2'b10: VLAN tag insertion • 2'b11: VLAN tag replacement MAC: • Removes the VLAN type (bytes 17 and 18) and VLAN tag (bytes 19 and 20) of all the transmitted packets with VLAN tags • Inserts VLT in bytes 19 and 20 of the packet after inserting the Type value (8100h or 88a8h) in bytes 17 and 18. This operation is performed on all the transmitted packets, irrespective of whether they already have a VLAN tag. • Replaces VLT in bytes 19 and 20 for all the VLAN-type transmitted packets (bytes 17 and 18 are 8100h or 88a8h). **NOTE** Changes to this field take effect only on the start of a packet. If you write to the field when a packet is being transmitted, only the subsequent packets can use the updated value. That is, the current packet does not use the updated value. 00b - No VLAN tag deletion, insertion, or replacement 01b - VLAN tag deletion 10b - VLAN tag insertion

Table continues on the next page...

Table continued from the previous page...

Field	Function
	11b - VLAN tag replacement
15-0 VLT	VLAN Tag For Transmit Packets Contains the value of the VLAN tag to be inserted or replaced. The value must only be changed when the transmit lines are inactive or during the initialization phase. The following list describes the bits of this field: • Bits [15:13]: User priority • Bit 12: CFI or DEI • Bits [11:0]: MAC_VLAN_Tag_Data[VID]

72.18.26 MAC Q0 Tx Flow Control (MAC_Q0_Tx_Flow_Ctrl)

Offset

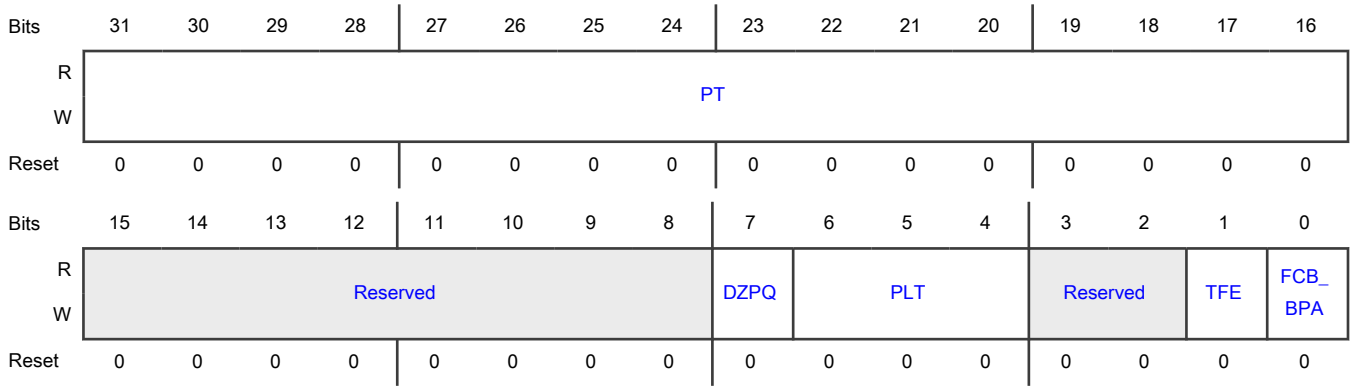
Register	Offset
MAC_Q0_Tx_Flow_Ctrl	70h

Function

Controls the generation and reception of the control (pause command) packets by MAC's flow control module. A write to the register with the Busy field = 1 triggers the flow control block to generate a pause packet. The 802.3x specification indicates the way the fields of the control packet are selected, and the pause time value from this register is used in the PT field of the control packet. The Busy field remains 1 until the control packet is transferred onto the cable. You must make sure that the Busy field is 0 before writing to this register.

If the value of the PFCE field in the MAC_Rx_Flow_Ctrl register is 1, this register controls the generation of priority flow control (PFC) frames with priorities mapped according to MAC_RxQ_Ctrl2[PSRQ0].

Diagram



Fields

Field	Function
31-16 PT	Pause Time Holds the value to be used in this field in the transmit control packet. If the bits of this field are configured to be double-synchronized with the (G)MII clock domain, consecutive writes to this register must be performed only after at least four clock cycles in the destination clock domain.
15-8 —	Reserved
7 DZPQ	Disable Zero-Quanta Pause Enables or disables zero-quanta pause packet generation. • If this field is 1, it disables the automatic generation of the zero-quanta pause packets that the flow-control signal from the FIFO layer (MTL or external sideband flow control signal sbd_flowctrl_i or mti_flowctrl_i) deasserts. • If this field is 0, normal operations with automatic zero-quanta pause packet generation are enabled. 0b - Enabled 1b - Disabled
6-4 PLT	Pause Low Threshold Configures the threshold of the pause timer at which the input flow control signal mti_flowctrl_i (or sbd_flowctrl_i) is checked for automatic retransmission of the pause packet. The threshold values must always be less than the pause time configured in bits [31:16]. For example, if the PT field = 100H (256 slot times), and the PLT field = 001, a second pause packet automatically transmits if the mti_flowctrl_i signal is asserted at 228 (256-28) slot times after the first pause packet transmits. This list provides the threshold values for different values: • The slot time is defined as the time taken to transmit 512 bits (64 bytes) on GMII or MII. • This (approximate) computation is based on the packet size (64, 1518, 2000, 9018, 16384, or 32768) + two pause packet sizes + IPG in slot times. 000b - Pause time minus 4 slot times (PT is 4 slot times) 001b - Pause time minus 28 slot times (PT is 28 slot times) 010b - Pause time minus 36 slot times (PT is 36 slot times) 011b - Pause time minus 144 slot times (PT is 144 slot times) 100b - Pause time minus 256 slot times (PT is 256 slot times) 101b - Pause time minus 512 slot times (PT is 512 slot times) 110b - Reserved
3-2 —	Reserved
1	Transmit Flow Control Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
TFE	Indicates whether transmit flow control is enabled or disabled. • Full-Duplex mode: If this field is 1, MAC enables the flow control operation to the transmit pause packets. When the field becomes 0, MAC's flow control operation disables and MAC does not transmit any pause packets. • Half-Duplex mode: If this field is 1, MAC enables the backpressure operation. When the field becomes 0, the backpressure operation disables. 0b - Disabled 1b - Enabled
0 FCB_BPA	Flow Control Busy Or Backpressure Activate Initiates if a pause packet is in Full-Duplex mode and activates the backpressure function in Half-Duplex mode if the TFE field is 1. • Full-Duplex mode: In this mode, FCB_BPA must be read as 1'b0 before writing to this register. To initiate a pause packet, the application must set this field to 1'b1. During control packet transfer, the field's value continues to be 1 to indicate that a packet transmission is in progress. When pause packet transmission is complete, MAC resets this field to 1'b0. You must not write to this register until this field becomes 0. • Half-Duplex mode: If FCB_BPA = 1 and TFE = 1 too, MAC asserts backpressure in this mode. During the backpressure function, when MAC receives a new packet, the transmitter starts sending a JAM pattern resulting in a collision. This control register field is logically ORed with the mti_flowctrl_i input signal for the backpressure function. When you configure MAC using Full-Duplex mode, this field automatically becomes 0. Access restrictions apply to this field: writing 1 sets it, writing 0 has no effect, and the field is self-clearing. 0b - Flow control busy or backpressure activate is disabled 1b - Flow control busy or backpressure activate is enabled

72.18.27 MAC Receive Flow Control (MAC_Rx_Flow_Ctrl)

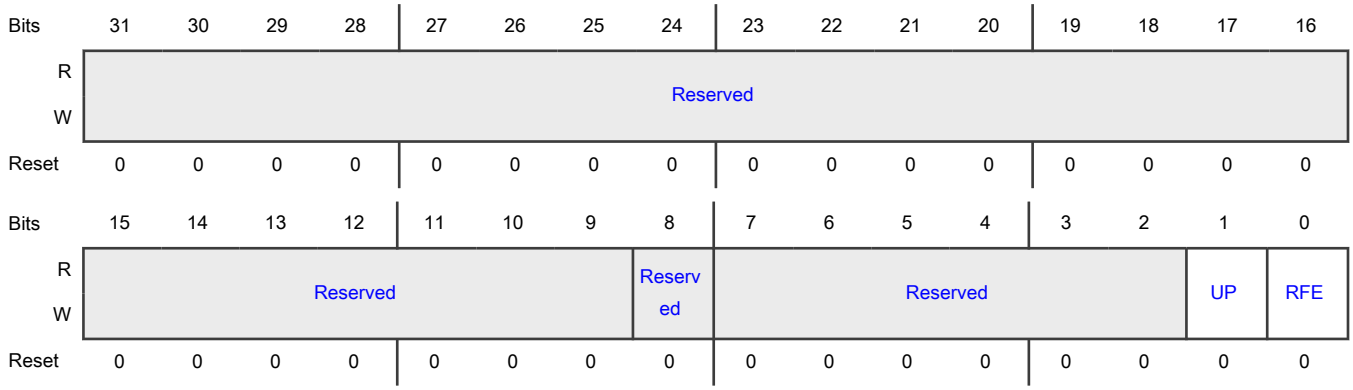
Offset

Register	Offset
MAC_Rx_Flow_Ctrl	90h

Function

Controls the pausing of MAC transmit based on the received pause packet.

Diagram



Fields

Field	Function
31-9 —	Reserved
8 —	Reserved
7-2 —	Reserved
1 UP	Unicast Pause Packet Detect Indicates whether the unicast pause packet is enabled or disabled. A pause packet is processed when it has the unique multicast address specified in IEEE 802.3. • If this field is 1, MAC can detect pause packets with a unicast address of the station. This address must comply with the specifications in MAC Address 0 High (MAC_Address0_High) and MAC Address 0 Low (MAC_Address0_Low). • If this field is 0, MAC only detects pause packets with a unique multicast address. **NOTE** MAC does not process a pause packet if the multicast address is different from the unique multicast address. This applies to the received PFC packet if PFC is enabled. The unique multicast address (01_80_C2_00_00_01h) complies with the IEEE 802.1 Qbb-2011 specifications. 0b - Disabled 1b - Enabled
0 RFE	Receive Flow Control Enable Indicates whether the receive flow control is enabled or disabled. • If this field is 1 and MAC is operating in Full-Duplex mode, MAC decodes the received pause packet and disables its transmitter for a specified (pause) time.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• If this field is 0 or if MAC is operating in Half-Duplex mode, the decode function of the pause packet disables. When PFC is enabled, the flow control for PFC packets is enabled too. MAC decodes the received PFC packet and disables the transmit queue, with matching priorities, for a duration of the received pause time. 0b - Disabled 1b - Enabled

72.18.28 MAC RxQ Control 4 (MAC_RxQ_Ctrl4)

Offset

Register	Offset
MAC_RxQ_Ctrl4	94h

Function

Controls the routing of unicast and multicast packets that fail the destination or source address filter to the receive queues.

Diagram

3-2 RXQ1EN	Receive Queue 1 Enable Performs in a manner similar to the RXQ0EN field and indicates if receive queue 1 is enabled for AV or DCB. 00b - Queue not enabled 01b - Queue enabled for AV 10b - Queue enabled for DCB/generic 11b - Reserved
1-0 RXQ0EN	Receive Queue 0 Enable Indicates whether receive queue 0 is enabled for AV or DCB. 00b - Queue not enabled 01b - Queue enabled for AV 10b - Queue enabled for DCB/generic 11b - Reserved

72.18.30 Receive Queue Control 1 (MAC_RxQ_Ctrl1)

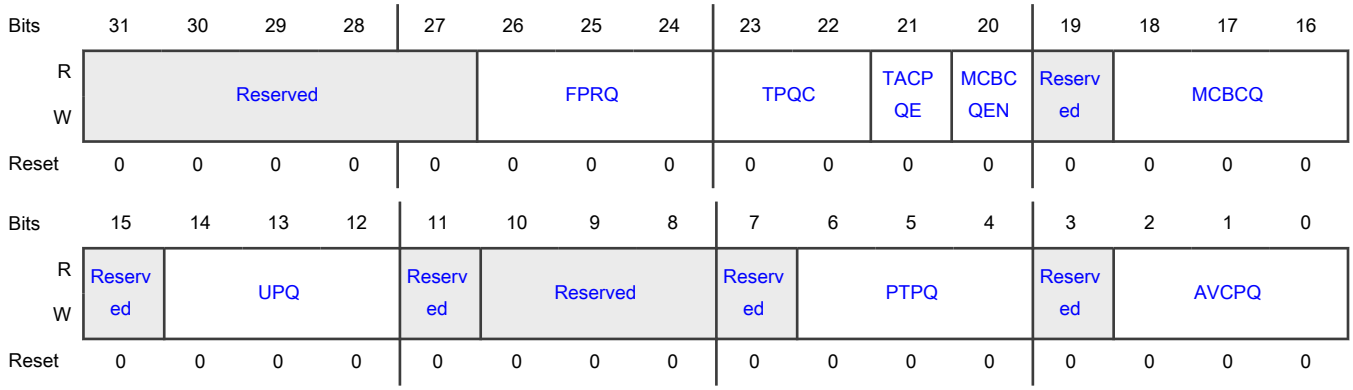
Offset

Register	Offset
MAC_RxQ_Ctrl1	A4h

Function

Controls the routing of multicast, broadcast, AV, DCB, and untagged packets to the receive queues.

Diagram



Fields

Field	Function
31-27 —	Reserved
26-24 FPRQ	Frame Preemption Residue Queue Holds the receive queue number to which the residual preemption frames must be forwarded. Preemption frames that are tagged and pass the SA, DA, or VLAN filtering are routed based on the settings of the PSRQ fields in MAC RxQ Control 2 (MAC_RxQ_Ctrl2). All other frames are treated as residual frames and are routed to the queue number mentioned in this field. Queue 0 is used as the default queue for express frames, so you cannot write 0 to this field.
23-22 TPQC	Tagged PTP Over Ethernet Packets Queuing Control Controls the routing of the VLAN-tagged PTPoE packets. These are the allowed programmable options: • 2'b00: VLAN-tagged PTPoE packets are routed as generic VLAN-tagged packets (based on the PSRQ fields in MAC RxQ Control 2 (MAC_RxQ_Ctrl2) for only non-AV enabled receive queues). • 2'b01: VLAN-tagged PTPoE packets are routed to the receive queue that the PTPQ field of this register specifies (this Rx queue can be enabled for AV or non-AV traffic). • 2'b10: VLAN-tagged PTPoE packets are routed to only AV-enabled receive queues based on the settings of the PSRQ fields.
21 TACPQE	Tagged AV Control Packets Queuing Enable Indicates the status of tagged AV control packet queuing. • If this field is 1, MAC routes the received tagged AV control packets to the receive queue that the AVCPQ field specifies. • If this field is 0, MAC routes the received tagged AV control packets based on the tag priority matching the PSRQ fields in MAC RxQ Control 2 (MAC_RxQ_Ctrl2). 0b - Disabled 1b - Enabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
20 MCBCQEN	Multicast And Broadcast Queue Enable Specifies whether multicast or broadcast packet routing to the receive queue is enabled or disabled. The multicast or broadcast packets must be routed to the receive queue specified in the MCBCQ field. 0b - Disabled 1b - Enabled
19 —	Reserved
18-16 MCBCQ	Multicast And Broadcast Queue Specifies the receive queue onto which multicast or broadcast packets are routed. Any receive queue enabled for Generic, DCB, or AV traffic can be used to route the multicast or broadcast packets. 000b - Receive queue 0 001b - Receive queue 1 010b - Receive queue 2 011b - Receive queue 3 100b - Receive queue 4 101b - Receive queue 5 110b - Receive queue 6 111b - Receive queue 7
15 —	Reserved
14-12 UPQ	Untagged Packet Queue Indicates the receive queue to which the untagged packets need to be routed. Any receive queue enabled for generic, DCB, or AV traffic can be used to route the untagged packets. 000b - Receive queue 0 001b - Receive queue 1 010b - Receive queue 2 011b - Receive queue 3 100b - Receive queue 4 101b - Receive queue 5 110b - Receive queue 6 111b - Receive queue 7
11 —	Reserved

Table continues on the next page...

Fields

Field	Function
31-24 —	Reserved
23-16 —	Reserved
15-8 PSRQ1	Priorities Selected In Receive Queue 1 Determines the priorities assigned to receive queue 1. All the packets with priorities that match the values defined in this field are routed to receive queue 1. For example, if PSRQ1[4] = 1, packets with MAC_Ext_Configuration[USP] equal to 4 are routed to receive queue 1. You must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues. This means that the same priority is not mapped to multiple receive queues.
7-0 PSRQ0	Priorities Selected In Receive Queue 0 Determines the priorities assigned to receive queue 0. All the packets with priorities that match the values defined in this field are routed to receive queue 0. For example, if PSRQ0[5] = 1, packets with MAC_Ext_Configuration[USP] equal to 5 are routed to receive queue 0. You must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues. This means that the same priority is not mapped to multiple receive queues.

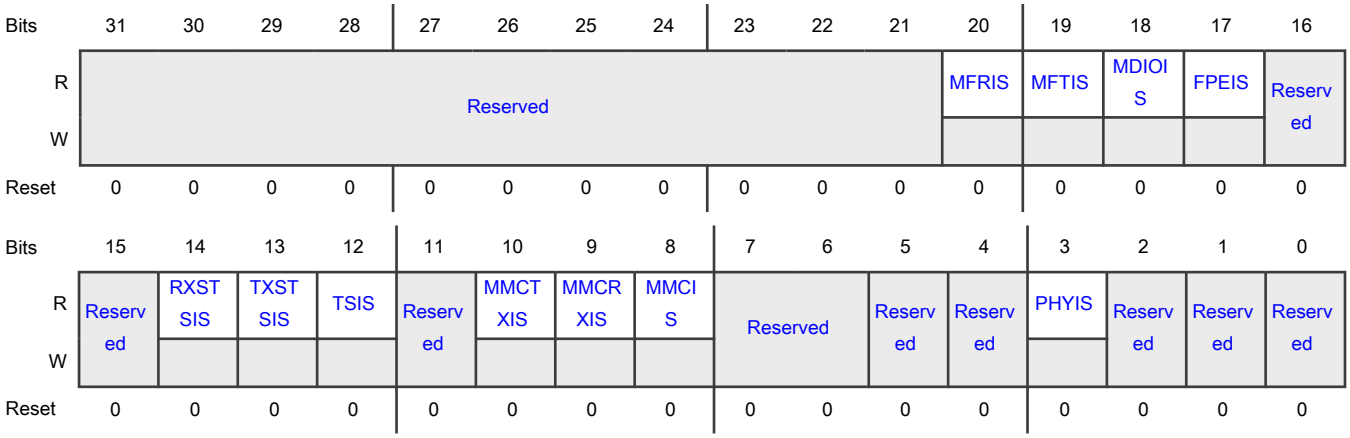
72.18.32 MAC Interrupt Status (MAC_Interrupt_Status)

Offset

Register	Offset
MAC_Interrupt_Status	B0h

Function
Contains the status of interrupts.

Diagram



Fields

Field	Function
31-21 —	Reserved
20 MFRIS	MMC FPE Receive Interrupt Status Indicates the status of MMC FPE receive interrupt. This field becomes 1 when any of the fields in MMC Receive Packet Assembly Error Counter Interrupt Status (MMC_FPE_Rx_Interrupt) is 1. The field becomes 0 when all the other fields in MMC Receive Packet Assembly Error Counter Interrupt Status (MMC_FPE_Rx_Interrupt) become 0 too. 0b - Inactive 1b - Active
19 MFTIS	MMC FPE Transmit Interrupt Status Indicates the status of MMC FPE transmit interrupt. This field becomes 1 when an interrupt generates in MMC Transmit FPE Fragment Counter Interrupt Status (MMC_FPE_Tx_Interrupt). The field becomes 0 when all the other fields in this register become 0 too. This field is valid only when you select the Enable MAC Management Counters (MMC) option along with FPE support.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Inactive 1b - Active
18 MDIOIS	MDIO Interrupt Status Indicates the status of an interrupt event after the completion of an MDIO operation. To reset this field, you must read this field or write 1 to it when MAC_CSR_SW_Ctrl[RCWE] = 1. Access restrictions apply to this field. It clears on a read or write of 1 when MAC_CSR_SW_Ctrl[RCWE] = 1. The field automatically becomes 1 on an internal event. 0b - Inactive 1b - Active
17 FPEIS	Frame Preemption Interrupt Status Indicates the status of an interrupt event during the frame preemption operation (the value of RVER, RRSP, TVER, and TRSP fields of MAC FPE Control STS (MAC_FPE_CTRL_STS) = 1). To reset this field, you must clear the event in MAC FPE Control STS (MAC_FPE_CTRL_STS) that caused the interrupt. 0b - Inactive 1b - Ative
16 —	Reserved
15 —	Reserved
14 RXSTSIS	Receive Status Interrupt Indicates the status of received packets. This field becomes 1 when MAC_Rx_Tx_Status[RWT] = 1. The field becomes 0 when you read the corresponding interrupt source field in MAC Rx Transmit Status (MAC_Rx_Tx_Status), or if you write to this interrupt source field when MAC_CSR_SW_Ctrl[RCWE] = 1. The field becomes 0 in either of these circumstances: • You read the corresponding interrupt-source field in MAC Rx Transmit Status (MAC_Rx_Tx_Status). • You write 1 to the corresponding interrupt-source field in MAC Rx Transmit Status (MAC_Rx_Tx_Status) when MAC_CSR_SW_Ctrl[RCWE] = 1. 0b - Inactive 1b - Active
13 TXSTSIS	Transmit Status Interrupt Indicates the status of transmitted packets.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field becomes 1 when any of the following fields is 1 in MAC Rx Transmit Status (MAC_Rx_Tx_Status): • Excessive collision (EXCOL) • Late collision (LCOL) • Excessive deferral (EXDEF) • Loss of carrier (LCARR) • No carrier (NCARR) • Jabber timeout (TJT) This field becomes 0 in either of these circumstances: • You read the corresponding interrupt-source field in MAC Rx Transmit Status (MAC_Rx_Tx_Status). • You write 1 to the corresponding interrupt-source field in MAC Rx Transmit Status (MAC_Rx_Tx_Status) when MAC_CSR_SW_Ctrl[RCWE] = 1. 0b - Inactive 1b - Active
12 TSIS	Timestamp Interrupt Status Indicates the status of timestamp interrupt. If the timestamp feature is enabled, this field becomes 1 when any of the following conditions is true: • The system time value is equal to or exceeds the value specified in MAC PPS1 Target Time In Seconds (MAC_PPS1_Target_Time_Seconds) and MAC PPS1 Target Time In Nanoseconds (MAC_PPS1_Target_Time_Nanoseconds). • There is an overflow in MAC System Time In Seconds (MAC_System_Time_Seconds). • The target time error occurred, which means, the programmed target time already elapsed. In configurations other than EQOS_CORE, when the drop transmit status is enabled in MTL, this field becomes 1 when the captured transmit timestamp is updated in MAC Transmit Timestamp Status In Nanoseconds (MAC_Tx_Timestamp_Status_Nanoseconds) and MAC Transmit Timestamp Status In Seconds (MAC_Tx_Timestamp_Status_Seconds). The field becomes 0 in either of these circumstances: • You read the corresponding interrupt-source field in MAC Rx Transmit Status (MAC_Rx_Tx_Status). • You write 1 to the corresponding interrupt-source field in MAC Rx Transmit Status (MAC_Rx_Tx_Status) when MAC_CSR_SW_Ctrl[RCWE] = 1. 0b - Inactive 1b - Active
11 —	Reserved
10 MMCTXIS	MMC Transmit Interrupt Status Indicates the status of MMC transmit interrupt.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field: • Becomes 1 when any field in MMC Transmit Interrupt (MMC_Tx_Interrupt) becomes 1. • Becomes 0 when all the fields in MMC Transmit Interrupt (MMC_Tx_Interrupt)return to 0. This field is valid only when you select the Enable MAC Management Counters (MMC) option. 0b - Inactive 1b - Active
9 MMCRXIS	MMC Receive Interrupt Status Indicates the status of MMC receive interrupt. This field: • Becomes 1 when any field in MMC Receive Interrupt (MMC_Rx_Interrupt) becomes 1. • Becomes 0 when all the fields in MMC Receive Interrupt (MMC_Rx_Interrupt)return to 0. This field is valid only when you select the Enable MAC Management Counters (MMC) option. 0b - Inactive 1b - Active
8 MMCIS	MMC Interrupt Status Indicates the status of MMC interrupt. This field becomes 1 when MMCRXIS = MMCTXIS = 1, and the field becomes 0 only when MMCRXIS = MMCTXIS = 0. MMCIS is valid only when you select the Enable MAC Management Counters (MMC) option. 0b - Inactive 1b - Active
7-6 —	Reserved
5 —	Reserved
4 —	Reserved
3 PHYIS	PHY Interrupt Indicates whether the PHY interrupt is detected. This field becomes 1 when rising edge is detected on the phy_intr_i input signal. The field becomes 0 when you read this register (or if you write 1 to this field when MAC_CSR_SW_Ctrl[RCWE] = 1). 0b - Not detected

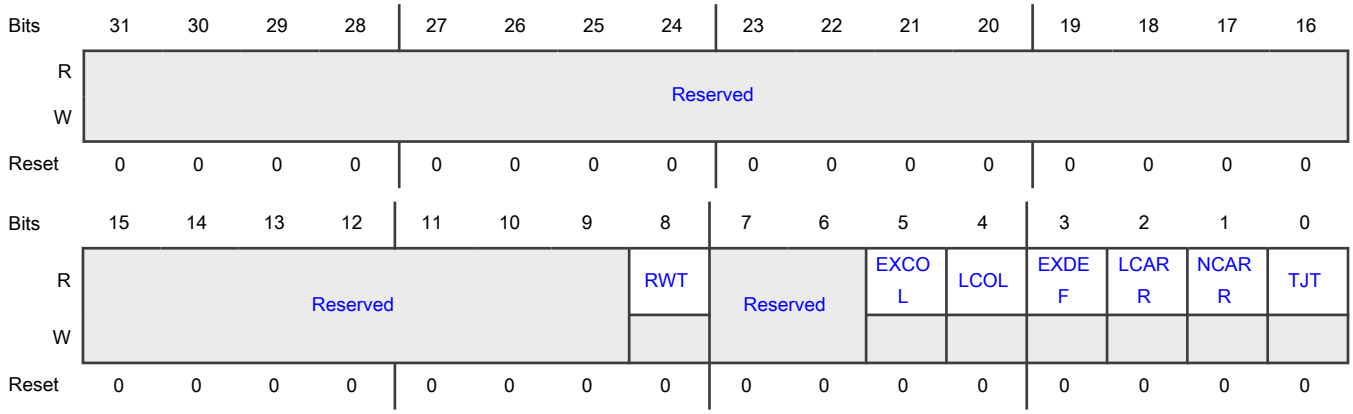
72.18.34 MAC Rx Transmit Status (MAC_Rx_Tx_Status)

Offset

Register	Offset
MAC_Rx_Tx_Status	B8h

Function
Contains the receive and transmit error status.

Diagram



Fields

Field	Function
31-9 —	Reserved
8 RWT	Receive Watchdog Timeout Indicates the status of receive watchdog. This field becomes 1 when a packet with a length greater than 2,048 bytes is received (10,240 bytes when Jumbo Packet mode is enabled) and MAC_Configuration[WD] = 0. RWT becomes 1 when a packet with length greater than 16,383 bytes is received and MAC_Configuration[WD] = 1. Access restrictions apply to RWT. It becomes 0 on read or write of 1 when MAC_CSR_SW_Ctrl[RCWE] = 1. RWT automatically becomes 1 on an internal event occurrence. 0b - No receive watchdog timed out 1b - Receive watchdog timed out
7-6 —	Reserved
5 EXCOL	Excessive Collisions Indicates the status of excessive collision. If MTL_Operation_Mode[DTXSTS] = 1, this field, EXCOL, indicates that the transmission aborted after 16 successive collisions while attempting to transmit the current packet. If MAC_Configuration[DR] = 1, EXCOL becomes 1 after the first collision and the packet transmission is aborted. Access restrictions apply to EXCOL. It becomes 0 on read or write of 1 when MAC_CSR_SW_Ctrl[RCWE] = 1. EXCOL automatically becomes 1 on an internal event occurrence. 0b - No collision 1b - Excessive collision is sensed
4	Late Collision

Table continues on the next page...

Table continued from the previous page...

Field	Function
LCOL	Indicates the status of late collision. If MTL_Operation_Mode[DTXSTS] = 1, this field, LCOL, indicates that the packet transmission aborted because a collision occurred after the collision window (64 bytes including preamble in MII mode; 512 bytes including preamble and carrier extension in GMII mode). This field is invalid if an underflow error occurs. Access restrictions apply to LCOL. It becomes 0 on read or write of 1 when MAC_CSR_SW_Ctrl[RCWE] = 1. LCOL automatically becomes 1 on an internal event occurrence. 0b - No collision 1b - Late collision is sensed
3 EXDEF	Excessive Deferral Indicates whether the transmission ended because of excessive deferral. If MTL_Operation_Mode[DTXSTS] = 1 and MAC_Configuration[DC] = 1 too, this field, EXDEF, indicates that the transmission ended because of excessive deferral of over 24,288 bit times (155,680 in 1000/2500 Mbit/s mode or when the jumbo packet is enabled). Access restrictions apply to EXDEF. It becomes 0 on read or write of 1 when MAC_CSR_SW_Ctrl[RCWE] = 1. EXDEF automatically becomes 1 on an internal event occurrence. 0b - No excessive deferral 1b - Excessive deferral
2 LCARR	Loss of Carrier Indicates the status of carrier signal. If MTL_Operation_Mode[DTXSTS] = 1, this field, LCARR, indicates that the loss of carrier occurred during packet transmission, which means, the phy_crs_i signal was inactive for one or more transmission clock periods during packet transmission. The field is valid only for packets transmitted without collision. Access restrictions apply to LCARR. It becomes 0 on read or write of 1 when MAC_CSR_SW_Ctrl[RCWE] = 1. LCARR automatically becomes 1 on an internal event occurrence. 0b - Carrier is present 1b - Loss of carrier
1 NCARR	No Carrier Indicates whether the carrier signal is present from the PHY at the end of preamble transmission. If MTL_Operation_Mode[DTXSTS] = 1, NCARR indicates that the carrier signal from the PHY is absent at the end of preamble transmission. Access restrictions apply to NCARR. It becomes 0 after either of these actions: • You read NCARR. • You write 1 to NCARR when MAC_CSR_SW_Ctrl[RCWE] = 1. NCARR automatically becomes 1 after an internal event occurs.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Present 1b - Absent
0 TJT	Transmit Jabber Timeout Indicates whether a transmit-jabber timer timeout occurred. The timeout occurs after any of these events: • MAC_Configuration[JD] = 0 and the normal packet size exceeds 2,048 bytes. • MAC_Configuration[JD] = 0 and the jumbo packet size exceeds 10240 bytes. • MAC_Configuration[JD] = 1 and the normal packet size exceeds 16383 bytes. Access restrictions apply to TJT. It becomes 0 after either of these actions: • You read TJT. • You write 1 to TJT when MAC_CSR_SW_Ctrl[RCWE] = 1. TJT automatically becomes 1 after an internal event occurs. 0b - No transmit jabber timeout occurred 1b - Transmit jabber timeout occurred

72.18.35 MAC Version (MAC_Version)

Offset

Register	Offset
MAC_Version	110h

Function

Identifies the version of the module.

Fields

Field	Function
31-19 —	Reserved
18-17	MAC Transmit Packet Controller Status

Table continues on the next page...

Table continued from the previous page...

Field	Function
TFCSTS	Indicates the state of the MAC transmit packet controller module. 00b - Idle state 01b - Waiting for one of these: status of the previous packet or IPG, or for the back-off period to be over 10b - Generating and transmitting a pause control packet (in Full-Duplex mode) 11b - Transferring input packet for transmission
16 TPESTS	MAC GMII Or MII Transmit Protocol Engine Status Indicates whether MAC GMII or MII transmit protocol engine is detected. If this field is 1, it indicates that the MAC GMII or MII transmit protocol engine is actively transmitting data and is not in an idle state. 0b - Not detected 1b - Detected
15-3 —	Reserved
2-1 RFCFCSTS	MAC Receive Packet Controller FIFO Status Indicates the status of the small FIFO read and write controllers of the MAC receive packet controller module. If this field is 1, it indicates that the small FIFO read and write controllers of the MAC receive packet controller module are in an active state. 00b - Inactive 01b - Active
0 RPESTS	Receive Protocol Engine Status Indicates whether MAC GMII or MII receive protocol engine is detected. If this field is 1, it indicates that the MAC GMII or MII receive protocol engine is actively receiving data and is not in an idle state. 0b - Not detected 1b - Detected

72.18.37 MAC Hardware Feature 0 (MAC_HW_Feature0)

Offset

Register	Offset
MAC_HW_Feature0	11Ch

Function

Indicates the presence of the first set of EMAC optional features or functions. You can use this register to dynamically enable or disable the programs related to these features.

Diagram

Fields

Field	Function
31 —	Reserved
30-28 ACTPHYSEL	Active PHY Feature Indicates the selected active PHY interface. If you have multiple PHY interfaces (GMII, MII, RevMII, RGMII, RMII, RTBI, SGMII, SGMII, or TBI) in your configuration, this field indicates the sampled value of the phy_intf_sel_i signal during reset deassertion. 000b - GMII or MII 001b - RGMII 010b - SGMII 011b - TBI 100b - RMII 101b - RTBI 110b - SMII 111b - RevMII
27 SAVLANINS	SA or VLAN Insertion Feature Indicates whether the feature that enables SA or VLAN insertion on transmit is selected. This field becomes 1 if you select the "enable SA and VLAN insertion on Tx" option. 0b - Not selected 1b - Selected

Table continues on the next page...

Table continued from the previous page...

Field	Function
26-25 TSSTSSEL	Timestamp System Time Source Feature Indicates the source of the timestamp system time. This field becomes 1 if you select the "enable IEEE 1588 timestamp support" option. 00b - Internal 01b - External 10b - Both internal and external 11b - Reserved
24 MACADR64SEL	MAC Addresses 64-127 Indicates whether the feature that enables additional 64 MAC address regsiters (64-127) is selected. This field becomes 1 if you enable the "MAC addresses (64-127) select" option. 0b - Not selected 1b - Selected
23 MACADR32SEL	MAC Addresses 32-63 Indicates whether the feature that enables additional 32 MAC address registers (32-63) is selected. This field becomes 1 if you select the "MAC addresses 32-63 select" option. 0b - Not selected 1b - Selected
22-18 ADDMACADRSEL	MAC Addresses 1-31 Indicates whether the feature that enables additional 1-31 MAC address registers is selected. This field becomes 1 if you select a non-zero value for enabling the "MAC addresses 1-31 select" option. 0_0000b - Not selected 0_0001b - Selected
17 —	Reserved
16 RXCOESEL	Receive Checksum Offload Feature Indicates whether the feature that enables receive TCP/IP checksum offload is selected. This field becomes 1 if you select the "enable receive TCP/IP checksum check" option. 0b - Not selected 1b - Selected
15 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
14 TXCOESEL	Transmit Checksum Offload Feature Indicates whether the feature that enables transmit TCP/IP checksum insertion is selected. This field becomes 1 if you select the "enable transmit TCP/IP checksum insertion" option. 0b - Not selected 1b - Selected
13 EEESEL	Energy Efficient Ethernet (EEE) Feature Indicates whether the feature that enables EEE is selected. This field becomes 1 if you select the "enable EEE" option. 0b - Not selected 1b - Selected
12 TSSEL	IEEE 1588-2008 Timestamp Feature Indicates whether the option that enables IEEE 1588-2008 timestamp is selected. This field becomes 1 if you select the "enable IEEE 1588 timestamp support" option. 0b - Not selected 1b - Selected
11-10 —	Reserved
9 ARPOFFSEL	ARP Offload Feature Indicates whether the feature that enables ARP offload is selected. This field becomes 1 if you select the "enable IPv4 ARP offload" option. 0b - Not selected 1b - Selected
8 MMCSEL	MAC Management Counters (MMC) Feature Indicates whether the feature that enables MMC is selected. This field becomes 1 if you select the "enable MMC" option. 0b - Not selected 1b - Selected
7 MGKSEL	PMT Magic Packet Feature Indicates whether the feature that enables PMT magic detection is selected. This field becomes 1 if you select the "enable magic packet detection" option. 0b - Not selected

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Selected
6 RWKSEL	PMT Remote Wake-Up Packet Feature Indicates whether the feature that enables PMT remote wake-up packet detection is selected. This field becomes 1 if you select the "enable remote wake-up packet detection" option. 0b - Not selected 1b - Selected
5 SMASEL	SMA (MDIO) Interface Feature Indicates whether the feature that enables station management (MDIO interface) is selected. This field becomes 1 if you select the "enable station management (MDIO interface)" option. 0b - Not selected 1b - Selected
4 VLHASH	VLAN Hash Filter Feature Indicates whether the filtering option based on VLAN hash table is selected. This field becomes 1 if you select the "enable VLAN hash table based filtering" option. 0b - Not selected 1b - Selected
3 PCSSEL	PCS Select Indicates if either of the TBI, SGMII, or RTBI PHY interface options is selected. This field becomes 1 if you select any one of the TBI, SGMII, or RTBI PHY interface options. 0b - No 1b - Yes
2 HDSEL	Half-Duplex Support Feature Indicates whether half-duplex support is available as the mode of operation. This field becomes 1 if you select Half-Duplex as the mode of operation. 0b - Unavailable 1b - Available
1 GMIISEL	1000 Mbit/s Support Feature Indicates whether 1000 Mbit/s support is available as the mode of operation. This field becomes 1 if you select 1000 Mbit/s as the mode of operation. 0b - Unavailable 1b - Available

Table continues on the next page...

Table continued from the previous page...

Field	Function
0 MIISEL	10 or 100 Mbit/s Support Feature Indicates whether 10 or 100 Mbit/s support is available as the mode of operation. This field becomes 1 if you select 10/100 Mbit/s as the mode of operation. 0b - Unavailable 1b - Available

72.18.38 MAC Hardware Feature 1 (MAC_HW_Feature1)

Offset

Register	Offset
MAC_HW_Feature1	120h

Function

Indicates the presence of the second set of optional features or functions of the module. You can use this register to dynamically enable or disable the programs related to these features.

Field	Function
31 —	Reserved
30-27	L3 Or L4 Filter Number

Table continues on the next page...

Table continued from the previous page...

Field	Function
L3L4FNUM	Indicates the total number of L3 or L4 filters. 0000b - No filters (0) 0001b - 1 0010b - 2 0011b - 3 0100b - 4 0101b - 5 0110b - 6 0111b - 7 1000b - 8
26 —	Reserved
25-24 HASHTBLSZ	Hash Table Size Indicates the size of the hash table. 00b - No hash table 01b - 64 10b - 128 11b - 256
23 POUOST	One Step For PTP Over UDP/IP Feature Indicates whether the feature that enables one step for PTP over UDP/IP is selected. This field becomes 1 if you select the "enable one-step timestamp for PTP over UDP/IP" option. 0b - Not selected 1b - Selected
22 —	Reserved
21 RAVSEL	Receive Side-Only AV Feature Indicates whether the feature that enables audio-video bridging only on the receive side is selected. This field becomes 1 if you select the "enable audio-video bridging on receive side only" option. 0b - Not selected 1b - Selected
20	AV Feature Indicates whether the feature that enables audio-video bridging is selected.

Table continues on the next page...

Table continued from the previous page...

Field	Function
AVSEL	This field becomes 1 if you select the "enable audio video bridging" option. 0b - Not selected 1b - Selected
19 DBGMEMA	DMA Debug Registers Enable Feature Indicates whether the feature that enables DMA debug regsiters is selected. This field becomes 1 if you select the "enable DMA debug mode" option. 0b - Not selected 1b - Selected
18 TSOEN	TCP Segmentation Offload Enable Feature Indicates whether the feature that enables TCP segmentation offload for TCP/IP packets is selected. This field becomes 1 if you select the "enable TCP segmentation offloading for TCP/IP packets" option. 0b - Not selected 1b - Selected
17 SPHEN	Split Header Enable Feature Indicates whether the feature that enables a split header structure is selected. This field becomes 1 if you select the "enable split header structure" option. 0b - Not selected 1b - Selected
16 DCBEN	DCB Enable Feature Indicates whether the feature that enables data center bridging is selected. This field becomes 1 if you select the "enable data center bridging" option. 0b - Not selected 1b - Selected
15-14 ADDR64	Address Width Feature Indicates the configured address width. 00b - 32 01b - 40 10b - 48 11b - Reserved
13 ADVTHWORD	IEEE 1588 High-Word Feature Indicates whether the feature that enables the IEEE 1588 high-word register is selected. This field becomes 1 if you select the "enable/add IEEE 1588 higher-word register" option.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Not selected 1b - Selected
12 PTOEN	PTP Offload Enable Feature Indicates whether the feature that enables PTP offload is selected. This field becomes 1 if you select the "enable PTP timestamp offload" option. 0b - Not selected 1b - Selected
11 OSTEN	One-Step Timestamping Enable Feature Indicates whether the feature that enables one-step timestamping is selected. This field becomes 1 if you select the "enable one-step timestamp" option. 0b - Not selected 1b - Selected
10-6 TXFIFOSIZE	MTL Transmit FIFO Size Feature Contains the configured value of MTL transmit FIFO (in bytes) expressed as log to base 2 minus 7, which means, Log 2 (TXFIFO_SIZE) - 7. 0_0000b - 128 bytes 0_0001b - 256 bytes 0_0010b - 512 bytes 0_0011b - 1024 bytes 0_0100b - 2048 bytes 0_0101b - 4096 bytes 0_0110b - 8192 bytes 0_0111b - 16384 bytes 0_1000b - 32 KB 0_1001b - 64 KB 0_1010b - 128 KB 0_1011b - Reserved
5 SPRAM	Single Port RAM Feature Indicates whether the single-port RAM feature is selected. This field becomes 1 if you select the option that enables the "use single port RAM" feature. 0b - Not selected 1b - Selected

Table continues on the next page...

Table continued from the previous page...

Field	Function
4-0 RXFIFOSIZE	MTL Receive FIFO Size Feature Contains the configured value of MTL receive FIFO (in bytes) expressed as log to base 2 minus 7, which means, Log 2 (RXFIFO_SIZE) - 7. 0_0000b - 128 bytes 0_0001b - 256 bytes 0_0010b - 512 bytes 0_0011b - 1024 bytes 0_0100b - 2048 bytes 0_0101b - 4096 bytes 0_0110b - 8192 bytes 0_0111b - 16384 bytes 0_1000b - 32 KB 0_1001b - 64 KB 0_1010b - 128 KB 0_1011b - 256 KB 0_1100b - Reserved

72.18.39 MAC Hardware Feature 2 (MAC_HW_Feature2)

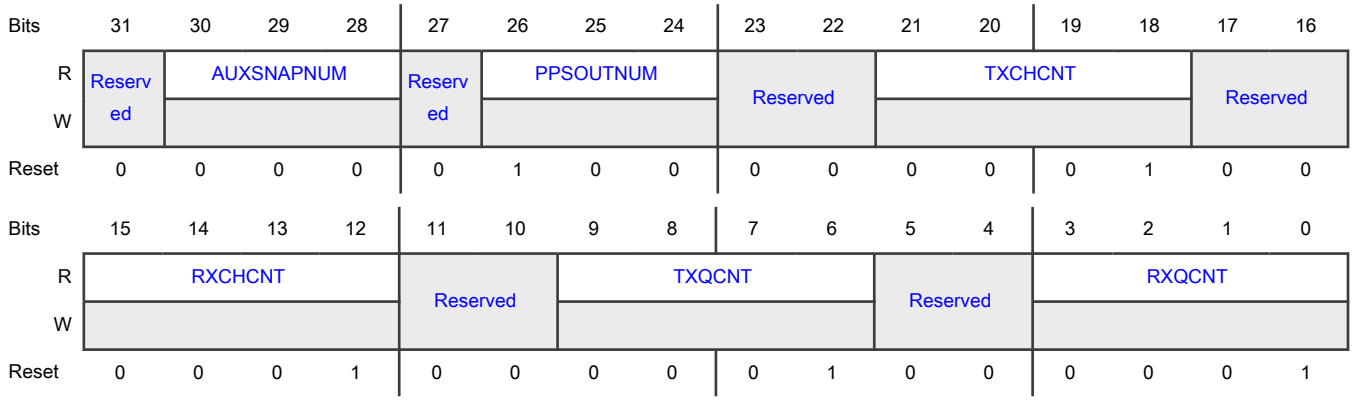
Offset

Register	Offset
MAC_HW_Feature2	124h

Function

Indicates the presence of the third set of optional features or functions of the module. You can use this register to dynamically enable or disable the programs related to these features.

Diagram



Fields

Field	Function
31 —	Reserved
30-28 AUXSNAPNUM	Number Of Auxiliary Snapshot Inputs Indicates the number of auxiliary snapshot inputs. 000b - No auxiliary input (0) 001b - 1 010b - 2 011b - 3 100b - 4 101b - Reserved
27 —	Reserved

R W	MAC_SCS1															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 MAC_SCS1	MAC SCS 1 Is reserved for NXP internal use. The value of this field must always be 0 unless NXP instructs you otherwise. Writing 1 to any of the bits of this field might cause expected chip behavior.

72.18.45 MAC MDIO Address (MAC_MDIO_Address)

Offset

Register	Offset
MAC_MDIO_Address	200h

Function
Controls the management cycles to external PHY through a management interface.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved				PSE	BTB	PA					RDA				
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved	NTC			CR				Reserved			SKAP	GOC_1	GOC_0	C45E	GB
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-28 —	Reserved
27 PSE	Preamble Suppression Enable Indicates the status of preamble suppression. • If this field is 1, SMA suppresses the 32-bit preamble and transmits MDIO frames with only 1 preamble bit. • If this field is 0, the MDIO frame always includes 32 bits of preamble as defined in the IEEE specification.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disabled 1b - Enabled
26 BTB	Back-To-Back Transactions Indicates the status of back-to-back transactions. When BTB = 1 and NTC > 0, MAC indicates the completion of a read or write command at the end of a frame transfer (before the trailing clocks are transmitted). Therefore, you can initiate the next command, and that command executes immediately irrespective of the number of trailing clocks generated for the previous frame. When BTB = 0, the read or write command completes (GB = 0) only after the trailing clocks generate. In this mode, you must ensure that: • NTC is always generated after each frame. • BTB must not be equal to 1 when NTC = 0. 0b - Disabled 1b - Enabled
25-21 PA	Physical Layer Address Indicates whether MAC accesses clause 22 PHY devices (out of 32) or clause 45 capable PHYs (out of 32).
20-16 RDA	Register Or Device Address Indicates whether MAC accesses clause 22 PHY devices (out of 32) or clause 45 capable PHYs (out of 32).
15 —	Reserved
14-12 NTC	Number Of Trailing Clocks Controls the number of trailing clock cycles generated on the gmii_mdc_o (MDC) signal after the end of MDIO frame transmission. The valid values can range from 0 to 7. Writing 3h to this field indicates that there are additional three clock cycles on the MDC line after the end of MDIO frame transfer.
11-8 CR	CSR Clock Range Determines the frequency of the MDC clock according to the CSR clock frequencies used in your design: • 0000: CSR clock = 60-100 MHz; MDC clock = CSR clock/42 • 0001: CSR clock = 100-150 MHz; MDC clock = CSR clock/62 • 0010: CSR clock = 20-35 MHz; MDC clock = CSR clock/16 • 0011: CSR clock = 35-60 MHz; MDC clock = CSR clock/26 • 0100: CSR clock = 150-250 MHz; MDC clock = CSR clock/102 • 0101: CSR clock = 250-300 MHz; MDC clock = CSR clock/124

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• 0110: CSR clock = 300-500 MHz; MDC clock = CSR clock/204 • 0111: CSR clock = 500-800 MHz; MDC clock = CSR clock/324 When bit 3 of this field is 0, the suggested CSR clock-frequency range applicable to each value ensures that the MDC clock frequency is approximately between 1.0 MHz and 2.5 MHz. When bit 3 of this field is 1, you can achieve a higher MDC clock frequency than the IEEE 802.3 frequency limit of 2.5 MHz, and program a clock divider of a lower value. For example, if the CSR clock frequency is 100 MHz and you write 1010 to this field, the resultant MDC clock frequency equals 12.5 MHz, which is above the range specified in IEEE 802.3. Program these values only if the interfacing chips support faster MDC clocks: • 1000: CSR clock/4 • 1001: CSR clock/6 • 1010: CSR clock/8 • 1011: CSR clock/10 • 1100: CSR clock/12 • 1101: CSR clock/14 • 1110: CSR clock/16 • 1111: CSR clock/18 These bits are not used for accessing RevMII. They are read-only if the RevMII interface is selected as a single PHY interface.
7-5 —	Reserved
4 SKAP	Skip Address Packet Indicates the status of the skip address packet. If this field is 1, SMA does not send the address packets before read, write, or post-read increment address packets. This field is valid only when C45E = 1. 0b - Disabled 1b - Enabled
3 GOC_1	GMII Operation Command 1 Indicates the status of GMII operation command 1. GMII operation command 1 represents the higher bit of the operation command to PHY or RevMII. The fields GOC_1 and GOC_O indicate these values: • 00: Reserved • 01: Write • 10: Post-read increment address for clause 45 PHY • 11: Read

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When clause 22 PHY or RevMII is enabled, only write and read commands are valid. 0b - Disabled 1b - Enabled
2 GOC_0	GMII Operation Command 0 Indicates the status of GMII operation command 0. GMII operation command 0 represents the lower bit of the operation command to PHY or RevMII. When in SMA mode (MDIO master), this field, along with the GOC_1 field, determines the operation to be performed to PHY. This field is read-only and tied to 1 when only RevMII is selected in configuration. 0b - Disabled 1b - Enabled
1 C45E	Clause 45 PHY Enable Indicates the status of clause 45 PHY. • If this field is 1, clause 45 capable PHY is connected to MDIO. • If this field is 0, clause 22 capable PHY is connected to MDIO. 0b - Disabled 1b - Enabled
0 GB	GMII Busy Indicates the status of GMII busy. Writing 1 to this field instructs SMA to initiate a read or write access to the MDIO slave. MAC writes 0 to the field after the MDIO frame transfer is complete. Therefore, you must not write or change any of the fields in the MAC_MDIO_Address and MAC_MDIO_Data registers as long as the value of this field is 1. For write transfers, before writing 1 to this field, you must write a 16-bit data to MAC_MDIO_Data[GD] and MAC_MDIO_Data[RA] if C45E = 1. If C45E = 1, you must also write to MAC_MDIO_Data[RA] before initiating a read transfer. After a read transfer completes (GB = 0), a data read from the PHY register is valid in MAC_MDIO_Data[GD]. **NOTE** Even if the addressed PHY is not present, there is no change in the functionality of this field. Access restrictions apply to this field. It clears automatically and writing 0 to it has no effect. 0b - Disabled 1b - Enabled

72.18.46 MAC MDIO Data (MAC_MDIO_Data)

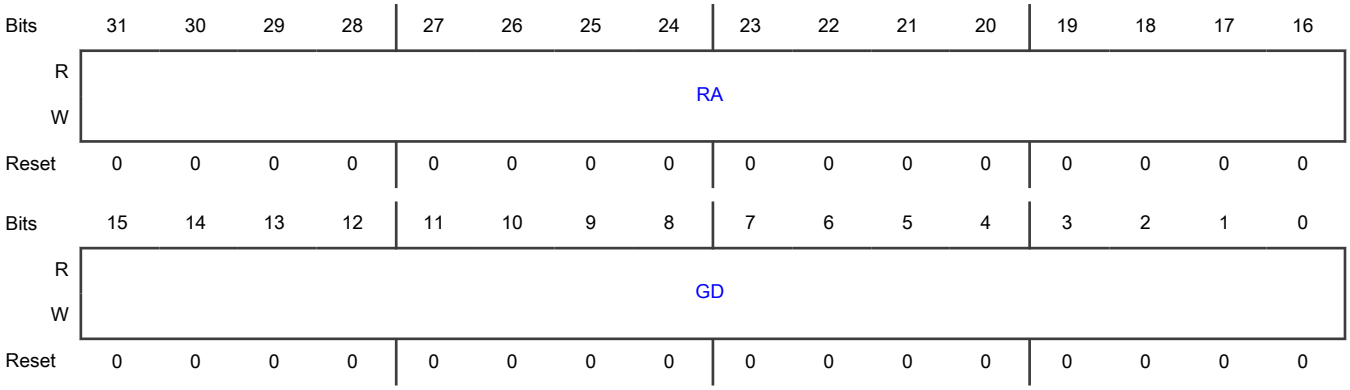
Offset

Register	Offset
MAC_MDIO_Data	204h

Function

Is used to store the write data to be written to the PHY register located at the address specified in MAC MDIO Address (MAC_MDIO_Address). This register also stores the read data from the PHY register located at the address that MAC MDIO Address (MAC_MDIO_Address) specifies.

Diagram



Fields

Field	Function
31-16 RA	Register Address Contains the PHY register address intended for the MDIO frame. This field is valid only when MAC_MDIO_Address[C45E] = 1.
15-0 GD	GMII Data Contains the 16-bit data value read from PHY or RevMII after a management read operation or the 16-bit data value to be written to PHY or RevMII before a management write operation.

72.18.47 MAC CSR Software Control (MAC_CSR_SW_Ctrl)

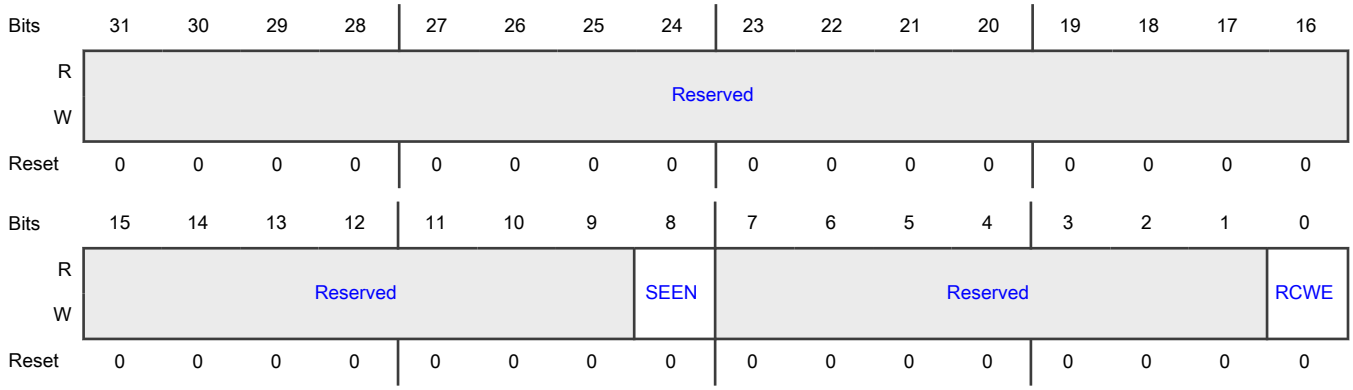
Offset

Register	Offset
MAC_CSR_SW_Ctrl	230h

Function

Contains software programmable controls for changing the CSR access response and clearing the status bits on read.

Diagram



Fields

Field	Function
31-9 —	Reserved
8 SEEN	Slave Error Response Enable Indicates the status of the slave error response. • If this field is 1, MAC responds with a slave error for accesses to reserved registers in the CSR space. • If this field is 0, MAC sends an "okay" response to registers accessed from the CSR space. 0b - Disabled 1b - Enabled
7-1 —	Reserved
0 RCWE	Enable Register Write 1 To Clear (W1C) Enables and disables the W1C feature for some registers. When this field is 1, the access mode of some of the other fields changes from R2C to W1C. When this field is 0, the access mode of those fields remains R2C. 0b - Disabled 1b - Enabled

72.18.48 MAC FPE Control STS (MAC_FPE_CTRL_STS)

Offset

Register	Offset
MAC_FPE_CTRL_STS	234h

Function

Controls the operation of frame preemption.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	Reserved												S1_SET_0	SRSP	SVER	EFPE
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-20 —	Reserved
19 TRSP	Transmitted Respond Frame Indicates whether the respond frame is transmitted. This field becomes 1 when a respond frame is transmitted (triggered by writing 1 to the SRSP field). An interrupt can be generated for this event if you write 1 to MAC_Interrupt_Enable[FPEIE]. Access restrictions apply to this field. TRSP becomes a W1C field when MAC_CSR_SW_Ctrl[RCWE] = 1, and becomes an R2C field when MAC_CSR_SW_Ctrl[RCWE] = 0. Thus, TRSP becomes 0 sometimes when you read it and sometimes when you write 1 to it. It automatically becomes 1 on an internal event. 0b - Not transmitted 1b - Transmitted
18 TVER	Transmitted Verify Frame Indicates whether the verify frame is transmitted. This field becomes 1 when a verify frame is transmitted (triggered by writing 1 to the SVER field). An interrupt can be generated for this event if you write 1 to MAC_Interrupt_Enable[FPEIE]. Access restrictions apply to this field. The field clears on read or write of 1 when MAC_CSR_SW_Ctrl[RCWE] = 1. It automatically becomes 1 on an internal event. 0b - Not transmitted 1b - Transmitted
17 RRSP	Received Respond Frame Indicates whether the respond frame is received.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field becomes 1 when a respond frame is received. An interrupt can be generated for this event if you write 1 to MAC_Interrupt_Enable[FPEIE]. Access restrictions apply to this field. The field clears on read or write of 1 when MAC_CSR_SW_Ctrl[RCWE] = 1. It automatically becomes 1 on an internal event. 0b - Not received 1b - Received
16 RVER	Received Verify Frame Indicates whether the verify frame is received. This field becomes 1 when a verify frame is received. An interrupt can be generated on the transmission of a packet if you write 1 to MAC_Interrupt_Enable[FPEIE]. Access restrictions apply to this field. The field clears on read or write of 1 when MAC_CSR_SW_Ctrl[RCWE] = 1. It automatically becomes 1 on an internal event. 0b - Not received 1b - Received
15-4 —	Reserved
3 S1_SET_0	S1 SET 0 Is reserved for NXP internal use and must always be 0 unless instructed by NXP. Writing 1 to this field may cause unexpected behavior.
2 SRSP	Send Respond mPacket Indicates the status of the send respond mPacket. If this field is 1, it indicates the hardware to send a respond mPacket. The hardware resets the field after sending the respond mPacket. Access restrictions apply to this field. It clears automatically and writing 0 to it has no effect. 0b - Disabled 1b - Enabled
1 SVER	Send Verify mPacket Enables and disables the sending of a verify mPacket. Write 1 to this field to command EMAC to send a verify mPacket. EMAC writes 0 to this field after sending the verify mPacket. Access restrictions apply to this field. It clears automatically and writing 0 to it has no effect. 0b - Disabled 1b - Enabled
0	Enable Transmit Frame Preemption

Table continues on the next page...

Table continued from the previous page...

Field	Function
EFPE	Enables or disables the frame preemption transmit functionality. 0b - Disabled 1b - Enabled

72.18.49 MAC Presentation Time (MAC_Presn_Time_ns)

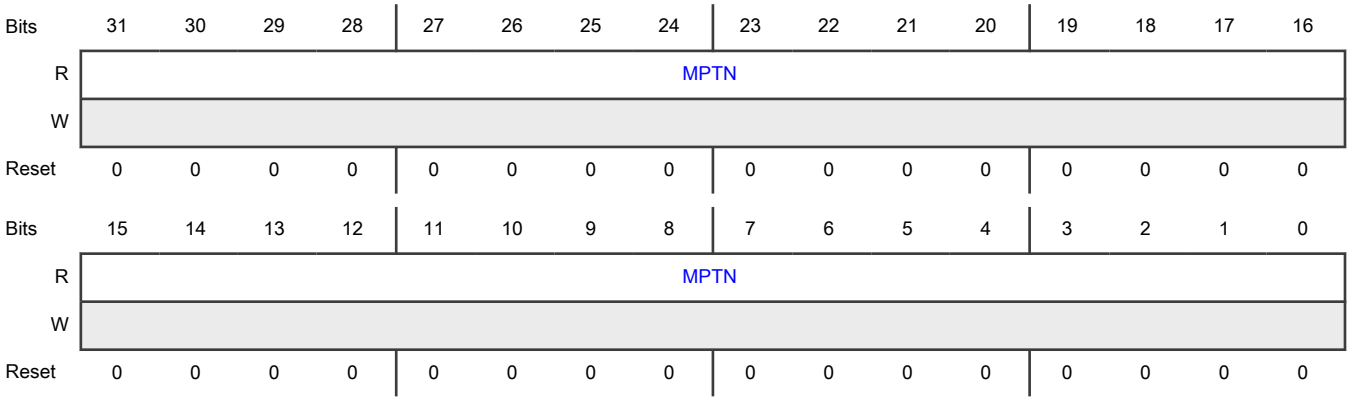
Offset

Register	Offset
MAC_Presn_Time_ns	240h

Function

Contains the 32-bit binary rollover equivalent time of the PTP system time (in nanoseconds) and exists when DWC_EQOS_FLEXI_PPS_OUT_EN is configured.

Diagram



Fields

Field	Function
31-0 MPTN	MAC 1722 Presentation Time (In Nanoseconds) Indicates the value of the 32-bit binary rollover equivalent time of the PTP System Time (in ns).

72.18.50 MAC Presentation Time Update (MAC_Presn_Time_Updt)

Offset

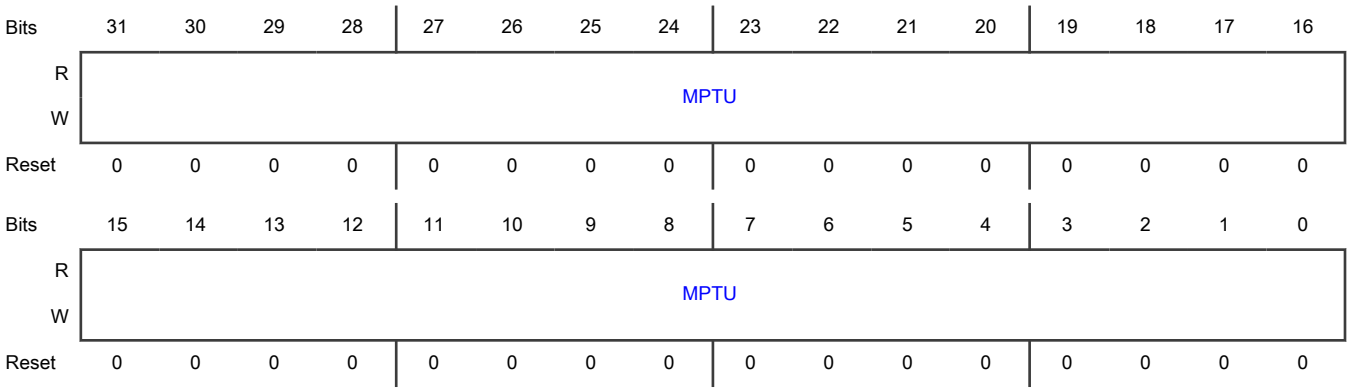
Register	Offset
MAC_Presn_Time_Updt	244h

Function

Holds the 32-bit value of MAC 1722 presentation time (in ns), which must be added to the current presentation time counter value. Initialization happens when MAC_Timestamp_Control[TSINIT] = 1, and an update happens when MAC_Timestamp_Control[TSUPDT] = 1.

Exists when DWC_EQOS_FLEXI_PPS_OUT_EN is configured.

Diagram



Fields

Field	Function
31-0 MPTU	MAC 1722 Presentation Time Update Holds the initial value or the update value for the presentation time. When used for an update, this field holds the 32-bit value (in ns), which must be added to the current presentation time counter value. Initialization happens when MAC_Timestamp_Control[TSINIT] = 1, and an update happens when MAC_Timestamp_Control[TSUPDT] = 1. When MAC_System_Time_Nanoseconds_Update[ADDSUB] = 1, this value is directly used for subtraction.

72.18.51 MAC Address 0 High (MAC_Address0_High)

Offset

Register	Offset
MAC_Address0_High	300h

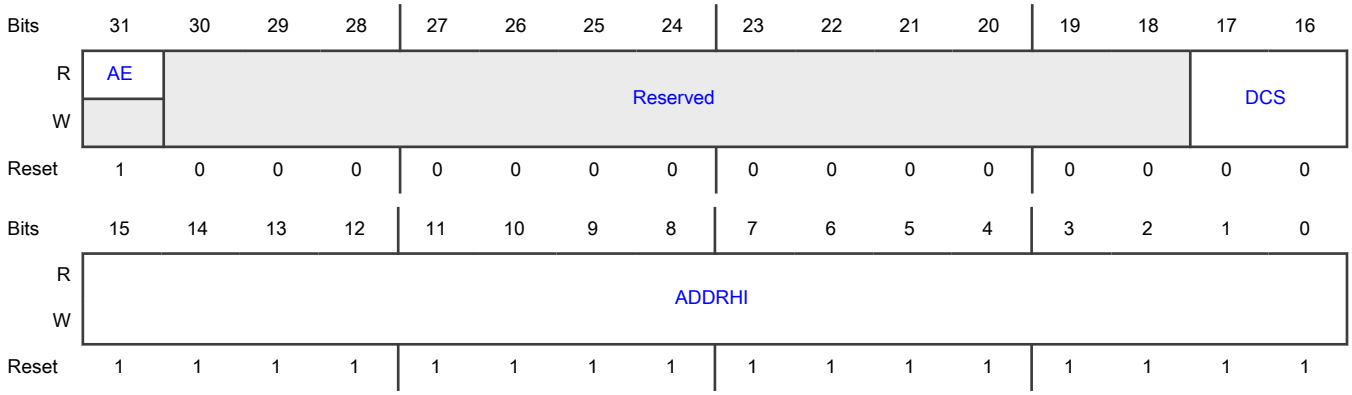
Function

Holds the upper 16 bits of the first 6-byte MAC address of the station.

The first DA byte that is received on the (G)MII interface corresponds to the LS byte (bits [7:0]) of MAC Address 0 Low (MAC_Address0_Low). For example, if 112233445566h is received (11h in lane 0 of the first column) on (G)MII as the destination address, MAC Address 0 Low (MAC_Address0_Low)[47:0] is compared to 665544332211h.

If MAC address registers are configured to be double-synchronized with the (G)MII clock domains, the synchronization is triggered only when bits [31:24] (in Little-Endian mode) or bits [7:0] (in Big-Endian mode) of MAC Address 0 Low (MAC_Address0_Low) are written to. For proper synchronization updates, the consecutive writes to MAC Address 0 Low (MAC_Address0_Low) must be performed after at least four clock cycles in the destination clock domain.

Diagram



Fields

Field	Function
31 AE	Address Enable Enables MAC address 0b - Disabled and invalid (the field's value must always be 1) 1b - Enabled
30-18 —	Reserved
17-16 DCS	DMA Channel Select If MAC_Ext_Configuration[PDC] = 0, this field contains the binary representation of the DMA channel number to which a receive packet whose DA matches MAC Address 0 Low (MAC_Address0_Low) content is routed. If MAC_Ext_Configuration[PDC] = 1, this field contains the one-hot representation of one or more DMA channel numbers to which a receive packet whose DA matches MAC Address 0 Low (MAC_Address0_Low) content is routed.
15-0 ADDRHI	MAC Address 0 [47:32] Contains the upper 16 bits [47:32] of the first 6-byte MAC address. MAC uses this field for filtering the received packets and inserting the MAC address in the transmit flow control (pause) packets.

72.18.52 MAC Address 0 Low (MAC_Address0_Low)

Offset

Register	Offset
MAC_Address0_Low	304h

Function

Holds the lower 32 bits of the 6-byte first MAC address of the station.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	ADDRLO															
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Fields

Field	Function
31-0 ADDRLO	MAC Address 0 [31:0] Contains the lower 32 bits of the first 6-byte MAC address. MAC uses this field to filter the received packets and insert the MAC address in the transmit flow control (pause) packets.

72.18.53 MAC Address 1 High (MAC_Address1_High)

Offset

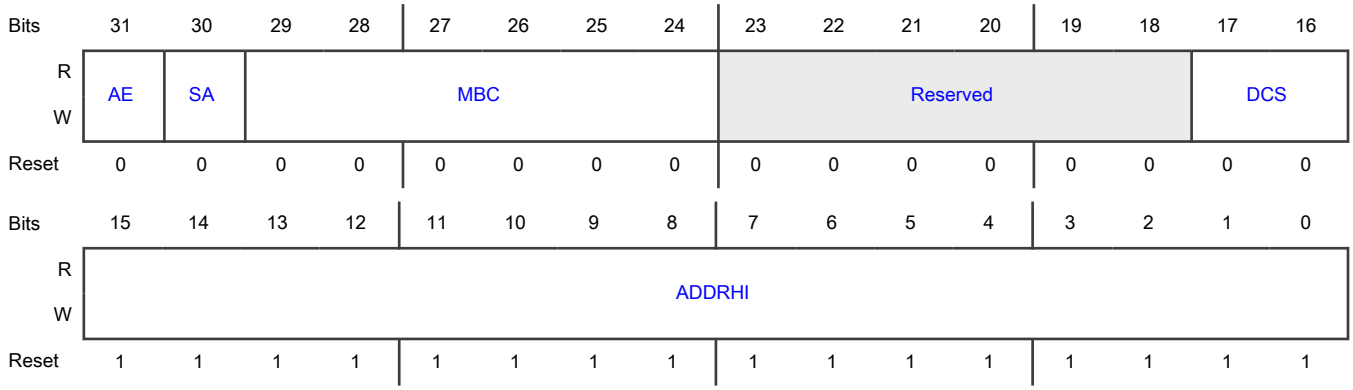
Register	Offset
MAC_Address1_High	308h

Function

Holds the upper 16 bits of the second 6-byte MAC address of the station.

If the MAC address registers are configured to be double-synchronized with the (G)MII clock domains, the synchronization is triggered only when bits [31:24] (in Little-Endian mode) or bits [7:0] (in Big-Endian mode) of MAC Address 1 Low (MAC_Address1_Low) are written to. For proper synchronization updates, the consecutive writes to MAC Address 1 Low (MAC_Address1_Low) must be performed after at least four clock cycles in the destination clock domain.

Diagram



Fields

Field	Function
31 AE	Address Enable Indicates whether the MAC address is enabled or ignored. If this field is 1, the address filter module uses the second MAC address for perfect filtering. If this field is 0, the address filter module ignores the address used for filtering. 0b - Ignored 1b - Enabled
30 SA	Source Address Indicates whether the MAC address is compared to the source or destination address. If this field is 1, MAC Address 1[47:0] is compared to the SA fields of the received packet. If this field is 0, MAC Address 1[47:0] is compared to the DA fields of the received packet. 0b - Destination address 1b - Source address
29-24 MBC	Mask Byte Control Contains mask control bits for comparing each of the MAC address bytes. If this field is 1, MAC does not compare the corresponding byte of the received DA or SA with the contents of the MAC address 1 registers. Each bit controls the masking of the bytes as follows: • Bit 29: MAC Address 1 High[15:8] • Bit 28: MAC Address 1 High[7:0] • Bit 27: MAC Address 1 Low[31:24] • - .. • Bit 24: MAC Address 1 Low[7:0] You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address.
23-18	Reserved

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-9 —	Reserved
8 UCDBC	Update MMC Counters For Dropped Broadcast Packets Indicates the status of MMC counters for dropped broadcast packets. • If this field is 1, MAC updates all the related MMC counters for broadcast packets that are dropped because MAC_Packet_Filter[DBF] = 1. • If this field is 0, the MMC counters are not updated for dropped broadcast packets. **NOTE** The CNTRST field has a higher priority than the CNTPRST field. Therefore, if you write 1 to both these fields in the same write cycle, all the counters are cleared and the CNTPRST field becomes 0. 0b - Disabled 1b - Enabled
7-6 —	Reserved
5 CNTPRSTLVL	Full-Half Preset Indicates whether full-half preset is enabled or disabled. • If this field is 0 and the CNTPRST field is 1, all the MMC counters are preset to the almost-half value. All octet counters are preset to 7FFF_F800h (half 2 Kbytes) and all packet counters are preset to 7FFF_FFF0h (half 16). • If this field is 1 and the CNTPRST field is 1 too, all MMC counters are preset to the almost-full value. All octet counters are preset to FFFF_F800h (full 2 Kbytes) and all packet counters are preset to FFFF_FFF0h (full 16). For 16-bit counters, the almost-half preset values are 7800h and 7FF0h for the respective octet and packet counters. Similarly, the almost-full preset values for the 16-bit counters are 0xF800 and 0xFFF0. 0b - Disabled 1b - Enabled
4 CNTPRST	Counters Preset Indicates whether MMC counter preset is enabled or disabled. If this field is 1, all the counters are initialized or preset to almost full or almost half according to the settings of the CNTPRSTLVL field. This field clears automatically after 1 clock cycle, and along with the CNTPRSTLVL field, is useful for debugging and testing the assertion of interrupts because of the MMC counter becoming half-full or full. Access restrictions apply to this field, which clears automatically. 0b - Disabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Enabled
3 CNTFREEZ	MMC Counter Freeze Indicates the status of MMC counter freeze. If this field is 1, the field freezes all the MMC counters to their current values. Until this field becomes 0, no MMC counter is updated because of any transmitted or received packets. If an MMC counter is read when RSTONRD = 1, that counter is also cleared in this mode. 0b - Disabled 1b - Enabled
2 RSTONRD	Reset On Read Indicates whether the reset on read for MMC counters is enabled or disabled. If this field is 1, MMC counters are reset to 0 after read (they clear automatically after reset). The counters are cleared when the least significant byte lane (bits [7:0]) is read. 0b - Disabled 1b - Enabled
1 CNTSTOPRO	Counter Stop Rollover Indicates the status of counter stop rollover. If this field is 1, the counter does not roll over to 0 after reaching the maximum value. 0b - Disabled 1b - Enabled
0 CNTRST	Counters Reset Indicates whether MMC counters are reset. If this field is 1, all the counters are reset. This field clears automatically after 1 clock cycle. Access restrictions apply to this field that clears automatically. 0b - Counters are not reset 1b - All counters are reset

72.18.58 MMC Receive Interrupt (MMC_Rx_Interrupt)

Offset

Register	Offset
MMC_Rx_Interrupt	704h

Function

Maintains the interrupts generated from all receive statistics counters when the following conditions occur:

- Receive statistic counters reach half of their maximum values (8000_0000h for a 32-bit counter and 8000h for a 16-bit counter).
- Receive statistic counters cross their maximum values (FFFF_FFFFh for a 32-bit counter and FFFFh for a 16-bit counter).

If MMC_Control[CNTSTOPRO] = 1, interrupts are set but the counter remains at all-ones. This is a 32-bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (bits [7:0]) of the respective counter must be read to clear the interrupt bit.

NOTE

R_SS_RC means that this register bit is set internally, and is cleared when the counter register is read.

This field becomes 1 when the rxpacketcount_gb counter reaches half of its maximum value or its maximum value. Access restrictions apply to this field, which clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected

72.18.59 MMC Transmit Interrupt (MMC_Tx_Interrupt)

Offset

Register	Offset
MMC_Tx_Interrupt	708h

Function

Maintains the interrupts generated from all the transmit statistics counters.

This register maintains those interrupts that are generated when transmit statistic counters:

- Reach half of their maximum values (8000_0000h for a 32-bit counter and 0x8000 for a 16-bit counter)
- Cross their maximum values (FFFF_FFFFh for a 32-bit counter and FFFFh for a 16-bit counter)

If MMC_Control[CNTSTOPRO] = 1, the interrupts are set but the counter remains at all-ones.

This is a 32 bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read.

The least significant byte lane (bits [7:0]) of the respective counter must be read to clear the interrupt bit.

Access restrictions apply to this field, which clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
0 TXGBOCTIS	MMC Transmit Good Bad Octet Counter Interrupt Status Indicates whether the status of the MMC transmit good bad octet counter interrupt is detected. This field becomes 1 when the txoctetcount_gb counter reaches half of its maximum value or the maximum value. Access restrictions apply to this field, which clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected

72.18.60 MMC Receive Interrupt Mask (MMC_Rx_Interrupt_Mask)

Offset

Register	Offset
MMC_Rx_Interrupt_Mask	70Ch

Function

Maintains the masks for interrupts generated from all the receive statistic counters. These interrupts are generated when the receive statistic counters reach half of their maximum values or the maximum values.

Diagram

27 —	Reserved
26 —	Reserved
25 RXCTRLPIM	MMC Receive Control Packet Counter Interrupt Mask Indicates the status of the MMC receive control packet counter interrupt mask. Writing 1 to this field masks the interrupt when the rxctrlpackets_g counter reaches half of its maximum value or the maximum value. 0b - Disabled 1b - Enabled
24 RXRCVERRPIM	MMC Receive Error Packet Counter Interrupt Mask Indicates the status of the MMC receive error packet counter interrupt mask. Writing 1 to this field masks the interrupt when the rxrcverror counter reaches half of its maximum value or the maximum value. 0b - Disabled 1b - Enabled
23	MMC Receive Watchdog Error Packet Counter Interrupt Mask

Table continues on the next page...

Table continued from the previous page...

Field	Function
RXWDOGPIM	Indicates the status of the MMC receive watchdog error packet counter interrupt mask. Writing 1 to this field masks the interrupt when the rxwatchdog counter reaches half of its maximum value or the maximum value. 0b - Disabled 1b - Enabled
22 RXVLANGBPIM	MMC Receive VLAN Good Bad Packet Counter Interrupt Mask Indicates the status of the MMC receive VLAN good bad packet counter interrupt mask. Writing 1 to this field masks the interrupt when the rxvlanpackets_gb counter reaches half of its maximum value or the maximum value. 0b - Disabled 1b - Enabled
21 RXFOVPIM	MMC Receive FIFO Overflow Packet Counter Interrupt Mask Indicates the status of the MMC receive FIFO overflow packet counter interrupt mask. Writing 1 to this field masks the interrupt when the rxfifooverflow counter reaches half of its maximum value or the maximum value. 0b - Disabled 1b - Enabled
20 RXPAUSPIM	MMC Receive Pause Packet Counter Interrupt Mask Indicates the status of the MMC receive pause packet counter interrupt mask. Writing 1 to this field masks the interrupt when the rxpausepackets counter reaches half of its maximum value or the maximum value. 0b - Disabled 1b - Enabled
19 RXORANGEPIM	MMC Receive Out-Of-Range Error Packet Counter Interrupt Mask Indicates the status of the MMC receive out-of-range error packet counter interrupt mask. Writing 1 to this field masks the interrupt when the rxoutofrangetype counter reaches half of its maximum value or the maximum value. 0b - Disabled 1b - Enabled
18 RXLENERPIM	MMC Receive Length Error Packet Counter Interrupt Mask Indicates the status of the MMC receive length error packet counter interrupt mask. Writing 1 to this field masks the interrupt when the rxlengtherror counter reaches half of its maximum value or the maximum value.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disabled 1b - Enabled
17 RXUCGPIM	MMC Receive Unicast Good Packet Counter Interrupt Mask Indicates the status of the MMC receive unicast good packet counter interrupt mask. Writing 1 to this field masks the interrupt when the rxunicastpackets_g counter reaches half of its maximum value or the maximum value. 0b - Disabled 1b - Enabled
16 RX1024TMAXOCTGBPIM	MMC Receive 1024 To Maximum Octet Good Bad Packet Counter Interrupt Mask Indicates the status of the MMC receive 1024 to maximum octet good bad packet counter interrupt mask. Writing 1 to this field masks the interrupt when the rx1024tomaxoctets_gb counter reaches half of its maximum value or the maximum value. 0b - Disabled 1b - Enabled
15 RX512T1023OCTGBPIM	MMC Receive 512 To 1023 Octet Good Bad Packet Counter Interrupt Mask Indicates the status of the MMC receive 512 to 1023 octet good bad packet counter interrupt mask. Writing 1 to this field masks the interrupt when the rx512to1023octets_gb counter reaches half of its maximum value or the maximum value. 0b - Disabled 1b - Enabled
14 RX256T511OCTGBPIM	MMC Receive 256 To 511 Octet Good Bad Packet Counter Interrupt Mask Indicates the status of the MMC receive 256 to 511 octet good bad packet counter interrupt mask. Writing 1 to this field masks the interrupt when the rx256to511octets_gb counter reaches half of its maximum value or the maximum value. 0b - Disabled 1b - Enabled
13 RX128T255OCTGBPIM	MMC Receive 128 To 255 Octet Good Bad Packet Counter Interrupt Mask Indicates the status of the MMC receive 128 to 255 octet good bad packet counter interrupt mask. Writing 1 to this field masks the interrupt when the rx128to255octets_gb counter reaches half of its maximum value or the maximum value. 0b - Disabled 1b - Enabled
12	MMC Receive 65 To 127 Octet Good Bad Packet Counter Interrupt Mask

Table continues on the next page...

Table continued from the previous page...

Field	Function
RX65T127OCTGBPIM	Indicates the status of the MMC receive 65 to 127 octet good bad packet counter interrupt mask. Writing 1 to this field masks the interrupt when the rx65to127octets_gb counter reaches half of its maximum value or the maximum value. 0b - Disabled 1b - Enabled
11 RX64OCTGBPIM	MMC Receive 64-Octet Good Bad Packet Counter Interrupt Mask Indicates the status of the MMC receive 64-octet good bad packet counter interrupt mask. Writing 1 to this field masks the interrupt when the rx64octets_gb counter reaches half of its maximum value or the maximum value. 0b - Disabled 1b - Enabled
10 RXOSIZEGPIM	MMC Receive Oversize Good Packet Counter Interrupt Mask Indicates the status of the MMC receive oversize good packet counter interrupt mask. Writing 1 to this field masks the interrupt when the rxoversize_g counter reaches half of its maximum value or the maximum value. 0b - Disabled 1b - Enabled
9 RXUSIZEGPIM	MMC Receive Undersize Good Packet Counter Interrupt Mask Indicates the status of the MMC receive undersize good packet counter interrupt mask. Writing 1 to this field masks the interrupt when the rxundersize_g counter reaches half of its maximum value or the maximum value. 0b - Disabled 1b - Enabled
8 RXJABERPIM	MMC Receive Jabber Error Packet Counter Interrupt Mask Indicates the status of the MMC receive jabber error packet counter interrupt mask. Writing 1 to this field masks the interrupt when the rxjabbererror counter reaches half of its maximum value or the maximum value. 0b - Disabled 1b - Enabled
7 RXRUNTPIM	MMC Receive Runt Packet Counter Interrupt Mask Indicates the status of the MMC receive runt packet counter interrupt mask. Writing 1 to this field masks the interrupt when the rxrunterror counter reaches half of its maximum value or the maximum value.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disabled 1b - Enabled
6 RXALGNERPIM	MMC Receive Alignment Error Packet Counter Interrupt Mask Indicates the status of the MMC receive alignment error packet counter interrupt mask. Writing 1 to this field masks the interrupt when the rxalignmenterror counter reaches half of its maximum value or the maximum value. 0b - Disabled 1b - Enabled
5 RXCRCERPIM	MMC Receive CRC Error Packet Counter Interrupt Mask Indicates the status of the MMC receive CRC error packet counter interrupt mask. Writing 1 to this field masks the interrupt when the rxcrcerror counter reaches half of its maximum value or the maximum value. 0b - Disabled 1b - Enabled
4 RXMCGPIM	MMC Receive Multicast Good Packet Counter Interrupt Mask Indicates the status of the MMC receive multicast good packet counter interrupt mask. Writing 1 to this field masks the interrupt when the rxmulticastpackets_g counter reaches half of its maximum value or the maximum value. 0b - Disabled 1b - Enabled
3 RXBCGPIM	MMC Receive Broadcast Good Packet Counter Interrupt Mask Indicates the status of the MMC receive broadcast good packet counter interrupt mask. Writing 1 to this field masks the interrupt when the rxbroadcastpackets_g counter reaches half of its maximum value or the maximum value. 0b - Disabled 1b - Enabled
2 RXGOCTIM	MMC Receive Good Octet Counter Interrupt Mask Indicates the status of the MMC receive good octet counter interrupt mask. Writing 1 to this field masks the interrupt when the rxoctetcount_g counter reaches half of its maximum value or the maximum value. 0b - Disabled 1b - Enabled
1	MMC Receive Good Bad Octet Counter Interrupt Mask

Table continues on the next page...

Table continued from the previous page...

Field	Function
RXGBOCTIM	Indicates the status of the MMC receive good bad octet counter interrupt mask. Writing 1 to this field masks the interrupt when the rxoctetcount_gb counter reaches half of its maximum value or the maximum value. 0b - Disabled 1b - Enabled
0 RXGBPKTIM	MMC Receive Good Bad Packet Counter Interrupt Mask Indicates the status of the MMC receive good bad packet counter interrupt mask. Writing 1 to this field masks the interrupt when the rxpacketcount_gb counter reaches half of its maximum value or the maximum value. 0b - Disabled 1b - Enabled

72.18.61 MMC Transmit Interrupt Mask (MMC_Tx_Interrupt_Mask)

Offset

Register	Offset
MMC_Tx_Interrupt_Mask	710h

Function

Maintains the masks for interrupts that are generated when the transmit statistic counters reach half of their maximum values or their maximum values.

Field	Function
31-0 TXOSIZG	Transmit O Size Packets Good Indicates the number of packets transmitted without errors, and having a length greater than the maximum size, which is 1,518 or 1,522 bytes for VLAN-tagged packets. This size is 2000 bytes if MAC_Configuration[S2KP] = 1.

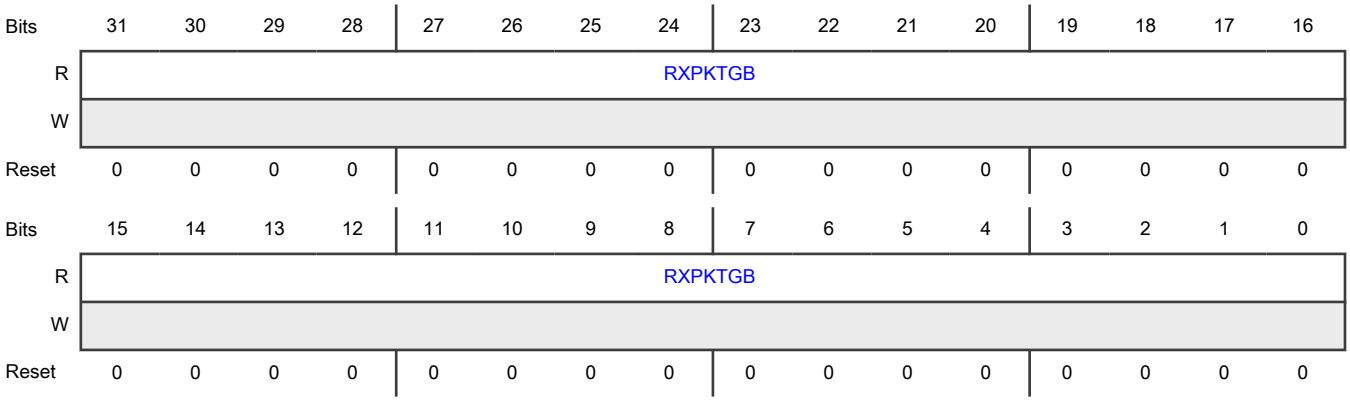
72.18.88 Receive Packets Count Good Bad (Rx_Packets_Count_Good_Bad)

Offset

Register	Offset
Rx_Packets_Count_Good_Bad	780h

Function
Provides the number of good and bad packets that the module received.

Diagram



Fields

Field	Function
31-0 RXPKTGB	Receive Packets Count Good Bad Indicates the number of good and bad packets received.

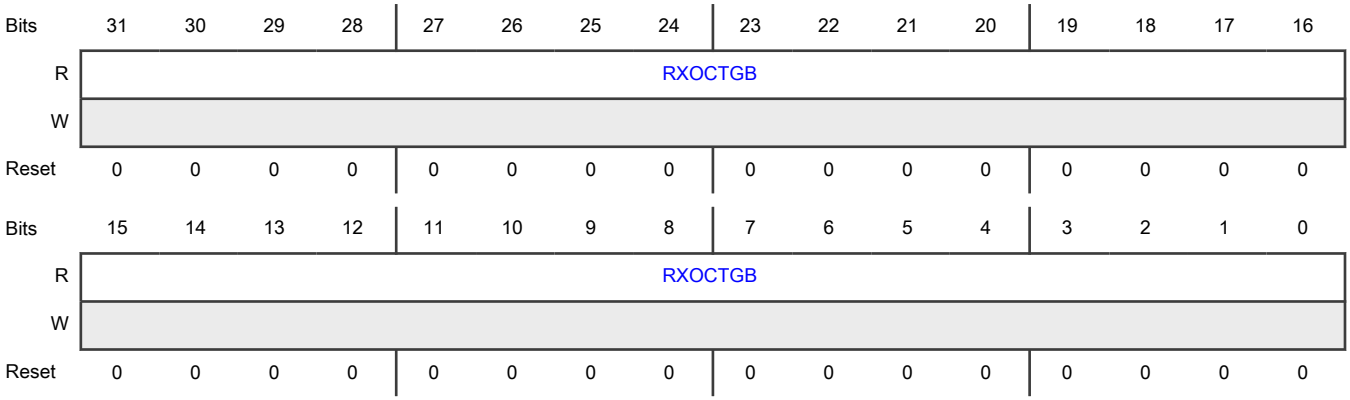
72.18.89 Receive Octet Count Good Bad (Rx_Octet_Count_Good_Bad)

Offset

Register	Offset
Rx_Octet_Count_Good_Bad	784h

Function
Provides the number of bytes that DWC_ther_qos received, exclusive of preamble, in good and bad packets.

Diagram



Fields

Field	Function
31-0 RXOCTGB	Receive Octet Count Good Bad Indicates the number of bytes received, exclusive of preamble, in good and bad packets.

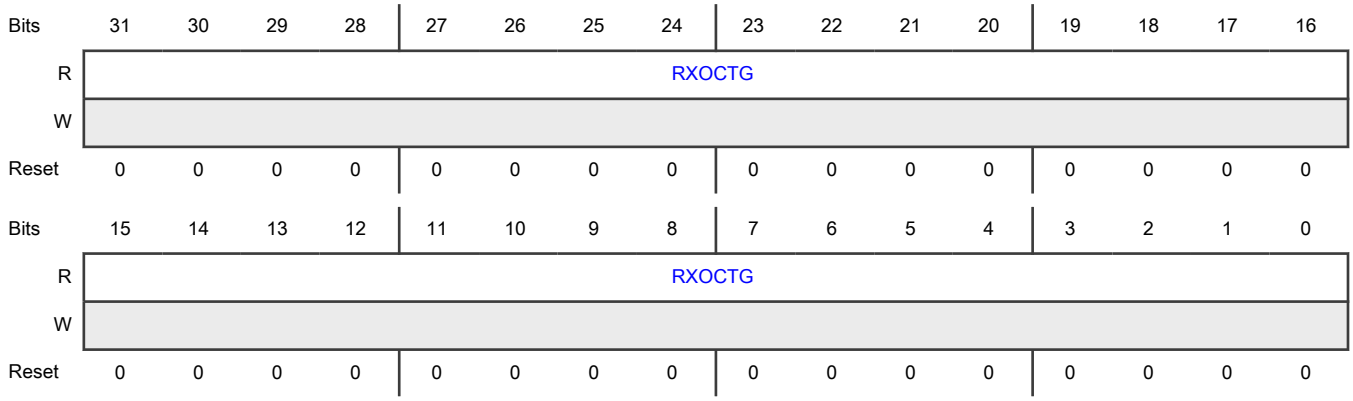
72.18.90 Receive Octet Count Good (Rx_Octet_Count_Good)

Offset

Register	Offset
Rx_Octet_Count_Good	788h

Function
Provides the number of bytes that the module received, exclusive of preamble, only in good packets.

Diagram



Fields

Field	Function
31-0 RXOCTG	Receive Octet Count Good Indicates the number of bytes received, exclusive of preamble, only in good packets.

72.18.91 Receive Broadcast Packets Good (Rx_Broadcast_Packets_Good)

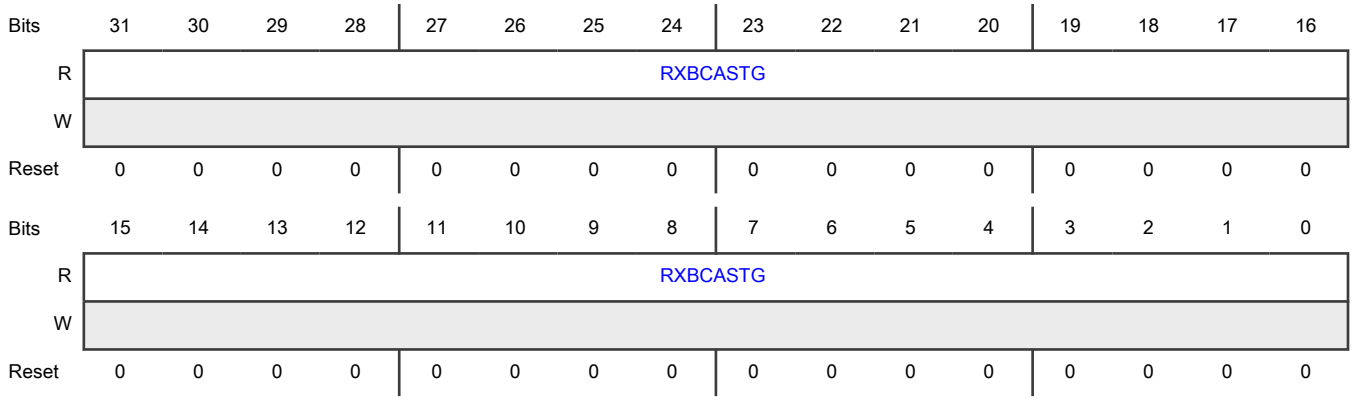
Offset

Register	Offset
Rx_Broadcast_Packets_Good	78Ch

Function

Provides the number of good broadcast packets that the module received.

Diagram



Fields

Field	Function
31-0 RXBCASTG	Receive Broadcast Packets Good Indicates the number of good broadcast packets received.

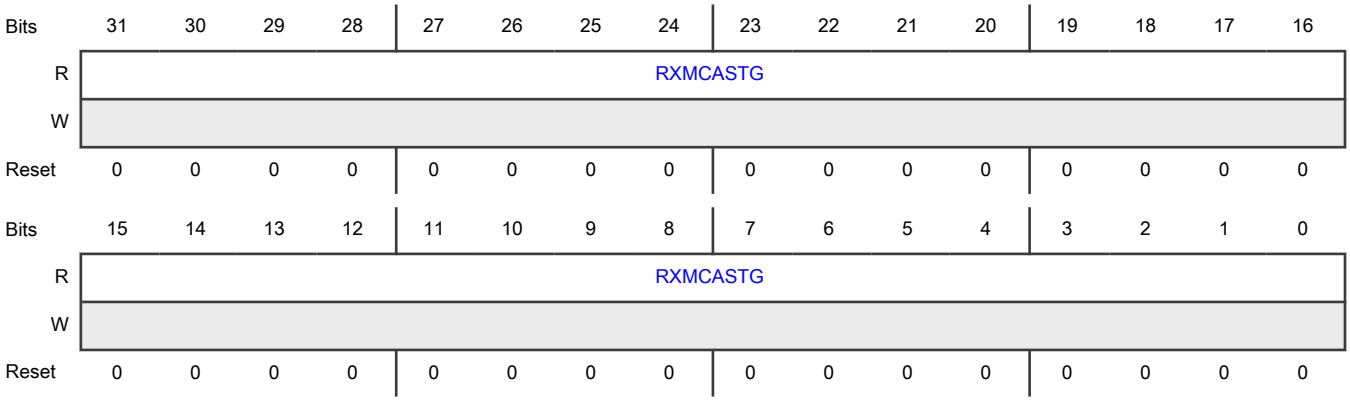
72.18.92 Receive Multicast Packets Good (Rx_Multicast_Packets_Good)

Offset

Register	Offset
Rx_Multicast_Packets_Good	790h

Function
Provides the number of good multicast packets that the module received.

Diagram



Fields

Field	Function
31-0 RXMCASTG	Receive Multicast Packets Good Indicates the number of good multicast packets received.

72.18.93 Receive CRC Error Packets (Rx_CRC_Error_Packets)

Offset

Register	Offset
Rx_CRC_Error_Packets	794h

Function

Provides the number of packets that the module received with a CRC error.

Diagram

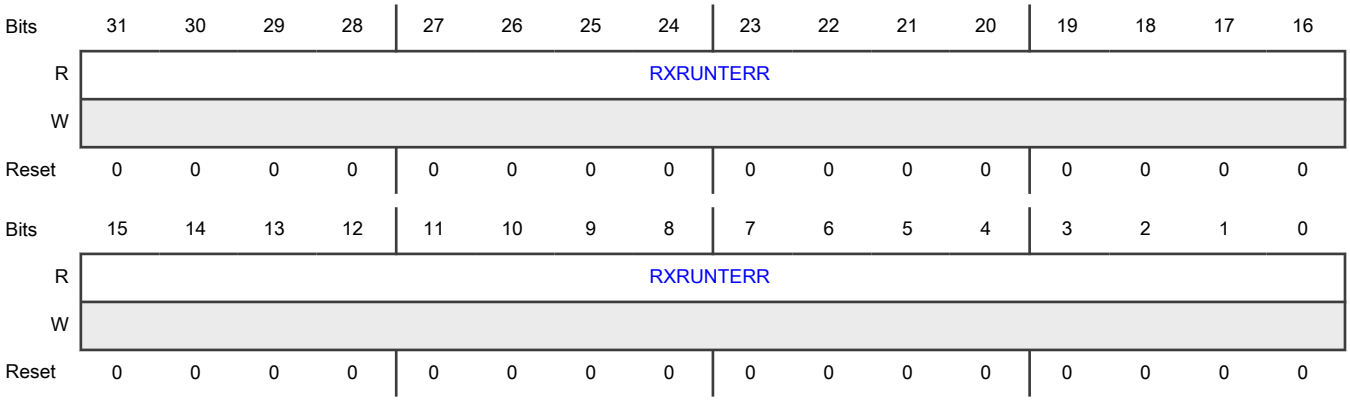
72.18.95 Receive Runt Error Packets (Rx_Runt_Error_Packets)

Offset

Register	Offset
Rx_Runt_Error_Packets	79Ch

Function
Provides the number of runt packets, which have a length less than 64 bytes and a CRC error, that the module received.

Diagram



Fields

Field	Function
31-0 RXRUNTERR	Receive Runt Error Packets Indicates the number of runt packets received.

72.18.96 Receive Jabber Error Packets (Rx_Jabber_Error_Packets)

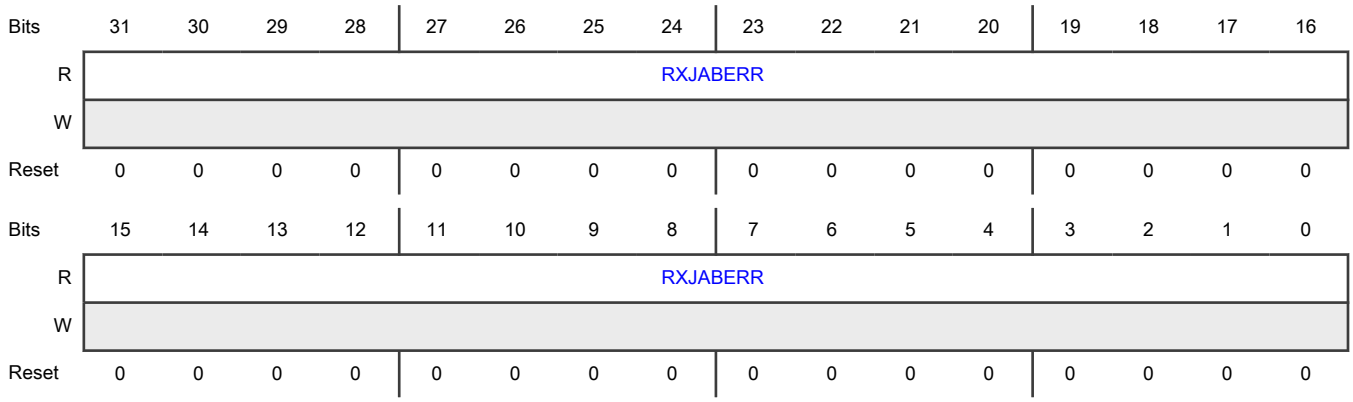
Offset

Register	Offset
Rx_Jabber_Error_Packets	7A0h

Function

Provides the number of giant packets that the module received, having a length (including CRC) greater than 1,518 bytes (1,522 bytes for VLAN-tagged packets), and with a CRC error. If Jumbo Packet mode is enabled, packets of length greater than 9,018 bytes (9,022 bytes for VLAN-tagged packets) are considered as giant packets.

Diagram



Fields

Field	Function
31-0 RXJABERR	Receive Jabber Error Packets Indicates the number of giant packets received, having a length (including CRC) greater than 1,518 bytes (1,522 bytes for VLAN-tagged packets), and with a CRC error. If Jumbo Packet mode is enabled, packets of length greater than 9,018 bytes (9,022 bytes for VLAN-tagged packets) are considered as giant packets.

72.18.97 Receive Undersize Packets Good (Rx_Undersize_Packets_Good)

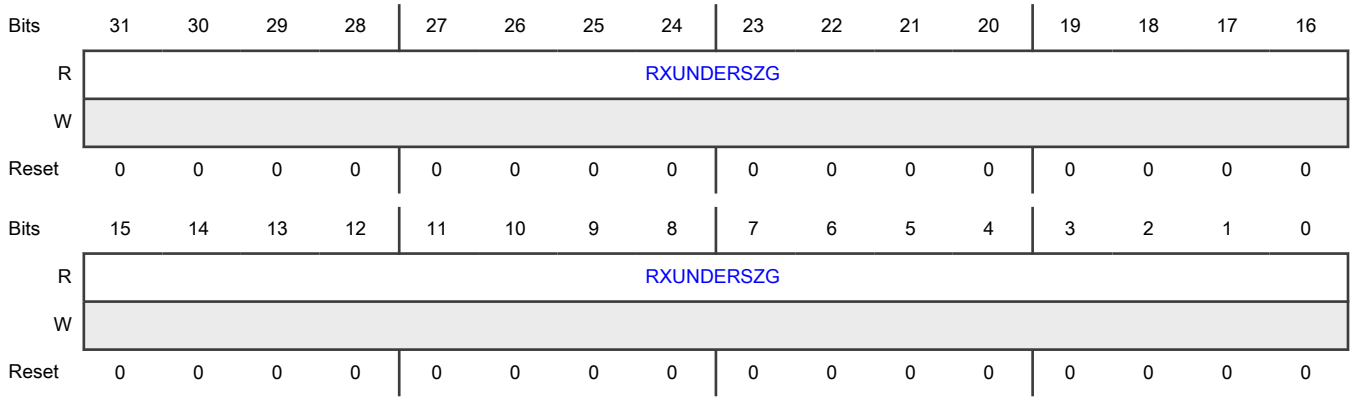
Offset

Register	Offset
Rx_Undersize_Packets_Good	7A4h

Function

Provides the number of packets that the module received, having a length less than 64 bytes, but without any errors.

Diagram



Fields

Field	Function
31-0 RXUNDERSZG	Receive Undersize Packets Good Indicates the number of packets received, having a length less than 64 bytes, but without any errors.

72.18.98 Receive Oversize Packets Good (Rx_Oversize_Packets_Good)

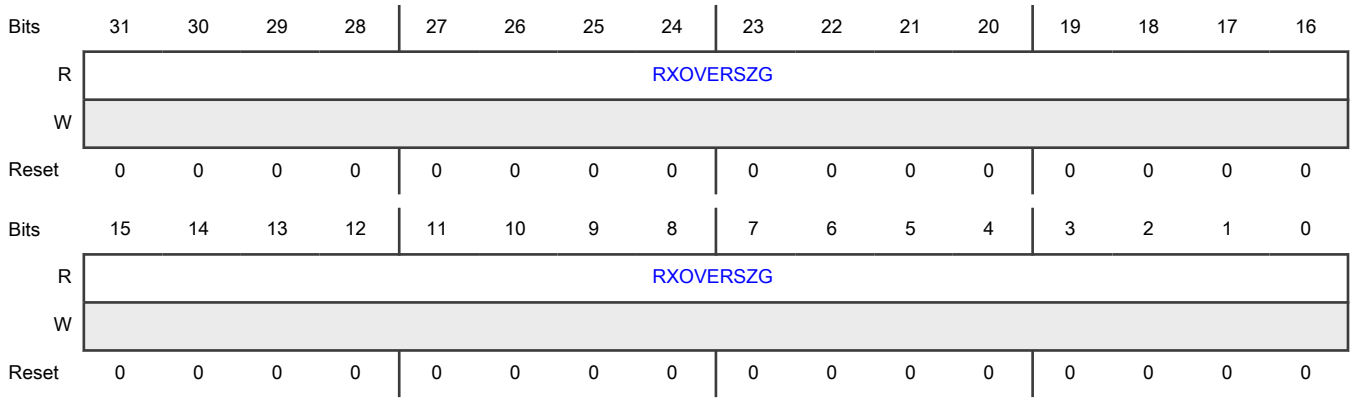
Offset

Register	Offset
Rx_Oversize_Packets_Good	7A8h

Function

Provides the number of packets that the module received without any errors, having a length greater than the maximum size (1,518 bytes or 1,522 bytes for VLAN-tagged packets; 2000 bytes if MAC_Configuration[S2KP] = 1).

Diagram



Fields

Field	Function
31-0 RXOVERSZG	Receive Oversize Packets Good Indicates the number of packets received without errors, with a length greater than the maximum size (1,518 bytes or 1,522 bytes for VLAN-tagged packets; 2000 bytes if MAC_Configuration[S2KP] = 1).

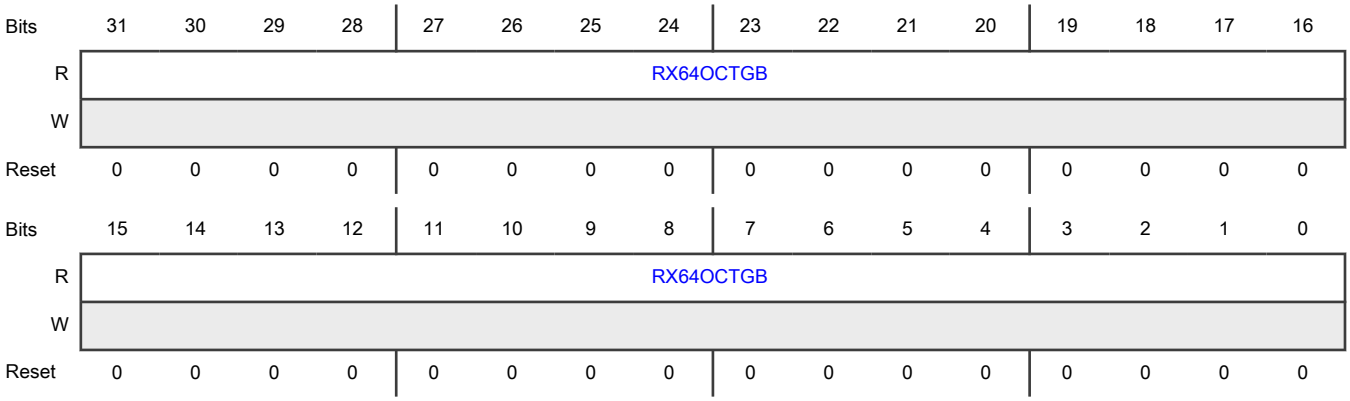
72.18.99 Receive 64 Octets Packets Good Bad (Rx_64Octets_Packets_Good_Bad)

Offset

Register	Offset
Rx_64Octets_Packets_Good_Bad	7ACh

Function
Provides the number of 64-byte good and bad packets that the module received, exclusive of the preamble.

Diagram



Fields

Field	Function
31-0 RX64OCTGB	Receive 64 Octets Packets Good Bad Provides the number of 64-byte good and bad packets that the module received, exclusive of the preamble.

Offset

Register	Offset
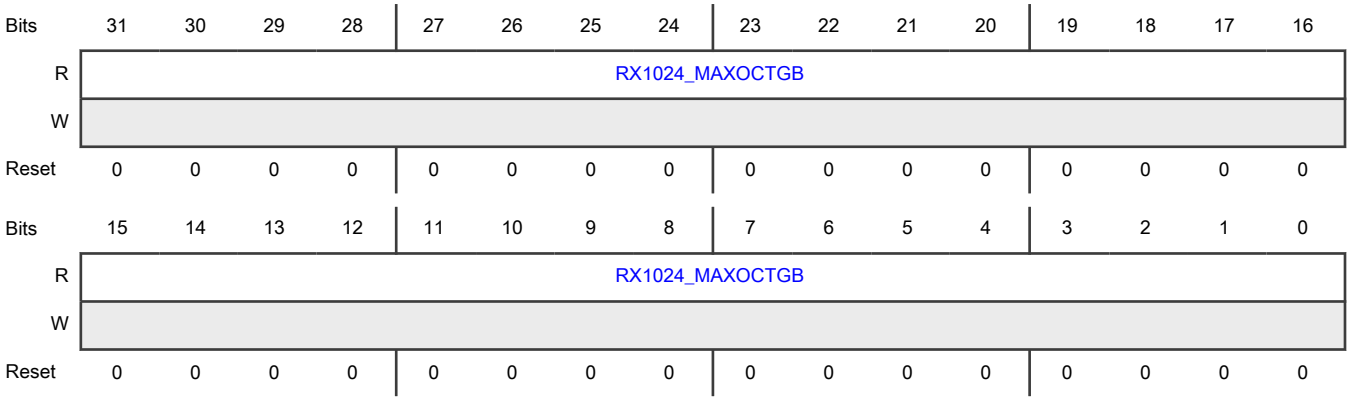
Rx_1024ToMaxOctets_Packets_Good_Bad	7C0h

Function

Provides the number of good and bad packets that the module received, having an inclusive packet length between 1024 bytes and the maximum byte size, exclusive of the preamble.

Diagram



Fields

Field	Function
31-0 RX1024_MAXOCTGB	Receive 1024-Max Octets Good Bad Indicates the number of good and bad packets received with length between 1024 and the maximum size (inclusive) bytes, exclusive of the preamble.

72.18.105 Receive Unicast Packets Good (Rx_Unicast_Packets_Good)

Offset

Register	Offset
Rx_Unicast_Packets_Good	7C4h

Function

Provides the number of good unicast packets that the module received.

Diagram

Field	Function
31-0 RXUCASTG	Receive Unicast Packets Good Indicates the number of good unicast packets received.

72.18.106 Receive Length Error Packets (Rx_Length_Error_Packets)

Offset

Register	Offset
Rx_Length_Error_Packets	7C8h

Function

Provides the number of packets that the module received with a length error (the Length/Type (LT) field of the RDES3 normal descriptor not equal to the packet size) for all the packets with a valid length field. For more information on the LT field, see the "RDES3 normal descriptor (write-back format)" section.

Fields

Field	Function
31-0 RXOUTOFRNG	Receive Out of Range Type Packet Indicates the number of packets received with length field not equal to the valid packet size (greater than 1,500 but less than 1,536).

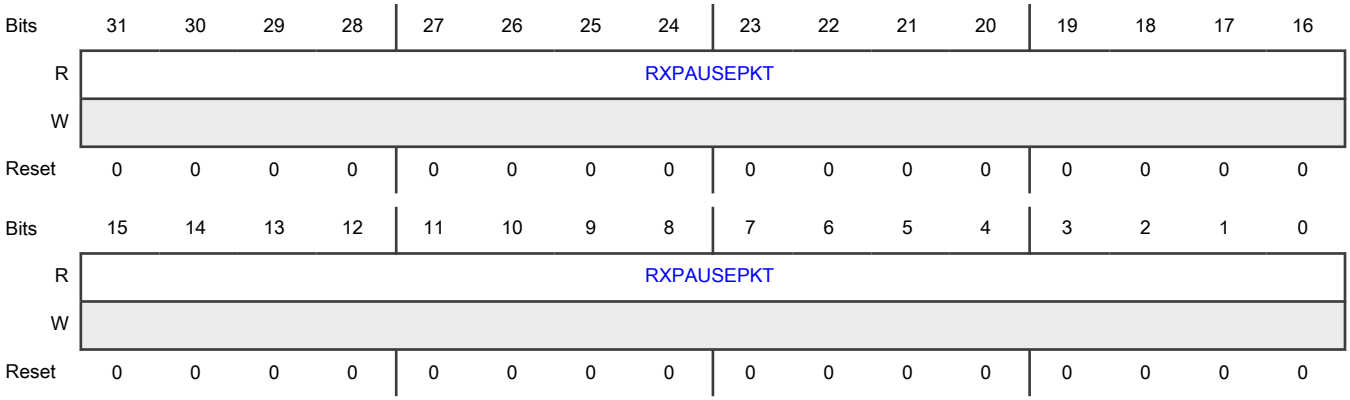
72.18.108 Receive Pause Packets (Rx_Pause_Packets)

Offset

Register	Offset
Rx_Pause_Packets	7D0h

Function
Provides the number of good and valid pause packets that the module received.

Diagram



Fields

Field	Function
31-0 RXPAUSEPKT	Receive Pause Packets Indicates the number of good and valid pause packets received.

72.18.109 Receive FIFO Overflow Packets (Rx_FIFO_Overflow_Packets)

Offset

Register	Offset
Rx_FIFO_Overflow_Packets	7D4h

Function
Provides the number of missed received packets because of FIFO overflow in the module.

Diagram

Field	Function
31-0 RXVLANPKTGB	Receive VLAN Packets Good Bad Indicates the number of good and bad VLAN packets received.

72.18.111 Receive Watchdog Error Packets (Rx_Watchdog_Error_Packets)

Offset

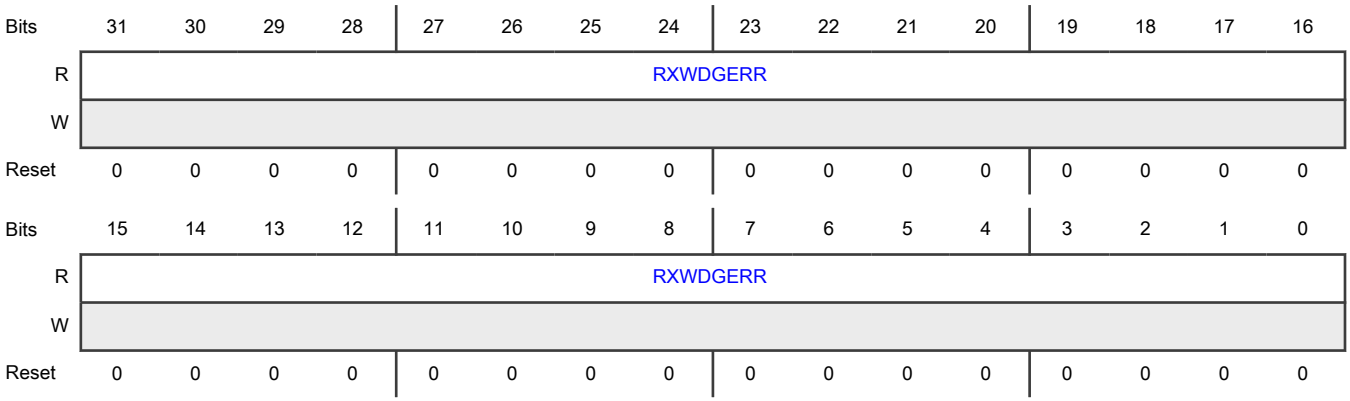
Register	Offset
Rx_Watchdog_Error_Packets	7DCh

Function

Provides the number of packets that the module received with a watchdog timeout error. Packets with a data load larger than the following are received:

- 2,048 bytes when MAC_Configuration[JE] = 0 and MAC_Configuration[WD] = 0
- 10,240 bytes when MAC_Configuration[JE] = 1 and MAC_Configuration[WD] = 0
- 16,384 bytes when MAC_Configuration[WD] = 1 or the value programmed in MAC Watchdog Timeout (MAC_Watchdog_Timeout)

Diagram



Fields

Field	Function
31-0 RXWDGERR	Receive Watchdog Error Packets Indicates the number of packets received with a watchdog timeout error. Packets with a data load larger than the following are received:

Table continues on the next page...

Field	Function
	• 2,048 bytes when MAC_Configuration[JE] = 0 and MAC_Configuration[WD] = 0 • 10,240 bytes when MAC_Configuration[JE] = 1 and MAC_Configuration[WD] = 0 • 16,384 bytes when MAC_Configuration[WD] = 1 or the value programmed in MAC Watchdog Timeout (MAC_Watchdog_Timeout)

72.18.112 Receive Receive Error Packets (Rx_Receive_Error_Packets)

Offset

Register	Offset
Rx_Receive_Error_Packets	7E0h

Function

Provides the number of packets that the module received with a receive or packet extension error on GMII or MII.

Diagram

Field	Function
31-0 RXCTRLG	Receive Control Packets Good Indicates the number of good control packets received.

72.18.114 MMC Transmit FPE Fragment Counter Interrupt Status (MMC_FPE_Tx_Interrupt)

Offset

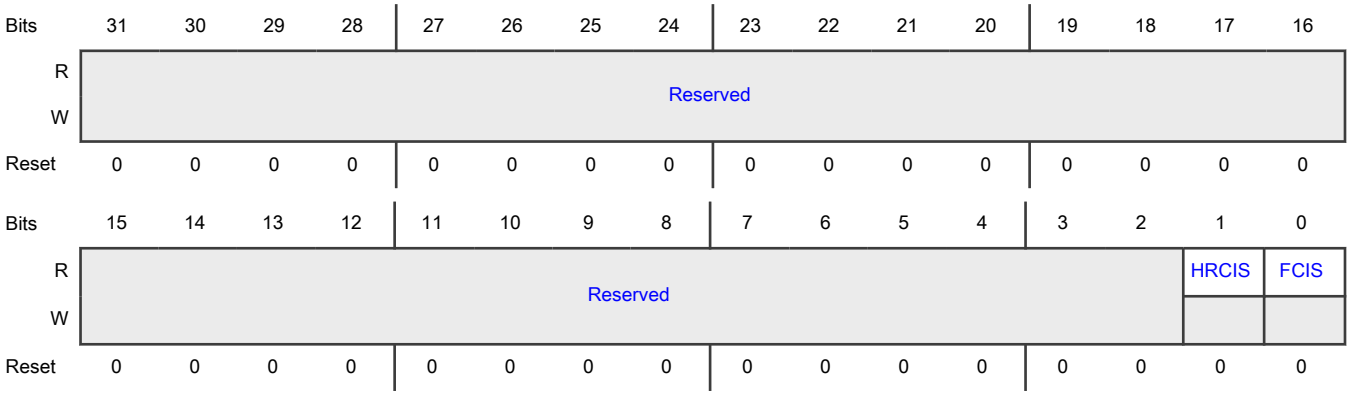
Register	Offset
MMC_FPE_Tx_Interrupt	8A0h

Function

Maintains the interrupts generated from all the FPE-related transmit statistic counters when they reach half of their maximum values (8000_0000h for a 32-bit counter and 8000h for a 16-bit counter), and when they cross their maximum values (FFFF_FFFFh for a 32-bit counter and FFFFh for a 16-bit counter). When MMC_Control[CNTSTOPRO] = 1, the interrupts are set but the counter remains at all-ones.

An interrupt bit of this register becomes 0 when the respective MMC counter that caused the interrupt is read. The least significant byte lane (bits [7:0]) of the respective counter must be read to clear the interrupt bit.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 HRCIS	MMC Transmit Hold Request Counter Interrupt Status Indicates whether the MMC Transmit hold request counter interrupt status is detected. This field: • Becomes 1 when the Tx_Hold_Req_Cntr counter reaches half of the maximum value or the maximum value. • Exists when any one of the receive or transmit MMC counters is enabled during FPE with AV_EST-enabled configuration. Access restrictions apply to this field that clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
0 FCIS	MMC Transmit FPE Fragment Counter Interrupt Status Indicates whether the MMC Transmit FPE fragment counter interrupt status is detected. This field: • Becomes 1 when the Tx_FPE_Fragment_Cntr counter reaches half of the maximum value or the maximum value. • Exists when any one of the receive or transmit MMC counters is enabled during FPE-enabled configuration. Access restrictions apply to this field that clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected

72.18.115 MMC FPE Transmit Interrupt Mask (MMC_FPE_Tx_Interrupt_Mask)

Offset

Register	Offset
MMC_FPE_Tx_Interrupt_Mask	8A4h

Function

Maintains the masks for interrupts generated from all FPE-related transmit statistics counters. MMC Receive Interrupt Mask (MMC_Rx_Interrupt_Mask) maintains the masks for the interrupts generated when FPE-related receive statistic counters reach half of their maximum value or the maximum value.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-0 TXFFC	Transmit FPE Fragment Counter Indicates the number of additional mPackets transmitted because of preemption. Exists when any one of the receive, transmit, or MMC counters is enabled during FPE-enabled configuration.

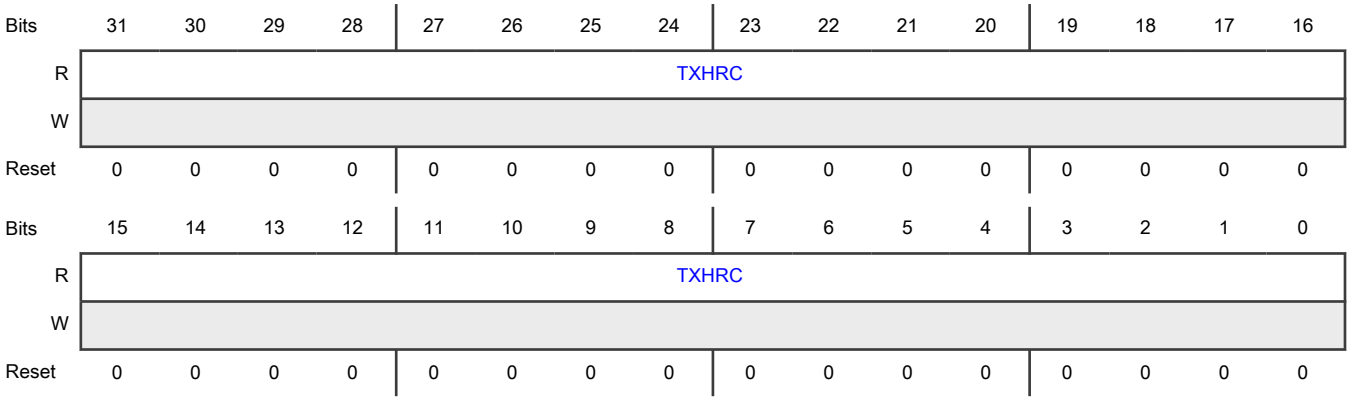
72.18.117 Transmit Hold Request Counter (MMC_Tx_Hold_Req_Cntr)

Offset

Register	Offset
MMC_Tx_Hold_Req_Cntr	8ACh

Function
Provides the count of times that a hold request is given to MAC.

Diagram



Fields

Field	Function
31-0 TXHRC	Transmit Hold Request Counter Indicates the count of times that a hold request is given to MAC. Exists when any one of the receive, transmit, or MMC counters is enabled during FPE with AV_EST-enabled configuration.

72.18.118 MMC Receive Packet Assembly Error Counter Interrupt Status (MMC_FPE_Rx_Interrupt)

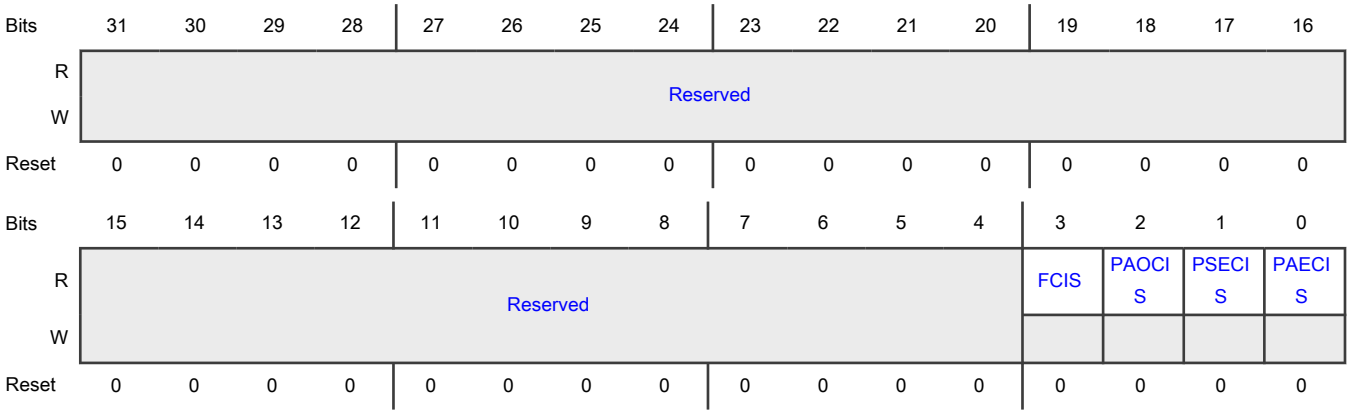
Offset

Register	Offset
MMC_FPE_Rx_Interrupt	8C0h

Function
Maintains the interrupts generated from all the FPE-related receive statistic counters, when these transmit statistic counters reach half of their maximum values (8000_0000h for a 32-bit counter and 8000h for a 16-bit counter), and when they cross their maximum values (FFFF_FFFFh for a 32-bit counter and FFFFh for 16-bit counter). When MMC_Control[CNTSTOPRO] = 1, the interrupts are set but the counter remains at all-ones. An interrupt bit of this register becomes 0 when the respective

MMC counter that caused the interrupt is read. The least significant byte lane (bits [7:0]) of the respective counter must be read to clear the interrupt bit.

Diagram



Fields

Field	Function
31-4 —	Reserved
3 FCIS	MMC Receive FPE Fragment Counter Interrupt Status Indicates whether the MMC receive FPE fragment counter interrupt status is detected. This field becomes 1 when the Rx_FPE_Fragment_Cntr counter reaches half of its maximum value or the maximum value. Exists when any one of the receive, transmit, or MMC counters is enabled during FPE-enabled configuration. Access restrictions apply to this field that clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
2 PAOCIS	MMC Receive Packet Assembly OK Counter Interrupt Status Indicates whether the MMC receive packet assembly OK counter interrupt status is detected. This field becomes 1 when the Rx_Packet_Assemble_Ok_Cntr counter reaches half of its maximum value or the maximum value. Exists when any one of the receive, transmit, or MMC counters is enabled during FPE-enabled configuration. Access restrictions apply to this field that clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected

Table continues on the next page...

Table continued from the previous page...

Field	Function
1 PSECIS	MMC Receive, Transmit, Packet SMD Error Counter Interrupt Status Indicates whether the status of the MMC receive packet SMD error counter interrupt is detected. This field becomes 1 when the Rx_Packet_SMD_Err_Cntr counter reaches half of its maximum value or the maximum value. Exists when any one of the receive, transmit, or MMC counters is enabled during FPE-enabled configuration. Access restrictions apply to this field that clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
0 PAECIS	MMC Receive, transmit, Packet Assembly Error Counter Interrupt Status Indicates whether the status of the MMC receive packet assembly error counter interrupt is detected. This field becomes 1 when the Rx_Packet_Assemble_Err_Cntr counter reaches half of its maximum value or the maximum value. Exists when any one of the receive, transmit, or MMC counters is enabled during the FPE-enabled configuration. Access restrictions apply to this field that clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected

72.18.119 MMC FPE Receive Interrupt Mask (MMC_FPE_Rx_Interrupt_Mask)

Offset

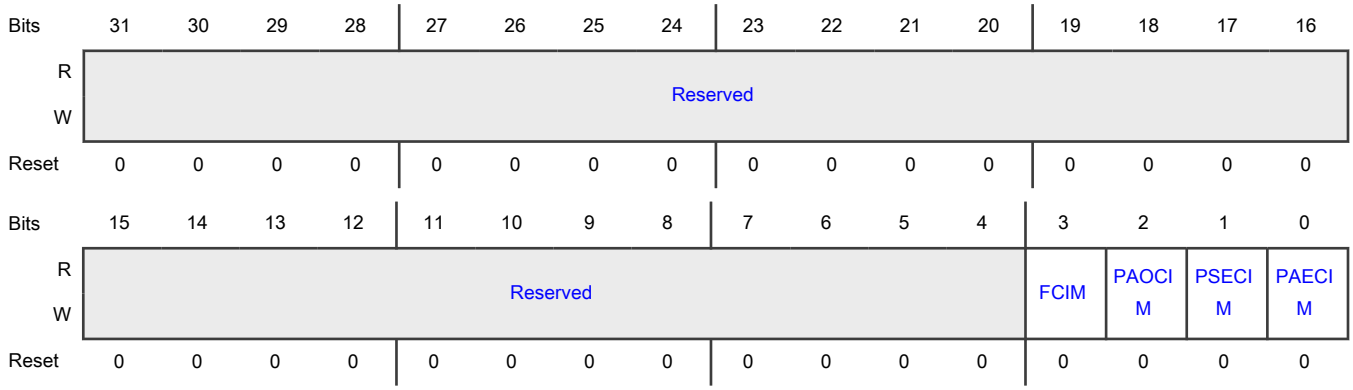
Register	Offset
MMC_FPE_Rx_Interrupt_Mask	8C4h

Function

Maintains the masks for interrupts generated from all FPE-related receive statistic counters.

This register maintains the masks for the interrupts generated when FPE-related receive statistic counters reach half of their maximum value or the maximum value.

Diagram



Fields

Field	Function
31-4 —	Reserved
3 FCIM	MMC Receive FPE Fragment Counter Interrupt Mask Indicates the status of the MMC receive FPE fragment counter interrupt mask. Writing 1 to this field masks the interrupt when the Tx_FPE_Fragment_Cntr counter reaches half of its maximum value or the maximum value. Exists when any one of the receive, transmit, or MMC counters is enabled during FPE-enabled configuration. 0b - Disabled 1b - Enabled
2 PAOCIM	MMC Receive Packet Assembly OK Counter Interrupt Mask Indicates the status of the MMC receive packet assembly OK counter interrupt mask. Writing 1 to this field masks the interrupt when the Rx_Packet_Assemble_Ok_Cntr counter reaches half of its maximum value or the maximum value. Exists when any one of the receive, transmit, or MMC counters is enabled during FPE-enabled configuration. 0b - Disabled 1b - Enabled
1 PSECIM	MMC Receive Packet SMD Error Counter Interrupt Mask Indicates the status of the MMC receive packet SMD error counter interrupt mask. Writing 1 to this field masks the interrupt when the Rx_Packet_SMD_Err_Cntr counter reaches half of its maximum value or the maximum value. Exists when any one of the receive, transmit, or MMC counters is enabled during FPE-enabled configuration.

Table continues on the next page...

Fields

Field	Function
31-0 PAEC	Packet Assembly Error Counter Indicates the number of MAC frames having reassembly errors on the receiver arising out of mismatch in the fragment count value. Exists when any one of the receive, transmit, or MMC counters is enabled during FPE-enabled configuration.

72.18.121 MMC Receive Packet SMD Error Counter (MMC_Rx_Packet_SMD_Err_Cntr)

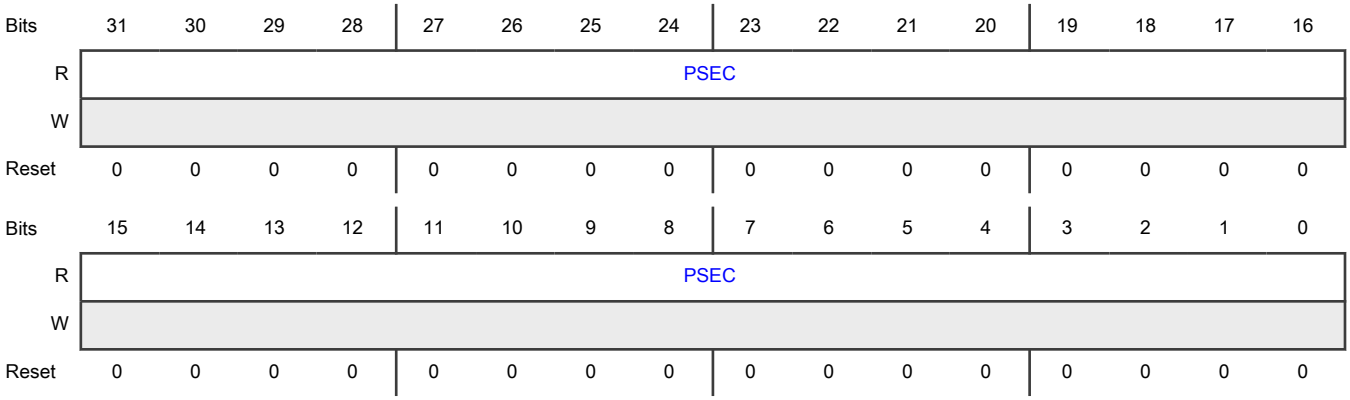
Offset

Register	Offset
MMC_Rx_Packet_SMD_Err_Cntr	8CCh

Function

Provides the number of received MAC frames rejected because of an unknown SMD value and MAC frame fragments rejected because of arriving with SMD-C when there was no preceding preempted frame.

Diagram



Fields

Field	Function
31-0 PSEC	Packet SMD Error Counter Indicates the number of MAC frames rejected because of an unknown SMD value and MAC frame fragments rejected because of arriving with SMD-C when there was no preceding preempted frame. Exists when at least one of the receive, transmit, or MMC counters is enabled during FPE-enabled configuration.

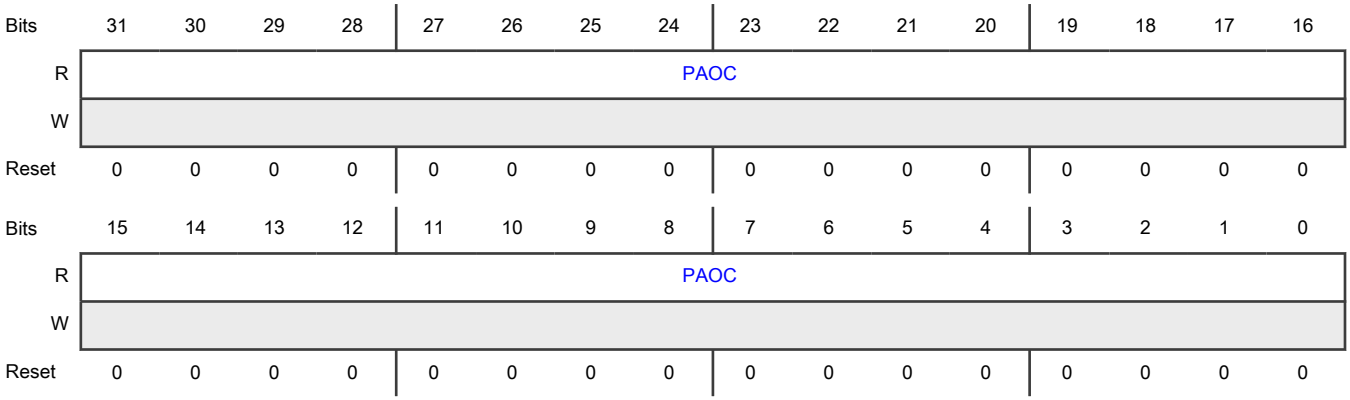
72.18.122 MMC Receive Packet Assembly OK Counter (MMC_Rx_Packet_Assembly_OK_Cntr)

Offset

Register	Offset
MMC_Rx_Packet_Assembly_OK_Cntr	8D0h

Function
Provides the number of MAC frames that were successfully reassembled and delivered to MAC.

Diagram



Fields

Field	Function
31-0 PAOC	Packet Assembly OK Counter Indicates the number of MAC frames that were successfully reassembled and delivered to MAC. Exists when at least one of the receive, transmit, or MMC counters is enabled during FPE-enabled configuration.

72.18.123 MMC Receive FPE Fragment Counter (MMC_Rx_FPE_Fragment_Cntr)

Offset

Register	Offset
MMC_Rx_FPE_Fragment_Cntr	8D4h

Function
Provides the number of additional mPackets received because of preemption.

Fields

Field	Function
31-29 —	Reserved
28 DMCHEN0	DMA Channel Select Enable Indicates the status of the DMA channel number. • If this field is 1, it enables the selection of the DMA channel number for the packet that the L3_L4 filter passes. The DMCHN fields indicate the DMA channel number. • If this field is 0, the filter does not decide the DMA channel number. 0b - Disabled 1b - Enabled
27-25 —	Reserved
24 DMCHN0	DMA Channel Number Indicates the DMA channel number. If the value of the DMCHEN fields is 1, this field selects the DMA channel number to which the packet that this filter passes is routed. The width of this field depends on the number of the DMA channels present in your configuration.
23-22 —	Reserved
21 L4DPIM0	Layer 4 Destination Port Inverse Match Enable Indicates the status of layer 4 destination port inverse matching. • If this field is 1, MAC_Layer4_Address0[L4DP0] is enabled for inverse matching. • If this field is 0, MAC_Layer4_Address0[L4DP0] is enabled for perfect matching. This field is valid and applicable only when the L4DPM0 field is 1. 0b - Disabled 1b - Enabled
20 L4DPM0	Layer 4 Destination Port Match Enable Indicates the status of layer 4 destination port matching. • If this field is 1, MAC_Layer4_Address0[L4DP0] is enabled for matching. • If this field is 0, MAC ignores MAC_Layer4_Address0[L4DP0] for matching. 0b - Disabled 1b - Enabled
19	Layer 4 Source Port Inverse Match Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
L4SPIM0	Indicates the status of layer 4 source port inverse matching. • If this field is 1, MAC_Layer4_Address0[L4SP0] is enabled for inverse matching. • If this field is 0, MAC_Layer4_Address0[L4SP0] is enabled for perfect matching. This field is valid and applicable only when MAC_Layer4_Address0[L4SP0] = 1. 0b - Disabled 1b - Enabled
18 L4SPM0	Layer 4 Source Port Match Enable Indicates the status of layer 4 source port matching. • If this field is 1, MAC_Layer4_Address0[L4SP0] is enabled for matching. • If this field is 0, MAC ignores MAC_Layer4_Address0[L4SP0] for matching. 0b - Disabled 1b - Enabled
17 —	Reserved
16 L4PEN0	Layer 4 Protocol Enable Indicates the status of layer 4 protocol. • If this field is 1, MAC_Layer4_Address0[L4SP0] and MAC_Layer4_Address0[L4DP0] are used for matching UDP packets. • If this field is 0, MAC_Layer4_Address0[L4SP0] and MAC_Layer4_Address0[L4DP0] are used for matching TCP packets. Layer 4 matching is performed only when the L4SPM0 field or the L4DPM0 field is 1. 0b - Disabled 1b - Enabled
15-11 L3HDBM0	Layer 3 IP DA Higher Bits Match IPv4 packets: This field contains the number of higher bits of IP DA that are matched in the IPv4 packets. The following list describes the values of this field: • 0: No bits are masked. • 1: LSb[0] is masked. • 2: Two LSbs [1:0] are masked. • - .. • 31: All bits except MSb are masked. IPv6 packets:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Bits [12:11] of this field correspond to bits [6:5] of the L3HSBM0 field, which indicates the number of lower bits of IP SA or DA that are masked in the IPv6 packets. The following list describes the concatenated values of the L3HDBM0[1:0] and L3HSBM0 fields: • 0: No bits are masked. • 1: LSb[0] is masked. • 2: Two LSbs [1:0] are masked. • .. • 127: All bits except MSb are masked. This field is valid and applicable only when the L3DAM0 field or the L3SAM0 field is 1.
10-6 L3HSBM0	Layer 3 IP SA Higher Bits Match IPv4 packets: This field contains the number of lower bits of IP SA that are masked for matching in the IPv4 packets. The following list describes the values of this field: • 0: No bits are masked. • 1: LSb[0] is masked. • 2: Two LSbs [1:0] are masked. • .. • 31: All bits except MSb are masked. IPv6 packets: This field contains bits [4:0] of L3HSBM0. These bits indicate the number of higher bits of IP SA or DA matched in the IPv6 packets. The field is valid and applicable only when the L3DAM0 field or the L3SAM0 field is 1.
5 L3DAIM0	Layer 3 IP DA Inverse Match Enable Indicates the status of layer 3 IP DA inverse matching. • If this field is 1, layer 3 IP DA is enabled for inverse matching. • If this field is 0, layer 3 IP DA is enabled for perfect matching. This field is valid and applicable only if L3DAM0 = 1. 0b - Disabled 1b - Enabled
4 L3DAM0	Layer 3 IP DA Match Enable Indicates the status of layer 3 IP DA matching. • If this field is 1, layer 3 IP DA is enabled for matching. • If this field is 0, MAC ignores layer 3 IP DA for matching.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE If L3PEN0 = 1, you must write 1 to either this field or the L3SAM0 field because either the IPv6 DA or SA can be checked for filtering. 0b - Disabled 1b - Enabled
3 L3SAIM0	Layer 3 IP SA Inverse Match Enable Indicates the status of layer 3 IP SA inverse matching. • If this field is 1, layer 3 IP SA is enabled for inverse matching. • If this field is 0, layer 3 IP SA is enabled for perfect matching. This field is valid and applicable only if the L3SAM0 field is 1. 0b - Disabled 1b - Enabled
2 L3SAM0	Layer 3 IP SA Match Enable Indicates the status of layer 3 IP SA matching. • If this field is 1, layer 3 IP SA matching is enabled. • If this field is 0, MAC ignores layer 3 IP SA matching. **NOTE** If L3PEN0 = 1, you must write 1 to either this field or the L3DAM0 field because either IPv6 SA or DA can be checked for filtering. 0b - Disabled 1b - Enabled
1 —	Reserved
0 L3PEN0	Layer 3 Protocol Enable Indicates the status of layer 3 protocol. • If this field is 1, the layer 3 IP SA or DA matching is enabled for IPv6 packets. • If this field is 0, the layer 3 IP SA or DA matching is enabled for IPv4 packets. The layer 3 matching is performed only when either the L3SAM0 field or the L3DAM0 field is 1. 0b - Disabled 1b - Enabled

72.18.125 MAC Layer 4 Address 0 (MAC_Layer4_Address0)

Offset

Register	Offset
MAC_Layer4_Address0	904h

Function

Provides the layer 4 source and destination port numbers.

MAC Layer 4 Address 1 (MAC_Layer4_Address1), MAC L3 L4 Control 1 (MAC_L3_L4_Control1), MAC Layer 3 Address 0 Reg 1 (MAC_Layer3_Addr0_Reg1), MAC Layer 3 Address 1 Reg 1 (MAC_Layer3_Addr1_Reg1), MAC Layer 3 Address 2 Reg 1 (MAC_Layer3_Addr2_Reg1), and MAC Layer 3 Address 3 Reg 1 (MAC_Layer3_Addr3_Reg1) are reserved registers (RO with a default value) if MAC_Packet_Filter[IPFE] is 0 when configuring the core.

You can configure the layer 3 and layer 4 address registers to be double-synchronized by selecting the synchronize layer 3 and layer 4 address registers to the receive clock domain option while configuring the core. When you select this option, the synchronization is triggered only when bits [31:24] (in Little-Endian mode) or bits [7:0] (in Big-Endian mode) of the layer 3 and layer 4 address registers are written to. For proper synchronization updates, you must perform consecutive writes to the same layer 3 and layer 4 address registers after a delay of at least four destination clock cycles.

The layer 3 matching is performed only when either MAC_L3_L4_Control0[L3SAM0] or MAC_L3_L4_Control0[L3DAM0] is 1. 0b - Disabled 1b - Enabled

72.18.131 MAC Layer 4 Address 1 (MAC_Layer4_Address1)

Offset

Register	Offset
MAC_Layer4_Address1	934h

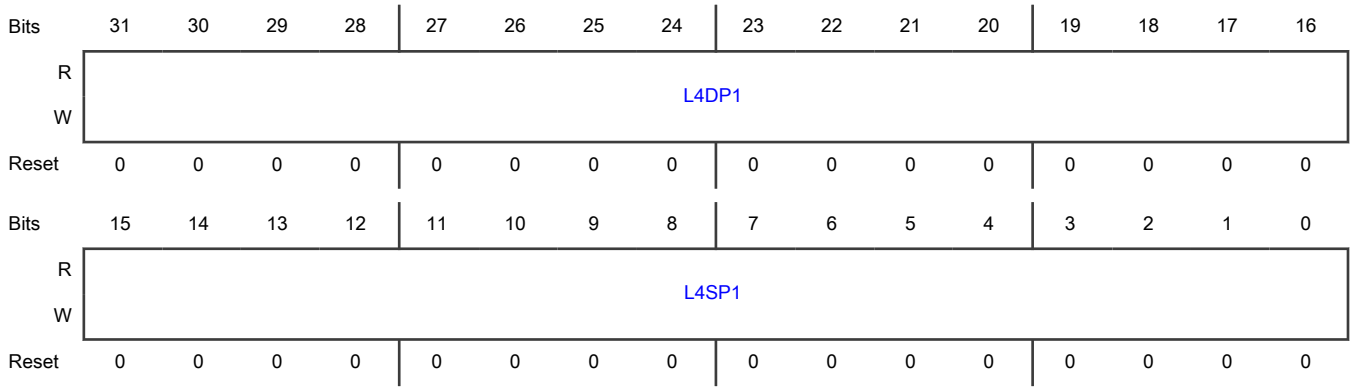
Function

Provides the layer 4 source and destination port numbers.

MAC Layer 4 Address 1 (MAC_Layer4_Address1), MAC L3 L4 Control 1 (MAC_L3_L4_Control1), MAC Layer 3 Address 0 Reg 1 (MAC_Layer3_Addr0_Reg1), MAC Layer 3 Address 1 Reg 1 (MAC_Layer3_Addr1_Reg1), MAC Layer 3 Address 2 Reg 1 (MAC_Layer3_Addr2_Reg1), and MAC Layer 3 Address 3 Reg 1 (MAC_Layer3_Addr3_Reg1) are reserved registers (RO with a default value) if the enable layer 3 and layer 4 packet filter option is not selected when configuring the core.

You can configure the layer 3 and layer 4 address registers to be double-synchronized by selecting the synchronize layer 3 and layer 4 address registers to the receive clock domain option while configuring the core. When you select this option, the synchronization is triggered only when bits [31:24] (in Little-Endian mode) or bits [7:0] (in Big-Endian mode) of the layer 3 and layer 4 address registers are written to. For proper synchronization updates, you must perform consecutive writes to the same layer 3 and layer 4 address registers after a delay of at least four destination clock cycles.

Diagram



Fields

Field	Function
31-16 L4DP1	Layer 4 Destination Port Number 1 Indicates layer 4 destination port number. If MAC_L3_L4_Control0[L4PEN0] = 0 and MAC_L3_L4_Control0[L4DPM0] = 1, this field contains the value to be matched with the TCP destination port number field in the IPv4 or IPv6 packets. If MAC_L3_L4_Control0[L4PEN0] and MAC_L3_L4_Control0[L4DPM0] are 1, this field contains the value to be matched with the UDP destination port number field in the IPv4 or IPv6 packets.
15-0 L4SP1	Layer 4 Source Port Number 1 Indicates layer 4 source port number. If MAC_L3_L4_Control0[L4PEN0] = 0 and MAC_L3_L4_Control0[L4SPM0] = 1, this field contains the value to be matched with the TCP source port number field in the IPv4 or IPv6 packets. If MAC_L3_L4_Control0[L4PEN0] and MAC_L3_L4_Control0[L4SPM0] are 1, this field contains the value to be matched with the UDP source port number field in the IPv4 or IPv6 packets.

72.18.132 MAC Layer 3 Address 0 Reg 1 (MAC_Layer3_Addr0_Reg1)

Offset

Register	Offset
MAC_Layer3_Addr0_Reg1	940h

Function

Contains the 32-bit IP source address field for IPv4 packets. For IPv6 packets, the field contains bits [31:0] of the 128-bit IP source address or destination address field.

Fields

Field	Function
31-29 —	Reserved
28 DMCHEN2	DMA Channel Select Enable 2 Indicates the status of the DMA channel number. • If this field is 1, it enables the selection of the DMA channel number for the packet that the L3_L4 filter passes. The DMCHN fields indicate the DMA channel number. • If this field is 0, the filter does not decide the DMA channel number. 0b - Disabled 1b - Enabled
27-25 —	Reserved
24 DMCHN2	DMA Channel Number 2 Indicates the DMA channel number. If the value of the DMCHEN fields is 1, this field selects the DMA channel number to which the packet that this filter passes is routed. The width of this field depends on the number of the DMA channels present in your configuration.
23-22 —	Reserved
21 L4DPIM2	Layer 4 Destination Port Inverse Match Enable 2 Indicates the status of layer 4 destination port inverse matching. • If this field is 1, MAC_Layer4_Address0[L4DP0] is enabled for inverse matching. • If this field is 0, MAC_Layer4_Address0[L4DP0] is enabled for perfect matching. This field is valid and applicable only when the L4DPM0 field is 1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disabled 1b - Enabled
20 L4DPM2	Layer 4 Destination Port Match Enable 2 Indicates the status of layer 4 destination port matching. • If this field is 1, MAC_Layer4_Address0[L4DP0] is enabled for matching. • If this field is 0, MAC ignores MAC_Layer4_Address0[L4DP0] for matching. 0b - Disabled 1b - Enabled
19 L4SPIM2	Layer 4 Source Port Inverse Match Enable 2 Indicates the status of layer 4 source port inverse matching. • If this field is 1, MAC_Layer4_Address0[L4SP0] is enabled for inverse matching. • If this field is 0, MAC_Layer4_Address0[L4SP0] is enabled for perfect matching. This field is valid and applicable only when MAC_Layer4_Address0[L4SP0] = 1. 0b - Disabled 1b - Enabled
18 L4SPM2	Layer 4 Source Port Match Enable 2 Indicates the status of layer 4 source port matching. • If this field is 1, MAC_Layer4_Address0[L4SP0] is enabled for matching. • If this field is 0, MAC ignores MAC_Layer4_Address0[L4SP0] for matching. 0b - Disabled 1b - Enabled
17 —	Reserved
16 L4PEN2	Layer 4 Protocol Enable 2 Indicates the status of layer 4 protocol. • If this field is 1, MAC_Layer4_Address0[L4SP0] and MAC_Layer4_Address0[L4DP0] of UDP packets are used for matching. • If this field is 0, MAC_Layer4_Address0[L4SP0] and MAC_Layer4_Address0[L4DP0] of TCP packets are used for matching. Layer 4 matching is performed only when the L4SPM0 field or the L4DPM0 field is 1. 0b - Disabled 1b - Enabled

0 L3PEN2	Layer 3 Protocol Enable 2 Indicates the status of layer 3 protocol. • If this field is 1, the layer 3 IP SA or DA matching is enabled for IPv6 packets. • If this field is 0, the layer 3 IP SA or DA matching is enabled for IPv4 packets. The layer 3 matching is performed only when either MAC_L3_L4_Control0[L3SAM0] or MAC_L3_L4_Control0[L3DAM0] is 1. 0b - Disabled 1b - Enabled

72.18.137 MAC Layer 4 Address 2 (MAC_Layer4_Address2)

Offset

Register	Offset
MAC_Layer4_Address2	964h

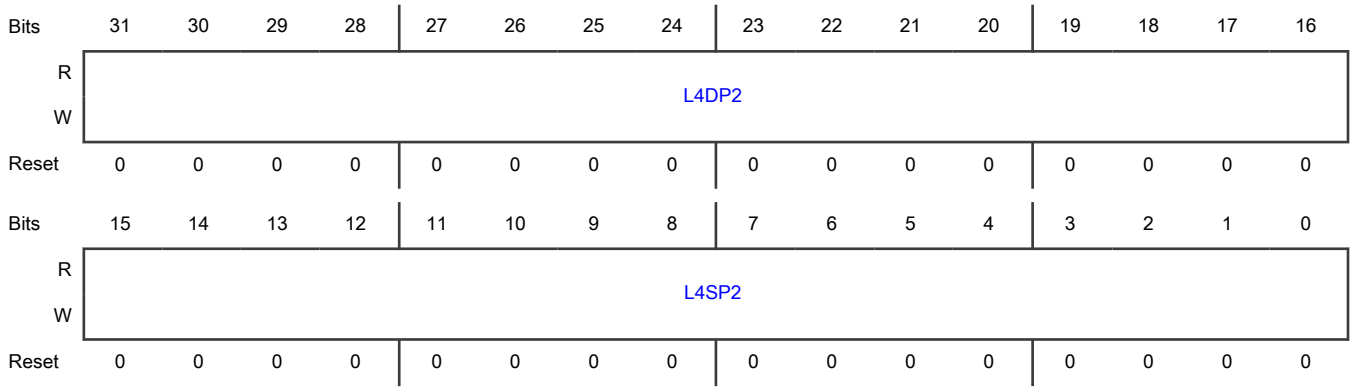
Function

Provides the layer 4 source and destination port numbers.

MAC Layer 4 Address 1 (MAC_Layer4_Address1), MAC L3 L4 Control 1 (MAC_L3_L4_Control1), MAC Layer 3 Address 0 Reg 1 (MAC_Layer3_Addr0_Reg1), MAC Layer 3 Address 1 Reg 1 (MAC_Layer3_Addr1_Reg1), MAC Layer 3 Address 2 Reg 1 (MAC_Layer3_Addr2_Reg1), and MAC Layer 3 Address 3 Reg 1 (MAC_Layer3_Addr3_Reg1) are reserved registers (RO with a default value) if the enable layer 3 and layer 4 packet filter option is not selected when configuring the core.

You can configure the layer 3 and layer 4 address registers to be double-synchronized by selecting the synchronize layer 3 and layer 4 address registers to the receive clock domain option while configuring the core. When you select this option, the synchronization is triggered only when bits [31:24] (in Little-Endian mode) or bits [7:0] (in Big-Endian mode) of the layer 3 and layer 4 address registers are written to. For proper synchronization updates, you must perform consecutive writes to the same layer 3 and layer 4 address registers after a delay of at least four destination clock cycles.

Diagram



Fields

Field	Function
31-16 L4DP2	Layer 4 Destination Port Number 2 Indicates layer 4 destination port number. If MAC_L3_L4_Control0[L4PEN0] = 0 and MAC_L3_L4_Control0[L4DPM0] = 1, this field contains the value to be matched with the TCP destination port number field in the IPv4 or IPv6 packets. If MAC_L3_L4_Control0[L4PEN0] and MAC_L3_L4_Control0[L4DPM0] are 1, this field contains the value to be matched with the UDP destination port number field in the IPv4 or IPv6 packets.
15-0 L4SP2	Layer 4 Source Port Number 2 Indicates layer 4 source port number. If MAC_L3_L4_Control0[L4PEN0] = 0 and MAC_L3_L4_Control0[L4SPM0] = 1, this field contains the value to be matched with the TCP source port number field in the IPv4 or IPv6 packets. If MAC_L3_L4_Control0[L4PEN0] and MAC_L3_L4_Control0[L4SPM0] are 1, this field contains the value to be matched with the UDP source port number field in the IPv4 or IPv6 packets.

72.18.138 MAC Layer 3 Address 0 Reg 2 (MAC_Layer3_Addr0_Reg2)

Offset

Register	Offset
MAC_Layer3_Addr0_Reg2	970h

Function

Contains the 32-bit IP source address field for IPv4 packets. For IPv6 packets, the field contains bits [31:0] of the 128-bit IP source address or destination address field.

Diagram

72.18.143 MAC Layer 4 Address 3 (MAC_Layer4_Address3)

Offset

Register	Offset
MAC_Layer4_Address3	994h

Function

Provides the layer 4 source and destination port numbers.

MAC Layer 4 Address 1 (MAC_Layer4_Address1), MAC L3 L4 Control 1 (MAC_L3_L4_Control1), MAC Layer 3 Address 0 Reg 1 (MAC_Layer3_Addr0_Reg1), MAC Layer 3 Address 1 Reg 1 (MAC_Layer3_Addr1_Reg1), MAC Layer 3 Address 2 Reg 1 (MAC_Layer3_Addr2_Reg1), and MAC Layer 3 Address 3 Reg 1 (MAC_Layer3_Addr3_Reg1) are reserved registers (RO with a default value) if the enable layer 3 and layer 4 packet filter option is not selected when configuring the core.

You can configure the layer 3 and layer 4 address registers to be double-synchronized by selecting the synchronize layer 3 and layer 4 address registers to the receive clock domain option while configuring the core. When you select this option, the synchronization is triggered only when bits [31:24] (in Little-Endian mode) or bits [7:0] (in Big-Endian mode) of the layer 3 and layer 4 address registers are written to. For proper synchronization updates, you must perform consecutive writes to the same layer 3 and layer 4 address registers after a delay of at least four destination clock cycles.

Fields

Field	Function
31-16 L4DP3	Layer 4 Destination Port Number 3 Indicates layer 4 destination port number. If MAC_L3_L4_Control0[L4PEN0] = 0 and MAC_L3_L4_Control0[L4DPM0] = 1, this field contains the value to be matched with the TCP destination port number field in the IPv4 or IPv6 packets. If MAC_L3_L4_Control0[L4PEN0] and MAC_L3_L4_Control0[L4DPM0] are 1, this field contains the value to be matched with the UDP destination port number field in the IPv4 or IPv6 packets.
15-0 L4SP3	Layer 4 Source Port Number 3 Indicates layer 4 source port number. If MAC_L3_L4_Control0[L4PEN0] = 0 and MAC_L3_L4_Control0[L4SPM0] = 1, this field contains the value to be matched with the TCP source port number field in the IPv4 or IPv6 packets. If MAC_L3_L4_Control0[L4PEN0] and MAC_L3_L4_Control0[L4SPM0] are 1, this field contains the value to be matched with the UDP source port number field in the IPv4 or IPv6 packets.

72.18.144 MAC Layer 3 Address 0 Reg 3 (MAC_Layer3_Addr0_Reg3)

Offset

Register	Offset
MAC_Layer3_Addr0_Reg3	9A0h

Function

Contains the 32-bit IP source address field for IPv4 packets. For IPv6 packets, the field contains bits [31:0] of the 128-bit IP source address or destination address field.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-0 L3A23	Layer 3 Address 2 Indicates layer 3 address 2. • If MAC_L3_L4_Control0[L3PEN0] and MAC_L3_L4_Control0[L3SAM0] are 1, this field contains the value to be matched with bits [95:64] of the IP source address field in the IPv6 packets. • If MAC_L3_L4_Control0[L3PEN0] and MAC_L3_L4_Control0[L3DAM0] are 1, this field contains the value to be matched with bits [95:64] of the IP destination address field in the IPv6 packets. • If MAC_L3_L4_Control0[L3PEN0] = 0, this field is not used.

72.18.147 MAC Layer 3 Address 3 Reg 3 (MAC_Layer3_Addr3_Reg3)

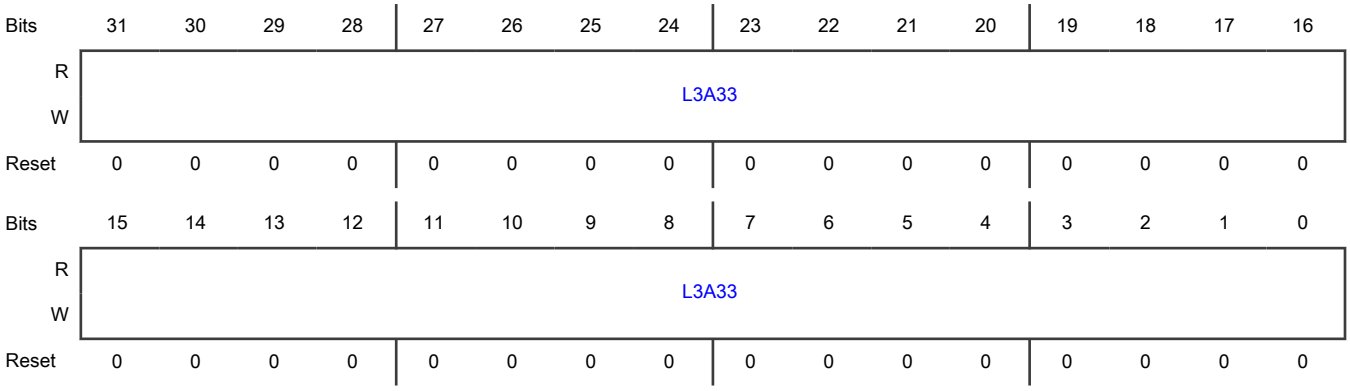
Offset

Register	Offset
MAC_Layer3_Addr3_Reg3	9ACh

Function

Contains the 32-bit IP destination address field for IPv4 packets. For IPv6 packets, the field contains bits [127:96] of the 128-bit IP source address or destination address field.

Diagram



Fields

Field	Function
31-0 L3A33	Layer 3 Address 3 Indicates layer 3 address 3. • If MAC_L3_L4_Control0[L3PEN0] and MAC_L3_L4_Control0[L3SAM0] are 1, this field contains the value to be matched with bits [127:96] of the IP source address field in the IPv6 packets. • If MAC_L3_L4_Control0[L3PEN0] and MAC_L3_L4_Control0[L3DAM0] are 1, this field contains the value to be matched with bits [127:96] of the IP destination address field in the IPv6 packets. • If MAC_L3_L4_Control0[L3PEN0] = 0, this field is not used.

72.18.148 MAC Timestamp Control (MAC_Timestamp_Control)

Offset

Register	Offset
MAC_Timestamp_Control	B00h

Function

Controls the operation of the system time generator and processing of PTP packets for timestamping in the receiver.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-29 —	Reserved
28 AV8021ASMEN	AV 802.1AS Mode Enable Indicates the status of AV 802.1AS mode. If this field is 1, MAC processes only untagged PTP over Ethernet packets for providing PTP status and capturing timestamp snapshots, which means using the IEEE 802.1AS mode of operation. If MAC_HW_Feature1[PTOEN] = 1, for the purpose of PTP offload, the transport-specific field in the PTP header is generated and checked based on the value of the AV8021ASMEN field. 0b - Disabled 1b - Enabled
27-25 —	Reserved
24 TXTSSTSM	Transmit Timestamp Status Mode Indicates the status of transmit timestamp status mode. • If this field is 1, MAC overwrites the previous transmit timestamp status even if the software does not read it. MAC indicates this by writing 1 to MAC_Tx_Timestamp_Status_Nanoseconds[TXTSSMIS]. • If this field is 0, MAC ignores the timestamp status of the current packet if the software does not read the timestamp status of the previous packet. MAC indicates this by writing 1 to MAC_Tx_Timestamp_Status_Nanoseconds[TXTSSMIS]. 0b - Disabled 1b - Enabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
23-21 —	Reserved
20 ESTI	External System Time Input Indicates the status of external system time input. If this field is 1, MAC uses the external 64-bit reference system time input for these functions: • To consider the timestamp provided as status • To insert the timestamp in transmit PTP packets if the one-step timestamp or the timestamp offload feature is enabled If this field is 1, MAC uses the internal reference system time. 0b - Disabled 1b - Enabled
19 —	Reserved
18 TSENMACADDR	Enable MAC Address For PTP Packet Filtering Indicates whether the MAC address for PTP packet filtering is enabled. If this field is 1, the DA MAC address, which matches any MAC Address register, is used to filter the PTP packets when PTP is directly sent over Ethernet. If this field is 1, received PTP packets with DA containing a special multicast or unicast address that matches the one programmed in the MAC address registers are considered for processing when PTP is directly sent over Ethernet. • For a normal time stamping operation, MAC address registers 0 to 31 are considered for unicast destination address matching. • For PTP offload, only MAC address register 0 is considered for unicast destination address matching. 0b - Disabled 1b - Enabled
17-16 SNAPTYPSEL	Select PTP Packets For Taking Snapshots Determines the set of PTP packet types for which a snapshot needs to be taken. This field, along with the TSEVNTENA and TSMSTRENA fields, determines the set of PTP packet types for which a snapshot needs to be taken. See Receive path functions for encoding.
15 TSMSTRENA	Enable Snapshot For Messages Relevant To Master Indicates whether the snapshot for messages relevant to master is enabled. If this field is 1, the snapshot is taken only for the messages that are relevant to the master node. Otherwise, the snapshot is taken for the messages relevant to the slave node.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disabled 1b - Enabled
14 TSEVNTENA	Enable Timestamp Snapshot For Event Messages Enables or disables timestamp snapshot for event messages. If this field is 1, the timestamp snapshot is taken only for event messages (SYNC, Delay_Req, Pdelay_Req, or Pdelay_Resp). When the field becomes 0, the snapshot is taken for all the messages except Announce, Management, and Signaling. For more information on timestamp snapshot dependency on register bits, see Receive path functions. 0b - Disabled 1b - Enabled
13 TSIPV4ENA	Enable Processing Of PTP Packets Sent Over IPv4-UDP Indicates whether the processing of PTP packets sent over IPv4-UDP is enabled. If this field is 1, the MAC receiver processes the PTP packets encapsulated in the IPv4-UDP packets. When this field becomes 0, MAC ignores the PTP transported over the IPv4-UDP packets. The default value of this field is 1. 0b - Disabled 1b - Enabled
12 TSIPV6ENA	Enable Processing Of PTP Packets Sent Over IPv6-UDP Indicates whether the processing of PTP packets sent over IPv6-UDP is enabled. If this field is 1, the MAC receiver processes the PTP packets encapsulated in the IPv6-UDP packets. If the value is 0, MAC ignores the PTP transported over IPv6-UDP packets. 0b - Disabled 1b - Enabled
11 TSIPENA	Enable Processing Of PTP Over Ethernet Packets Indicates the status of PTP processing over Ethernet packets. If this field is 1, the MAC receiver processes the PTP packets encapsulated directly in the Ethernet packets. When the field becomes 0, MAC ignores the PTP over Ethernet packets. 0b - Disabled 1b - Enabled
10 TSVER2ENA	Enable PTP Packet Processing For Version 2 Format Indicates the status of PTP packet processing for version 2 format. If this field is 1, the IEEE 1588 version 2 format is used to process the PTP packets. When this field becomes 0, the IEEE 1588 version 1 format is used to process the PTP packets. See PTP processing and control for more information on the IEEE 1588 formats.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disabled 1b - Enabled
9 TSCTRLSSR	Timestamp Digital Or Binary Rollover Control Indicates the status of timestamp digital or binary rollover control. • If this field is 1, the Timestamp Low register rolls over after the 3B9A_C9FFh value (that is, 1 nanosecond accuracy) and increments the timestamp (high) seconds. • If this field is 0, the rollover value of the Subsecond register is 7FFF_FFFFh. The sub-second increment must be programmed correctly depending on the PTP reference clock frequency and the value of this field. 0b - Disabled 1b - Enabled
8 TSENALL	Enable Timestamp For All Packets Indicates the status of timestamp snapshot for all packets. If this field is 1, the timestamp snapshot is enabled for all packets that MAC receives. 0b - Disabled 1b - Enabled
7 —	Reserved
6 PTGE	Presentation Time Generation Enable Indicates the status of presentation time generation. If this field is 1, the presentation time generation is enabled. 0b - Disabled 1b - Enabled
5 TSADDREG	Update Addend Register Indicates whether MAC Timestamp Addend (MAC_Timestamp_Addend) is updated. If this field is 1, the contents of MAC Timestamp Addend (MAC_Timestamp_Addend) are updated in the PTP block for fine correction. The field becomes 0 after the update completes. The value of the field must also be 0 before you write 1 to it. Access restrictions apply to this field that clears automatically. Writing 0 has no effect. 0b - Not updated 1b - Updated
4 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
3 TSUPDT	Update Timestamp Indicates whether the timestamp is updated. If this field is 1, the system time is updated (added or subtracted) with the value specified in MAC System Time Seconds Update (MAC_System_Time_Seconds_Update) and MAC System Time Nanoseconds Update (MAC_System_Time_Nanoseconds_Update). The value of this field must be 0 before you update it. It resets after the update is complete in hardware. MAC_System_Time_Higher_Word_Seconds[TSHWR], if enabled during core configuration, is not updated. When media clock generation and recovery is configured (DWC_EQOS_FLEXI_PPS_OUT_EN) and enabled, MAC Presentation Time Update (MAC_Presn_Time_Updt) must also be updated before you write 1 to this field. Access restrictions apply to this field that clears automatically. Writing 0 has no effect. 0b - Not updated 1b - Updated
2 TSINIT	Initialize Timestamp Indicates whether the timestamp is initialized. If this field is 1, the system time is initialized (overwritten) with the value specified in MAC System Time Seconds Update (MAC_System_Time_Seconds_Update) and MAC System Time Nanoseconds Update (MAC_System_Time_Nanoseconds_Update). The value of this field must be 0 before you update it, and the field is reset after the initialization is complete. MAC_System_Time_Higher_Word_Seconds[TSHWR], if enabled during core configuration, can only be initialized. When media clock generation and recovery is configured (DWC_EQOS_FLEXI_PPS_OUT_EN) and enabled, MAC Presentation Time Update (MAC_Presn_Time_Updt) must also be updated before you write 1 to this field. Access restrictions apply to this field that clears automatically. Writing 0 has no effect. 0b - Not initialized 1b - Initialized
1 TSCFUPDT	Fine Or Coarse Timestamp Update Indicates the method used to update system timestamp. • If this field is 1, the fine method is used to update system timestamp. • If this field is 0, the coarse method is used to update the system timestamp. 0b - Coarse method 1b - Fine method
0 TSENA	Timestamp Enable Enables or disables timestamp for transmit and receive packets.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• If this field is 1, the timestamp is added for transmit and receive packets. • If this field is 0, timestamp is not added for transmit and receive packets and the timestamp generator is also suspended. You need to initialize the timestamp (system time) after enabling this mode. On the receive side, MAC processes the 1588 packets only if this field is 1. 0b - Disabled 1b - Enabled

72.18.149 MAC Sub Second Increment (MAC_Sub_Second_Increment)

Offset

Register	Offset
MAC_Sub_Second_Increment	B04h

Function

Specifies the value to be added to the internal system time register at every cycle of the clk_ptp_ref_i clock.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved								SSINC							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	SNSINC								Reserved							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-24 —	Reserved
23-16 SSINC	Sub-Second Increment Value

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Contains the sub-second incement value, which accumulates every clock cycle (of clk_ptp_i) with the contents of the Subsecond register. For example, if the PTP clock is 50 MHz (period is 20 ns), you must program 20 (14h) when MAC System Time In Nanoseconds (MAC_System_Time_Nanoseconds) has an accuracy of 1 ns (MAC_Timestamp_Control[TSCTRLSSR] = 1). When TSCTRLSSR = 0, the Nanoseconds register has a resolution of ~0.465 ns. In this case, you must program a value of 43 (2Bh), which is derived by 20 ns/0.465.
15-8 SNSINC	Sub-Nanosecond Increment Value Contains the sub-nanosecond increment value, represented in nanoseconds multiplied by 2^8. This value is accumulated in the sub-nanoseconds field of the Subsecond register. For example, if MAC_Timestamp_Control[TSCTRLSSR] = 1, and if the required increment is 5.3 ns, then this field must be 4Ch and the SSINC field must be 05h.
7-0 —	Reserved

72.18.150 MAC System Time In Seconds (MAC_System_Time_Seconds)

Offset

Register	Offset
MAC_System_Time_Seconds	B08h

Function

Indicates, along with MAC System Time In Nanoseconds (MAC_System_Time_Nanoseconds), the current value of the system time that MAC maintains. Although it is updated on a continuous basis, there is some delay from the actual time because of clock domain transfer latencies (from clk_ptp_ref_i to the CSR clock).

Diagram

Fields

Field	Function
31-0 TSS	Timestamp Second Indicates the current value, in seconds, of the system time that MAC maintains.

72.18.151 MAC System Time In Nanoseconds (MAC_System_Time_Nanoseconds)

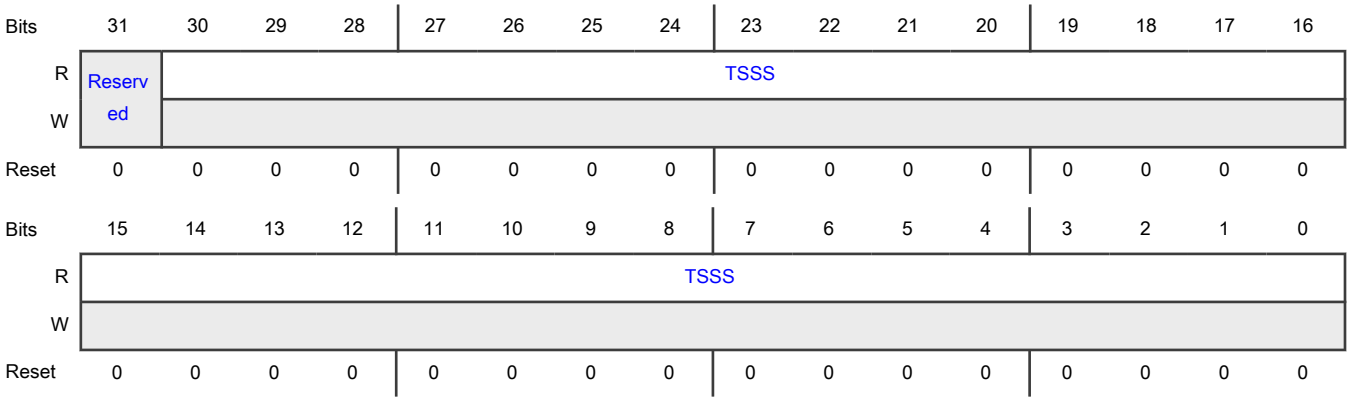
Offset

Register	Offset
MAC_System_Time_Nanoseconds	B0Ch

Function

Indicates, along with MAC System Time In Seconds (MAC_System_Time_Seconds), the current value of the system time that MAC maintains.

Diagram



Fields

Field	Function
31 —	Reserved
30-0 TSSS	Timestamp Sub Seconds Indicates the sub-second representation of time, with an accuracy of 0.46 ns. When MAC_Timestamp_Control[TSCTRLSSR] = 1, each bit represents 1 ns. The maximum value is 3B9A_C9FFh after which it rolls over to 0.

72.18.152 MAC System Time Seconds Update (MAC_System_Time_Seconds_Update)

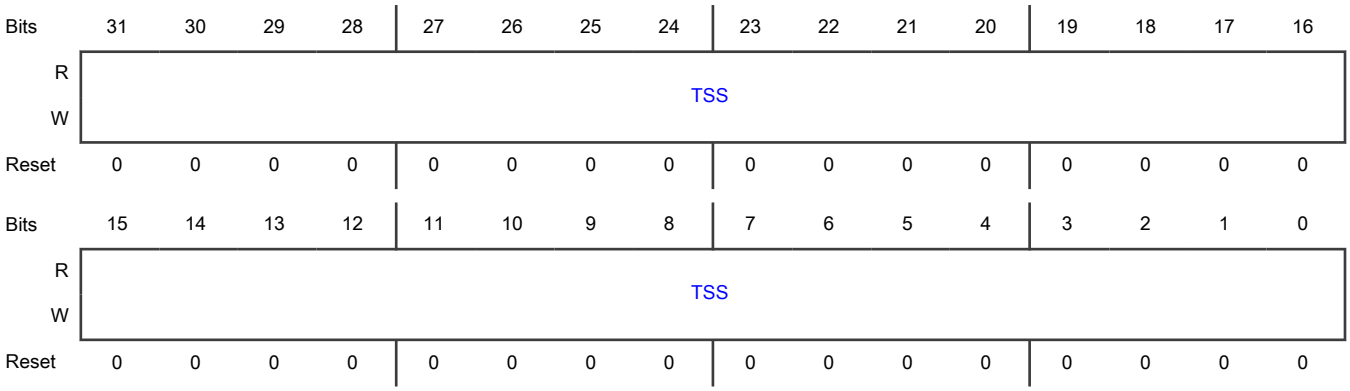
Offset

Register	Offset
MAC_System_Time_Seconds_Update	B10h

Function

Initializes or updates, along with MAC System Time Nanoseconds Update (MAC_System_Time_Nanoseconds_Update), the system time that MAC maintains. You must write both to this register and the MAC System Time Nanoseconds Update register before writing 1 to MAC_Timestamp_Control[TSINIT] and MAC_Timestamp_Control[TSUPDT].

Diagram



Fields

Field	Function
31-0 TSS	Timestamp Seconds Indicates the timestamp seconds value. The value in this field is the seconds part of the update. • If MAC_System_Time_Nanoseconds_Update[ADDSUB] = 0, this field must be programmed with the seconds part of the update value. • If MAC_System_Time_Nanoseconds_Update[ADDSUB] = 1, this field must be programmed with the complement of the seconds part of the update value. For example, if 2.000000001 seconds need to be subtracted from the system time, MAC_System_Time_Seconds[TSS] must be FFFF_FFFEh (that is, 2^32 - 2).

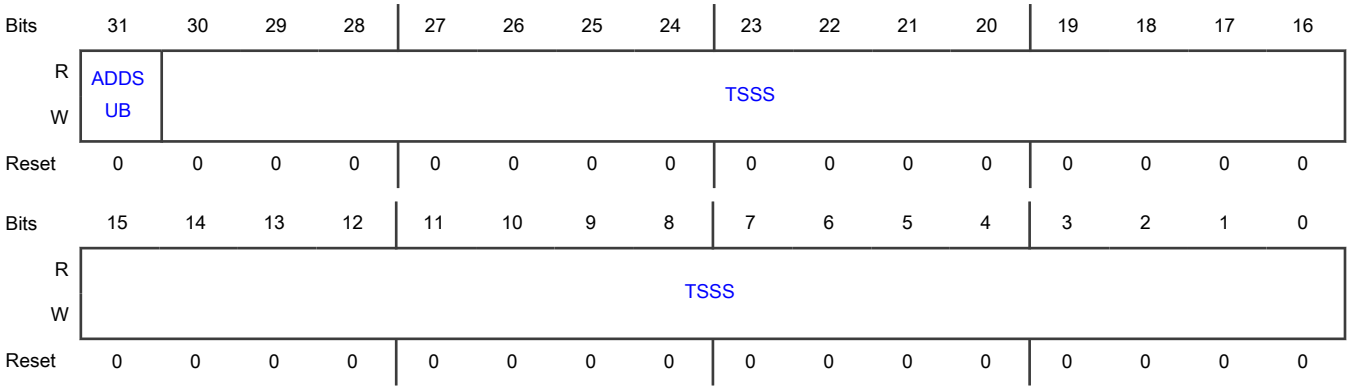
72.18.153 MAC System Time Nanoseconds Update (MAC_System_Time_Nanoseconds_Update)

Offset

Register	Offset
MAC_System_Time_Nanoseconds_Update	B14h

Function
Indicates system time nanoseconds update.

Diagram



Fields

Field	Function
31 ADDSUB	Add Or Subtract Time Indicates whether the time value is added or subtracted from the contents of the update register. • If this field is 1, the time value is subtracted from the contents of the update register. • If this field is 0, the time value is added to the contents of the update register. 0b - Add time 1b - Subtract time
30-0 TSSS	Timestamp Subseconds Indicates the sub-second part of the update. • If ADDSUB = 0, this field must be programmed with the sub-second part of the update value, with an accuracy based on MAC_Timestamp_Control[TSCTRLSSR]. • If ADDSUB = 0, this field must be programmed with the complement of the sub-second part of the update value as described below. • If MAC_Timestamp_Control[TSCTRLSSR] = 1, the programmed value must be 10^9 - <sub-second value>, and if MAC_Timestamp_Control[TSCTRLSSR] = 0, the programmed value must be 2^31 - <sub-second_value>.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• If MAC_Timestamp_Control[TSCTRLSSR] = 0, each bit of it represents an accuracy of 0.46 ns, and if MAC_Timestamp_Control[TSCTRLSSR] = 1, each bit represents 1 ns and the programmed value must not exceed 3B9A_C9FFh. For example, if 2.000000001 seconds need to be subtracted from the system time, this field must be 7FFF_FFFFh (that is, 2^31 - 1) if MAC_Timestamp_Control[TSCTRLSSR] = 0. This field must be 3B9A_C9FFh (that is, 10^9 - 1) if MAC_Timestamp_Control[TSCTRLSSR] = 1.

72.18.154 MAC Timestamp Addend (MAC_Timestamp_Addend)

Offset

Register	Offset
MAC_Timestamp_Addend	B18h

Function

Is used only when the system time is configured for Fine Update mode (MAC_Timestamp_Control[TSINIT] = 1). The contents of this register are added to a 32-bit accumulator in every clock cycle (of clk_ptp_ref_i), and the system time is updated whenever the accumulator overflows.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	TSAR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 TSAR	Timestamp Addend Register Indicates the 32-bit time value to be added to the Accumulator register to achieve time synchronization.

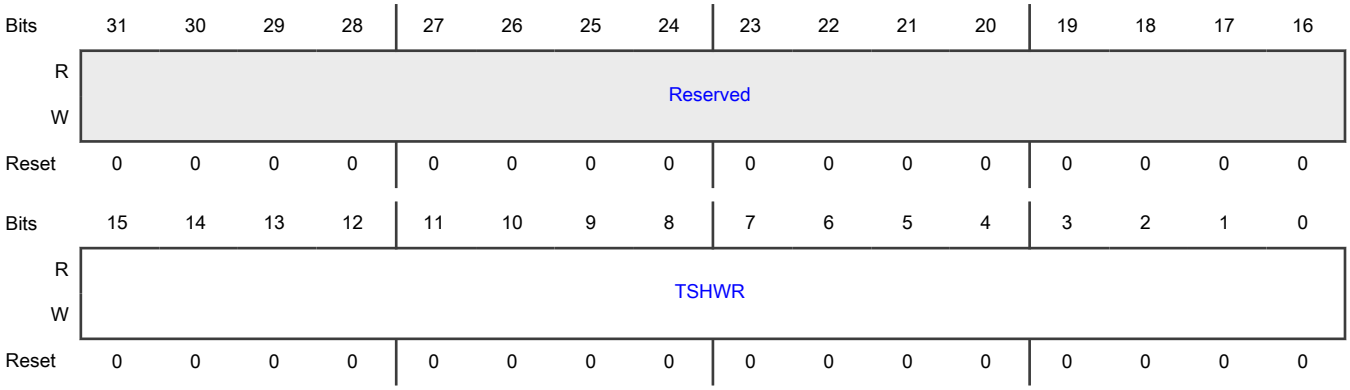
72.18.155 MAC System Time Higher Word In Seconds (MAC_System_Time_Higher_Word_Seconds)

Offset

Register	Offset
MAC_System_Time_Higher_Word_Seconds	B1Ch

Function
Indicates system time - higher word in seconds.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 TSHWR	Timestamp Higher Word Register Contains the most-significant 16 bits of the timestamp seconds value. This register is optional, and you can add it if you select the IEEE 1588 higher-word register option. You write to this register directly to initialize the value, which increments when there is an overflow from the 32 bits of MAC System Time In Seconds (MAC_System_Time_Seconds). Access restrictions apply to this field, which updates based on an event occurrence.

72.18.156 MAC Timestamp Status (MAC_Timestamp_Status)

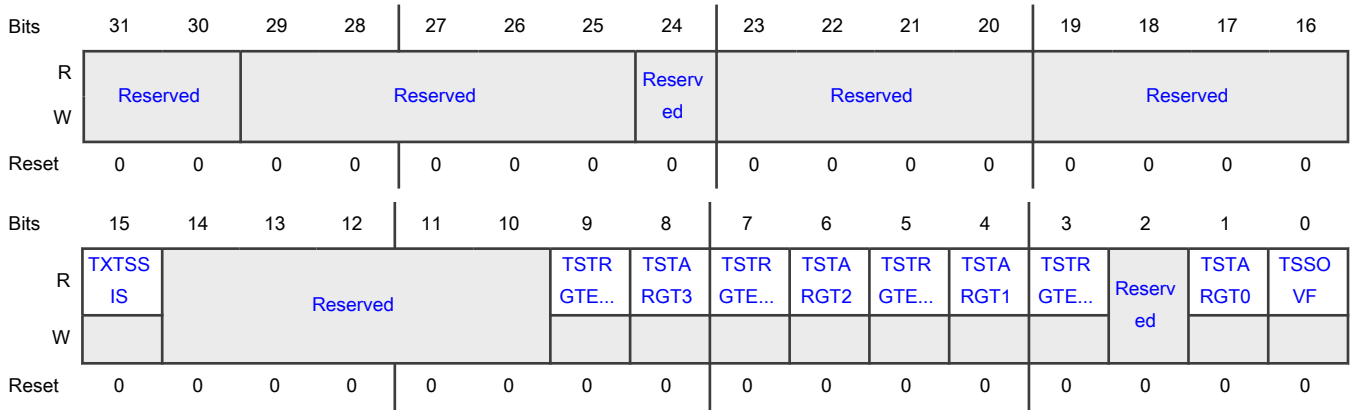
Offset

Register	Offset
MAC_Timestamp_Status	B20h

Function

Indicates timestamp status. All the bits except [27:25] are cleared when the application reads this register.

Diagram



Fields

Field	Function
31-30 —	Reserved
29-25 —	Reserved
24 —	Reserved
23-20 —	Reserved
19-16 —	Reserved
15 TXTSSIS	Transmit Timestamp Status Interrupt Status Indicates whether the transmit timestamp interrupt status is detected. In non-EQOS_CORE configurations, if the drop transmit status is enabled in MTL, this field becomes 1 when the captured transmit timestamp is updated in MAC Transmit Timestamp Status In Seconds (MAC_Tx_Timestamp_Status_Seconds) and MAC Transmit Timestamp Status In Nanoseconds (MAC_Tx_Timestamp_Status_Nanoseconds). If MAC_HW_Feature1[PTOEN] = 1, TXTSSIS becomes 1 when the captured transmit timestamp is updated in MAC Transmit Timestamp Status In Seconds (MAC_Tx_Timestamp_Status_Seconds) and MAC Transmit Timestamp Status In Nanoseconds (MAC_Tx_Timestamp_Status_Nanoseconds) for PTO-generated delay request and Pdelay request packets.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field becomes 0 if you read or write to MAC Transmit Timestamp Status In Seconds (MAC_Tx_Timestamp_Status_Seconds) when MAC_CSR_SW_Ctrl[RCWE] = 1. 0b - Not detected 1b - Detected
14-10 —	Reserved
9 TSTRGTERR3	Timestamp Target Time Error Indicates whether the timestamp target time error status is detected. This field becomes 1 if the latest target time programmed in MAC PPS3 Target Time In Seconds (MAC_PPS3_Target_Time_Seconds) and MAC PPS3 Target Time In Nanoseconds (MAC_PPS3_Target_Time_Nanoseconds) elapses. The field becomes 0 when the application reads it. Access restrictions apply to this field that clears when read (or when this field is written to 1 if MAC_CSR_SW_Ctrl[RCWE] = 1). Also, the field automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
8 TSTARGT3	Timestamp Target Time Reached For Target Time PPS3 Indicates whether the timestamp target time reached for target time PPS3 status is detected. If this field is 1, it indicates that the value of the system time is greater than or equal to the value specified in MAC PPS3 Target Time In Seconds (MAC_PPS3_Target_Time_Seconds) and MAC PPS3 Target Time In Nanoseconds (MAC_PPS3_Target_Time_Nanoseconds). Access restrictions apply to this field that clears when read (or when this field is written to 1 if MAC_CSR_SW_Ctrl[RCWE] = 1). Also, the field automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
7 TSTRGTERR2	Timestamp Target Time Error Indicates whether the timestamp target time error status is detected. This field becomes 1 when the latest target time programmed in MAC PPS2 Taget Time In Seconds (MAC_PPS2_Target_Time_Seconds) and MAC PPS2 Target Time In Nanoseconds (MAC_PPS2_Target_Time_Nanoseconds) elapses. The field becomes 0 when the application reads it. Access restrictions apply to this field that clears when read (or when this field is written to 1 if MAC_CSR_SW_Ctrl[RCWE] = 1). Also, the field automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
6 TSTARGT2	Timestamp Target Time Reached For Target Time PPS2 Indicates whether the timestamp target time reached for the target time PPS2 status is detected.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If this field is 1, it indicates that the value of system time is greater than or equal to the value specified in MAC PPS2 Taget Time In Seconds (MAC_PPS2_Target_Time_Seconds) and MAC PPS2 Target Time In Nanoseconds (MAC_PPS2_Target_Time_Nanoseconds). Access restrictions apply to this field that clears when read (or when this field is written to 1 if MAC_CSR_SW_Ctrl[RCWE] = 1). Also, the field automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
5 TSTRGTERR1	Timestamp Target Time Error Indicates whether the timestamp target time error status is detected. This field becomes 1 when the latest target time programmed in MAC PPS1 Target Time In Seconds (MAC_PPS1_Target_Time_Seconds) and MAC PPS1 Target Time In Nanoseconds (MAC_PPS1_Target_Time_Nanoseconds) elapses. The field becomes 0 when the application reads it. Access restrictions apply to this field that clears when read (or when this field is written to 1 if MAC_CSR_SW_Ctrl[RCWE] = 1). Also, the field automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
4 TSTARGT1	Timestamp Target Time Reached For Target Time PPS1 Indicates whether the timestamp target time reached for target time PPS1 status is detected. If this field is 1, it indicates that the value of system time is greater than or equal to the value specified in MAC PPS1 Target Time In Seconds (MAC_PPS1_Target_Time_Seconds) and MAC PPS1 Target Time In Nanoseconds (MAC_PPS1_Target_Time_Nanoseconds) Access restrictions apply to this field that clears when read (or when this field is written to 1 if MAC_CSR_SW_Ctrl[RCWE] = 1). Also, the field automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
3 TSTRGTERR0	Timestamp Target Time Error Indicates whether the timestamp target time error status is detected. This field becomes 1 when the latest target time programmed in MAC PPS0 Target Time In Seconds (MAC_PPS0_Target_Time_Seconds) and MAC PPS0 Target Time In Nanoseconds (MAC_PPS0_Target_Time_Nanoseconds) elapses. The field becomes 0 when the application reads it. Access restrictions apply to this field that clears when read (or when this field is written to 1 if MAC_CSR_SW_Ctrl[RCWE] = 1). Also, the field automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
2 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
1 TSTARGT0	Timestamp Target Time Reached Indicates whether the timestamp target time reached status is detected. If this field is 1, it indicates that the value of the system time is greater than or equal to the value specified in MAC PPS0 Target Time In Seconds (MAC_PPS0_Target_Time_Seconds) and MAC PPS0 Target Time In Nanoseconds (MAC_PPS0_Target_Time_Nanoseconds) Access restrictions apply to this field that clears when read (or when this field is written to 1 if MAC_CSR_SW_Ctrl[RCWE] = 1). Also, the field automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
0 TSSOVF	Timestamp Seconds Overflow Indicates whether the timestamp seconds overflow status is detected. If this field is 1, it indicates that the seconds value of the timestamp (when supporting version 2 format) has overflowed beyond 32'hFFFF_FFFF. Access restrictions apply to this field that clears when read (or when this field is written to 1 if MAC_CSR_SW_Ctrl[RCWE] = 1). Also, the field automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected

72.18.157 MAC Transmit Timestamp Status In Nanoseconds (MAC_Tx_Timestamp_Status_Nanoseconds)

Offset

Register	Offset
MAC_Tx_Timestamp_Status_Nanoseconds	B30h

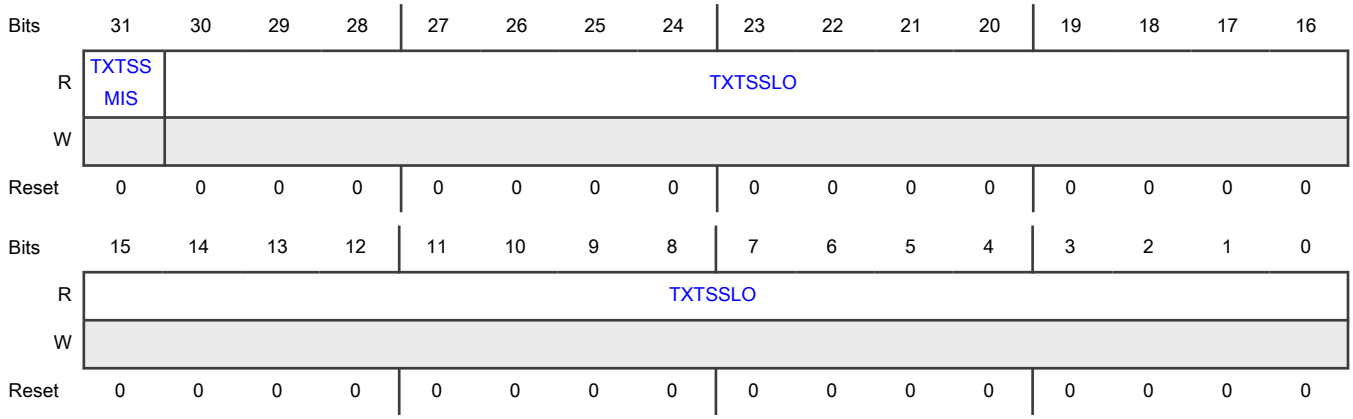
Function

Contains the nanosecond part of the timestamp captured for tansmit packets when the transmit status is disabled.

This register, along with MAC Transmit Timestamp Status In Seconds (MAC_Tx_Timestamp_Status_Seconds), gives the 64-bit timestamp captured for the PTP packet that MAC successfully transmits. The application considers reading this value after the last byte of this register is read. In Little-Endian mode, this means when bits [31:24] are read, and in Big-Endian mode, this means when bits [7:0] are read.

If the application does not read these registers and the timestamp of another packet is captured, then either the current timestamp is lost (overwritten) or the new timestamp is lost (dropped), depending on the settings specified in MAC_Timestamp_Control[TXTSSTSM]. The status bit TXTSC bit [15] in the MAC_Timestamp_Status register is set whenever the MAC transmitter captures the timestamp.

Diagram



Fields

Field	Function
31 TXTSSMIS	Transmit Timestamp Status Missed Indicates whether the transmit timestamp missed status is detected. If this field is 1, it indicates one of these conditions: • The timestamp of the current packet is ignored if MAC_Timestamp_Control[TXTSSTSM] = 0. • The timestamp of the previous packet is overwritten with the timestamp of the current packet if MAC_Timestamp_Control[TXTSSTSM] = 1. Access restrictions apply to this field that cleas on read and automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
30-0 TXTSSLO	Transmit Timestamp Status Low Contains 31 bits of the Nanoseconds field of the transmit packet's captured timestamp.

72.18.158 MAC Transmit Timestamp Status In Seconds (MAC_Tx_Timestamp_Status_Seconds)

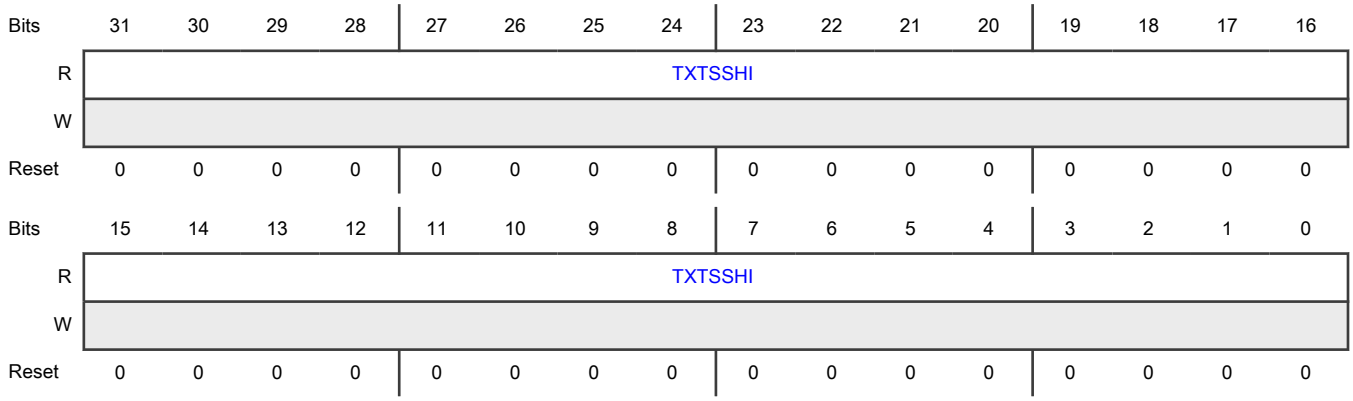
Offset

Register	Offset
MAC_Tx_Timestamp_Status_Seconds	B34h

Function

Contains the higher 32 bits of the timestamp (in seconds) captured when a PTP packet is transmitted.

Diagram



Fields

Field	Function
31-0 TXTSSHI	Transmit Timestamp Status High Contains the lower 32 bits of the Seconds field of the transmitted packet's captured timestamp.

72.18.159 MAC Timestamp Ingress Asymmetry Correction (MAC_Timestamp_Ingress_Asym_Corr)

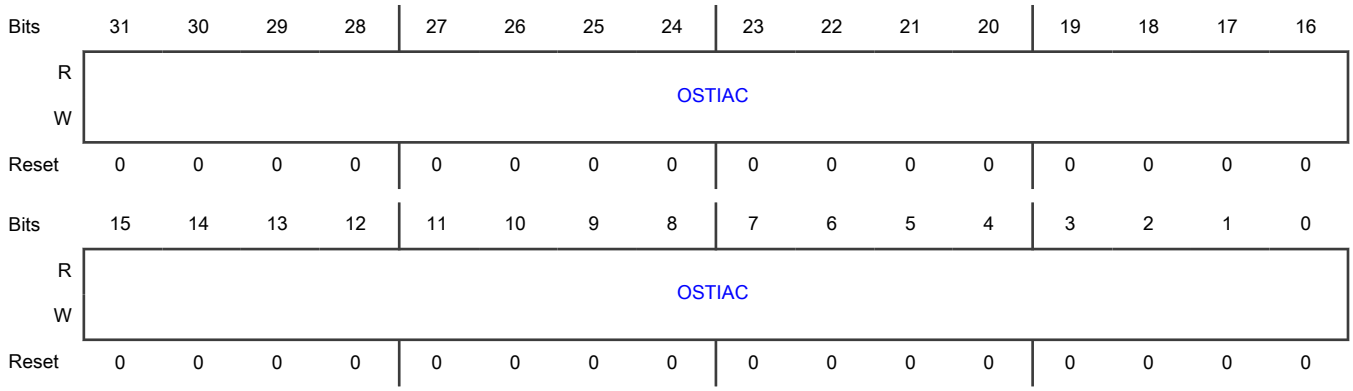
Offset

Register	Offset
MAC_Timestamp_Ingress_Asym_Corr	B50h

Function

Contains the ingress asymmetry correction value to be used when updating the correction field in the PDelay_Resp PTP messages.

Diagram



Fields

Field	Function
31-0 OSTIAC	One-Step Timestamp Ingress Asymmetry Correction Contains the ingress path asymmetry value to be added to the correctionField of the Pdelay_Resp PTP packet. The programmed value must be expressed in units of nanoseconds and multiplied by 2^16. For example, 2.5 ns is represented as 00028000h. This value can also be negative, which is represented in the two's-complement form with bit 31 representing the sign bit.

72.18.160 MAC Timestamp Egress Asymmetry Correction (MAC_Timestamp_Egress_Asym_Corr)

Offset

Register	Offset
MAC_Timestamp_Egress_Asym_Corr	B54h

Function

Contains the egress asymmetry correction value to be used when updating the correction field in the PDelay_Req PTP messages.

Diagram

Fields

Field	Function
31-0 OSTEAC	One-Step Timestamp Egress Asymmetry Correction Contains the egress path asymmetry value to be subtracted from the correctionField of the Pdelay_Resp PTP packet. The programmed value must be the negated value in units of nanoseconds multiplied by 2^16. For example, if the required correction is +2.5 ns, the programmed value must be FFFD_8000h, which is the two's-complement of 0002_8000h (2.5 * 216). Similarly, if the required correction is -3.3 ns, the programmed value is 0003_4CCCh (3.3 * 216).

72.18.161 MAC Timestamp Ingress Correction In Nanoseconds (MAC_Timestamp_Ingress_Corr_Nanosecond)

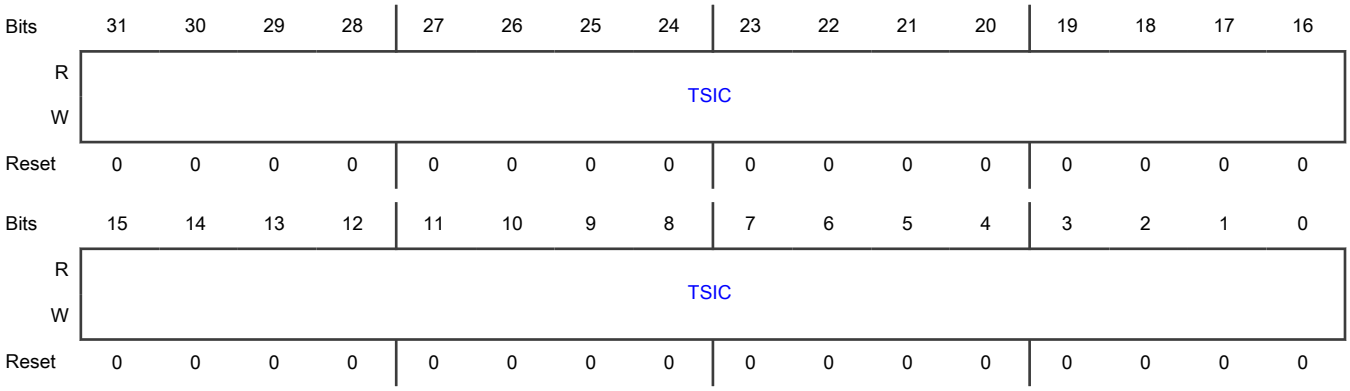
Offset

Register	Offset
MAC_Timestamp_Ingress_Corr_Nanosecond	B58h

Function

Contains the correction value, in nanoseconds, to be used with the captured timestamp value in the ingress path.

Diagram



Fields

Field	Function
31-0 TSIC	Timestamp Ingress Correction Contains the ingress path correction value as defined by the ingress correction expression.

72.18.162 MAC Timestamp Egress Correction In Nanoseconds (MAC_Timestamp_Egress_Corr_Nanosecond)

Offset

Register	Offset
MAC_Timestamp_Egress_Corr_Nanosecond	B5Ch

Function

Contains the correction value, in nanoseconds, to be used with the captured timestamp value in the egress path.

Table continued from the previous page...

Field	Function
	10b - Target Time registers are programmed for generating the interrupt event and starting or stopping the PPS0 output signal generation. 11b - Target Time registers are programmed only for starting or stopping the PPS0 output signal generation. No interrupt is asserted.
20 —	Reserved
19-16 PPSCMD2	Flexible PPS2 Output Control Controls the flexible PPS2 output (ptp_pps_o[2]) signal. The functioning of this field is similar to that of the PPSCMD0 (presentation time control bits). If MCGREN2 = 1, the bits included in PPSCMD2 [19:16] are considered as presentation time control bits for media clock generation and recovery for comparator instance 2. If MCGREN2 is not 1, only three bits [18:16] are used as PPSCMD2 and the fourth bit becomes 0. Access restrictions apply to this field that clears automatically. Writing 0 to it has no effect.
15 MCGREN1	MCGR Mode Enable For PPS1 Output Enables or disables the first PPS instance to operate in PPS or MCGR mode. If this field is 1, it operates in MCGR mode, and if the value is 0, it operates in PPS mode. 0b - Disabled 1b - Enabled
14-13 TRGTMODSEL1	Target Time Register Mode For PPS1 Output Indicates MAC PPS1 Target Time In Seconds (MAC_PPS1_Target_Time_Seconds) and MAC PPS1 Target Time In Nanoseconds (MAC_PPS1_Target_Time_Nanoseconds) mode for the PPS1 output signal. 00b - Target Time registers are programmed only for generating the interrupt event. The flexible PPS function must not be 1 in this mode, otherwise spurious transitions may be observed on the corresponding ptp_pps_o output port. 01b - Reserved 10b - Target Time registers are programmed for generating the interrupt event and starting or stopping the PPS0 output signal generation. 11b - Target Time registers are programmed only for starting or stopping the PPS0 output signal generation. No interrupt is asserted.
12 —	Reserved
11-8 PPSCMD1	Flexible PPS1 Output Control Controls the flexible PPS1 output (ptp_pps_o[1]) signal. The functioning of this field is similar to that of the PPSCMD0 field.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If MCGREN1 = 1, the bits included in PPSCMD1 [11:8] are considered as presentation time control bits for media clock generation and recovery for comparator instance 1. The functioning of PPSCMD1 is similar to that of the PPSCMD0 presentation time control bits. If MCGREN1 is not 1, only three bits [10:8] are used as PPSCMD1 and the fourth bit becomes 0. Access restrictions apply to this field that clears automatically. Writing 0 to it has no effect.
7 MCGREN0	MCGR Mode Enable For PPS0 Output Indictaes whether the 0th PPS instance is enabled to operate in PPS or MCGR mode. If this field is 1, it operates in MCGR mode, and if the value is 0, it operates in PPS mode. 0b - PPS mode 1b - MCGR mode
6-5 TRGTMODSEL0	Target Time Register Mode For PPS0 Output Indicates MAC PPS0 Target Time In Seconds (MAC_PPS0_Target_Time_Seconds) and MAC PPS0 Target Time In Nanoseconds (MAC_PPS0_Target_Time_Nanoseconds) mode for the PPS0 output signal. 00b - Target Time registers are programmed only for generating the interrupt event. The flexible PPS function must not be 1 in this mode, otherwise spurious transitions may be observed on the corresponding ptp_pps_o output port. 01b - Reserved 10b - Target Time registers are programmed for generating the interrupt event and starting or stopping the PPS0 output signal generation. 11b - Target Time registers are programmed only for starting or stopping the PPS0 output signal generation. No interrupt is asserted.
4 PPSEN0	Flexible PPS Output Mode Enable 0 Indicates the status of Flexible PPS Output mode. • If this field is 1, the PPSCTRL_PPSCMD field functions as PPSCMD. • If this field is 0, the PPSCTRL_PPSCMD field functions as PPSCTRL (fixed PPS mode). 0b - Disabled 1b - Enabled
3-0 PPSCTRL_PPSCMD	PPS Output Frequency Control Controls the frequency of the PPS0 output (ptp_pps_o[0] signal). The default value of this field is 0, and the PPS output is 1 pulse (of width clk_ptp_i) every second. For the other values of PPSCTRL, the PPS output becomes a generated clock having these frequencies: • 0001: The binary rollover is 2 Hz, and the digital rollover is 1 Hz. • 0010: The binary rollover is 4 Hz, and the digital rollover is 2 Hz. • 0011: The binary rollover is 8 Hz, and the digital rollover is 4 Hz. • 0100: The binary rollover is 16 Hz, and the digital rollover is 8 Hz.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• .. • 1111: The binary rollover is 32.768 kHz and the digital rollover is 16.384 kHz. **NOTE** In Binary Rollover mode, the PPS output (ptp_pps_o) has a duty cycle of 50 percent with these frequencies. In Digital Rollover mode, the PPS output frequency is an average number. The actual clock has a different frequency that is synchronized every second. For example, • If PPSCTRL = 0001, PPS (1 Hz) has a low period of 537 ms and a high period of 463 ms. • If PPSCTRL = 0010, PPS (2 Hz) is a sequence of one clock of 50 percent duty cycle and a 537 ms period. The second clock has a period of 463 ms (268 ms low and 195 ms high). • If PPSCTRL = 0011, PPS (4 Hz) is a sequence of three clocks of 50 percent duty cycle and a 268 ms period, and the fourth clock of 195 ms period (134 ms low and 61 ms high). This behavior is a result of the non-linear toggling of bits in Digital Rollover mode in MAC System Time In Nanoseconds (MAC_System_Time_Nanoseconds) or flexible PPS output (ptp_pps_o[0]) control. Programming these bits with a non-zero value instructs MAC to initiate an event. When the command is transferred or synchronized with the PTP clock domain, these bits automatically become 0. You must ensure that these bits are programmed only when they are "all-zero." The following list describes the values of PPSCMD0. • 0000: No command • 0001: Start a single pulse. This command generates a single pulse rising at the start point defined in MAC PPS0 Target Time In Seconds (MAC_PPS0_Target_Time_Seconds) and MAC PPS0 Target Time In Nanoseconds (MAC_PPS0_Target_Time_Nanoseconds), for a duration defined in MAC PPS0 Width (MAC_PPS0_Width). • 0010: Start pulse train. This command generates the train of pulses rising at the start point defined in the Target Time registers and for a duration defined in MAC PPS0 Width (MAC_PPS0_Width), repeated at an interval defined in the PPS Interval registers. By default, the PPS pulse train runs freely unless the "stop pulse train at time" or "stop pulse train immediately" command stops it. • 0011: Cancel start. This command cancels the start single pulse and start pulse train commands if the system time has not crossed the programmed start time. • 0100: Stop pulse train at time. This command stops the train of pulses that the start pulse train command (PPSCMD = 0010) initiates after the time programmed in the Target Time registers elapses. • 0101: Stop pulse train immediately. This command immediately stops the train of pulses that the start pulse train command (PPSCMD = 0010) initiates. • 110: Cancel stop pulse train. This command cancels the stop pulse train at the time command if the programmed stop time has not elapsed. The PPS pulse train runs freely if the command executes successfully. • 0111-1111: Reserved or presentation time control. If MAC_PPS_Control[MCGREN0] = 0, then these are treated as presentation time control bits. This list describes the values of PPSCMD0:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• 0000: The MCGR operation is not carried out. If set to this value in the mid of clock recovery or generation, all the processing inputs are flushed. • 0001: Captures the presentation time at the rising edge of mcg_pst_trig_i[0] in MAC PPS0 Target Time In Seconds (MAC_PPS0_Target_Time_Seconds) • 0010: Captures the presentation time at the falling edge of mcg_pst_trig_i[0] in MAC PPS0 Target Time In Seconds (MAC_PPS0_Target_Time_Seconds) • 0011: Captures the presentation time at both the edges of mcg_pst_trig_i[0] in MAC PPS0 Target Time In Seconds (MAC_PPS0_Target_Time_Seconds) • 0100-1000: Reserved • 1001: Toggle output on compare • 1010: Pulse output low on compare for one PTP-clock cycle • 1011: Pulse output high on compare for one PTP-clock cycle • 1100-1111: Reserved

72.18.168 MAC PPS0 Target Time In Seconds (MAC_PPS0_Target_Time_Seconds)

Offset

Register	Offset
MAC_PPS0_Target_Time_Seconds	B80h

Function

Is used, along with the PPS Target Time Nanoseconds register, to schedule an interrupt event (MAC_Timestamp_Status[TSTARGT0]) when the system time exceeds the value programmed in these registers.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	TSTRH0															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 TSTRH0	PPS Target Time In Seconds Register Stores the target time in seconds. When the timestamp value matches or exceeds both the Target Timestamp registers, MAC starts or stops the PPS signal output and generates an interrupt (if enabled), based on Target Time mode selected for the corresponding PPS output in MAC PPS Control (MAC_PPS_Control). If DWC_EQOS_FLEXI_PPS_OUT_EN is enabled in the configuration and MAC_Timestamp_Control[PTGE] = 1, with the presentation time control set in Recovery mode, these fields indicate that the application programs the TPT. In Generation mode, it indicates that CPT is generated at the sampled trigger.

72.18.169 MAC PPS0 Target Time In Nanoseconds (MAC_PPS0_Target_Time_Nanoseconds)

Offset

Register	Offset
MAC_PPS0_Target_Time_Nanoseconds	B84h

Function
Indicates the target time in nanoseconds for PPS0.

Fields

Field	Function
31 TRGTBUSY0	PPS Target Time Busy Status 0 Indicates whether the PPS target time busy status 0 is detected.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• MAC writes 1 to this field when MAC_PPS_Control[PPSCTRL_PPSCMD] is programmed to 010 or 011. This instructs MAC to synchronize the Target Time registers with the PTP clock domain. • MAC writes 0 to this field after synchronizing the Target Time registers with the PTP clock domain. The application must not update the Target Time registers when this field is read as 1. Otherwise, the synchronization of the previously programmed time is corrupted. 0b - Not detected 1b - Detected
30-0 TTSL0	Target Time Low For PPS0 Stores the time in (signed) nanoseconds. If the value of the timestamp matches the value in both the Target Timestamp registers, MAC starts or stops the PPS signal output and generates an interrupt, if enabled, based on MAC_PPS_Control[TRGTMODSEL0]. • If MAC_Timestamp_Control[TSCTRLSSR] = 0, this value must be calculated as (time in ns / 0.465). The actual start or stop time of the PPS signal output might have an error margin up to one unit of the sub-second increment value. • If MAC_Timestamp_Control[TSCTRLSSR] = 1, this value must not exceed 3B9A_C9FFh. The actual start or stop time of the PPS signal output might have an error margin up to one unit of the sub-second increment value. Access restriction apply to this field that clears automatically. Writing 0 to it has no effect.

72.18.170 MAC PPS0 Interval (MAC_PPS0_Interval)

Offset

Register	Offset
MAC_PPS0_Interval	B88h

Function

Contains the number of units of the sub-second increment value between the rising edges of the PPS0 signal output (ptp_pps_o[0]).

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	PPSINT0															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 PPSINT0	PPS Output Signal Interval 0 Stores the interval between the rising edges of the PPS0 signal output. The interval is stored in terms of the number of units of the sub-second increment value. You must program one value less than the required interval. For example, if the PTP reference clock is 50 MHz (period of 20 ns), and the desired interval between the rising edges of the PPS0 signal output is 100 ns (that is, five units of the sub-second increment value), you must program value 4 (5-1) in this register.

72.18.171 MAC PPS0 Width (MAC_PPS0_Width)

Offset

Register	Offset
MAC_PPS0_Width	B8Ch

Function

Contains the number of units of the sub-second increment value between the rising and corresponding falling edges of the PPS0 signal output (ptp_pps_o[0]).

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	PPSWIDTH0															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 PPSWIDTH0	PPS Output Signal Width 0 Stores the width between the rising and corresponding falling edges of the PPS0 signal output. The width is stored in terms of the number of units of the sub-second increment value. You must program one value less than the required interval. For example, if the PTP reference clock has a frequency of 50 MHz (period of 20 ns), and a width between the rising and corresponding falling edges of the PPS0 signal output is 80 ns (that is, four units of the sub-second increment value), you should program value 3 (4-1) in this register. **NOTE** The value programmed in this register must be lesser than the value programmed in MAC PPS0 Interval (MAC_PPS0_Interval).

72.18.172 MAC PPS1 Target Time In Seconds (MAC_PPS1_Target_Time_Seconds)

Offset

Register	Offset
MAC_PPS1_Target_Time_Seconds	B90h

Function
Is used to schedule an interrupt event (MAC_Timestamp_Status[TSTARGT0]), along with the PPS Target Time Nanoseconds register, when the system time exceeds the value programmed in these registers.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-0	PPS Target Time In Seconds 1

Table continues on the next page...

Field	Function
TSTRH1	Stores the target time in seconds. When the timestamp value matches or exceeds both the Target Timestamp registers, MAC starts or stops the PPS signal output and generates an interrupt, if enabled, based on Target Time mode selected for the corresponding PPS output in MAC PPS Control (MAC_PPS_Control). If DWC_EQOS_FLEXI_PPS_OUT_EN is enabled in the configuration and MAC_Timestamp_Control[PTGE] = 1, with the presentation time control set in Recovery mode, these fields indicate that the application programs the TPT. In Generation mode, it indicates that CPT is generated at the sampled trigger.

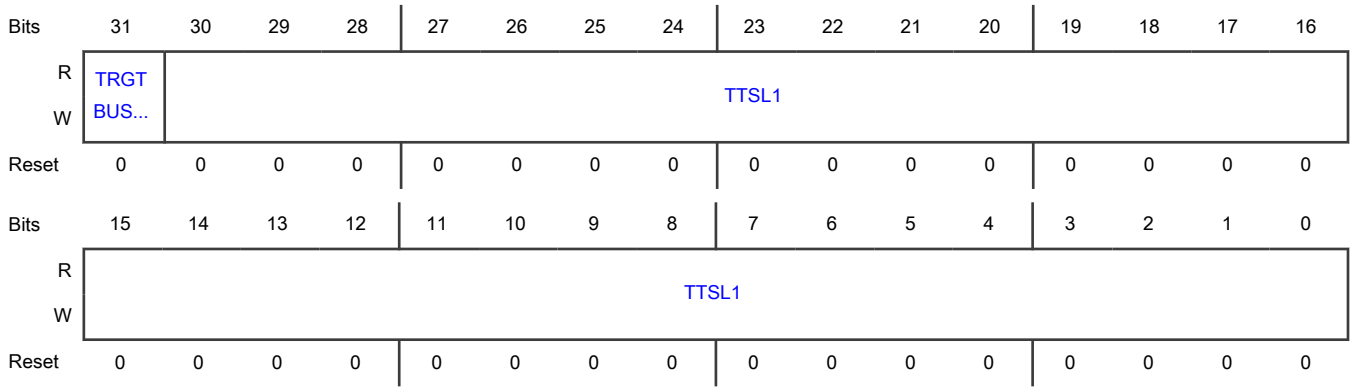
72.18.173 MAC PPS1 Target Time In Nanoseconds (MAC_PPS1_Target_Time_Nanoseconds)

Offset

Register	Offset
MAC_PPS1_Target_Time_Nanoseconds	B94h

Function
Indicates the target time in nanoseconds for PPS1.

Diagram



Fields

Field	Function
31 TRGTBUSY1	PPS Target Time Busy Status 1 Indicates whether the PPS target time busy status 1 is detected. • MAC writes 1 to this field when MAC_PPS_Control[PPSCTRL_PPSCMD] is programmed to 010 or 011. Programming the PPSCMD0 field as 010 or 011 instructs MAC to synchronize the Target Time registers with the PTP clock domain.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• MAC writes 0 to this field after synchronizing the Target Time registers with the PTP clock domain. The application must not update the Target Time registers when this field is read as 1. Otherwise, the synchronization of the previously programmed time is corrupted. 0b - Not detected 1b - Detected
30-0 TTSL1	Target Time Low For PPS1 Stores the time in (signed) nanoseconds. If the value of the timestamp matches the value in both the Target Timestamp registers, MAC starts or stops the PPS signal output and generates an interrupt, if enabled, based on MAC_PPS_Control[TRGTMODSEL0]. • If MAC_Timestamp_Control[TSCTRLSSR] = 0, this value must be defined as (time in ns / 0.465). The actual start or stop time of the PPS signal output might have an error margin up to one unit of the sub-second increment value. • If MAC_Timestamp_Control[TSCTRLSSR] = 1, this value must not exceed 3B9A_C9FFh. The actual start or stop time of the PPS signal output might have an error margin up to one unit of the sub-second increment value. Access restriction apply to this field that clears automatically. Writing 0 to it has no effect.

72.18.174 MAC PPS1 Interval (MAC_PPS1_Interval)

Offset

Register	Offset
MAC_PPS1_Interval	B98h

Function

Contains the number of units of the sub-second increment value between the rising edges of the PPS0 signal output (ptp_pps_o[0]).

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	PPSINT1															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 PPSINT1	PPS Output Signal Interval 1 Stores the interval between the rising edges of the PPS0 signal output. The interval is stored in terms of the number of units of the sub-second increment value. You must program one value less than the required interval. For example, if the PTP reference clock is 50 MHz (period of 20 ns), and the desired interval between the rising edges of the PPS0 signal output is 100 ns (that is, five units of the sub-second increment value), you must program value 4 (5-1) in this register.

72.18.175 MAC PPS1 Width (MAC_PPS1_Width)

Offset

Register	Offset
MAC_PPS1_Width	B9Ch

Function

Contains the number of units of the sub-second increment value between the rising and corresponding falling edges of the PPS0 signal output (ptp_pps_o[0]).

Diagram

Fields

Field	Function
31-0 PPSWIDTH1	PPS Output Signal Width 1 Stores the width between the rising and corresponding falling edges of the PPS0 signal output. The width is stored in terms of the number of units of the sub-second increment value. You must program one value less than the required interval. For example, if the PTP reference clock has a frequency of 50 MHz (period of 20 ns), and a width between the rising and corresponding falling edges of the PPS0 signal output is 80 ns (that is, four units of the sub-second increment value), you should program value 3 (4-1) in this register.

Table continues on the next page...

Field	Function
	NOTE The value programmed in this register must be lesser than the value programmed in MAC PPS0 Interval (MAC_PPS0_Interval).

72.18.176 MAC PPS2 Taget Time In Seconds (MAC_PPS2_Target_Time_Seconds)

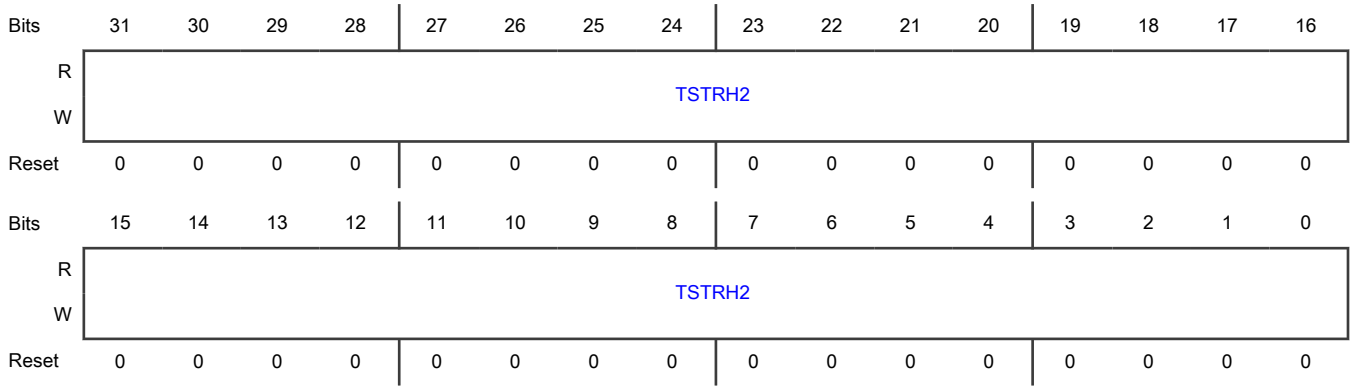
Offset

Register	Offset
MAC_PPS2_Target_Time_Seconds	BA0h

Function

Is used to schedule an interrupt event (MAC_Timestamp_Status[TSTARGT0]), along with the PPS Target Time Nanoseconds register, when the system time exceeds the value programmed in these registers.

Diagram



Fields

Field	Function
31-0 TSTRH2	PPS Target Time In Seconds 2 Stores the target time in seconds. When the timestamp value matches or exceeds both the Target Timestamp registers, MAC starts or stops the PPS signal output and generates an interrupt, if enabled, based on Target Time mode selected for the corresponding PPS output in MAC PPS Control (MAC_PPS_Control). If DWC_EQOS_FLEXI_PPS_OUT_EN is enabled in the configuration and MAC_Timestamp_Control[PTGE] = 1, with the presentation time control set in Recovery mode, these fields indicate that the application programs the TPT. In Generation mode, it indicates that CPT is generated at the sampled trigger.

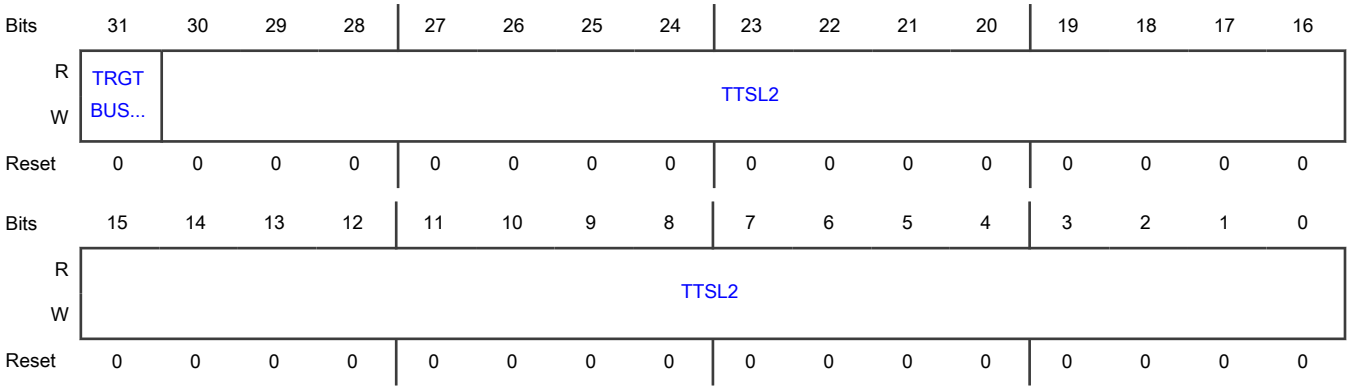
72.18.177 MAC PPS2 Target Time In Nanoseconds (MAC_PPS2_Target_Time_Nanoseconds)

Offset

Register	Offset
MAC_PPS2_Target_Time_Nanoseconds	BA4h

Function
Indicates the target time in nanoseconds for PPS2.

Diagram



Fields

Field	Function
31 TRGTBUSY2	PPS Target Time Busy Status 2 Indicates whether the PPS target time busy status 2 is detected. • MAC writes 1 to this field when MAC_PPS_Control[PPSCTRL_PPSCMD] is programmed to 010 or 011. This instructs MAC to synchronize the Target Time registers with the PTP clock domain. • MAC writes 0 to this field after synchronizing the Target Time registers with the PTP clock domain. The application must not update the Target Time registers when this field is read as 1. Otherwise, the synchronization of the previously programmed time is corrupted. 0b - Not detected 1b - Detected
30-0 TTSL2	Target Time Low For PPS2 Stores the time in (signed) nanoseconds. If the value of the timestamp matches the value in both the Target Timestamp registers, MAC starts or stops the PPS signal output and generates an interrupt, if enabled, based on MAC_PPS_Control[TRGTMODSEL0].

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• If MAC_Timestamp_Control[TSCTRLSSR] = 0, this value must be defined as (time in ns / 0.465). The actual start or stop time of the PPS signal output might have an error margin up to one unit of the sub-second increment value. • If MAC_Timestamp_Control[TSCTRLSSR] = 1, this value must not exceed 3B9A_C9FFh. The actual start or stop time of the PPS signal output might have an error margin up to one unit of the sub-second increment value. Access restriction apply to this field that clears automatically. Writing 0 to it has no effect.

72.18.178 MAC PPS2 Interval (MAC_PPS2_Interval)

Offset

Register	Offset
MAC_PPS2_Interval	BA8h

Function

Contains the number of units of the sub-second increment value between the rising edges of the PPS0 signal output (ptp_pps_o[0]).

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	PPSINT2															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 PPSINT2	PPS Output Signal Interval 2 Stores the interval between the rising edges of the PPS0 signal output. The interval is stored in terms of the number of units of the sub-second increment value. You must program one value less than the required interval. For example, if the PTP reference clock is 50 MHz (period of 20 ns), and the desired interval between the rising edges of the PPS0 signal output is 100 ns (that is, five units of the sub-second increment value), you must program value 4 (5-1) in this register.

72.18.179 MAC PPS2 Width (MAC_PPS2_Width)

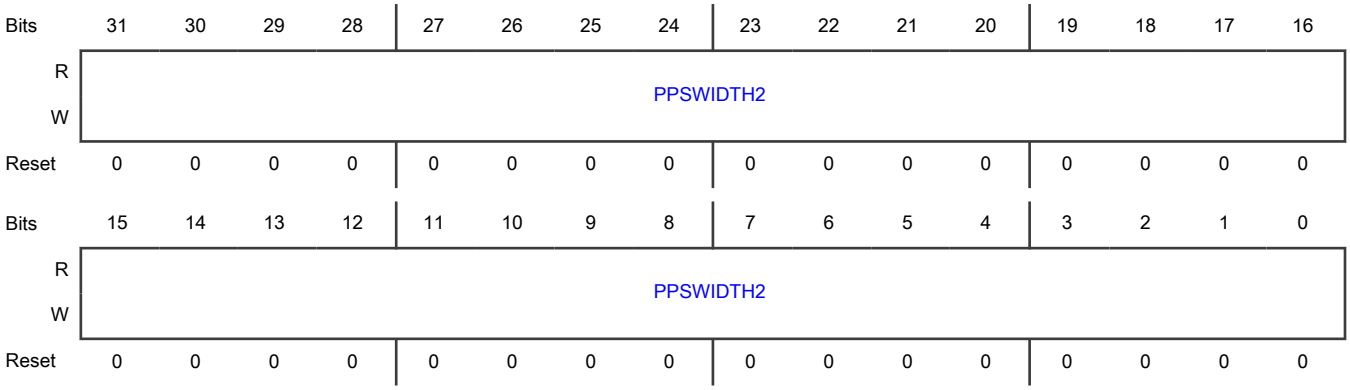
Offset

Register	Offset
MAC_PPS2_Width	BACh

Function

Contains the number of units of the sub-second increment value between the rising and corresponding falling edges of the PPS0 signal output (ptp_pps_o[0]).

Diagram



Fields

Field	Function
31-0 PPSWIDTH2	PPS Output Signal Width 2 Stores the width between the rising and corresponding falling edges of the PPS0 signal output. The width is stored in terms of the number of units of the sub-second increment value. You must program one value less than the required interval. For example, if the PTP reference clock has a frequency of 50 MHz (period of 20 ns), and a width between the rising and corresponding falling edges of the PPS0 signal output is 80 ns (that is, four units of the sub-second increment value), you should program value 3 (4-1) in this register. **NOTE** The value programmed in this register must be lesser than the value programmed in MAC PPS0 Interval (MAC_PPS0_Interval).

72.18.180 MAC PPS3 Target Time In Seconds (MAC_PPS3_Target_Time_Seconds)

Offset

Register	Offset
MAC_PPS3_Target_Time_Seconds	BB0h

Function

Is used to schedule an interrupt event (MAC_Timestamp_Status[TSTARGT0]), along with the PPS Target Time Nanoseconds register, when the system time exceeds the value programmed in these registers.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-0 TSTRH3	PPS Target Time In Seconds 3 Stores the target time in seconds. When the timestamp value matches or exceeds both the Target Timestamp registers, MAC starts or stops the PPS signal output and generates an interrupt, if enabled, based on Target Time mode selected for the corresponding PPS output in MAC PPS Control (MAC_PPS_Control). If DWC_EQOS_FLEXI_PPS_OUT_EN is enabled in the configuration and MAC_Timestamp_Control[PTGE] = 1, with the presentation time control set in Recovery mode, these fields indicate that the application programs the TPT. In Generation mode, it indicates that CPT is generated at the sampled trigger.

72.18.181 MAC PPS3 Target Time In Nanoseconds (MAC_PPS3_Target_Time_Nanoseconds)

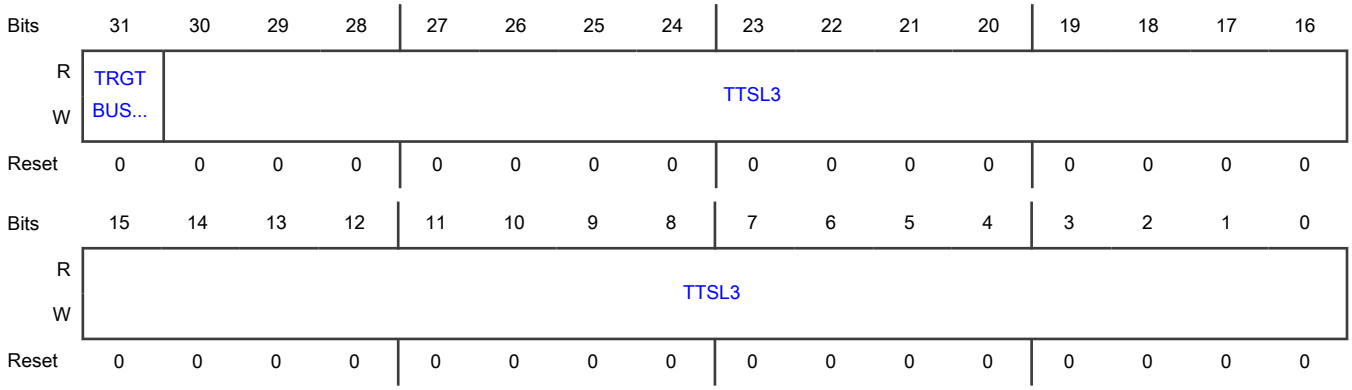
Offset

Register	Offset
MAC_PPS3_Target_Time_Nanoseconds	BB4h

Function

Indicates the target time in nanoseconds for PPS3.

Diagram



Fields

Field	Function
31 TRGTBUSY3	PPS Target Time Register Busy 3 Indicates whether the PPS target time register busy status is detected. MAC writes 1 to this field when MAC_PPS_Control[PPSCTRL_PPSCMD] is programmed to 010 or 011. This instructs MAC to synchronize the Target Time registers with the PTP clock domain. MAC writes 0 to this field after synchronizing the Target Time registers with the PTP clock domain. The application must not update the Target Time registers when this field is read as 1. Otherwise, the synchronization of the previously programmed time is corrupted. 0b - Not detected 1b - Detected
30-0 TTSL3	Target Time Low For PPS3 Stores the time in (signed) nanoseconds. If the value of the timestamp matches the value in both the Target Timestamp registers, MAC starts or stops the PPS signal output and generates an interrupt, if enabled, based on MAC_PPS_Control[TRGTMODSEL0]. • If MAC_Timestamp_Control[TSCTRLSSR] = 0, this value must be defined as (time in ns / 0.465). The actual start or stop time of the PPS signal output might have an error margin up to one unit of the sub-second increment value. • If MAC_Timestamp_Control[TSCTRLSSR] = 1, this value must not exceed 3B9A_C9FFh. The actual start or stop time of the PPS signal output might have an error margin up to one unit of the sub-second increment value. Access restriction apply to this field that clears automatically. Writing 0 to it has no effect.

72.18.182 MAC PPS3 Interval (MAC_PPS3_Interval)

Offset

Register	Offset
MAC_PPS3_Interval	BB8h

Function

Contains the number of units of the sub-second increment value between the rising edges of the PPS0 signal output (ptp_pps_o[0]).

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-0 PPSINT3	PPS Output Signal Interval Stores the interval between the rising edges of the PPS0 signal output. The interval is stored in terms of the number of units of the sub-second increment value. You must program one value less than the required interval. For example, if the PTP reference clock is 50 MHz (period of 20 ns), and the desired interval between the rising edges of the PPS0 signal output is 100 ns (that is, five units of the sub-second increment value), you must program value 4 (5-1) in this register.

72.18.183 MAC PPS3 Width (MAC_PPS3_Width)

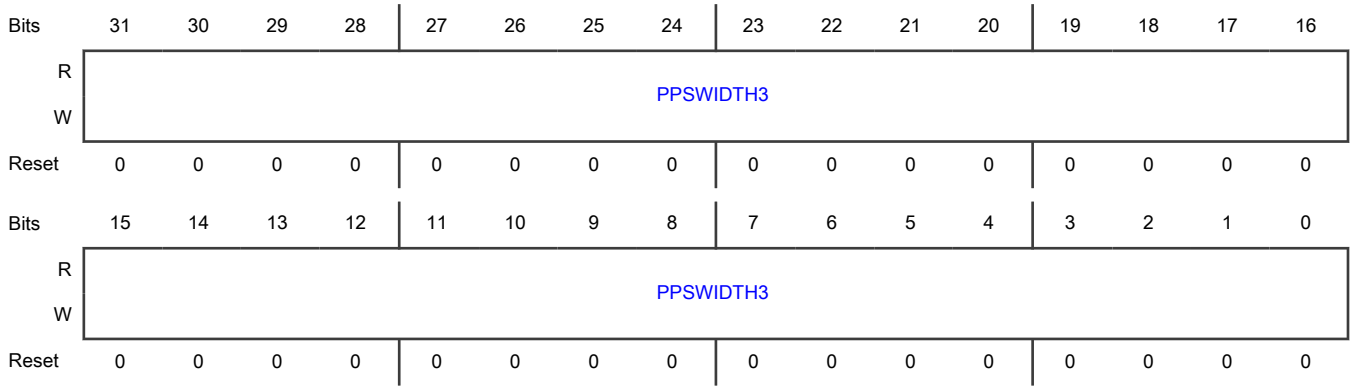
Offset

Register	Offset
MAC_PPS3_Width	BBCh

Function

Contains the number of units of the sub-second increment value between the rising and corresponding falling edges of the PPS0 signal output (ptp_pps_o[0]).

Diagram



Fields

Field	Function
31-0 PPSWIDTH3	PPS Output Signal Width 3 Stores the width between the rising and corresponding falling edges of the PPS0 signal output. The width is stored in terms of the number of units of the sub-second increment value. You must program one value less than the required interval. For example, if the PTP reference clock has a frequency of 50 MHz (period of 20 ns), and a width between the rising and corresponding falling edges of the PPS0 signal output is 80 ns (that is, four units of the sub-second increment value), you should program value 3 (4-1) in this register. **NOTE** The value programmed in this register must be lesser than the value programmed in MAC PPS0 Interval (MAC_PPS0_Interval).

72.18.184 MTL Operation Mode (MTL_Operation_Mode)

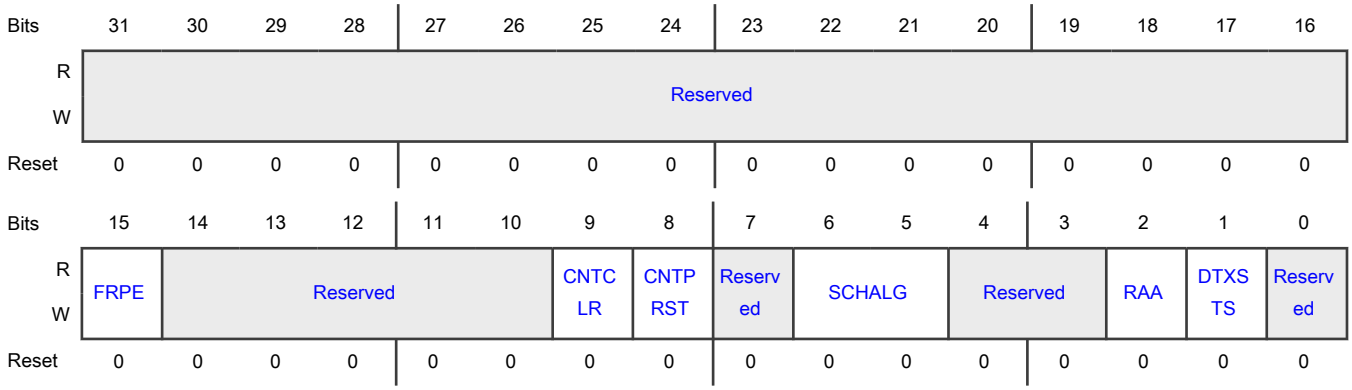
Offset

Register	Offset
MTL_Operation_Mode	C00h

Function

Establishes the transmit and receive operating modes and commands.

Diagram



Fields

Field	Function
31-16 —	Reserved
15 FRPE	Flexible Receive Parser Enable Indicates the status of the flexible receive parser. • If this field is 1, the programmable receive parser functionality is enabled. • If the receive parser is disabled and is in the middle of parsing, the receive parser functionality is disabled only after completing the current packet parsing. When the receive parser is enabled from the disabled state, the receive parser is activated for the next immediate packet. 0b - Disabled 1b - Enabled
14-10 —	Reserved
9 CNTCLR	Counters Reset Indicates whether the counters are reset. • If this field is 1, all the counters are reset. The field cleares automatically after one clock cycle. • If you write 1 to this field along with the CNTPRST field, the CNT_PRESET field takes precedence. Access restrictions apply to this field that clears automatically. Writing 0 to it has no effect. 0b - Not reset 1b - Reset
8 CNTPRST	Counters Preset Indicates the status of preset counters. If this field is 1,

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• MTL Tx Queue 0 Underflow (MTL_TxQ0_Underflow)[bits 0-7] is initialized or preset to 12'h7F0. • Missed packet and overflow packet counters in MTL Rx Queue Missed Packet Overflow Count (MTL_RxQ0_Missed_Packet_Overflow_Cnt)[bits 0-7] are initialized or preset to 12'h7F0. Access restrictions apply to this field that clears automatically. Writing 0 to it has no effect. 0b - Disabled 1b - Enabled
7 —	Reserved
6-5 SCHALG	Transmit Scheduling Algorithm Indicates the algorithm for transmit scheduling. 00b - WRR algorithm 01b - WFQ algorithm when DCB feature selected; otherwise, reserved 10b - DWRR algorithm when DCB feature selected; otherwise, reserved 11b - Strict priority algorithm
4-3 —	Reserved
2 RAA	Receive Arbitration Algorithm Is used to select the arbitration algorithm for the receive side. Queue 0 has the lowest priority and the last queue has the highest priority. 0b - Strict priority (SP) 1b - Weighted strict priority (WSP)
1 DTXSTS	Drop Transmit Status Indicates whether the drop transmit status is enabled. • If this field is 1, the transmit packet status received from MAC is dropped in MTL. • If this field is 0, the transmit packet status received from MAC is forwarded to the application. 0b - Disabled 1b - Enabled
0 —	Reserved

72.18.185 MTL Debug Control (MTL_DBG_CTL)

Offset

Register	Offset
MTL_DBG_CTL	C08h

Function

Controls, along with MTL Debug Status (MTL_DBG_STS), the operation mode of FIFO debug access.

Diagram

18-17 EIEC	ECC Inject Error Control Indicates the status of the ECC inject error control feature for transmit, receive, and TSO memories. If EIEE = 1, following are the errors inserted based on the value encoded in this field. 00b - 1-bit error 01b - 2-bit errors 10b - 3-bit errors 11b - 1-bit error in the address field
16 EIEE	ECC Inject Error Enable Indicates the status of the ECC error injection feature for transmit, receive, and TSO memories. • If the value if this field is 1, it enables the ECC error injection feature. • If the value if this field is 0, it disables the ECC error injection feature. 0b - Disabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Enabled
15 STSIE	Transmit Status Available Interrupt Status Enable Indicates whether the transmit packet available interrupt status is enabled. If this field is 1, an interrupt is generated when transmit status is available in Slave mode. 0b - Disabled 1b - Enabled
14 PKTIE	Receive Packet Available Interrupt Status Enable Indicates whether the receive packet available interrupt status is enabled. If this field is 1, an interrupt is generated when EOP of the received packet is written to the receive FIFO. 0b - Disabled 1b - Enabled
13-12 FIFOSEL	FIFO Selected for Access Indicates the FIFO selected for debug access. 00b - Transmit FIFO 01b - Transmit status FIFO (only read access when SLVMOD is set) 10b - TSO FIFO (cannot be accessed when SLVMOD is set) 11b - Receive FIFO
11 FIFOWREN	FIFO Write Enable Indicates the status of FIFO write. If this field is 1, it enables the write operation on the selected FIFO when FIFO debug access is enabled. This field must not be written to 1 when FIFO debug access is disabled, that is, when FDBGEN = 0. Access restrictions apply to this field that clears automatically. Also, writing 0 to the field clears it and writing 1 sets it. 0b - Disabled 1b - Enabled
10 FIFORDEN	FIFO Read Enable Indicates the status of FIFO read. If this field is 1, it enables the read operation on the selected FIFO when FIFO debug access is enabled. This field must not be written to 1 when FIFO debug access is disabled, that is, when FDBGEN = 0. Access restrictions apply to this field that clears automatically. Also, writing 0 to the field clears it and writing 1 sets it. 0b - Disabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Enabled
9 RSTSEL	Reset Pointers Of Selected FIFO Indicates whether the resetting of pointers for the selected FIFO is enabled. If this field is 1, the pointers of the currently selected FIFO are reset when FIFO debug access is enabled. This field must not be written to 1 when FIFO debug access is disabled, that is, when FDBGEN = 0. Access restrictions apply to this field that clears automatically. Also, writing 0 to the field clears it and writing 1 sets it. 0b - Disabled 1b - Enabled
8 RSTALL	Reset All Pointers Indicates whether the resetting of all the pointers is enabled. If this field is 1, the pointers of all the FIFOs are reset when the FIFO debug access is enabled. This field must not be written to 1 when FIFO debug access is disabled, that is, when FDBGEN = 0. Access restrictions apply to this field that clears automatically. Also, writing 0 to the field clears it and writing 1 sets it. 0b - Disabled 1b - Enabled
7 —	Reserved
6-5 PKTSTATE	Encoded Packet State Is used to write the control information to the transmit FIFO or receive FIFO. These are the values related to the transmit FIFO: • 00: Packet data • 01: Control word • 10: SOP data • 11: EOP data These are the values related to the receive FIFO: • 00: Packet data • 01: Normal status • 10: Last status • 11: EOP 00b - Packet data

Table continues on the next page...

Table continued from the previous page...

Field	Function
	01b - Control word/normal status 10b - SOP data/last status 11b - EOP data/EOP
4 —	Reserved
3-2 BYTEEN	Byte Enables Indicates the number of data bytes valid in the data register during a write operation. This is valid only when MTL_DBG_STS[PKTSTATE] is 2'b10 (EOP), and the transmit FIFO or receive FIFO is selected. 00b - Byte 0 valid 01b - Byte 0 and byte 1 valid 10b - Byte 0, byte 1, and byte 2 valid 11b - All four bytes valid
1 DBGMOD	Debug Mode Access to FIFO Indicates the status of Debug mode access to FIFO. If this field is 1, it indicates that the current access to FIFO is read, write, and debug. In this mode, the following access types are allowed: • Read and write access to transmit FIFO, TSO FIFO, and receive FIFO • Read access to transmit status FIFO If this field is 0, it indicates that the current access to FIFO is slave access bypassing DMA. In this mode, the following access types are allowed: • Write access to transmit FIFO • Read access to receive FIFO and transmit status FIFO 0b - Disabled 1b - Enabled
0 FDBGEN	FIFO Debug Access Enable Indicates the status of FIFO debug access. • If this field is 1, it indicates that the FIFO debug mode access is enabled. • If the value of the field is 0, it indicates that FIFO can be accessed only through a master interface. 0b - Disabled 1b - Enabled

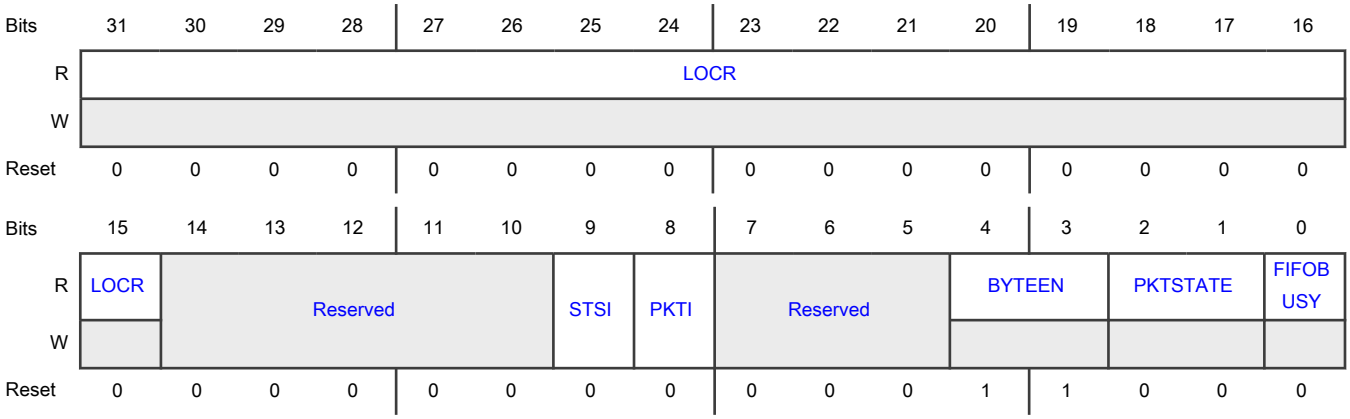
72.18.186 MTL Debug Status (MTL_DBG_STS)

Offset

Register	Offset
MTL_DBG_STS	C0Ch

Function
Contains the status of FIFO debug access.

Diagram



Fields

Field	Function
31-15 LOCR	Remaining Locations In FIFO Indicates the remaining locations in FIFO. For Slave Access mode, the field indicates the space available in the selected FIFO, and for Debug Access mode, this field contains the write or read pointer value of the selected FIFO during the write or read operation, respectively. Reset: In single transmit queue configurations, (DWC_EQOS_TXFIFO_SIZE/(DWC_EQOS_DATAWIDTH/8)), otherwise 0000h.
14-10 —	Reserved
9 STSI	Transmit Status Available Interrupt Status Indicates whether the transmit status available interrupt status is detected. If this field is 1, it indicates that Slave mode transmit packet is transmitted, and the status is available in transmit status FIFO. The field resets when you write 1 to it. 0b - Not detected 1b - Detected
8	Receive Packet Available Interrupt Status

Table continues on the next page...

Table continued from the previous page...

Field	Function
PKTI	Indicates whether the receive packet available interrupt status is detected. If this field is 1, it indicates that the MAC layer has written the EOP of the received packet to the receive FIFO. The field resets when you write 1 to it. 0b - Not detected 1b - Detected
7-5 —	Reserved
4-3 BYTEEN	Byte Enables Indicates the number of data bytes valid in the data register during a read operation. This is valid only when MTL_DBG_STS[PKTSTATE] is 2'b10 (EOP), and the transmit FIFO or receive FIFO is selected. 00b - Byte 0 valid 01b - Byte 0 and byte 1 valid 10b - Byte 0, byte 1, and byte 2 valid 11b - All four bytes valid
2-1 PKTSTATE	Encoded Packet State Is used to get the control or status information of the selected FIFO. These are the values related to the transmit FIFO. • 00: Packet data • 01: Control word • 10: SOP data • 11: EOP data These are the values related to the receive FIFO. • 00: Packet data • 01: Normal status • 10: Last status • 11: EOP This field is applicable only for transmit and receive FIFOs during a read operation. 00b - Packet data 01b - Control word/normal status 10b - SOP data/last status 11b - EOP data/EOP
0 FIFOBUSY	FIFO Busy Indicates whether the FIFO busy status is detected.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If this field is 1, it indicates that a FIFO operation is in progress in MAC and the content of the following is invalid: • All other fields of this register • All the fields of MTL FIFO Debug Data (MTL_FIFO_Debug_Data) 0b - Not detected 1b - Detected

72.18.187 MTL FIFO Debug Data (MTL_FIFO_Debug_Data)

Offset

Register	Offset
MTL_FIFO_Debug_Data	C10h

Function

Contains the data to be written to or read from the FIFOs.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-0 FDBGDATA	FIFO Debug Data Contains the data to be written to the transmit FIFO, receive FIFO, or TSO FIFO during a debug or slave access write operations. The field contains the data read from the transmit FIFO, receive FIFO, TSO FIFO, or transmit status FIFO during debug or slave access read operations.

72.18.188 MTL Interrupt Status (MTL_Interrupt_Status)

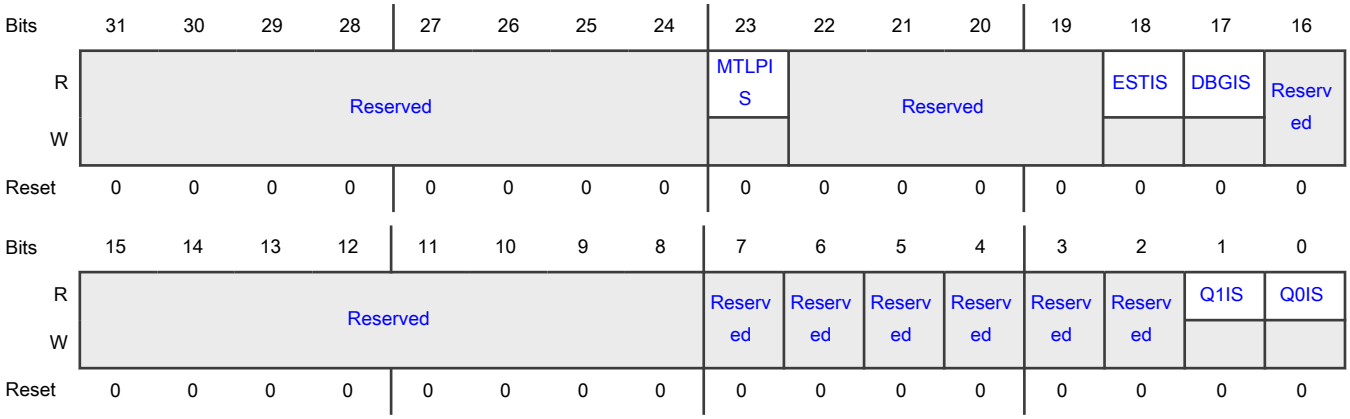
Offset

Register	Offset
MTL_Interrupt_Status	C20h

Function

Determines the interrupt status of MAC and MTL queues. The software driver (application) reads this register during an interrupt service routine or polling to perform this function.

Diagram



Fields

Field	Function
31-24 —	Reserved
23 MTLPIS	MTL Receive Parser Interrupt Status Indicates whether the MTL receive parser interrupt status is detected. This field indicates an interrupt from the receive parser block. To reset this field, the application must read MTL Rx Parser Interrupt Control Status (MTL_RXP_Interrupt_Control_Status) to get the exact cause of the interrupt and clear its source. 0b - Not detected 1b - Detected
22-19 —	Reserved
18 ESTIS	EST (TAS- 802.1Qbv) Interrupt Status Indicates whether the EST (TAS- 802.1Qbv) interrupt status is detected.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field indicates an interrupt event during the operation of 802.1Qbv. To reset the field, the application must clear the error or event that caused the interrupt. 0b - Not detected 1b - Detected
17 DBGIS	Debug Interrupt Status Indicates whether the debug interrupt status is detected. This field indicates an interrupt event during the slave access. To reset the field, the application must read MTL Debug Status (MTL_DBG_STS) to get the exact cause of the interrupt and clear its source. 0b - Not detected 1b - Detected
16 —	Reserved
15-8 —	Reserved
7 —	Reserved
6 —	Reserved
5 —	Reserved
4 —	Reserved
3 —	Reserved
2 —	Reserved
1 Q1IS	Queue 1 Interrupt Status Indicates whether the queue 1 interrupt status is detected. To reset this field, the application must read MTL Queue 1 Interrupt Control Status (MTL_Q1_Interrupt_Control_Status) to get the exact cause of the interrupt and clear its source. 0b - Not detected

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Detected
0 Q0IS	Queue 0 Interrupt Status Indicates whether the queue 0 interrupt status is detected. To reset this field, the application must read MTL Queue 0 Interrupt Control Status (MTL_Q0_Interrupt_Control_Status) to get the exact cause of the interrupt and clear its source. 0b - Not detected 1b - Detected

72.18.189 MTL Receive Queue DMA Map 0 (MTL_RxQ_DMA_Map0)

Offset

Register	Offset
MTL_RxQ_DMA_Map0	C30h

Function
Reserves in EQOS-CORE and EQOS-MTL configurations.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

19-17 —	Reserved.
16 —	Reserved.
15-13 —	Reserved.
12 Q1DDMACH	Queue 1 Enabled for DA-based DMA Channel Selection Enables or disables queue 1 for DA-based DMA channel selection. If this field is 1, it indicates that the packets received in queue 1 are routed to a particular DMA channel as decided in the MAC receiver based on the DMA channel number programmed in the L3-L4 filter registers, or the Ethernet DA address. When this field becomes 0, it indicates that the packets received in queue 1 are routed to the DMA Channel programmed in the MTL_RxQ_DMA_Map0[Q1MDMACH] (bits [10:8]). 0b - Disabled 1b - Enabled
11-9 —	Reserved.
8 Q1MDMACH	Queue 1 Mapped to DMA Channel Controls the routing of the received packet in Queue 1 to the DMA channel: 000b - DMA Channel 0 001b - DMA Channel 1 010b - DMA Channel 2 011b - DMA Channel 3

Table continues on the next page...

Table continued from the previous page...

Field	Function
	100b - DMA Channel 4 101b - DMA Channel 5 110b - DMA Channel 6 111b - DMA Channel 7 This field is valid when the MTL_RxQ_DMA_Map0[Q1DDMACH] resets. The field's width depends on the number of RX DMA channels and in some configurations all the values may not be valid . For example, if two RX DMA channels are selected, then only 000b and 001b are valid, the other bits are reserved.
7-5 —	Reserved.
4 Q0DDMACH	Queue 0 Enabled for DA-based DMA Channel Selection Enables or disables queue 0 for DA-based DMA channel selection. If this field is 1, it indicates that the packets received in queue 0 are routed to a particular DMA channel as decided in the MAC Receiver based on the DMA channel number programmed in the L3-L4 filter registers, or the Ethernet DA address. When this field becomes 0, it indicate that the packets received in queue 0 are routed to the DMA Channel programmed in the MTL_RxQ_DMA_Map0[Q0MDMACH]. 0b - Disable 1b - Enable
3-1 —	Reserved.
0 Q0MDMACH	Queue 0 Mapped to DMA Channel Controls the routing of the packet received in queue 0 to the DMA channel: 000b - DMA channel 0 001b - DMA channel 1 010b - DMA channel 2 011b - DMA channel 3 100b - DMA channel 4 101b - DMA channel 5 110b - DMA channel 6 111b - DMA channel 7 This field is valid when the MTL_RxQ_DMA_Map0[Q0DDMACH] resets.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	The field's width depends on the number of RX DMA channels in some configurations all the values may not be valid. For example, if the number of RX DMA channels selected is 2, only 000 and 001 bits are valid, the other bits are reserved.

72.18.190 MTL TBS Control (MTL_TBS_CTRL)

Offset

Register	Offset
MTL_TBS_CTRL	C40h

Function

Controls the operation of time based scheduling.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	LEOS															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	LEOS								Reserved	LEGOS			Reserved		LEOV	ESTM
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-8 LEOS	Launch Expiry Offset Computes the launch expiry time. To compute the launch expiry time the value in units of 256 nanoseconds is added to the launch time. The field value is valid only if MTL_TBS_CTRL[LEOV] is 1. Max value: 999,999,999 nanosecond should be smaller than CTR-1 value when ESTM mode = 1, because this value is a modulo CTR value.
7 —	Reserved.
6-4	Launch Expiry GSN Offset

Table continues on the next page...

Table continued from the previous page...

Field	Function
LEGOS	Computes the Launch expiry time. To compute the launch expiry time the number of GSN slots is to be added to the launch GSN. The field value is valid only if MTL_TBS_CTRL[LEOV] is 1.
3-2 —	Reserved.
1 LEOV	Launch Expiry Offset Valid Indicates if MTL_TBS_CTRL[LEOS] is valid or invalid. When this field is 1, it indicates that MTL_TBS_CTRL[LEOS] is valid. When not 1, it indicates that the launch expiry Offset is not valid and the MTL must not check for launch expiry time. 0b - Invalid 1b - Valid
0 ESTM	EST offset Mode Enables or disables EST Offset mode. If this field is 1, the launch time value used in Time Based Scheduling is interpreted as an EST offset value and is added to the BTR of the current list. When this field becomes 0, the launch time value is used as an absolute value that must be compared with the system time [39:8]. 0b - Disabled 1b - Enabled

72.18.191 MTL EST Control (MTL_EST_Control)

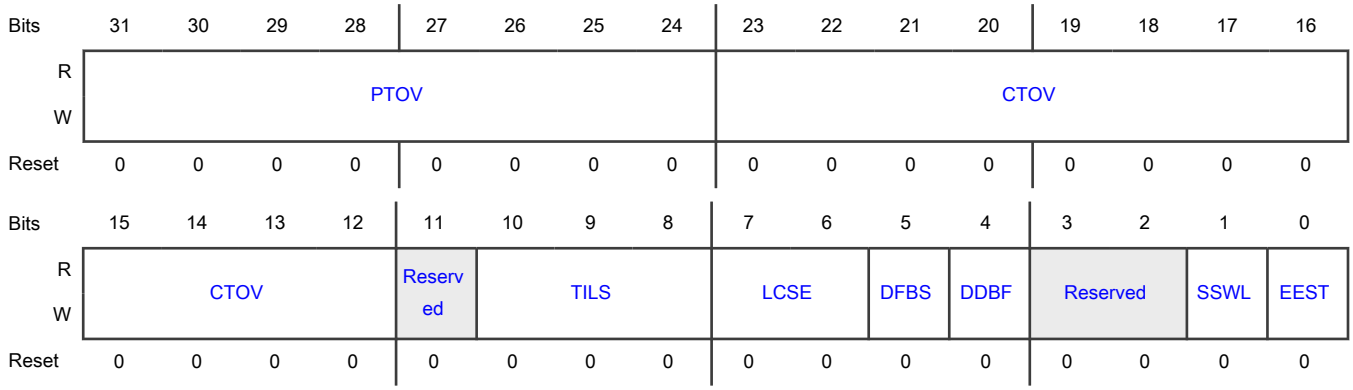
Offset

Register	Offset
MTL_EST_Control	C50h

Function

Controls the operation of enhancements to scheduled transmission (IEEE802.1Qbv).

Diagram



Fields

Field	Function
31-24 PTOV	PTP Time Offset Value Indicates the PTP time offset value. You must multiply 6 to the value of PTP clock period in nanoseconds. At the beginning of the installation of a new GCL this value avoid transmission overruns.
23-12 CTOV	Current Time Offset Value Provides a 12 bit time offset value in nano second which is added to the current time to compensate for all the implementation pipeline delays such as the CDC sync delay, buffering delays, data path delays and so on. This offset ensures that the impact of gate controls is visible on the line exactly at the pre-determined schedule (or as close to the schedule as possible).
11 —	Reserved.
10-8 TILS	Time Interval Left Shift Amount Provides the left shift amount for the programmed time interval values used in the gate control lists. 000b - No left shift needed (equal to x1ns) 001b - Left shift TI by 1 bit (equal to x2ns) 010b - Left shift TI by 2 bits (equal to x4ns) - - 100b - Left shift TI by 7 bits (equal to x128ns) On the basis of configuration you must consider one or more bits of this field as reserved or read-only.
7-6 LCSE	Loop Count to Report Scheduling Error Provides programmable number of GCL list iterations before reporting an HLBS error which is defined in MTL_EST_Status.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	00b - 4 iterations 01b - 8 iterations 10b - 16 iterations 11b - 32 iterations
5 DFBS	Drop Frames Causing Scheduling Error Provides the status of the frames causing scheduling error. If this field is 1 then the frames report to cause an HOL blocking because the MTL_EST_Status[HLBS] is not scheduled after 4,8,16,and 32 (on the basis of MTL_EST_Control[LCSE]) GCL iterations are dropped. 0b - Do not drop frames 1b - Drop frames
4 DDBF	Do not Drop Frames during Frame Size Error Provides status of frames during Frame Size Error. If this field is 1, it indicates that the frames are not dropped during head-of-line blocking because of the frame size error (MTL_EST_Status[HLBF]). 0b - Drop frames during frame size error 1b - Do not Drop frames during frame size error
3-2 —	Reserved.
1 SSWL	Switch to Software Owned List If this field is 1, it indicates that the software has programmed that list that it currently owns (SWOL) and the hardware should switch to the new list based on the new BTR. Hardware clears this bit when the switch to the SWOL happens to indicate the completion of the switch or when an BTR error (BTRE in Status register) is set. When BTRE is set this bit is cleared but SWOL is not updated as the switch was not successful. Access restriction apply to this field that clears on read and automatically becomes 1 on an internal event occurrence. Enables or disables the switch to the software owned list. 0b - Disabled 1b - Enabled
0 EEST	Enable EST Enables or disables EST. If the field becomes 0, it indicate that the gate control list processing is halted and all gates are assumed to be in open state. The field must be 1 for the hardware to start processing the gate control lists. During the toggle from 0 to 1, when the MTL_EST_Control[SSWL] is 1, the gate control list processing starts. During the configuration when DWC_EQOS_ASP_ECC is selected, the hardware resets this field and disables the EST function if any uncorrectable error is detected in the EST memory .

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disabled 1b - Enabled

72.18.192 MTL EST Status (MTL_EST_Status)

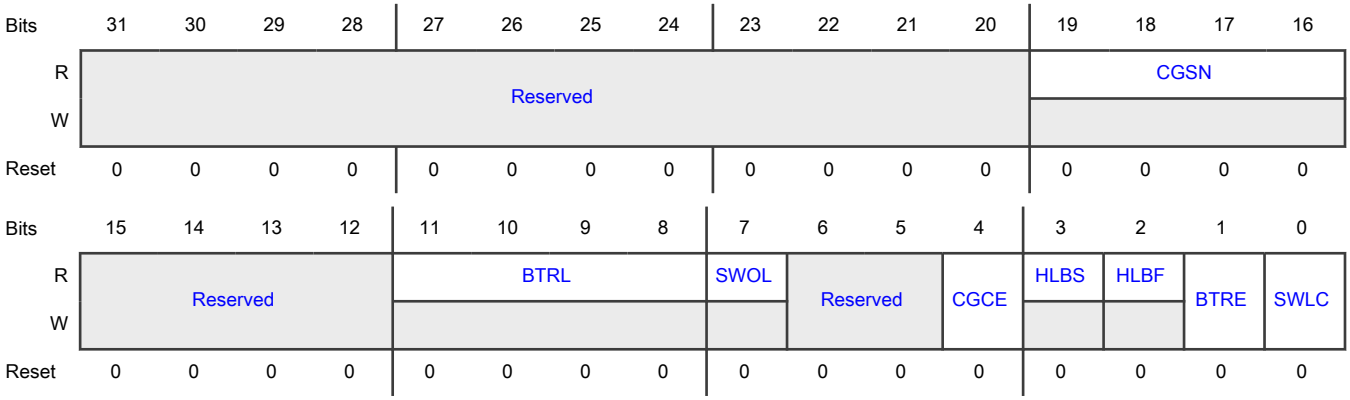
Offset

Register	Offset
MTL_EST_Status	C58h

Function

Provides status of enhancements to scheduled transmission (IEEE802.1Qbv).

Diagram



Fields

Field	Function
31-20 —	Reserved.
19-16 CGSN	Current GCL Slot Number Indicates the slot number of the GCL list. Slot number is a modulo 16 count of the GCL List loops executed so far. Even if a new GCL list is installed, the count is incremental.
15-12 —	Reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
11-8 BTRL	BTR Error Loop Count Provides the minimum count (N) for which the equation Current Time =< New BTR + (N * New Cycle Time) becomes true. N = "1111" indicates the iterations exceeded the value of 8 and the hardware was not able to update New BTR to be equal to or greater than Current Time. Software intervention is needed to update the New BTR. Value cleared when BTRE field of this register is cleared.
7 SWOL	S/W owned list When '0' indicates Gate control list number "0" is owned by software and when "1" indicates the Gate Control list "1" is owned by the software. Any reads/writes by the software (using indirect access via GCL_Control) is directed to the list indicated by this value by default. The inverse of this value is treated as HWOL. R/W operations performed by hardware are directed to the list pointed by HWOL by default. 0b - Gate control list number "0" is owned by software 1b - Gate control list number "1" is owned by software
6-5 —	Reserved.
4 CGCE	Constant Gate Control Error This error occurs when the list length (LLR) is 1 and the Cycle Time (CTR) is less than or equal to the programmed Time Interval (TI) value after the optional Left Shifting. The above programming implies Gates are either always Closed or always Open based on the Gate Control values; the same effect can be achieved by other simpler (non TSN) programming mechanisms. Since the implementation does not support such a programming an error is reported. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Constant Gate Control Error not detected 1b - Constant Gate Control Error detected
3 HLBS	Head-Of-Line Blocking due to Scheduling Set when the frame is not able to win arbitration and get scheduled even after 4 iterations of the GCL. Indicates to software a potential programming error. The one hot encoded values of the Queue Numbers that are not able to make progress are indicated in the MTL_EST_Sch_Error register. Bit cleared when MTL_EST_Sch_Error register is all zeros. 0b - Head-Of-Line Blocking due to Scheduling not detected 1b - Head-Of-Line Blocking due to Scheduling detected
2 HLBF	Head-Of-Line Blocking due to Frame Size Set when HOL Blocking is noticed on one or more Queues as a result of none of the Time Intervals of gate open in the GCL being greater than or equal to the duration needed for frame size (or frame fragment size when preemption is enabled) transmission. The one hot encoded Queue numbers that are experiencing HLBF are indicated in the MTL_EST_Frm_Size_Error register. Additionally, the first Queue number that experienced HLBF along with the frame size is captured in MTL_EST_Frm_Size_Capture register. Bit cleared when MTL_EST_Frame_Size_ Error register is all zeros.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Head-Of-Line Blocking due to Frame Size not detected 1b - Head-Of-Line Blocking due to Frame Size detected
1 BTRE	BTR Error Indicates whether the BTR error is detected. When this field is 1, it indicates a programming error in the BTR of SWOL where the programmed value is less than the current time. If the BTRL = "1111", SWOL is not updated and software must reprogram the BTR to a value greater than current time and then set SSWL to reinitiate the switch to SWOL. Else if the value of BTRL < "1111", SWOL is updated and this field indicates the number of iterations (of + CycleTime) taken by hardware to update the BTR to a value greater than Current Time. Access restrictions apply to this field. It sets automatically to 1 on an internal event occurence. Writing 1 clears this field and writing 0 has no effect. 0b - BTR Error not detected 1b - BTR Error detected
0 SWLC	Switch to Software Owned List Complete Indicates whether the switch to software owned list complete is detected. When the field is 1, it indicates that the hardware has successfully switched to the SWOL, and updated the MTL_EST_Status[SWOL] to that effect. This field is 0 when MTL_EST_Control[SSWL] transitions from 0 to 1, or on a software write. Access restrictions apply to this field. It clears automatically and writing 0 to it has no effect. 0b - Not detected 1b - Detected

72.18.193 MTL EST Scheduling Error (MTL_EST_Sch_Error)

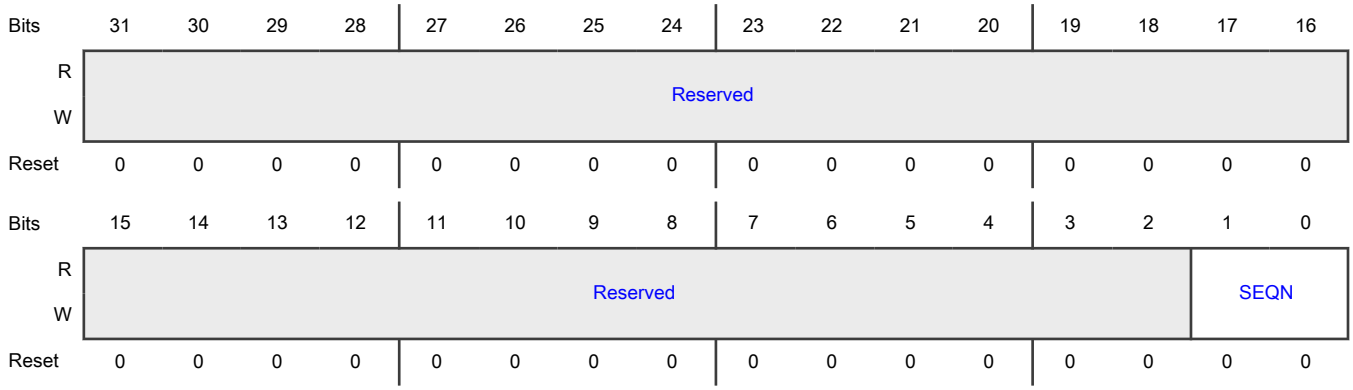
Offset

Register	Offset
MTL_EST_Sch_Error	C60h

Function

Provides the one hot encoded queue numbers that have the scheduling related error (timeout).

Diagram



Fields

Field	Function
31-2 —	Reserved.
1-0 SEQN	Schedule Error Queue Number Provides the one hot encoded queue numbers that have experienced error or timeout described in MTL_EST_Status[HLBS]. Access restriction apply to this field. It automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 to it has no effect.

72.18.194 MTL EST Frame Size Error (MTL_EST_Frm_Size_Error)

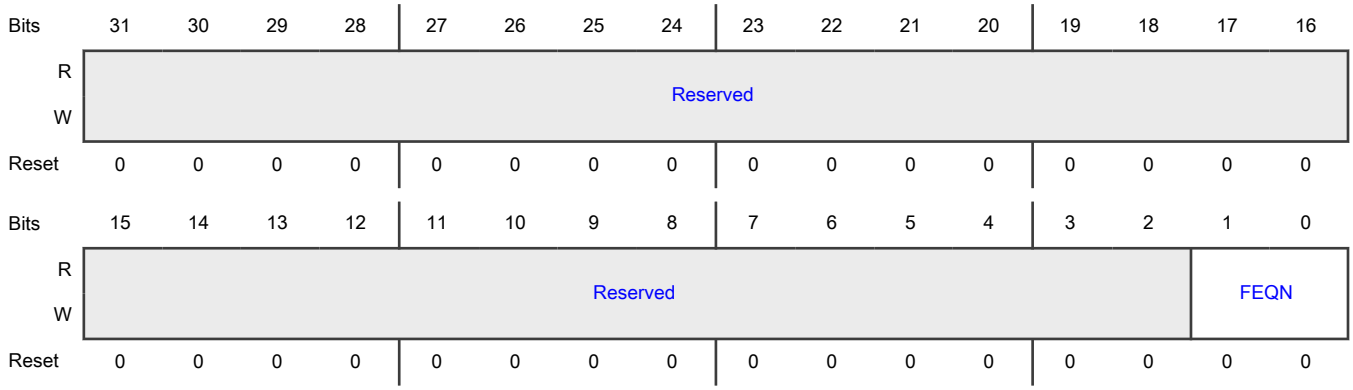
Offset

Register	Offset
MTL_EST_Frm_Size_Error	C64h

Function

Provides the one hot encoded queue numbers that have the frame Size related error.

Diagram



Fields

Field	Function
31-2 —	Reserved.
1-0 FEQN	Frame Size Error Queue Number Provides the one hot encoded queue Nnumbers that have experienced error described in MTL_EST_Status[HLBF]. Access restriction apply to this field. It automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 to it has no effect.

72.18.195 MTL EST Frame Size Capture (MTL_EST_Frm_Size_Capture)

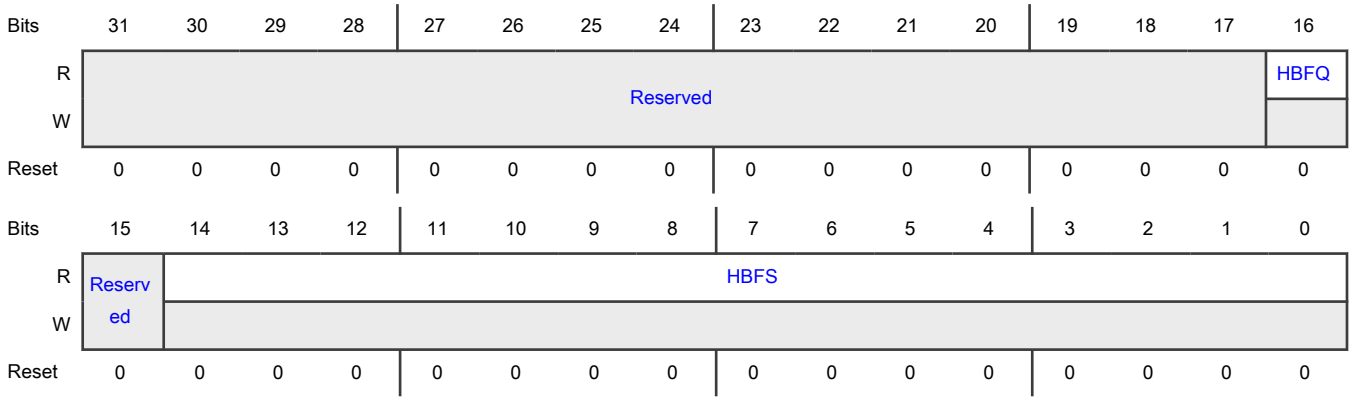
Offset

Register	Offset
MTL_EST_Frm_Size_Capture	C68h

Function

Captures the frame Size and queue number of the first occurrence of the frame Size related error. When you write 0, it captures the data of immediate next occurrence of a similar error.

Diagram



Fields

Field	Function
31-17 —	Reserved.
16 HBFQ	Queue Number of HLBF Captures the binary value of the first queue (number) which experiences the HLBF error (see MTL_EST_Status[HLBF]). Any subsequent queue errors similar to HLBF errors does not alter the value after it is written. After this field is 0, it captures the queue number of the next occurring HLBF error. Field's width is based on the number of transit queues configured; remaining fields are read-only. This field clears when MTL_EST_Frm_Size_Error is all zeros.
15 —	Reserved.
14-0 HBFS	Frame Size of HLBF Captures the frame Size of the dropped frame related to queue number indicated in MTL_EST_Frm_Size_Capture[HBFQ]. If this field is zero, then this register must be considered invalid. This field clears when MTL_EST_Frm_Size_Error is all zeros.

72.18.196 MTL EST Interrupt Enable (MTL_EST_Intr_Enable)

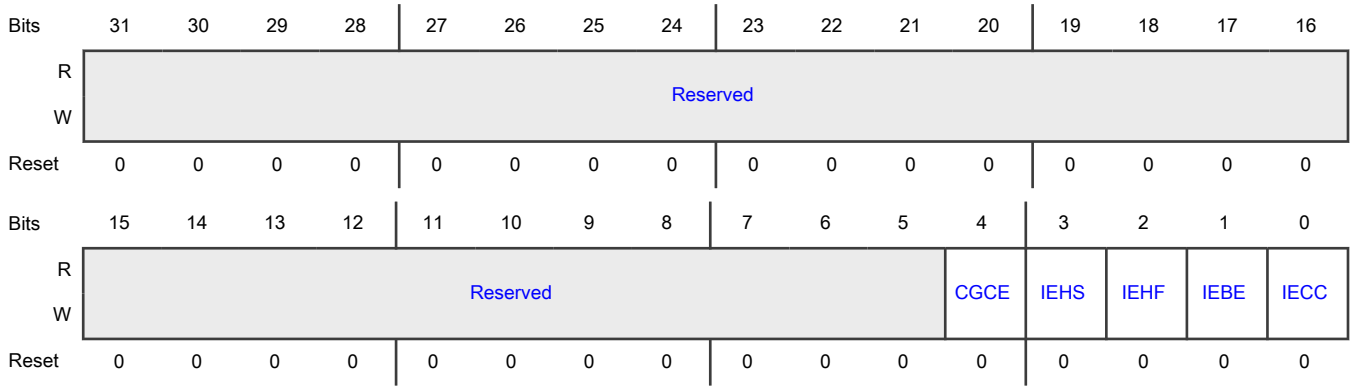
Offset

Register	Offset
MTL_EST_Intr_Enable	C70h

Function

Implements the interrupt enable fields for the various events that generate an interrupt. Bit positions have a 1 to 1 correlation with the status bit positions in MTL_ETS_Status register.

Diagram



Fields

Field	Function
31-5 —	Reserved.
4 CGCE	Interrupt Enable for CGCE Indicates whether an interrupt for MTL_EST_Intr_Enable[CGCE] is enabled. When this field is 1, it generates an interrupt when the constant gate control error occurs and is indicated in the status. When this field becomes 0, this event does not generate an interrupt 0b - Disabled 1b - Enabled
3 IEHS	Interrupt Enable for HLBS Indicates whether an interrupt for MTL_EST_Status[HLBS] is enabled. When this field is 1, it generates an interrupt when the head-of-line blocking due to scheduling issue occurs and is indicated in the status. When this field becomes 0, this event does not generate an interrupt. 0b - Disabled 1b - Enabled
2 IEHF	Interrupt Enable for HLBF Indicates whether an interrupt for MTL_EST_Status[HLBF] is enabled. When this field is 1, it generates an interrupt when the head-of-line blocking due to frame size error occurs and is indicated in the status. When this field becomes 0, this event does not generate an interrupt. 0b - Disabled 1b - Enabled
1 IEBE	Interrupt Enable for BTR Error Indicates whether an interrupt for BTR error is enabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When this field is 1, it generates an interrupt when the BTR error occurs and is indicated in the status. When this field becomes 0, this event does not generate an interrupt. 0b - Disabled 1b - Enabled
0 IECC	Interrupt Enable for Switch List Indicates whether the interrupt for switch list is enabled. When this field is 1, it generates an interrupt when the configuration change is successful and the hardware switches to the new list. When this field becomes 0, this event does not generate an interrupt. 0b - Disabled 1b - Enabled

72.18.197 MTL EST GCL Control (MTL_EST_GCL_Control)

Offset

Register	Offset
MTL_EST_GCL_Control	C80h

Function

Provides the control information for reading and writing to the gate control lists.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-24	Reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
23-22 ESTEIEC	ECC Inject Error Control for EST Memory Provides the status of inject error control for EST memory. When MTL_EST_GCL_Control[ESTEIEE] = 1, it indicates that on the basis of the value encoded in this field following errors are inserted. This field is valid only if you select DWC_EQOS_ASP_ECC feature during the configuration, otherwise it is reserved. 00b - Insert 1 bit error 01b - Insert 2 bit errors 10b - Insert 3 bit errors 11b - Insert 1 bit error in address field
21 ESTEIEE	EST ECC Inject Error Enable Indicates whether the EST ECC inject error is enabled. If this field along with MTL_EST_Control[EEST] = 1, it enables the ECC error injection feature. When this field becomes 0, it disables the ECC error injection feature. 0b - Disabled 1b - Enabled
20 ERR0	If this field is 1, it indicates that when the software writes to GCL the last write operation was aborted and when MTL_EST_Control[SSWL] is 1, GCL registers are prohibited. Access restriction apply to this field and automatically becomes 1 on an internal event occurrence. Writing 1 to this field clears it and writing 0 to this field has no effect. 0b - ERR0 is disabled 1b - ERR1 is enabled
19-16 —	Reserved.
15-8 ADDR	Gate Control List Address: (GCLA when GCRR is "0"). Provides the address (row number) of the gate control list at which the R/W operation has to be performed. By default the gate control list to which MTL_EST_Status[SWOL] points is selected for read and write. If MTL_EST_GCL_Control[DBGM] is 1, it indicates that MTL_EST_GCL_Control[DBGB] gives Debug mode access to read and write. The field's width depends on DWC_EQOS_EST_DEP and the unused bits must be treated as read only. Gate Control list Related Registers Address: (GCRA when GCRR is "1"). By default the GCL related register set pointed by MTL_EST_Status[SWOL] is selected for read or write. If MTL_EST_GCL_Control[DBGM], it indicates that MTL_EST_GCL_Control[DBGB] gives Debug mode access to read write. Lower 3 bits are only used in this mode, higher order bits are treated as dont cares.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	000b - BTR Low (31:0) 001b - BTR High (63:31) 010b - CTR Low (31:0) 011b - CTR High (39:32) 100b - TER (31:0) 101b - LLR (n:0) (where n is (log{DWC_EQOS_EST_DEP} / log2)) Others - Reserved
7-6 —	Reserved.
5 DBGB	Debug Mode Bank Select Indicates whether the read and write in Debug mode is directed to bank 0 or bank 1. When this field is 0, it indicates that read or write in Debug mode must be directed to bank 0 (GCL0 and corresponding Time related registers). When this field is 1, it indicates that read or write in Debug mode should be directed to bank 1 (GCL1 and corresponding Time related registers). When MTL_EST_GCL_Control[DBGM] is 1 you can use this value and overrides with the MTL_EST_Status[SWOL] value. 0b - Directed to bank 0 1b - Directed to bank 1
4 DBGM	Debug Mode Enables or disables Debug mode. When this field is 1, it indicates that the read and write is in Debug mode where the MTL_EST_GCL_Control[DBGB] value explicitly provides the memory bank (for GCL and time related registers). When this field is 0, it indicates that MTL_EST_Status[SWOL] determines which bank to use. 0b - Disabled 1b - Enabled
3 —	Reserved.
2 GCRR	Gate Control Related Registers Enables or disables gate control related registers. When this field is 1, it indicates that the read or write access is for the GCL related registers (BTR, CTR, TER, LLR) for which GCRA provides the address. When this field is 0, it indicates that read and write must be directed to GCL from the address which GCLA provides. 0b - Disabled 1b - Enabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
1 R1W0	Read '1', Write '0' Indicates whether this field performs read operation or write operation. When this field is 1 it indicates that it performs a read operation. When this field is 0 it indicates that it performs a write operation. 0b - Write operation 1b - Read operation
0 SRWO	Start Read/Write Operation Indicates whether the read/write operation is enabled. When this field is 1, it indicates that a read/write operation has started and is in progress. When hardware resets this field and MTL_EST_GCL_Control[ERR0] = 1 , it indicates that the read/write operation has completed or an error has occurred. Reads: When this field becomes 0, it indicates that MTL_EST_GCL_Data reads data. Writes: Before writing 1 to this field, you must program MTL_EST_GCL_Data with write data. Access restrictions apply to this field. It clears automatically. Writing 1 sets this field and writing 0 to it has no effect. 0b - Disabled 1b - Enabled

72.18.198 MTL EST GCL Data (MTL_EST_GCL_Data)

Offset

Register	Offset
MTL_EST_GCL_Data	C84h

Function

Holds the read data or write data in case of reads and writes respectively.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-0 GCD	Gate Control Data Provides the data corresponding to the address selected in the MTL_EST_GCL_Control. This field is used for both read and write operations.

72.18.199 MTL FPE Control Status (MTL_FPE_CTRL_STS)

Offset

Register	Offset
MTL_FPE_CTRL_STS	C90h

Function

Controls the operation of, and provides status for frame preemption (IEEE802.1Qbu/802.3br).

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	Reserved						PEC		Reserved						AFSZ	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-29 —	Reserved.
28 HRS	Hold/Release Status Indicates whether a set-and-release-MAC operation which was last executed and the pMAC is in release state or in hold state. 0b - Release state 1b - Hold state
27-16 —	Reserved.
15-10 —	Reserved.
9-8 PEC	Preemption Classification When this field is 1, it indicates that you must classify the corresponding queue as preemptable. When this field is 0, it indicates that you must classify the queue as express. When set indicates the corresponding Queue must be classified as preemptable, when '0' Queue is classified as express. When both EST (Qbv) and Preemption are enabled, Queue-0 is always assumed to be preemptable. When you enables EST (Qbv), the preemptable queues are always assumed to be in open state in gate control list.
7-2 —	Reserved.
1-0 AFSZ	Additional Fragment Size Indicates that, in units of 64 bytes, the minimum number of bytes over 64 bytes required in non-final fragments of preempted frames. The minimum non-final fragment size is (AFSZ +1) * 64 bytes.

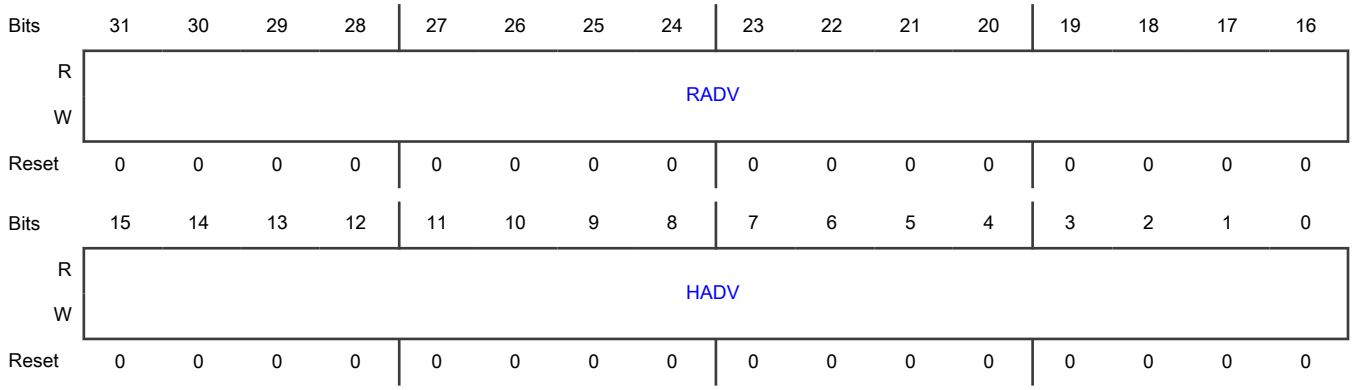
72.18.200 MTL FPE Advance (MTL_FPE_Advance)

Offset

Register	Offset
MTL_FPE_Advance	C94h

Function
Holds the hold and release advance time.

Diagram



Fields

Field	Function
31-16 RADV	Release Advance Provides the maximum time in nanoseconds that can elapse between issuing a release to the MAC and the MAC being ready to resume transmission of preemptable frames, in the absence of there being any express frames available for transmission.
15-0 HADV	Hold Advance Provides the maximum time in nanoseconds that can elapse between issuing a hold to the MAC and the MAC ceasing to transmit any preemptable frame that is in the process of transmission or any preemptable frames that are queued for transmission.

72.18.201 MTL Rx Parser Control Status (MTL_RXP_Control_Status)

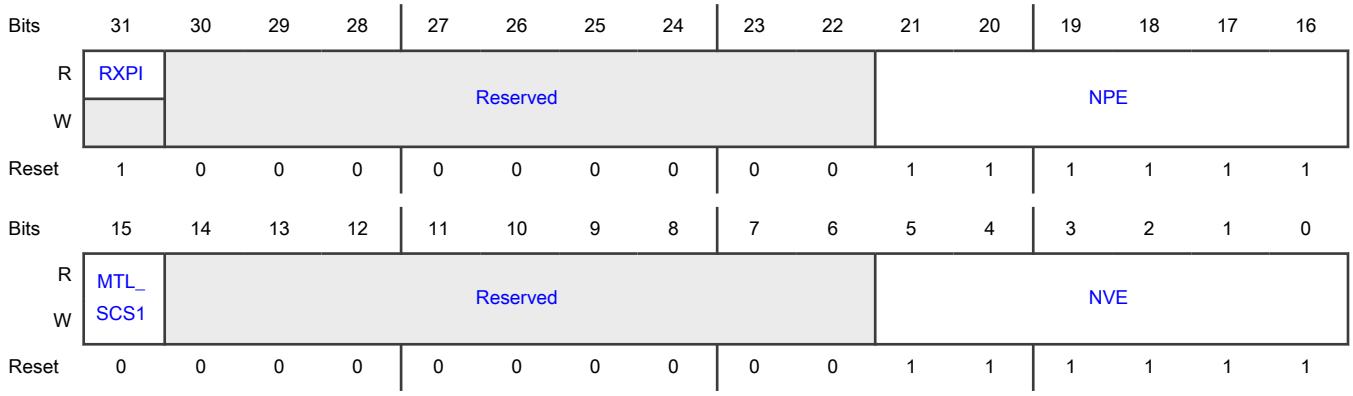
Offset

Register	Offset
MTL_RXP_Control_Status	CA0h

Function

Establishes the operating mode of receive parser and provides some status.

Diagram



Fields

Field	Function
31 RXPI	RX Parser in Idle State Indicates whether the receive parser is in idle state. When this field is 1, it indicates that the receive parser is in idle state and waiting for the processing of a new packet. When parser disables, you can use this field as a handshake with software and also the software can update the receive parser instruction table when you write 1 to this field. 0b - Not in Idle state 1b - Idle state
30-22 —	Reserved.
21-16 NPE	Number of parsable entries in the Instruction table Indicates the number of parsable entries in the instruction memory. This is used in receive parser logic to detect programming error. MTL_RXP_Interrupt_Control_Status[NPEOVIS] = 1, if the number of parsed entries for a packet is more than this entry.
15 MTL_SCS1	MTL_SCS1 Is reserved for NXP internal use. The value of this field must always be 0 unless NXP instructs you otherwise. Writing 1 to any of the bits of this field might cause unexpected behavior in th IP.
14-6 —	Reserved.
5-0 NVE	Number Of Valid Entry Address Or Index In The Instruction Table Indicates the number of valid entry address or index in the instruction memory.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	The maximum valid entry address is = NVE + 1 and the addresses or indices range from 0 to 32. Therefore, if the value of this field is 32, the number of valid entry address is 33. This value is used in receive parser logic to detect if any programming errors exist. When parsing, the module writes 1 to NVEOVIS if the number of the memory address is found to be more than the defined maximum valid entry address number. **NOTE** The minimum value of this field must be two.

72.18.202 MTL Rx Parser Interrupt Control Status (MTL_RXP_Interrupt_Control_Status)

Offset

Register	Offset
MTL_RXP_Interrupt_Control_Status	CA4h

Function

Provides enable control for the interrupts and also provides interrupt status.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved												PDRFIE	FOOVIE	NPEOVIE	NVEOVIE
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved												PDRFIS	FOOVIS	NPEOVIS	NVEOVIS
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-20 —	Reserved.
19 PDRFIE	Packet Drop due to RF Interrupt Enable Indicates whether the packet drop due to RF interrupt is enabled. If this field is 1, it enables the PDRFIS interrupt. When this field becomes 0, it disables the PDRFIS interrupt.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disabled 1b - Enabled
18 FOOVIE	Frame Offset Overflow Interrupt Enable Indicates whether the frame offset overflow interrupt is enabled. If this field is 1, it enables the FOOVIS interrupt. When this field becomes 0, it disables the FOOVIS interrupt. 0b - Disabled 1b - Enabled
17 NPEOVIE	Number of Parsable Entries Overflow Interrupt Enable Enables or disables the number of parsable entries overflow interrupt. If this field is 1, it enables the NPEOVIS interrupt. When this field becomes 0, it disables the NPEOVIS interrupt. 0b - Disable 1b - Enable
16 NVEOVIE	Number of Valid Entries Overflow Interrupt Enable Enables or disables the number of valid entries overflow interrupt. If this field is 1, it enables the NVEOVIS interrupt. When this field becomes 0, it disables the NVEOVIS interrupt. 0b - Disable 1b - Enable
15-4 —	Reserved.
3 PDRFIS	Packet Dropped due to RF Interrupt Status Indicates whether the packet dropped due to RF interrupt status is detected. If the Rx Parser result says to drop the packet by setting RF=1 in the instruction memory, then this bit is set to 1. This field clears when the application writes 1 to this field. Access apply to this field. It automatically sets to 1 on an internal event occurrence. Writing 1 clears this field and writing 0 to it has no effect. 0b - Not detected 1b - Detected
2	Frame Offset Overflow Interrupt Status

Table continues on the next page...

Table continued from the previous page...

Field	Function
FOOVIS	Indicates whether the frame offset overflow interrupt status is detected. If this field is 1, it indicates that when parsing, the instruction table entry's frame offset is more than the EOF offset. This field clears when the application writes 1 to this field. Access apply to this field. It automatically sets to 1 on an internal event occurrence. Writing 1 clears this field and writing 0 to it has no effect. 0b - Not detected 1b - Detected
1 NPEOVIS	Number of Parsable Entries Overflow Interrupt Status Indicates whether the number of parsable entries overflow interrupt status is detected. If this field is 1, it indicates that when parsing a packet the number of parsed entries are more than NPE[] (MTL_RXP_Control_Status[NPE]). This field clears when the application writes 1 to this field. Access apply to this field. It automatically sets to 1 on an internal event occurrence. Writing 1 clears this field and writing 0 to it has no effect. 0b - Not detected 1b - Detected
0 NVEOVIS	Number of Valid Entry Address/Index Overflow Interrupt Status Indicates whether the number of valid entry address or index overflow interrupt status is detected. If this field is 1, it indicates that when parsing, the instruction address is more than MTL_RXP_Control_Status[NVE]. For example, when MTL_RXP_Control_Status[NVE] = 31, the maximum valid entry address/index is NVE+1 that is 32 (addresses/indices = 0 to 32, or 33 entries). MTL_RXP_Interrupt_Control_Status[NVEOVIS] = 1 when currently processed entry indicates that the next address is 33 or more, that is 34th or later entries. This field clears when the application writes 1 to this field. Access apply to this field. It automatically sets to 1 on an internal event occurrence. Writing 1 clears this field and writing 0 to it has no effect. 0b - Not detected 1b - Detected

72.18.203 MTL Rx Parser Drop Count (MTL_RXP_Drop_Cnt)

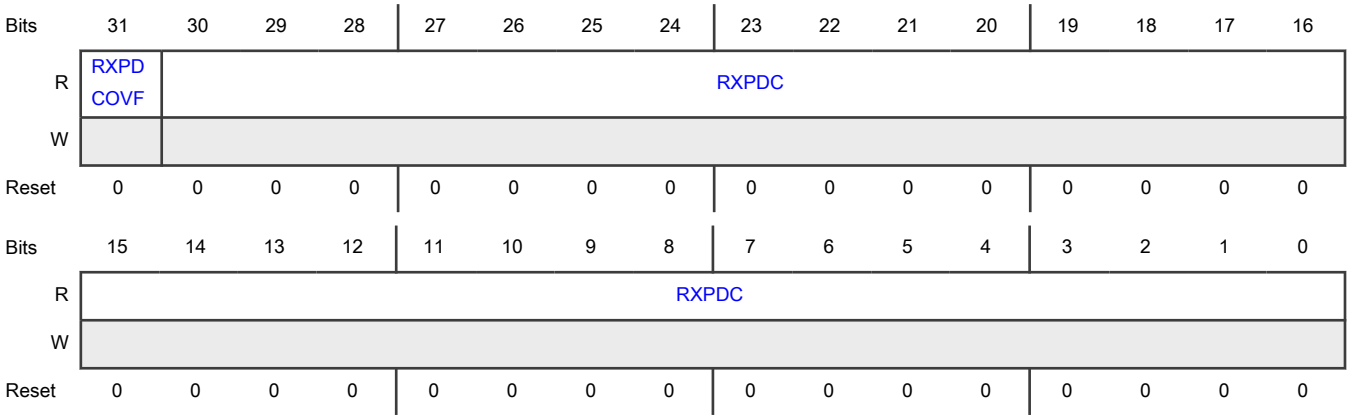
Offset

Register	Offset
MTL_RXP_Drop_Cnt	CA8h

Function

Provides the drop count of receive parser initiated drops.

Diagram



Fields

Field	Function
31 RXPDCOVF	Rx Parser Drop Counter Overflow Bit Indicates whether the receive parser drop count overflow has occurred. When this field is 1, it indicates that the MTL_RXP_Drop_Cnt[RXPDC] counter field has crossed the maximum limit. Access restrictions apply to this field, which clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not occurred 1b - Occurred
30-0 RXPDC	Rx Parser Drop Count Provides the receive parser drop count. This 31-bit counter is implemented whenever a receive parser drops a packet due to RF = 1. The counter clears when you read the register.

72.18.204 MTL Rx Parser Error Count (MTL_RXP_Error_Cnt)

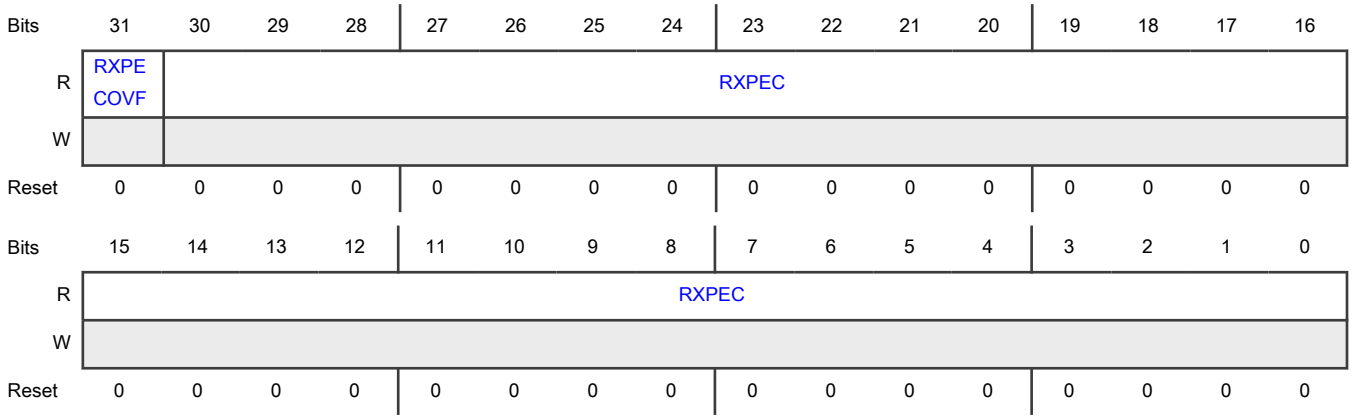
Offset

Register	Offset
MTL_RXP_Error_Cnt	CACh

Function

Provides the receive parser related error occurrence count.

Diagram



Fields

Field	Function
31 RXPECOVF	Rx Parser Error Counter Overflow Bit Indicates whether the receive parser error counter overflow has occurred. When this field is 1, it indicates that MTL_RXP_Error_Cnt[RXPEC] counter field has crossed the maximum limit. Access restrictions apply to this field, which clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not occurred 1b - Occurred
30-0 RXPEC	Rx Parser Error Count Provides the receive parser error count. This 31-bit counter is implemented whenever a receive parser encounters following error scenarios: Entry address >= NVE[] Number parsed entries >= NPE[] Entry address > EOF data entry address The counter clears when you read the register.

72.18.205 MTL Rx Parser Indirect Access Control Status (MTL_RXP_Indirect_Acc_Control_Status)

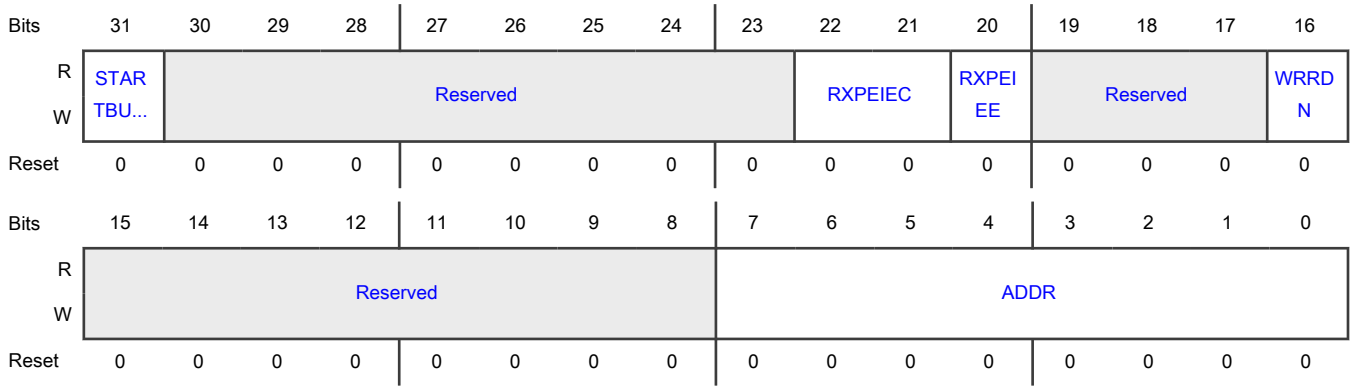
Offset

Register	Offset
MTL_RXP_Indirect_Acc_Control_Status	CB0h

Function

Provides the indirect access control and status for receive parser memory.

Diagram



Fields

Field	Function
31 STARTBUSY	FRP Instruction Table Access Busy When this bit is set to 1 by the software then it indicates to start the Read/Write operation from/to the Rx Parser Memory. Software should read this bit as 0 before issuing read or write request to access the Parser Memory Instructions. This bit when set to 1 indicates that hardware is busy until its gets cleared by hardware and software should not issue any read or write operation. 0b - hardware not busy 1b - hardware is busy (Read/Write operation from/to the Rx Parser Memory)
30-23 —	Reserved.
22-21 RXPEIEC	ECC Inject Error Control for Rx Parser Memory Controls the ECC inject error for receive parser memory. When MTL_RXP_Indirect_Acc_Control_Status[RXPEIEE] = 1, it indicates that on the basis of the value encoded in this field following errors are inserted: 00b - Insert 1 bit error 01b - Insert 2 bit errors 10b - Insert 3 bit errors 11b - Insert 1 bit error in address field
20 RXPEIEE	ECC Inject Error Enable for Rx Parser Memory Indicates whether the ECC inject error for receive parser memory is enabled. If this field is 1, it enables the ECC error injection feature. When this field becomes 0, it disables the ECC error injection feature.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disabled 1b - Enabled
19-17 —	Reserved.
16 WRRDN	Read Write Control Controls the read and write operation to the receive parser memory. If this field is 1, it indicates the write operation to the receive parser memory. When this field is 0, it indicates the read operation to the receive parser memory. 0b - Read operation to the receive parser memory 1b - Write operation to the receive parser memory
15-8 —	Reserved.
7-0 ADDR	FRP Instruction Table Offset Address Indicates the ADDR of the 32-bit entry in receive parser instruction table. Each entry has 128-bit (4x32-bit words). The X depends on the configurable DWC_EQOS_FRP_ENTRIES. If DWC_EQOS_FRP_ENTRIES = 256 , then X = 9 If DWC_EQOS_FRP_ENTRIES = 128 , then X = 8 If DWC_EQOS_FRP_ENTRIES = 64, then X = 7

72.18.206 MTL Rx Parser Indirect Access Data (MTL_RXP_Indirect_Acc_Data)

Offset

Register	Offset
MTL_RXP_Indirect_Acc_Data	CB4h

Function
Provides the data associated to indirect access to receive parser memory.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-9 —	Reserved.
8 MEEAO	MTL ECC Error Address Status Over-ride Enables or disables the MTL ECC error address status over-ride. When this field is 1, it indicates that MTL_ECC_Err_Addr_Status[EUEAS] and MTL_ECC_Err_Addr_Status[ECEAS] hold the last valid address where the error is detected. When this field becomes 0, it indicates that MTL_ECC_Err_Addr_Status[EUEAS] and MTL_ECC_Err_Addr_Status[ECEAS] hold the first address where the error is detected. 0b - Disable 1b - Enable
7-5 —	Reserved.
4 —	Reserved.
3 MRXPEE	MTL Rx Parser ECC Enable Indicates whether the MTL receive parser ECC is enabled. If this field is 1, it enables the ECC feature for receive parser memory. When this field is 0, it disables the ECC feature for receive parser memory. 0b - Disabled 1b - Enabled
2 MESTEE	MTL EST ECC Enable Indicates whether the MTL EST ECC is enabled. If this field is 1, it enables the ECC feature for EST memory. When this field is 0, it disables the ECC feature for EST memory. 0b - Disabled 1b - Enabled
1 MRXEE	MTL Rx FIFO ECC Enable Indicates whether the MTL Rx FIFO ECC is enabled. If this field is 1, it enables the ECC feature for MTL receive FIFO memory. When this field is 0, it disables the ECC feature for MTL receive FIFO memory. 0b - Disabled 1b - Enabled
0	MTL Tx FIFO ECC Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
MTXEE	Indicates whether the MTL Tx FIFO ECC is enabled. If this field is 1, it enables the ECC feature for MTL Tx FIFO memory. When field is 0, it disables the ECC feature for MTL Tx FIFO memory. 0b - Disabled 1b - Enabled

72.18.208 MTL Safety Interript Status (MTL_Safety_Interrupt_Status)

Offset

Register	Offset
MTL_Safety_Interrupt_Status	CC4h

Function

Provides safety interrupt status.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Function
31 —	Reserved Indicates whether the MAC safety uncorrectable interrupt status is detected. 0b - Not detected 1b - Detected
30-2	Reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
1 MEUIS	MTL ECC Uncorrectable Error Interrupt Status Indicates whether the MTL ECC uncorrectable error interrupt status is detected. Indicates that an uncorrectable error interrupt event in the MTL ECC safety feature. The application must read MTL_ECC_Interrupt_Status to get the exact cause of the interrupt. 0b - Not detected 1b - Detected
0 MECIS	MTL ECC Correctable Error Interrupt Status Indicates whether the MTL ECC correctable error interrupt status is detected. Indicates that a correctable error interrupt event in the MTL ECC safety feature. The application must read MTL_ECC_Interrupt_Status to get the exact cause of the interrupt . 0b - MTL ECC Correctable error Interrupt Status not detected 1b - MTL ECC Correctable error Interrupt Status detected

72.18.209 MTL ECC Interrupt Enable (MTL_ECC_Interrupt_Enable)

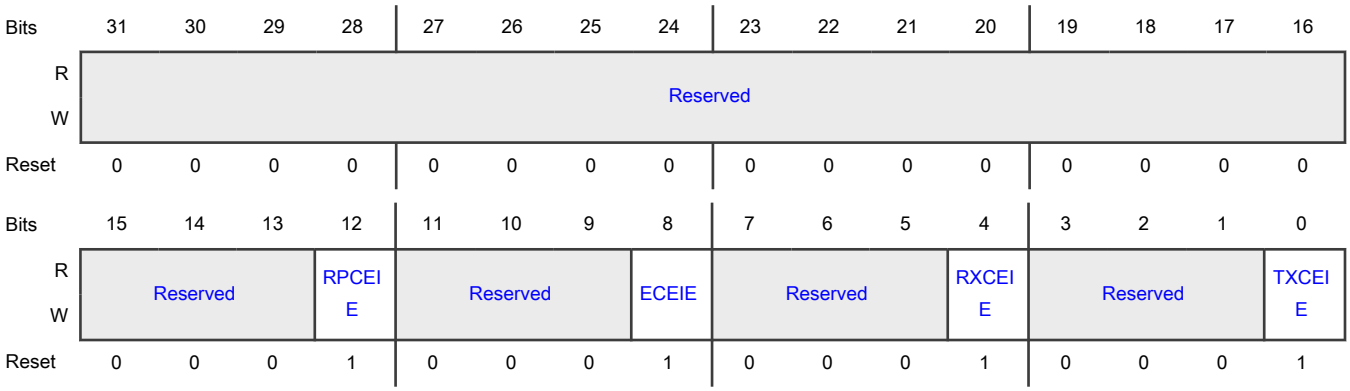
Offset

Register	Offset
MTL_ECC_Interrupt_Enable	CC8h

Function

Provides enable bits for the ECC interrupts.

Diagram



Fields

Field	Function
31-13 —	Reserved.
12 RPCEIE	Rx Parser Memory Correctable Error Interrupt Enable Indicates whether the Rx parser memory correctable error interrupt is enabled. When this field is 1, it generates an interrupt when an uncorrectable error is detected at the Rx parser memory interface. It is indicated in MTL_ECC_Interrupt_Status[RPCES]. When this field becomes 0, it indicates that this event does not generates an interrupt. 0b - Disabled 1b - Enabled
11-9 —	Reserved.
8 ECEIE	EST Memory Correctable Error Interrupt Enable Indicates whether the EST memory correctable error interrupt is enabled. When this field is 1, it generates an interrupt when a correctable error is detected at the MTL EST memory interface. It is indicated in MTL_ECC_Interrupt_Status[ECES]. When this field becomes 0, it indicates that this event does not generates an interrupt. 0b - Disabled 1b - Enabled
7-5 —	Reserved.
4 RXCEIE	Rx Memory Correctable Error Interrupt Enable Indicates whether the Rx memory correctable error interrupt is enabled. When this field is 1, it generates an interrupt when a correctable error is detected at the MTL Rx memory interface. It is indicated in MTL_ECC_Interrupt_Status[RXCES]. When this field becomes 0, it indicates that this event does not generates an interrupt. 0b - Disabled 1b - Enabled
3-1 —	Reserved.
0 TXCEIE	Tx Memory Correctable Error Interrupt Enable Indicates whether the Tx memory correctable error interrupt is enabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When this field is 1, it generates an interrupt when a correctable error is detected at the MTL Tx memory interface. It is indicated in MTL_ECC_Interrupt_Status[TXCES]. When this field becomes 0, it indicates that this event does not generates an interrupt. 0b - Disabled 1b - Enabled

72.18.210 MTL ECC Interrupt Status (MTL_ECC_Interrupt_Status)

Offset

Register	Offset
MTL_ECC_Interrupt_Status	CCCh

Function

Provides MTL ECC Interrupt Status.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Not detected 1b - Detected
13 RPAMS	MTL Rx Parser Memory Address Mismatch Status Indicates whether the MTL Rx parser memory address mismatch status is detected. When this field is 1, it indicates that an address mismatch is found for Rx parser memory's address bus. 0b - Not detected 1b - Detected
12 RPCES	MTL Rx Parser Memory Correctable Error Status Indicates whther the MTL Rx parser memory correctable error status is detected. When this field is 1, it indicates that a correctable error is detected at RX parser memory interface. 0b - Not detected 1b - Detected
11 —	Reserved.
10 EUES	MTL EST Memory Uncorrectable Error Status Indicates whether the MTL EST memory uncorrectable error status is detected. When this field is 1, it indicates that an uncorrectable error is detected at MTL EST memory interface. 0b - Not detected 1b - Detected
9 EAMS	MTL EST Memory Address Mismatch Status Indicates whether the MTL EST memory address mismatch status is detected. When this field is 1, it indicates that an address mismatch is found for MTL EST memory's address bus. 0b - Not detected 1b - Detected
8 ECES	MTL EST Memory Correctable Error Status Indicates whether the MTL EST memory correctable error status is detected. When this field is 1, it indicates that a correctable error is detected at the MTL EST memory. 0b - Not detected 1b - Detected
7 —	Reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
6 RXUES	MTL Rx Memory Uncorrectable Error Status Indicates whether the MTL Rx memory uncorrectable error status is detected. When this field is 1, it indicates that an uncorrectable error is detected at the MTL Rx memory interface. 0b - Not detected 1b - Detected
5 RXAMS	MTL Rx Memory Address Mismatch Status Indicates whether the MTL Rx memory address mismatch status is detected. When this field is 1, it indicates that an address mismatch is found for MTL Rx memory's address bus. 0b - Not detected 1b - Detected
4 RXCES	MTL Rx memory Correctable Error Status Indicates whether the MTL Rx memory correctable error status is detected. When this field is 1, it indicates that a correctable error is detected at the MTL Rx memory. 0b - Not detected 1b - Detected
3 —	Reserved.
2 TXUES	MTL Tx Memory Uncorrectable Error Status Indicates whether the MTL Tx memory uncorrectable error status is detected. When this field is 1, it indicates that an uncorrectable error is detected at the MTL TX memory interface. 0b - Not detected 1b - Detected
1 TXAMS	MTL Tx Memory Address Mismatch Status Indicates whether the MTL Tx memory address mismatch status is detected. When this field is 1, it indicates that an address mismatch is found for MTL Tx memory's address bus. 0b - Not detected 1b - Detected
0 TXCES	MTL Tx Memory Correctable Error Status Indicates whether the MTL Tx memory correctable error status is detected. When this field is 1, it indicates that a correctable error is detected at the MTL Tx memory. 0b - Not detected

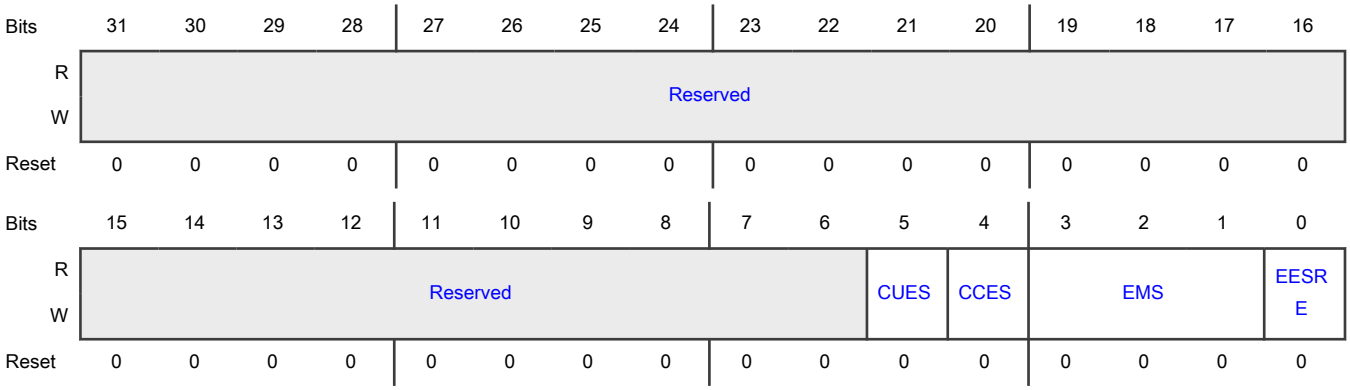
72.18.211 MTL ECC Error Status (MTL_ECC_Err_Sts_Rctl)

Offset

Register	Offset
MTL_ECC_Err_Sts_Rctl	CD0h

Function
Establishes the control for ECC error status capture.

Diagram



Fields

Field	Function
31-6 —	Reserved.
5 CUES	Clear Uncorrectable Error Status Indicates whether the clear uncorrectable error status is detected. When this field and MTL_ECC_Err_Sts_Rctl[EESRE] is 1, it indicates that based on the MTL_ECC_Err_Sts_Rctl[EMS], the respective memory's uncorrectable error address and uncorrectable error count values are cleared upon reading. When all the error status values are cleared hardware resets this field. 0b - Not detected 1b - Detected

Table continues on the next page...

Table continued from the previous page...

Field	Function
4 CCES	Clear Correctable Error Status Indicates whether the clear correctable error status is detected. When this field and MTL_ECC_Err_Sts_Rctl[EESRE] is 1, it indicates that based on the MTL_ECC_Err_Sts_Rctl[EMS],, the respective memory's correctable error address and correctable error count values are cleared upon reading. When all the error status values are cleared, hardware resets this field. 0b - Not detected 1b - Detected
3-1 EMS	MTL ECC Memory Selection Provides the memory selection encoding. When MTL_ECC_Err_Sts_Rctl[EESRE] is 1, this field indicates which memory's error status value to be read. The memory selection encoding is as described below. 000b - MTL Tx memory 001b - MTL Rx memory 010b - MTL EST memory 011b - MTL Rx Parser memory 100b - DMA TSO memory
0 EESRE	MTL ECC Error Status Read Enable Indicates whether the MTL ECC error status read is enabled. When this field is 1, it indicates that based on MTL_ECC_Err_Sts_Rctl[EMS], the respective memory's error status values are captured as described below: • The correctable and uncorrectable error count values are captured into MTL_ECC_Err_Cnt_Status. • The address location of correctable and uncorrectable errors are captured into MTL_ECC_Err_Addr_Status. When all the status values are captured into MTL_ECC_Err_Cnt_Status and MTL_ECC_Err_Addr_Status, hardware resets this field. 0b - Disabled 1b - Enabled

72.18.212 MTL ECC Error Adress Status (MTL_ECC_Err_Addr_Status)

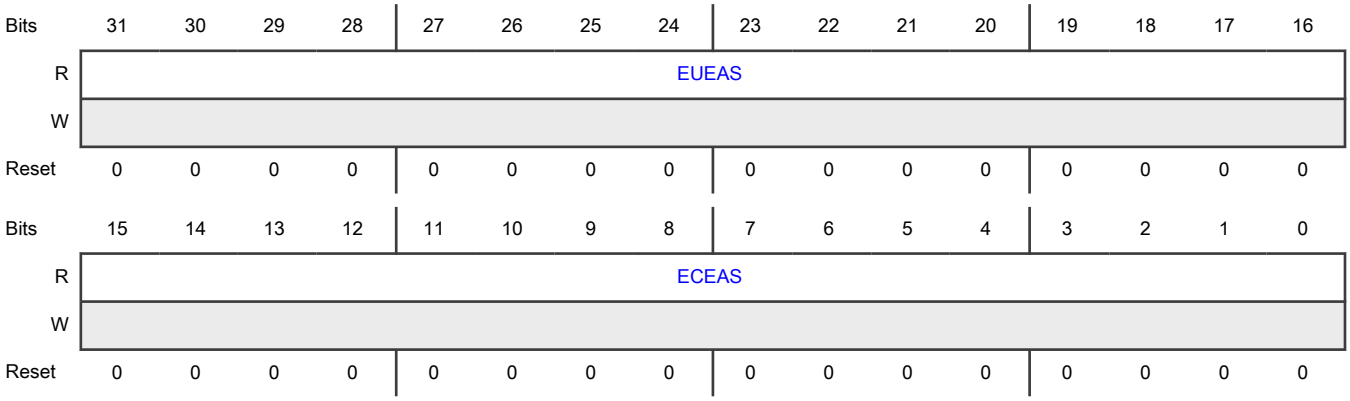
Offset

Register	Offset
MTL_ECC_Err_Addr_Status	CD4h

Function

Provides the memory addresses for the correctable and uncorrectable errors.

Diagram



Fields

Field	Function
31-16 EUEAS	MTL ECC Uncorrectable Error Address Status Based on the MTL_ECC_Err_Sts_Rctl[EMS], this field holds the respective memory's address locations for which an uncorrectable error or address mismatch is detected. When MTL_ECC_Control[MEEAO] = 1, this field holds the last valid address of memory for which either an uncorrectable error or an address mismatch is detected. When MTL_ECC_Control[MEEAO] = 0, this field holds the first address of the memory for which either an uncorrectable error or address mismatch is detected.
15-0 ECEAS	MTL ECC Correctable Error Address Status Based on the MTL_ECC_Err_Sts_Rctl[EMS], this field holds the respective memory's address locations for which a correctable error is detected. When MTL_ECC_Control[MEEAO] = 1, this field holds the last valid address of memory for which the correctable error or address mismatch is detected. When MTL_ECC_Control[MEEAO] = 0, this field holds the first address of the memory for which correctable error is detected.

72.18.213 MTL ECC Error Control Status (MTL_ECC_Err_Cntr_Status)

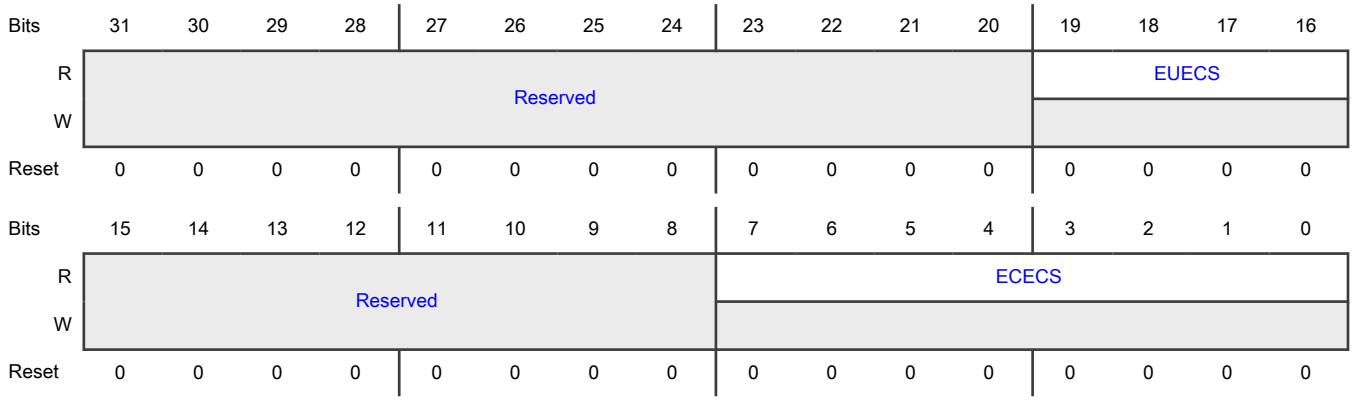
Offset

Register	Offset
MTL_ECC_Err_Cntr_Status	CD8h

Function

Provides ECC Error count for correctable and uncorrectable errors.

Diagram



Fields

Field	Function
31-20 —	Reserved.
19-16 EUECS	MTL ECC Uncorrectable Error Counter Status Based on the EMS field of MTL_ECC_Err_Cntr_Rctl register, this field holds the respective memory's uncorrectable error count value.
15-8 —	Reserved.
7-0 ECECS	MTL ECC Correctable Error Counter Status Based on the EMS field of MTL_ECC_Err_Cntr_Rctl register, this field holds the respective memory's correctable error count value.

72.18.214 MTL DPP Control (MTL_DPP_Control)

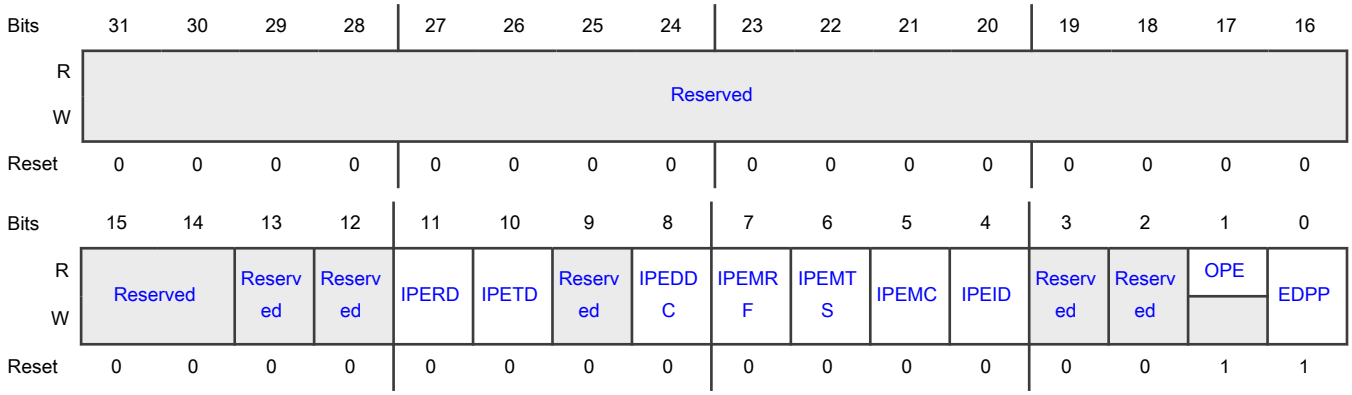
Offset

Register	Offset
MTL_DPP_Control	CE0h

Function

Establishes the operating mode of data parity protection and error injection.

Diagram



Fields

Field	Function
31-14 —	Reserved.
13 —	Reserved.
12 —	Reserved.
11 IPERD	Insert Parity error in Rx write-back Descriptor parity generator Indicates whether the insert parity error in receive write-back descriptor parity generator is enabled. When this field is 1, it flips the parity bit of first valid data to which the DMA Rx write-back descriptor parity generator(or at PG8 as shown in Receive data path parity protection diagram) generates. 0b - Disabled 1b - Enabled
10 IPETD	Insert Parity error in Tx write-back Descriptor parity generator Indicates whether the insert parity error in transit write-back descriptor parity generator is enabled. When this field is 1, it flips the parity bit of first valid data to which the DMA Tx write-back descriptor parity generator(or at PG4 as shown in Transmit data path parity protection diagram) generates. Hardware clears this field, when the respective parity bit flips. 0b - Disabled 1b - Enabled
9 —	Reserved.
8	Insert Parity Error in DMA DTX Control Word Parity Generator

Table continues on the next page...

Table continued from the previous page...

Field	Function
IPEDDC	Indicates whether the insert parity error in DMA DTX control word parity generator is enabled. When this field is 1, it flips the parity bit of first valid data to which the DMA DTX Control word parity generator (or at PG2 as shown in Transmit data path parity protection diagram) generates. Hardware clears this field, when the respective parity bit flips. 0b - Disabled 1b - Enabled
7 IPEMRF	Insert Parity Error in MTL Rx FIFO Read Control Parity Generator Inserts parity Eerror in MTL receive FIFO read control parity generator. When this field is 1, it flips the parity bit of first valid data to which the MTL Rx FIFO read control parity generator (or at PG7 as shown in Receive data path parity protection diagram) generates. Hardware clears this field, when the respective parity bit flips. 0b - Disabled 1b - Enabled
6 IPEMTS	Insert Parity Error in MTL Tx Status Parity Generator Indicates whether the insert parity error in MTL transit status parity generator is enabled. When this field is 1, it flips the parity bit of first valid data to which the MTL Tx Status parity generator (or at PG6 as shown in Transmit data path parity protection diagram) generates. Hardware clears this field, when the respective parity bit flips. 0b - Disabled 1b - Enabled
5 IPEMC	Insert Parity Error in MTL Checksum Parity Generator Indicates whether the insert parity error in MTL checksum parity generator is enabled. When this field is 1, it flips the parity bit of first valid data to which the MTL checksum parity generator (or at PG5 as shown in Transmit data path parity protection diagram) generates. Hardware clears this field, when the respective parity bit flips. 0b - Disabled 1b - Enabled
4 IPEID	Insert Parity Error in Interface Data Parity Generator Indicates whether the insert parity error in interface data parity generator is enabled. When this field is 1, it flips the parity bit of first valid input data to which the interface data parity generator (or at PG1 as shown in Transmit data path parity protection diagram) generates. Following are the input data bus on which parity bits are generated on the basis of configuration selected. In AHB Config, hrdata_i In AXI config, rdata_m_i

Table continues on the next page...

Table continued from the previous page...

Field	Function
	In DMA Config, mdc_rdata_i In MTL Config, ati_data_i Hardware clears this field, when the respective parity bit flips. 0b - Disabled 1b - Enabled
3 —	Reserved.
2 —	Reserved.
1 OPE	Odd Parity Enable Indicates whether an odd parity protection is enabled. When this field is 1, it enables an odd parity protection on all the external interfaces and when this field is 0, it enables an even parity protection on all the external interfaces. 0b - Disabled 1b - Enabled
0 EDPP	Enable Data path Parity Protection Enables or disables the data path parity protection. When this field is 1, it indicates that by generating and checking the parity on EQOS datapath it enables the parity protection for EQOS datapath . When this field is 0, it disables the parity protection for EQOS datapath. 0b - Disable 1b - Enable

72.18.215 MTL Tx Queue 0 Operation Mode (MTL_TxQ0_Operation_Mode)

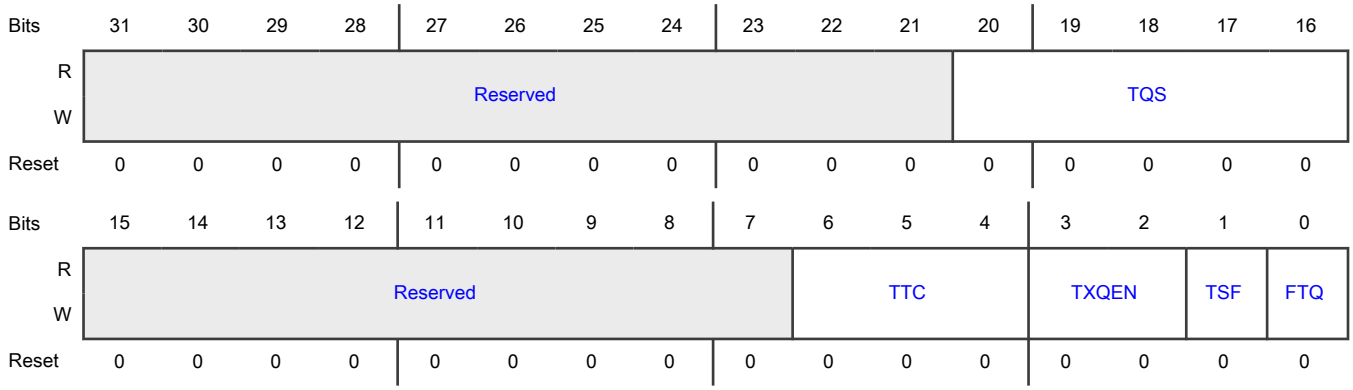
Offset

Register	Offset
MTL_TxQ0_Operation_Mode	D00h

Function

Establishes the transmit queue operating modes and commands.

Diagram



Fields

Field	Function
31-21 —	Reserved.
20-16 TQS	Transmit Queue Size Indicates the size of the allocated transmit queues in blocks of 256 bytes. This field is read-write only if the number of transit queues are more than one, the reset value is 0x0 and indicates 256 bytes size. This means that value of 0x0 = 256 bytes, 0x1 = 512 bytes and so on. You must program TQS [5:0] = 6'b001111 to allocate queue size of 4096 (4K) bytes . In general, the size of the Queue = (TQS+1)*256 bytes. When the number of transit queue is one, the field is read-only and the reset value reflects the configured TX FIFO size in blocks of 256 bytes. The field's width depends on the transit memory size selected in your configuration. For example, if the memory size is 2048, the field's width is 3 bits: LOG2(2048/256) = LOG2(8) = 3 bits
15-7 —	Reserved.
6-4 TTC	Transmit Threshold Control Controls the threshold level of the MTL transit queue. The transmission starts when the packet size within the MTL transit queue is larger than the threshold, also transmits full packets with length less than the threshold. These fields are used only when MTL_TxQ0_Operation_Mode[TSF] resets. 000b - 32 001b - 64 010b - 96 011b - 128 100b - 192 101b - 256

Table continues on the next page...

Table continued from the previous page...

Field	Function
	110b - 384 111b - 512
3-2 TXQEN	Transmit Queue Enable Enables or disables the transmit queue 0. 2'b00 - Not enabled 2'b01 - Reserved 2'b10 - Enabled 2'b11 - Reserved This field is read only in single queue configurations and read write in multiple queue configurations. **NOTE** In multiple transit queue configuration, all the queues disables by default and programming this field enables the transit queue. 00b - Not enabled 01b - Enable in AV mode (Reserved in non-AV) 10b - Enabled 11b - Reserved
1 TSF	Transmit Store and Forward Indicates whether the transmit store and forward is enabled. When this field is 1, it indicates that the transmission starts when a full packet resides in the MTL transit queue and the TTC values specified in Bits[6:4] of this register are ignored. This field must be changed only when you stop the transmission. 0b - Disabled 1b - Enabled
0 FTQ	Flush Transmit Queue Indicates whether the flush transmit queue is enabled. When this field is 1, it indicates that the transit queue controller logic resets to its default values. Therefore, all the data in the transit queue is lost or flushed. After the flushing operation completes this field resets internally. You must not write to the MTL_TxQ1_Operation_Mode until this field resets. The data to which the MAC transmitter has already accepted is not flushed. It is scheduled for transmission and results in underflow and runt packet transmission. **NOTE** The flush operation completes only when the transit queue is empty and the application accepts the pending transit status of all the transmitted packets. To complete the flush operation, the PHY Tx clock (clk_tx_i) must be active.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Access restriction apply to this field. It clears automatically. Writing 1 sets this field and writing 0 has no effect. 0b - Disabled 1b - Enabled

72.18.216 MTL Tx Queue 0 Underflow (MTL_TxQ0_Underflow)

Offset

Register	Offset
MTL_TxQ0_Underflow	D04h

Function

Contains the counter for packets aborted because of transmit queue underflow and packets missed because of receive queue packet flush.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-12 —	Reserved.
11 UFCNTOVF	Overflow Bit for Underflow Packet Counter Indicates whether the overflow is detected for underflow packet counter.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field is 1, when the transit queue underflow packet counter field overflows, that is, it has crossed the maximum count. In such a scenario, the overflow packet counter resets to all-zeros and this field indicates that the rollover occured. Access restriction apply to this field. It clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
10-0 UFFRMCNT	Underflow Packet Counter Indicates the number of packets aborted by the controller because of transit queue underflow. This counter increments each time the MAC aborts outgoing packet because of underflow. The counter clears when this register is read with mci_be_i[0] at 1'b1. Access restriction apply to this field. It clears on read and automatically becomes 1 on an internal event occurrence.

72.18.217 MTL Tx Queue 0 Debug (MTL_TxQ0_Debug)

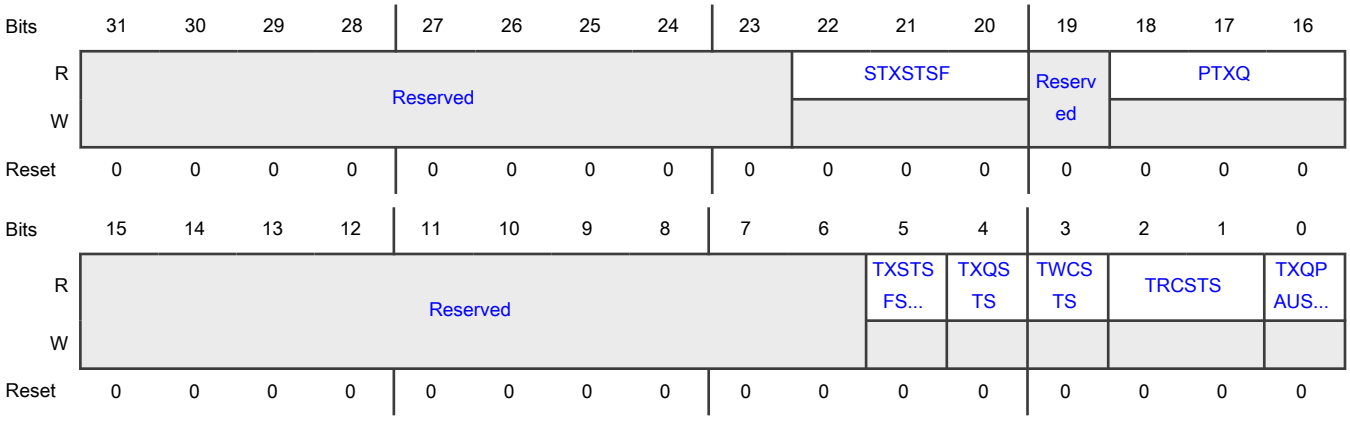
Offset

Register	Offset
MTL_TxQ0_Debug	D08h

Function

Provides the debug status of various blocks related to the transmit queue.

Diagram



Fields

Field	Function
31-23 —	Reserved.
22-20 STXSTSF	Number of Status Words in Tx Status FIFO of Queue Indicates the current number of status in the transit status FIFO of this queue. This field does not reflect the number of status words in transit status FIFO, when MTL_Operation_Mode[DTXSTS] = 1.
19 —	Reserved.
18-16 PTXQ	Number of Packets in the Transmit Queue Indicates the current number of packets in the transit queue. This field does not reflect the number of packets in the transmit queue, when MTL_Operation_Mode[DTXSTS] = 1.
15-6 —	Reserved.
5 TXSTSFSTS	MTL Tx Status FIFO Full Status Indicates whether the MTL transit status and FIFO full status is detected. When this field is 1, it indicates that the MTL transit status FIFO is full. Therefore, MTL cannot accept any more packets for transmission. 0b - Not detected 1b - Detected
4 TXQSTS	MTL Tx Queue Not Empty Status Indicates whether the MTL transit queue not empty status is detected. When this field is high, it indicates that the MTL transit queue is not empty and some data is left for transmission. 0b - Not detected 1b - Detected
3 TWCSTS	MTL Tx Queue Write Controller Status Indicates whether the MTL transit queue write controller status is detected. When high, this field indicates that the MTL transit queue write controller is active, and transfers the data to the transit queue. 0b - Not detected 1b - Detected

Table continues on the next page...

Table continued from the previous page...

Field	Function
2-1 TRCSTS	MTL Tx Queue Read Controller Status Indicates the state of the transit queue read controller. 00b - Idle state 01b - Read state (transferring data to the MAC transmitter) 10b - Waiting for pending transit status from the MAC transmitter 11b - Flushing the transit queue because of the packet abort request from the MAC
0 TXQPAUSED	Transmit Queue in Pause Indicates whether the transmit queue in pause is detected. When this field is 1 and the receive flow control is enabled, it indicates that the transit queue is in the pause condition (in the full-duplex only mode) because of the following scenario: • Receives PFC packet with the priorities assigned to the transit queue when PFC is enabled. • Receives 802.3x pause packet when PFC is disabled. 0b - Not detected 1b - Detected

72.18.218 MTL Tx Queue 0 ETS Status (MTL_TxQ0_ETS_Status)

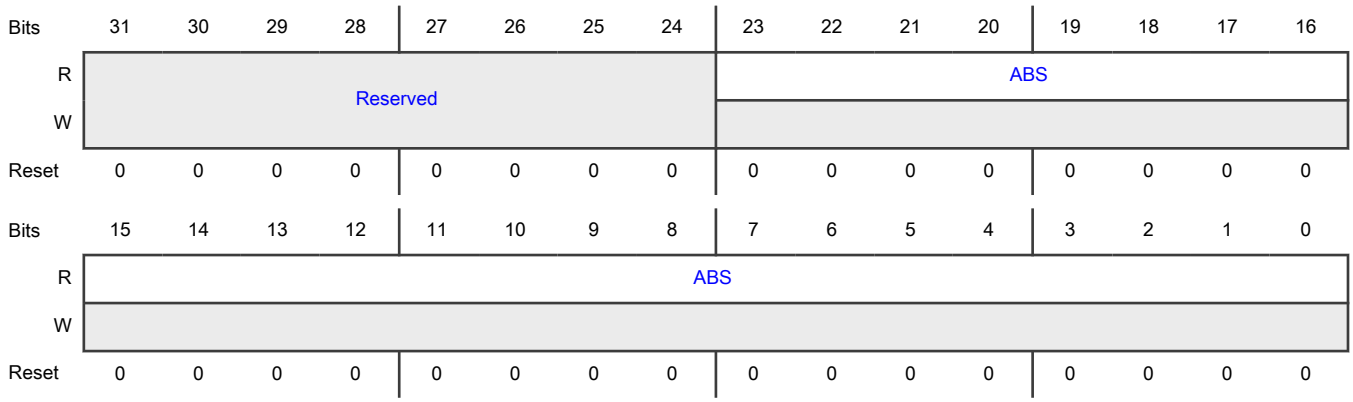
Offset

Register	Offset
MTL_TxQ0_ETS_Status	D14h

Function

Provides the average traffic transmitted in queue 0.

Diagram



Fields

Field	Function
31-24 —	Reserved.
23-0 ABS	Average Bits per Slot Contains the average transmitted bits per slot. Computes over every 10 million bit times slot (4 ms in 2500 Mbit/s; 10 ms in 1000 Mbit/s; 100 ms in 100 Mbit/s), when the DCB operation enables for queue 0. The maximum value is 0x989680.

72.18.219 MTL Tx Queue Quantum Weight (MTL_TxQ0_Quantum_Weight)

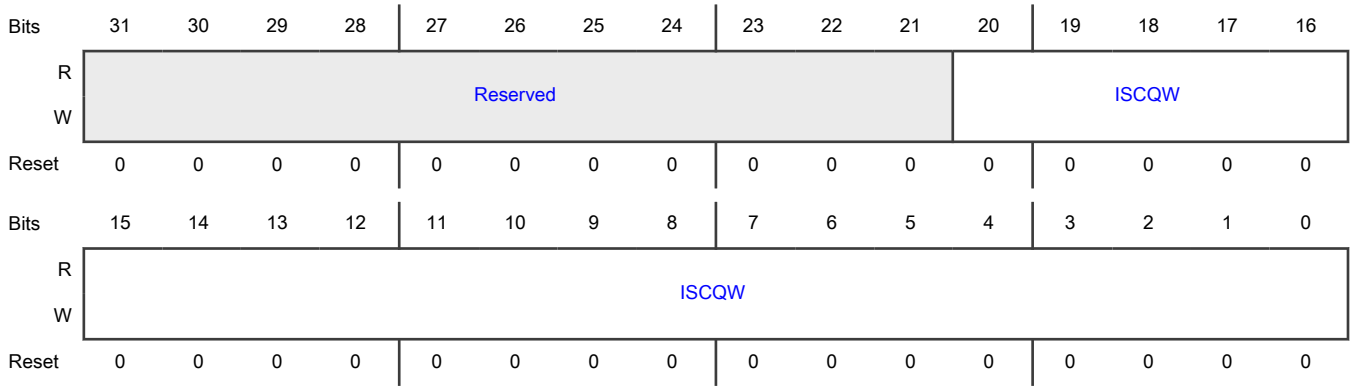
Offset

Register	Offset
MTL_TxQ0_Quantum_Weight	D18h

Function

Contains the quantum value for Deficit Weighted Round Robin (DWRR), weights for the Weighted Round Robin (WRR), and Weighted Fair Queuing (WFQ) for queue 0.

Diagram



Fields

Field	Function
31-21 —	Reserved.
20-0	Quantum or Weights

Table continues on the next page...

Table continued from the previous page...

Field	Function
ISCQW	Contains the quantum value in bytes which is added to credit during every queue scanning cycle, when DCB operation enables with DWRR algorithm for queue 0 traffic. The maximum value is 0x1312D0 bytes. Contains the weight for this queue, when DCB operation enables with WFQ algorithm for queue 0 traffic. The maximum value is 0x3FFF where weight of 0 indicates 100% bandwidth. Write 0 to bits[20:14]. The higher the programmed weights, the lesser is the bandwidth that is allocated for the particular transmit queue. This is because the weights compute the packet finish time (weights*packet_size). The lesser the finish time, the higher is the probability of the packet getting scheduled first and consuming more bandwidth. Contains the weight for this queue, when DCB operation or generic queuing operation enables with WRR algorithm for queue 0 traffic. The maximum value is 0x64. Write 0 to bits [20:7].

72.18.220 MTL Queue 0 Interrupt Control Status (MTL_Q0_Interrupt_Control_Status)

Offset

Register	Offset
MTL_Q0_Interrupt_Control_Status	D2Ch

Function

Contains the interrupt enable and status bits for the queue 0 interrupts.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved							RXOIE	Reserved							RXOVFIS
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved						ABPSIE	TXUIE	Reserved						ABPSIS	TXUNFIS
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-25 —	Reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
24 RXOIE	Receive Queue Overflow Interrupt Enable Enables or disables the receive queue overflow interrupt. When this field is 1, it enables the receive queue overflow interrupt. When this field becomes 0, it disables the receive queue overflow interrupt. 0b - Disabled 1b - Enabled
23-17 —	Reserved.
16 RXOVFIS	Receive Queue Overflow Interrupt Status Indicates whether the status of receive queue overflow interrupt is detected. This bit indicates that the receive queue had an overflow when you receive the packet. If you transfer a partial packet to the application, the overflow status sets in RDES3[21]. This fiels is 0 when the application writes 1 to it. Access restriction apply to this field. It becomes 0 automatically on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected
15-10 —	Reserved.
9 ABPSIE	Average Bits Per Slot Interrupt Enable Enables or disables the average bits per slot interrupt. When this field is 1, it indicates that when you update the average bits per slot status, the MAC asserts the sbd_intr_o or mci_intr_o interrupt. When this field is 0, it indicates that the interrupt do not assert for such an event. 0b - Disabled 1b - Enabled
8 TXUIE	Transmit Queue Underflow Interrupt Enable Enables or disables transmit queue underflow interrupt. When this field is 1, it enables the transmit queue underflow interrupt. When this field becomes 0, it disables the transmit queue underflow interrupt. 0b - Disabled 1b - Enabled
7-2	Reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
1 ABPSIS	Average Bits Per Slot Interrupt Status Indicates whether the status of average bits per slot interrupt is detected. When this field is 1, it indicates that the MAC has updated the ABS value. This field is 0 when the application writes 1 it. Access restriction apply to this field. It becomes 0 automatically on an internal event occurrence. Writing 1 sets this field and writing 0 has no effect. 0b - Not detected 1b - Detected
0 TXUNFIS	Transmit Queue Underflow Interrupt Status Indicates whether the status of transmit queue underflow interrupt is detected. This field indicates that, when you transmit the packet,the transmit queue had an underflow. Suspend the transmission and write 1 to an underflow error TDES3[2]. This field is 0, when the application writes 1 to it. Access restriction apply to this field. It becomes 0 automatically on an internal event occurrence. Writing 1 sets this field and writing 0 has no effect. 0b - Not detected 1b - Detected

72.18.221 MTL Rx Queue 0 Operation Mode (MTL_RxQ0_Operation_Mode)

Offset

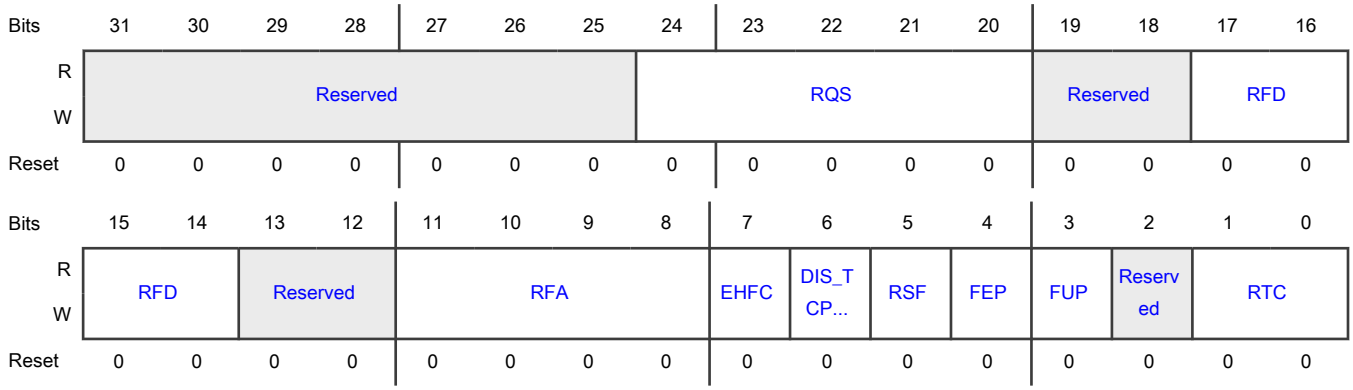
Register	Offset
MTL_RxQ0_Operation_Mode	D30h

Function

Establishes the receive queue operating modes and command.

The RFA and RFD fields are not backward compatible with the RFA and RFD fields of 4.00a release

Diagram



Fields

Field	Function
31-25 —	Reserved.
24-20 RQS	Receive Queue Size Indicates the size of the allocated receive queues in blocks of 256 bytes. The MTL_RxQ0_Operation_Mode[RQS] is read-write only if the number of receive queues are more than one, the reset value is 0x0 and indicates size of 256 bytes. This means that value of 0x0 = 256 bytes, 0x1 = 512 bytes and so on. You must program RQS [5:0] = 6'b001111 to allocate queue size of 4096 (4K) bytes. In general, the size of the Queue = (RQS+1)*256 bytes. When the number of receive queues is one, the field is read-only and the configured receive FIFO size in blocks of 256 bytes is reflected in the reset value. The field width depends on the receive memory size selected in your configuration. For example, if the memory size is 2048, the field width is 3 bits: LOG2(2048/256) = LOG2(8) = 3 bits
19-18 —	Reserved.
17-14 RFD	Threshold for Deactivating Flow Control (in half-duplex and full-duplex modes) Controls the threshold (fill-level of Rx queue) at which the flow control is de-asserts after activation. 0 - Full minus 1 KB, that is, FULL 1 KB 1 - Full minus 1.5 KB, that is, FULL 1.5 KB 2 - Full minus 2 KB, that is, FULL 2 KB 3 - Full minus 2.5 KB, that is, FULL 2.5 KB ... 14 - Full minus 8 KB, that is, FULL 8 KB 15 - Full minus 8.5 KB, that is, FULL 8.5 KB

Table continues on the next page...

Table continued from the previous page...

Field	Function
	De-assertion is effective only after flow control is asserted. **NOTE** You must program the value in such a way that the threshold is a positive number. When MTL_RxQ0_Operation_Mode[EHFC] = 1, these values are applicable only when the receive queue size which the MTL_RxQ0_Operation_Mode[RQS] determines is equal to or greater than 4 KB. For a given queue size, the values ranges between 0 and the encoding for FULL minus (QSIZE - 0.5 KB) and all other values are illegal. Here the term FULL and QSIZE refers to the queue size which the MTL_RxQ0_Operation_Mode[RQS] determines. The field width depends on RX FIFO size selected during the configuration. Remaining bits are reserved and read only.
13-12 —	Reserved.
11-8 RFA	Threshold for Activating Flow Control (in half-duplex and full-duplex) Controls the threshold (fill-level of receive queue) at which the flow control is activated. See MTL_RxQ0_Operation_Mode[RFD] for more information on encoding for this field.
7 EHFC	Enable Hardware Flow Control Enables or disables hardware flow control. If this field is 1, it enables the flow control signal operation, on the basis of the fill-level of receive queue. When this field becomes 0, it disables the flow control operation. 0b - Disable 1b - Enable
6 DIS_TCP_EF	Disable Dropping of TCP/IP Checksum Error Packets Enables or disable dropping of TCP or IP checksum error packets. When this field is 1, it indicates that the MAC does not drop the packets which only have the errors which the receive checksum offload engine detects. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC. When this field becomes 0, it indicates that all error packets are dropped if MTL_RxQ0_Operation_Mode[FEP] resets. 0b - Enable 1b - Disable
5 RSF	Receive Queue Store and Forward Indicates whether the receive queue store and forward is enabled. When this field is 1, it indicates that the module reads a packet from the receive queue only after the complete packet has been written to it, ignores the MTL_RxQ0_Operation_Mode[RTC].

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When this field becomes 0, it indicates that the receive queue operates in the Threshold (cut-through) mode, subject to the threshold which the MTL_RxQ0_Operation_Mode[RTC] specifies. 0b - Disabled 1b - Enabled
4 FEP	Forward Error Packets Indicates whether the forward error packets are enabled. When this field becomes 0, it indicates that the receive queue drop packets with an error status (CRC error, GMII_ER, watchdog timeout, or overflow). However, the packet does not drop if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode). When this field is 1, it indicates that all packets except the runt error packets are forwarded to the application or DMA. The packet is dropped irrespective of the setting of this field, if MTL_RxQ0_Operation_Mode[RSF] is 1 and the receive queue overflows when a partial packet is written. However, if MTL_RxQ0_Operation_Mode[RSF] becomes 0 and the receive queue overflows when a partial packet is written, a partial packet might be forwarded to the application or DMA. 0b - Disabled 1b - Enabled
3 FUP	Forward Undersized Good Packets Indicates whether the forward undersized good packets are enabled. When this field is 1, it indicates that the receive queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. When this field becomes 0, it indicates that the receive queue drops all packets of less than 64 bytes, unless a packet is already transferred because of the lower value of receive threshold, for example, MTL_RxQ0_Operation_Mode[RTC] = 01. 0b - Disabled 1b - Enabled
2 —	Reserved.
1-0 RTC	Receive Queue Threshold Control Controls the threshold level of the MTL receive queue (in bytes). The received packet is transferred to the application or DMA when the packet size within the MTL receive queue is larger than the threshold. In addition, automatically tranfer full packets with length less than the threshold. This field is valid only when MTL_RxQ0_Operation_Mode[RSF] = 0. This field is ignored when MTL_RxQ0_Operation_Mode[RSF] = 1. 00b - 64

Fields

Field	Function
31-28 —	Reserved.
27 MISCNTOVF	Missed Packet Counter Overflow Bit Indicates whether the missed packet counter overflow is detected. When this field is 1, it indicates that the receive queue missed packet counter has crossed the maximum limit.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Access restriction apply to this field. It clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
26-16 MISPKTCNT	Missed Packet Counter Indicates the number of packets this module has missed because the application asserts ari_pkt_flush_i[] for this queue. This counter resets when this register reads with mci_be_i[0] at 1b1. This counter increments by 1 when the DMA discards the packet because of buffer unavailability. Access restriction apply to this field. It clears on read and automatically becomes 1 on an internal event occurrence.
15-12 —	Reserved.
11 OVFCNTOVF	Overflow Counter Overflow Bit Indicates whether the counter overflow is detected. When this field is 1, it indicates that the receive queue overflow packet counter field has crossed the maximum limit. Access restriction apply to this field. It clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
10-0 OVFPKTCNT	Overflow Packet Counter Indicates the number of packets which this module discards because of receive queue overflow. This counter increments each time the module discards an incoming packet because of overflow. This counter resets when this register reads with mci_be_i[0] at 1'b1. Access restriction apply to this field. It clears on read and automatically becomes 1 on an internal event occurrence.

72.18.223 MTL Rx Queue 0 Debug (MTL_RxQ0_Debug)

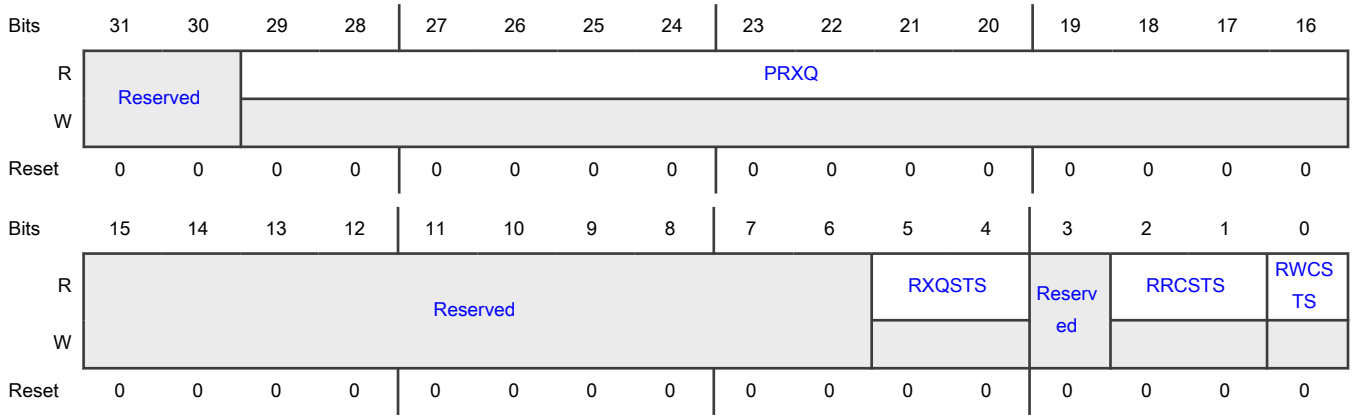
Offset

Register	Offset
MTL_RxQ0_Debug	D38h

Function

Provides the debug status of various blocks related to the receive queue.

Diagram



Fields

Field	Function
31-30 —	Reserved.
29-16 PRXQ	Number of Packets in Receive Queue Indicates the current number of packets in the receive queue. The theoretical maximum value for this field is 256KB/16B = 16K packets, that is, Max_Queue_Size/Min_Packet_Size.
15-6 —	Reserved.
5-4 RXQSTS	MTL Rx Queue Fill-Level Status Provides the status of the receive queue fill-level. 00b - Rx Queue empty 01b - Rx Queue fill-level below flow-control deactivate threshold 10b - Rx Queue fill-level above flow-control activate threshold 11b - Rx Queue full
3 —	Reserved.
2-1 RRCSTS	MTL Rx Queue Read Controller State Provides the state of the receive queue read controller. 00b - Idle state 01b - Reading packet data 10b - Reading packet status (or timestamp) 11b - Flushing the packet data and status

Table continues on the next page...

Table continued from the previous page...

Field	Function
0 RWCSTS	MTL Rx Queue Write Controller Active Status Indicates whether the MTL receive queue write controller active status is detected. When high, this bit indicates that the MTL receive queue write controller is active, and it is transferring a received packet to the receive queue. 0b - Not detected 1b - Detected

72.18.224 MTL Rx Queue 0 Control 0 (MTL_RxQ0_Control)

Offset

Register	Offset
MTL_RxQ0_Control	D3Ch

Function

Controls the receive arbitration and passing of received packets to the application.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-4 —	Reserved.
3 RXQ_FRM_ARBIT	Receive Queue Packet Arbitration Indicates whether the receive queue packet arbitration is enabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When this field is 1, it indicates that the module drives the packet data to the ARI interface such that the entire packet data of currently-selected queue transmits before switching to other queue. When this field becomes 0, it indicates that the module drives the packet data to the ARI interface such that the following amount of data of currently-selected queue transmits before switching to other queue: • PBL amount of data (indicated by ari_qN_pbl_i[]), or • Complete data of a packet The status and the timestamp are not a part of the PBL data. Therefore, the module drives the complete status (including timestamp status) during first PBL request for the packet (in store-and-forward mode) or the last PBL request for the packet (in Threshold mode). 0b - Disabled 1b - Enabled
2-0 RXQ_WEGT	Receive Queue Weight Indicates the weight assigned to receive queue 0. You must write a value to this field that is 1 less than the required queue weight. Therefore, if this field is 0, it indicates that the queue weight is 1, if this field is 1, it indicates that the queue weight is 2, and so on. You must use this weight to calculate the number of continuous PBL or packet requests, depending on the value of RXQ_FRM_ARBIT, allocated to the queue in an arbitration cycle. The field's value changes when the current service round completes or when there is a change from RAA=SP to RAA=WSP algorithm. This approach is required for a smooth transition. You must configure MTL Rx Queue 0 Control 0 (MTL_RxQ0_Control) before MTL Operation Mode (MTL_Operation_Mode) if you want to change the field's value before either of these two processes completes.

72.18.225 MTL Tx Queue 1 Operation Mode (MTL_TxQ1_Operation_Mode)

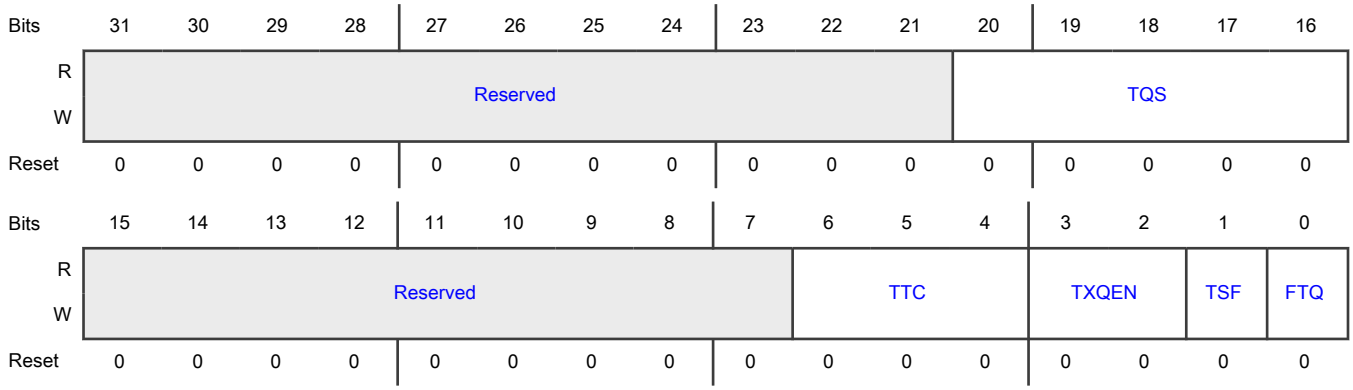
Offset

Register	Offset
MTL_TxQ1_Operation_Mode	D40h

Function

Establishes the transmit queue operating modes and commands.

Diagram



Fields

Field	Function
31-21 —	Reserved.
20-16 TQS	Transmit Queue Size Indicates the size of the allocated transmit queues in blocks of 256 bytes. This field is read-write only if the number of transit queues is more than one, the reset value is 0x0 and indicates size of 256 bytes. This means that value of 0x0 = 256 bytes, 0x1 = 512 bytes and so on. You must program TQS [5:0] = 6'b001111 to allocate queue size of 4096 (4K) bytes. In general, the size of the queue = (TQS+1)*256 bytes. When the number of transit queues is one, the field is read-only and the reset value reflects the configured TX FIFO size in blocks of 256 bytes. The field width depends on the transit memory size selected in your configuration. For example, if the memory size is 2048, the field width is 3 bits: LOG2(2048/256) = LOG2(8) = 3 bits
15-7 —	Reserved.
6-4 TTC	Transmit Threshold Control Controls the threshold level of the MTL Tx Queue. The transmission starts when the packet size within the MTL Tx Queue is larger than the threshold. In addition, it also transmit full packets with length less than the threshold. These fields are used only when the MTL_TxQ1_Operation_Mode[TSF] resets. 000b - 32 001b - 64 010b - 96 011b - 128 100b - 192 101b - 256

Table continues on the next page...

Table continued from the previous page...

Field	Function
	110b - 384 111b - 512
3-2 TXQEN	Transmit Queue Enable Enables or disables the transmit queue 0. 2'b00 - Not enabled 2'b01 - Enable in AV mode 2'b10 - Enabled 2'b11 - Reserved **NOTE** All the queues disables by default, in multiple transit queues configuration. You must program this field to enable the transit queue. 00b - Not enabled 01b - Enable in AV mode (Reserved in non-AV) 10b - Enabled 11b - Reserved
1 TSF	Transmit Store and Forward Indicates whether the transmit store and forward is enabled. When this field is 1, it indicates that the transmission starts when full packet resides in the MTL transit queue and the TTC values specified in MTL_TxQ1_Operation_Mode[TTC] are ignored. This field must change only when the transmission stops. 0b - Transmit Store and Forward is disabled 1b - Transmit Store and Forward is enabled
0 FTQ	Flush Transmit Queue Indicates whether the flush transmit queue is enabled. When this field is 1, it indicates that the transmit queue controller logic resets to its default values. Therefore, all the data in the transit queue is lost or flushed. This field resets internally when the flushing operation completes. Until this field becomes 0, you must not write to MTL_TxQ1_Operation_Mode. The data which the MAC transmitter has already accepted is not flushed. It is scheduled for transmission and results in an underflow and runt packet transmission. **NOTE** The flush operation completes only when the transit queue is empty and the application has accepted the pending transit status of all transmitted packets. To complete this flush operation, the PHY Tx clock (clk_tx_i) must be active. Access restriction apply to this field. Writing 1 sets this field and it clears automatically. Writing 0 has no effect.

Field	Function
31-23	Reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
22-20 STXSTSF	Number of Status Words in Tx Status FIFO of Queue Indicates the current number of status in the transit status FIFO of this queue. When MTL_Operation_Mode[DTXSTS] = 1, this field does not reflect the number of status words in transit status FIFO.
19 —	Reserved.
18-16 PTXQ	Number of Packets in the Transmit Queue Indicates the current number of packets in the transit queue. When MTL_Operation_Mode[DTXSTS] = 1, this field does not reflect the number of packets in the transmit queue.
15-6 —	Reserved.
5 TXSTSFSTS	MTL Tx Status FIFO Full Status Indicates whether the MTL transit status FIFO full status is detected. When this field is 1, it indicates that the MTL transit status FIFO is full. Therefore, the MTL cannot accept any more packets for transmission. 0b - Not detected 1b - Detected
4 TXQSTS	MTL Tx Queue Not Empty Status Indicates whether the MTL transit queue not empty status is detected. When this field is 1, it indicates that the MTL transit queue is not empty and some data is left for transmission. 0b - Not detected 1b - Detected
3 TWCSTS	MTL Tx Queue Write Controller Status Indicates whether the MTL transit queue write controller status is detected. When this field is 1, it indicates that the MTL transit queue write controller is active, and it is transferring the data to the transit queue. 0b - Not detected 1b - Detected
2-1 TRCSTS	MTL Tx Queue Read Controller Status Indicates the state of the transit queue read controller.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	00b - Idle state 01b - Read state (transferring data to the MAC transmitter) 10b - Waiting for pending transit status from the MAC transmitter 11b - Flushing the transit queue because of the packet abort request from the MAC
0 TXQPAUSED	Transmit Queue in Pause Indicates whether the transmit queue in pause status is detected. When this field is 1 and the receive flow control is enabled, it indicates that the transit queue is in the pause condition (in the full-duplex only mode) because of these scenarios: • Reception of the PFC packet for the priorities assigned to the transit queue when PFC is enabled. • Reception of 802.3x pause packet when PFC is disabled. 0b - Not detected 1b - Detected

72.18.228 MTL Tx Queue 1 ETS Control (MTL_TxQ1_ETS_Control)

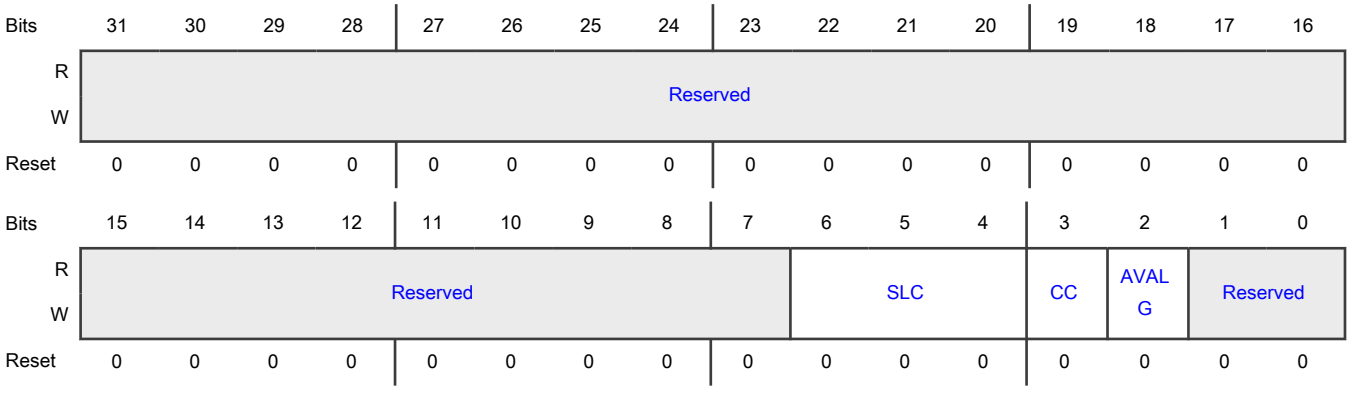
Offset

Register	Offset
MTL_TxQ1_ETS_Control	D50h

Function

Controls the enhanced transmission selection operation.

Diagram



Fields

Field	Function
31-7 —	Reserved.
6-4 SLC	Slot Count If the credit-based shaper algorithm is enabled, then you can program the number of slots (of duration programmed in DMA_CH(#i)_Slot_Interval register) over which the average transmitted bits per slot, provided in the MTL_TxQ(#i)_ETS_Status register, is computed for queue. The encoding is as follows: 000b - 1 slot 001b - 2 slots 010b - 4 slots 011b - 8 slots 100b - 16 slots 101b - Reserved
3 CC	Credit Control Indicates whether the credit control is enabled. When this field is 1, it indicates that the accumulated credit parameter in the credit-based shaper algorithm logic is not reset to zero, when there is positive credit and no packet to transmit in channel 1. The credit accumulates even when no packet is waiting in channel 1 and another channel is transmitting. When this field becomes 0, it indicates that the accumulated credit parameter in the credit-based shaper algorithm logic sets to zero, when there is positive credit and no packet to transmit in channel 1. No credit accumulates when no packet is waiting in channel 1 and other channel is transmitting. 0b - Disabled 1b - Enabled
2 AVALG	AV Algorithm Indicates whether the CBS algorithm is enabled. If you program queue 1 for AV, this field configures the scheduling algorithm for this queue. When this field is 1, it indicates that the credit based shaper algorithm (CBS) is selected for queue 1 traffic. If this field becomes 0, strict priority is selected. 0b - Disabled 1b - Enabled
1-0 —	Reserved.

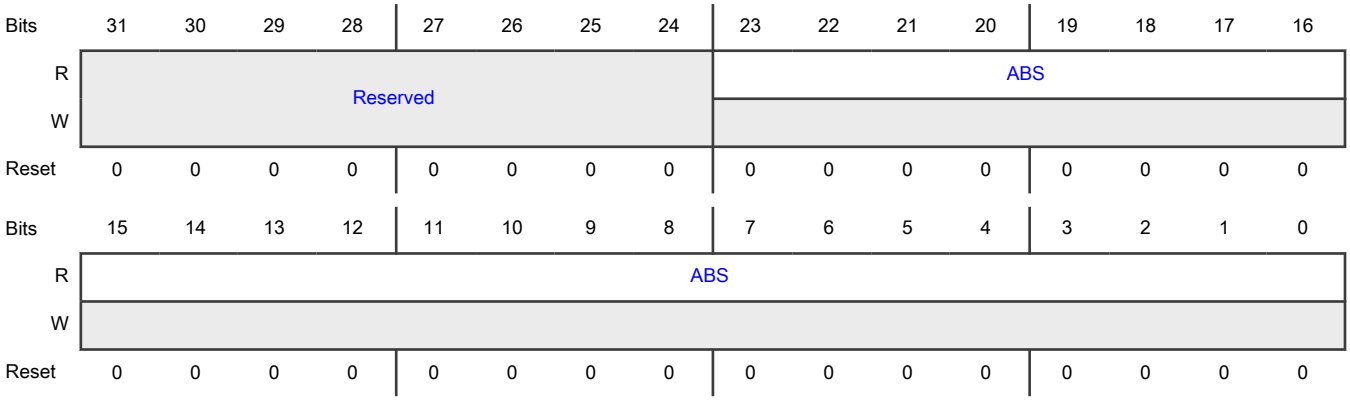
72.18.229 MTL Tx Queue 1 ETS Status (MTL_TxQ1_ETS_Status)

Offset

Register	Offset
MTL_TxQ1_ETS_Status	D54h

Function
Provides the average traffic transmitted in queue 1.

Diagram



Fields

Field	Function
31-24 —	Reserved.
23-0 ABS	Average Bits per Slot Contains the average transmitted bits per slot. Computes this field over number of slots programmed in the MTL_TxQ(#i)_ETS_CONTROL register's SLC field of, if you enables AV operation. This field's maximum value is 0x6_4000 in 100 Mbit/s, 0x3E_8000 in 1000 Mbit/s and 9C_4000 in 2500 Mbit/s mode respectively. Computes this field over every 10 million bit times slot (4 ms in 2500 Mbit/s; 10 ms in 1000 Mbit/s; 100 ms in 100 Mbit/s) when you enables DCB operation for queue. The maximum value is 0x989680.

72.18.230 MTL Tx Queue 1 Quantum Weight (MTL_TxQ1_Quantum_Weight)

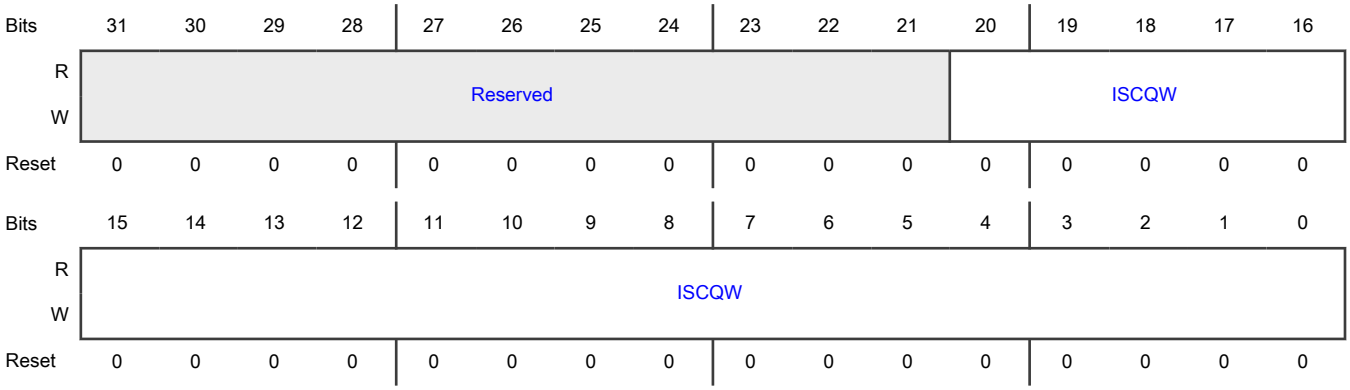
Offset

Register	Offset
MTL_TxQ1_Quantum_Weight	D58h

Function

Provides the average traffic transmitted in queue 1.

Diagram



Fields

Field	Function
31-21 —	Reserved.
20-0 ISCQW	idleSlopeCredit, Quantum or Weights idleSlopeCredit Contains the idleSlopeCredit value required for the credit-based shaper algorithm for queue 1, when you enables the AV feature. This is the rate of change of credit in bits per cycle (40 ns for 100 Mbit/s; 8 ns for 1000 Mbit/s; 3.2 ns for 2500 Mbit/s) when the credit is increasing. You must program this field with computed credit in bits per cycle scaled by 1,024. The maximum value is portTransmitRate, that is, 0x2000 in 1000/2500 Mbit/s mode and 0x1000 in 100 Mbit/s mode. Bits[20:14] must be written to zero. Quantum Contains the quantum value in bytes to be added to credit during every queue scanning cycle, when you enables the DCB operation with DWRR algorithm for queue 1 traffic. The maximum value is 0x1312D0 bytes. Weights Contains the weight for this queue, when you enables the DCB operation with WFQ algorithm for queue 1 traffic. The maximum value is 0x3FFF where weight of 0 indicates 100% bandwidth. Bits[20:14] must be written to zero. Contains the weight for this queue, when you enables the DCB operation or generic queuing operation with WRR algorithm for queue 1 traffic. The maximum value is 0x64. Bits [20:7] must be written to zero.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE In multiple Queue configuration you must program this field in respective per queue register to some non-zero value when multiple queues are enabled or single queue other than Q0 is enabled. You must not program this field when only Q0 is enabled. In general, you must program a non-zero value on both receive and transmit when WRR algorithm is selected. In receive, the register is MTL_Operation_Mode register. **NOTE** For WFQ algorithm, higher the programmed weights lesser the bandwidth allocated for that transmit queue. The finish time is not a function of particular packet alone but it is according to the formula: (previous_finish_time of particular Transmit Queue + (weights*packet_size)) **NOTE** The programmed weights do not correspond to the number of packets but the fraction of bandwidth or time allocated for particular queue w.r.t. total BW or time.

72.18.231 MTL Tx Queue 1 Sendslope Credit (MTL_TxQ1_SendSlopeCredit)

Offset

Register	Offset
MTL_TxQ1_SendSlopeCredit	D5Ch

Function

Contains the sendSlope credit value required for the credit-based shaper algorithm for the queue.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-14 —	Reserved.
13-0 SSC	sendSlopeCredit Value Contains the sendSlopeCredit value required for credit-based shaper algorithm for Queue 1, when you enables the AV operation. This is the rate of change of credit in bits per cycle (40 ns, 8 ns and 3.2 ns for 100 Mbit/s, 1000 Mbit/s and 2500 Mbit/s respectively) when the credit is decreasing. You must program this field with computed credit in bits per cycle scaled by 1,024. The maximum value is portTransmitRate, that is, 0x2000 in 1000/2500 Mbit/s mode and 0x1000 in 100 Mbit/s mode. You must program this fiels with absolute sendSlopeCredit value. The credit-based shaper logic subtracts it from the accumulated credit when channel 1 is selected for transmission.

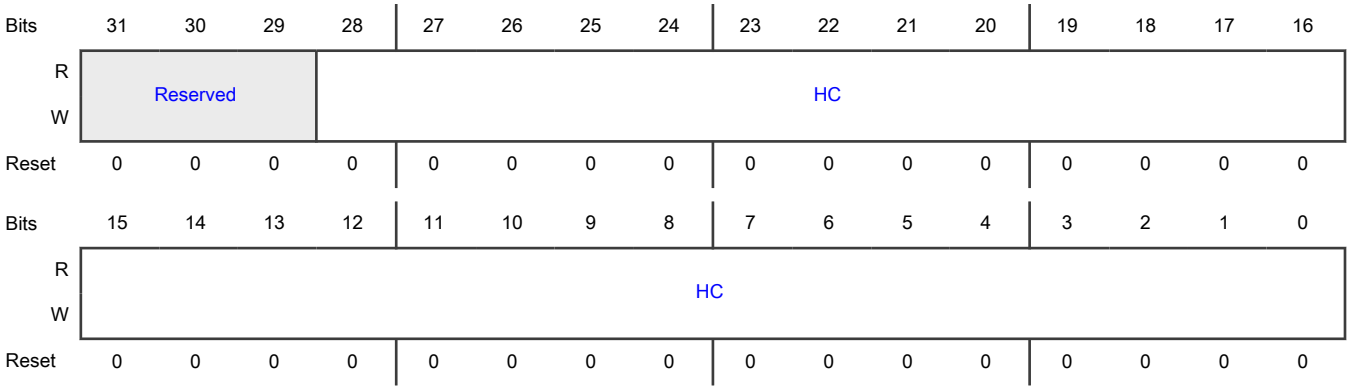
72.18.232 MTL Tx Queue 1 HiCredit (MTL_TxQ1_HiCredit)

Offset

Register	Offset
MTL_TxQ1_HiCredit	D60h

Function
Contains the hiCredit value required for the credit-based shaper algorithm for the queue.

Diagram



Fields

Field	Function
31-29 —	Reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
28-0 HC	hiCredit Value Contains the hiCredit value required for the credit-based shaper algorithm, when you enables the AV feature. This is the maximum value that you can accumulate in the credit parameter. This is specified in bits scaled by 1,024. The maximum value is maxInterferenceSize, that is, best-effort maximum packet size (16,384 bytes or 131,072 bits). The specified value is 131,072 * 1,024 = 134,217,728 or 0x0800_0000.

72.18.233 MTL Tx Queue 1 LoCredit (MTL_TxQ1_LoCredit)

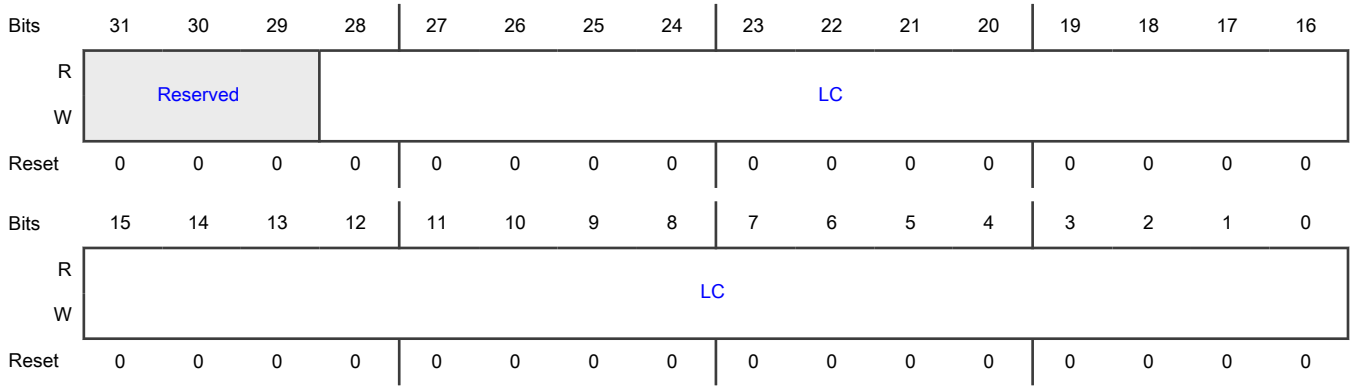
Offset

Register	Offset
MTL_TxQ1_LoCredit	D64h

Function

Contains the loCredit value required for the credit-based shaper algorithm for the queue.

Diagram



Fields

Field	Function
31-29 —	Reserved.
28-0 LC	loCredit Value Contains the loCredit value required for the credit-based shaper algorithm, when you enables the AV operation. This is the minimum value that you can accumulate in the credit parameter. This is specified in bits scaled by 1,024. The maximum value you can program corresponds to twice the maxFrameSize this queue transmits. If the maxFrameSize is 8192 bytes, then (8192*2) * 8 * 1024 = 134,217,728 or 0x0800_0000. The programmed value is 2's complement of the value, that is, 0x1800_0000 because it is a negative value.

72.18.234 MTL Queue 1 Interrupt Control Status (MTL_Q1_Interrupt_Control_Status)

Offset

Register	Offset
MTL_Q1_Interrupt_Control_Status	D6Ch

Function
Contains the interrupt enable and status bits for the queue 1 interrupts.

Diagram

	reset value is 0x0 and indicates 256 bytes size. This means that value of 0x0 = 256 bytes, 0x1 = 512 bytes and so on. You must program RQS [5:0] = 6'b001111 to allocate queue size of 4096 (4K) bytes. In general, the size of the Queue = (RQS+1)*256 bytes. When the number of receive queues is one, the field is read-only and the reset value reflects the configured RX FIFO size in blocks of 256 bytes. The field width depends on the receive memory size selected in your configuration. For example, if the memory size is 2048, the field width is 3 bits: LOG2(2048/256) = LOG2(8) = 3 bits
19-18 —	Reserved.
17-14 RFD	Threshold for Deactivating Flow Control (in half-duplex and full-duplex modes) Controls the threshold (fill-level of Rx queue) at which the flow control de-asserts after activation 0 - Full minus 1 KB, that is, FULL 1 KB 1 - Full minus 1.5 KB, that is, FULL 1.5 KB 2 - Full minus 2 KB, that is, FULL 2 KB 3 -Full minus 2.5 KB, that is, FULL 2.5 KB ... 14 - Full minus 8 KB, that is, FULL 8 KB 15 - Full minus 8.5 KB, that is, FULL 8.5 KB The de-assertion is effective only when flow control asserts. **NOTE** Program the value in such a way that the threshold is a positive number. When MTL_RxQ1_Operation_Mode[EHFC] = 1, these values are applicable only when the receive queue size which MTL_RxQ1_Operation_Mode[RQS] determines, is equal to or greater than 4 KB. For a given queue size, the values ranges between 0 and the encoding for FULL minus (QSIZE - 0.5 KB) and all other values are illegal. Here the term FULL and QSIZE refers to the queue size which MTL_RxQ1_Operation_Mode[RQS] determines. The field width depends on RX FIFO size selected during the configuration. Remaining bits are reserved and read only.
13-12 —	Reserved.
11-8 RFA	Threshold for Activating Flow Control (in half-duplex and full-duplex Controls the threshold (fill-level of Rx queue) at which the flow control activates. See MTL_RxQ1_Operation_Mode[RFD], for more information on encoding for this field.

Table continues on the next page...

Table continued from the previous page...

Field	Function
7 EHFC	Enable Hardware Flow Control Enables or disables hardware flow control. If this field is 1, it enables the flow control signal operation, based on the receive queue's fill-level. When this field becomes 0, it disables the flow control operation. 0b - Disable 1b - Enable
6 DIS_TCP_EF	Disable Dropping of TCP or IP Checksum Error Packets Indicates whether the dropping of TCP or IP checksum error packets is enabled. When this field is 1, it indicates that the MAC does not drop the packets which only have the errors that the receive checksum offload engine detects. Such packets have errors only in the encapsulated payload. MAC receives an Ethernet packet in which there are no errors (including FCS error). When this field becomes 0, it indicates that all the error packets drop if MTL_RxQ1_Operation_Mode[FEP] resets. 0b - Enabled 1b - Disabled
5 RSF	Receive Queue Store and Forward Indicates whether the receive queue store and forward is enabled. When this field is 1, it indicates that the module reads a packet from the receive queue only after the complete packet is written to it and ignores MTL_RxQ1_Operation_Mode[RTC]. When this field becomes 0, it indicates that the receive queue operates in the Threshold (cut-through) mode, subject to the threshold which MTL_RxQ1_Operation_Mode[RTC] specifies. 0b - Disabled 1b - Enabled
4 FEP	Forward Error Packets Indicates whether the forward error packets are enabled. If this field becomes 0, it indicates that the receive queue drops the packets with an error status (CRC error, GMII_ER, watchdog timeout, or overflow). However, the packet does not drops, if the start byte (write) pointer of a packet is already transferred to the read controller side in Threshold mode. When this field is 1, it indicates that all the packets except the runt error packets forward to the application or DMA. If MTL_RxQ1_Operation_Mode[RSF] is 1 and the receive queue overflows when a partial packet is written, the packet drops irrespective of the setting of this field. However, if MTL_RxQ1_Operation_Mode[RSF] resets and the receive queue overflows when a partial packet is written, you may forward a partial packet to the application or DMA. 0b - Disabled 1b - Enabled
3	Forward Undersized Good Packets

Table continues on the next page...

Table continued from the previous page...

Field	Function
FUP	Indicates whether the forward undersized good packets are enabled. When this field is 1, it indicates that the receive queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. When this field becomes 0, it indicates that the receive queue drops all the packets of less than 64 bytes, unless a packet is already transferred because of the lower value of Rx Threshold, for example, RTC = 01. 0b - Disabled 1b - Enabled
2 —	Reserved.
1-0 RTC	Receive Queue Threshold Control Controls the threshold level of the MTL Rx queue (in bytes): The received packet is transferred to the application or DMA when the packet size within the MTL receive queue is larger than the threshold. Also, the full packets with length less than the threshold are automatically transferred. This field is valid only when MTL_RxQ1_Operation_Mode[RSF] = 0. This field is ignored when MTL_RxQ1_Operation_Mode[RSF] = 1. 00b - 64 01b - 32 10b - 96 11b - 128

72.18.236 MTL Rx Queue 1 Missed Packet Overflow Counter (MTL_RxQ1_Missed_Packet_Overflow_Cnt)

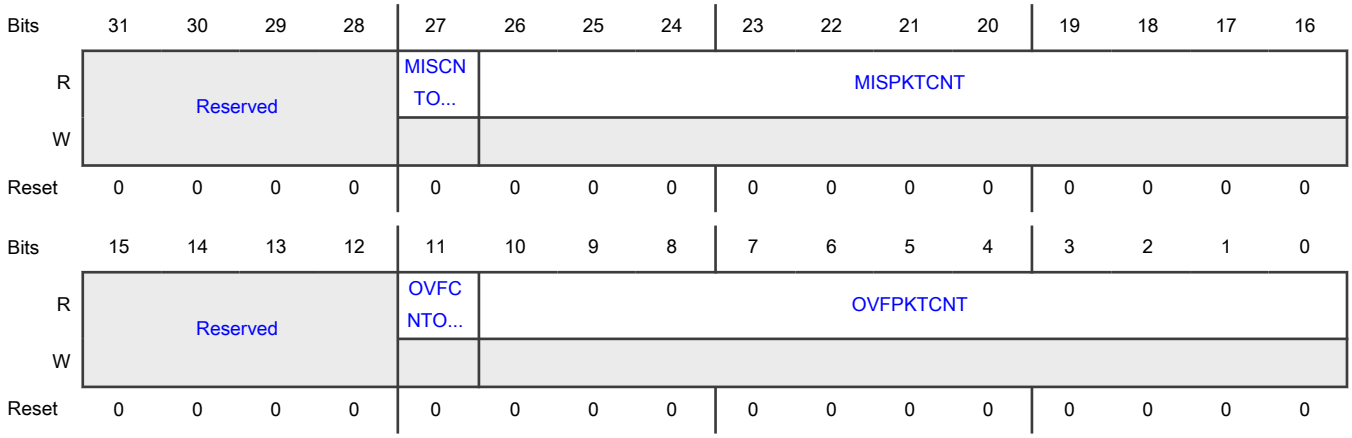
Offset

Register	Offset
MTL_RxQ1_Missed_Packet_Overflow_Cnt	D74h

Function

Contains the counter for packets missed because of receive queue packet flush and packets discarded because of receive queue overflow.

Diagram



Fields

Field	Function
31-28 —	Reserved.
27 MISCNTOVF	Missed Packet Counter Overflow Bit Indicates whether the missed packet counter overflow is detected. When this field is 1, it indicates that the receive queue missed packet counter has crossed the maximum limit. Access restriction apply to this field. It clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
26-16 MISPKTCNT	Missed Packet Counter Indicates the number of packets the module has missed because the application asserted ari_pkt_flush_i[] for this queue. This counter resets when this register is read with mci_be_i[0] at 1b1. This counter increases by 1 when the DMA discards the packet because of buffer unavailability. Access restriction apply to this field. It clears on read and automatically becomes 1 on an internal event occurrence.
15-12 —	Reserved.
11 OVFCNTOVF	Overflow Counter Overflow Bit Indicates whether the counter overflow status is detected. When this field is 1, it indicates that the receive queue overflow packet counter field has crossed the maximum limit.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Access restriction apply to this field. It clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not detected 1b - Detected
10-0 OVFPKTCNT	Overflow Packet Counter Indicates the number of packets which the module discards because of receive queue overflow. This counter increments each time the module discards an incoming packet because of overflow. It resets when this register is read with mci_be_i[0] at 1'b1. Access restriction apply to this field. It clears on read and automatically becomes 1 on an internal event occurrence.

72.18.237 MTL Rx Queue 1 Debug (MTL_RxQ1_Debug)

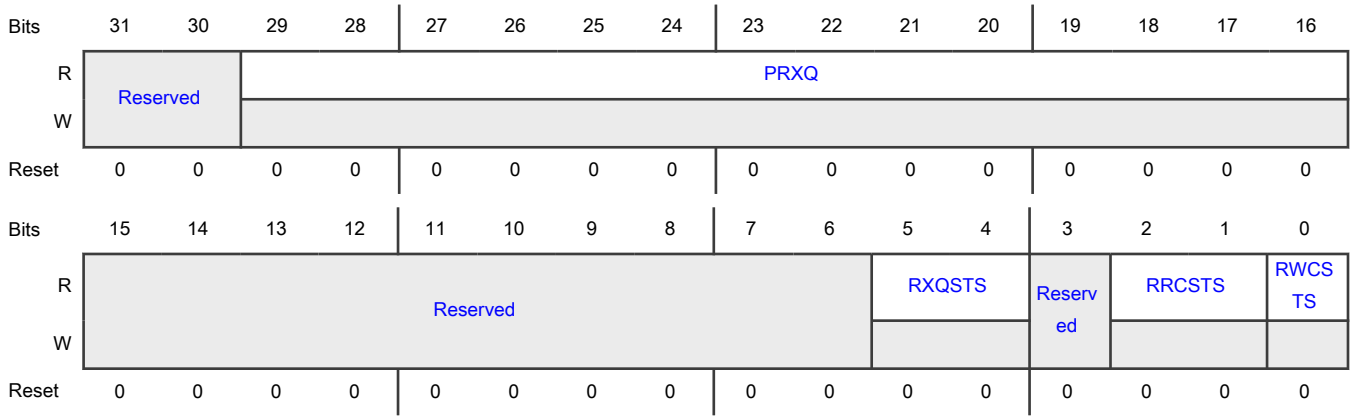
Offset

Register	Offset
MTL_RxQ1_Debug	D78h

Function

Provides the debug status of various blocks related to the receive queue.

Diagram



Fields

Field	Function
31-30	Reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
29-16 PRXQ	Number of Packets in Receive Queue Indicates the current number of packets in the receive queue. The theoretical maximum field value is 256KB/16B = 16K packets, that is, Max_Queue_Size/Min_Packet_Size.
15-6 —	Reserved.
5-4 RXQSTS	MTL Rx Queue Fill-Level Status Provides the status of the receive queue fill-level. 00b - Rx Queue empty 01b - Rx Queue fill-level below flow-control deactivate threshold 10b - Rx Queue fill-level above flow-control activate threshold 11b - Rx Queue full
3 —	Reserved.
2-1 RRCSTS	MTL Rx Queue Read Controller State Provides the state of the receive queue read controller. 00b - Idle state 01b - Reading packet data 10b - Reading packet status (or timestamp) 11b - Flushing the packet data and status
0 RWCSTS	MTL Rx Queue Write Controller Active Status Indicates whether the MTL receive queue write controller active status is detected. When this field is 1, it indicates that the MTL receive queue write controller is active, and it is transferring a received packet to the receive queue. 0b - Not detected 1b - Detected

72.18.238 MTL Rx Queue 1 Control (MTL_RxQ1_Control)

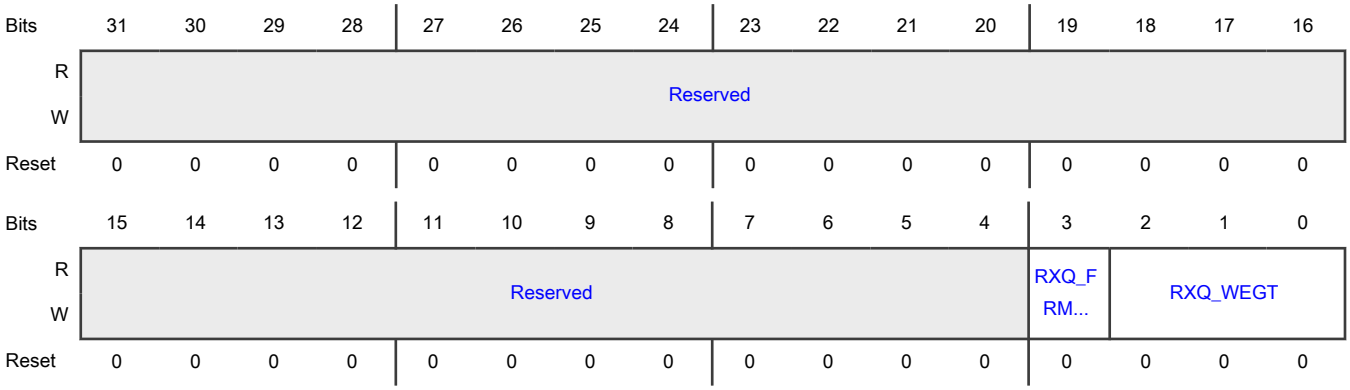
Offset

Register	Offset
MTL_RxQ1_Control	D7Ch

Function

Controls the receive arbitration and passing of received packets to the application.

Diagram



Fields

Field	Function
31-4 —	Reserved.
3 RXQ_FRM_ARBIT	Receive Queue Packet Arbitration Indicates whether the receive queue packet arbitration is enabled. When this field is 1, it indicates that the module drives the packet data to the ARI interface such that the entire packet data of currently-selected queue transmits before switching to other queue. When this field becomes 0, it indicates that the module drives the packet data to the ARI interface such that the following amount of data of currently-selected queue transmits before switching to other queue: • PBL amount of data (indicated by ari_qN_pbl_i[]), or • Complete data of a packet The status and the timestamp are not a part of the PBL data. Therefore, the module drives the complete status (including timestamp status) during the packet's first PBL request (in store-and-forward mode) or the last PBL request (in Threshold mode). 0b - Disabled 1b - Enabled
2-0 RXQ_WEGT	Receive Queue Weight Indicates the weight assigned to the receive queue 0. Program this field with one value less than the required weight, that is reset value of 0 indicates weight of 1, value of 1 indicates weight of 2, and so on. The weight is used as the number of continuous PBL or packets requests (depending on the RXQ_FRM_ARBIT) allocated to the queue in one arbitration cycle. Note: The change in value of RXQ_WEGT takes effect only after the completion of current service round or when there is change from RAA=SP to RAA=WSP algorithm. This approach is taken so that there is smooth transition. For the RXQ_WEGT value to take effect at the start, the MTL_RxQ(#i)_Control registers must be programmed before the MTL_Operation_Mode register.

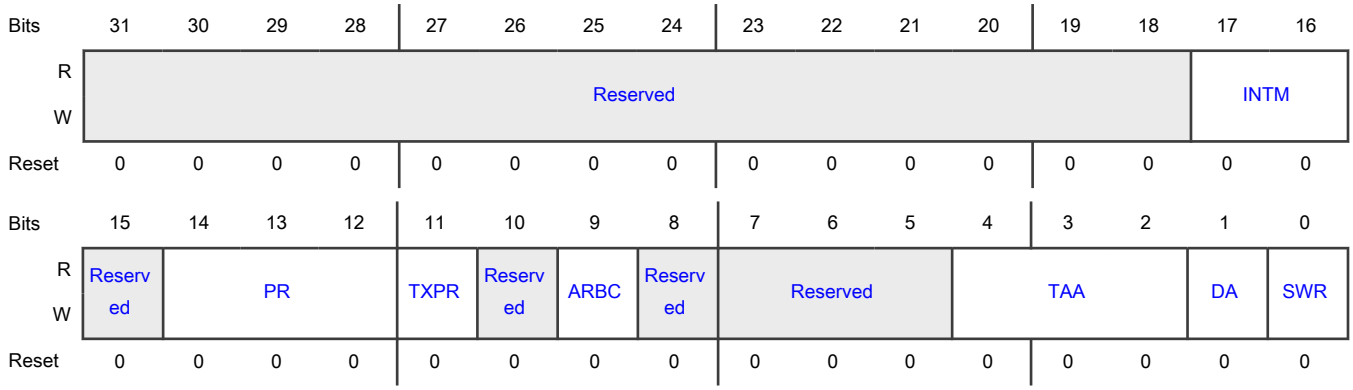
72.18.239 DMA Mode (DMA_Mode)

Offset

Register	Offset
DMA_Mode	1000h

Function
Establishes the bus operating modes for the DMA.

Diagram



Fields

Field	Function
31-18 —	Reserved.
17-16 INTM	Interrupt Mode Defines the interrupt mode of module. The behavior of the following outputs changes depending on these settings: sbd_perch_tx_intr_o[] (Transmit per channel interrupt) sbd_perch_rx_intr_o[] (Receive per channel interrupt) sbd_intr_o (Common interrupt) It also changes the behavior of the RI/TI bits in DMA_CH0_Status. 00 - sbd_perch_* are pulse signals for each TX/RX packet transfer completion events (irrespective of whether corresponding interrupts are enabled) for which IOC bits are enabled in descriptor. sbd_intr_o is also asserted when corresponding interrupts are enabled and cleared only when software clears the corresponding RI/TI status bits. 01 - sbd_perch_* are level signals asserted on TX/RX packet transfer completion event when corresponding interrupts are enabled and de-asserted when the software clears the corresponding RI/TI status bits. The sbd_intr_o is not asserted for these TX/RX packet transfer completion events.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	10 - sbd_perch_* are level signals asserted on TX/RX packet transfer completion event when corresponding interrupts are enabled and de-asserted when the software clears the corresponding RI/TI status bits. However, the signal is asserted again if the same event occurred again before it was cleared. The sbd_intr_o is not asserted for these TX/RX packet transfer completion events. 11 - Reserved See table "Transfer Complete Interrupt Behavior" for more information. 00b - See above description 01b - See above description 10b - See above description 11b - Reserved
15 —	Reserved.
14-12 PR	Priority Ratio Controls the priority ratio in weighted round-robin arbitration between the Rx DMA and Tx DMA. These fields are valid only when DMA_Mode[DA] resets. The priority ratio is Rx:Tx or Tx:Rx depending on whether DMA_Mode[TXPR] = 1 or it resets. 000b - The priority ratio is 1:1 001b - The priority ratio is 2:1 010b - The priority ratio is 3:1 011b - The priority ratio is 4:1 100b - The priority ratio is 5:1 101b - The priority ratio is 6:1 110b - The priority ratio is 7:1 111b - The priority ratio is 8:1
11 TXPR	Transmit Priority Indicates whether the transmit priority is enabled. When this field is 1, it indicates that the Tx DMA has higher priority than the Rx DMA during arbitration for the system-side bus. 0b - Disabled 1b - Enabled
10 —	Reserved.
9 ARBC	Is reserved for NXP internal use. This field must always be 0 unless instructed by NXP. Writing 1 to this field may cause unexpected behavior.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - NXP reserved field disabled 1b - NXP reserved field enabled up on NXP request
8 —	Reserved.
7-5 —	Reserved.
4-2 TAA	Transmit Arbitration Algorithm Selects the arbitration algorithm for the transmit side when you select multiple transit DMAs. 000b - Fixed priority (Channel 0 has the lowest priority and the last channel has the highest priority) 001b - Weighted Strict Priority (WSP) 010b - Weighted Round-Robin (WRR) 011b - Reserved (for 3'b011 to 3'b111)
1 DA	DMA Tx or Rx Arbitration Scheme Specifies the arbitration scheme between the transmit and receive paths of all channels. 0 - Weighted round-robin with Rx:Tx or Tx:Rx The priority between the paths is according to the priority specified in bits[14:12] and the priority weight is specified in DMA_Mode[TXPR]. 1 - Fixed Priority The transit path has priority over the receive path when DMA_Mode[TXPR] = 1. Otherwise, the receive path has priority over the transit path. 0b - Weighted Round-Robin with Rx:Tx or Tx:Rx 1b - Fixed Priority
0 SWR	Software Reset Indicates whether the software reset is enabled. When this field is 1, it indicates that the MAC and the DMA controller resets the logic and all internal registers of the DMA, MTL, and MAC. This field automatically clears after the reset operation completes in all module clock domains. A value of zero should be read in this field before reprogramming any module register. When this field is 1, it indicates that this field must read at least 4 CSR clock cycles. **NOTE** The reset operation completes only when all resets in all active clock domains de-assert. Therefore, to complete software reset, it is essential that all PHY input clocks (applicable for the selected PHY interface) are present. The time to complete the software reset operation depends on the frequency of the slowest active clock.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Access restriction apply to this field. It clears automatically. Writing 1 sets this field and writting 0 has no effect. 0b - Disabled 1b - Enabled

72.18.240 DMA System Bus Mode (DMA_SysBus_Mode)

Offset

Register	Offset
DMA_SysBus_Mode	1004h

Function

Controls the behavior of the AHB or AXI master. It mainly controls burst splitting and the number of outstanding requests.

Diagram

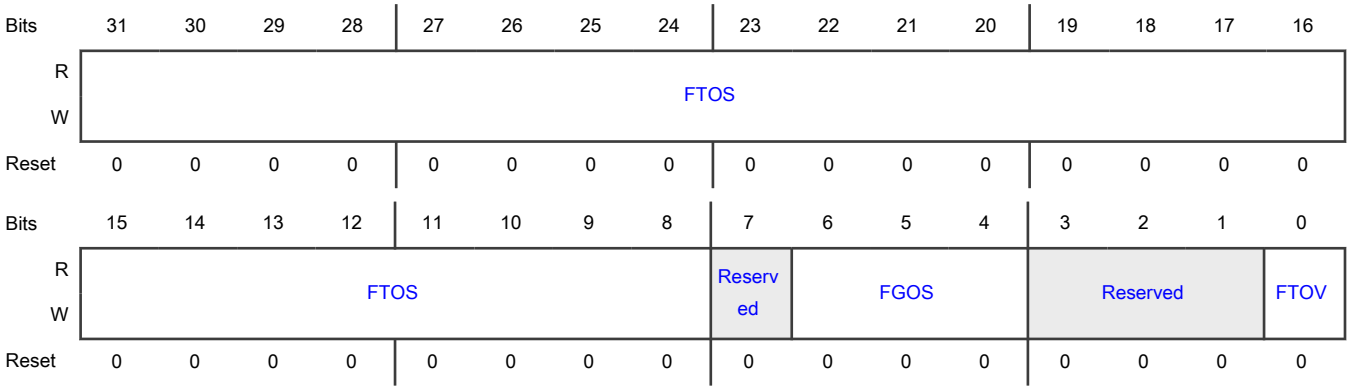
72.18.243 DMA TBS Control (DMA_TBS_CTRL)

Offset

Register	Offset
DMA_TBS_CTRL	1050h

Function
Controls the TBS attributes.

Diagram



Fields

Field	Function
31-8 FTOS	Fetch Time Offset Deduct the value in units of 256 nanoseconds, from the launch time to compute the fetch Time. Max value: 999,999,999 nanosecond, must be smaller than CTR-1 value when ESTM mode = 1, because this value is a modulo CTR value.
7	Reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
6-4 FGOS	Fetch GSN Offset Deduct the number GSN slots from the launch GSN to compute the fetch GSN. The value is valid only when DMA_TBS_CTRL[FTOV] = 1.
3-1 —	Reserved.
0 FTOV	Fetch Time Offset Valid Indicates whether the fetch time offset is valid. When this field is 1, it indicates that DMA_TBS_CTRL[FTOS] is valid. When this field is not 1, it indicates that the fetch offset is not valid and the DMA engine can fetch the frames from host memory without any time restrictions. 0b - Invalid 1b - Valid

72.18.244 DMA Safety Interrupt Status (DMA_Safety_Interrupt_Status)

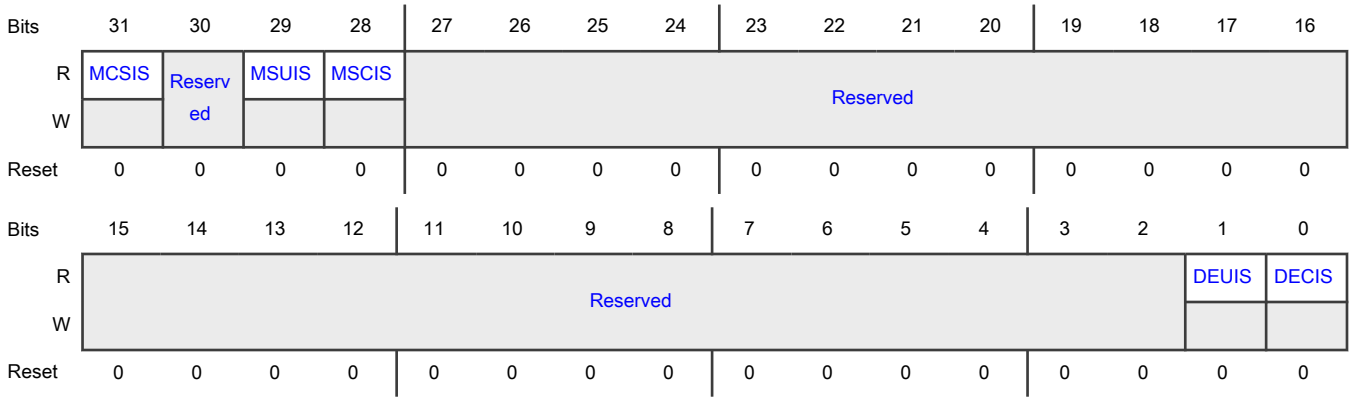
Offset

Register	Offset
DMA_Safety_Interrupt_Status	1080h

Function

Indicates summary (whether error occured in DMA/MTL/MAC and correctable/uncorrectable) of the automotive safety related error interrupts.

Diagram



Fields

Field	Function
31 MCSIS	MAC Safety Uncorrectable Interrupt Status Indicates whether the MAC safety uncorrectable interrupt status is detected. Indicates that an uncorrectable safety related interrupt is 1 in the MAC module. When this field is 1, it indicates that you must read the MAC_DPP_FSM_Interrupt_Status, to get the cause of the safety interrupt in MAC. 0b - Not detected 1b - Detected
30 —	Reserved.
29 MSUIS	MTL Safety Uncorrectable Error Interrupt Status Indicates whether the MTL safety uncorrectable error interrupt status is detected. Indicates an uncorrectable error interrupt event in MTL. To get exact cause of the interrupt you must read the MTL_Safety_Interrupt_Status. 0b - Not detected 1b - Detected
28 MSCIS	MTL Safety Correctable Error Interrupt Status Indicates whether the MTL safety correctable error interrupt status is detected. Indicates a correctable error interrupt event in MTL. To get the exact cause of the interrupt you must read the MTL_Safety_Interrupt_Status. 0b - Not detected 1b - Detected
27-2 —	Reserved.
1 DEUIS	DMA ECC Uncorrectable Error Interrupt Status Indicates whether the DMA ECC uncorrectable error interrupt status is deducted. Indicates an interrupt event in the DMA ECC safety feature. To get the exact cause of the interrupt the application must read the DMA_ECC_Interrupt_Status register. 0b - Not detected 1b - Detected
0 DECIS	DMA ECC Correctable Error Interrupt Status Indicates whether the DMA ECC correctable error interrupt status is detected. Indicates an interrupt event in the DMA ECC safety feature. To get the exact cause of the interrupt the application must read the DMA_ECC_Interrupt_Status register.

Table continues on the next page...

24 —	Reserved.
23-21 —	Reserved.
20-18	Descriptor Skip Length

Table continues on the next page...

Table continued from the previous page...

Field	Function
DSL	Specifies the Word, Dword, or Lword number (depending on the 32-bit, 64-bit, or 128-bit bus) to skip between two unchained descriptors. The address skipping starts from the end of the current descriptor to the start of the next descriptor. The DMA assumes the descriptor table as contiguous, when the DSL value is equal to zero.
17 —	Reserved.
16 PBLx8	8xPBL mode Indicates whether 8xPBL mode is enabled. When this field is 1, it indicates that the PBL value programmed in Bits[21:16] in DMA_CH(#i)_Tx_Control and Bits[21:16] in DMA_CH(#i)_Rx_Control is multiplied by eight times. Therefore, the DMA transfers the data in 8, 16, 32, 64, 128, and 256 beats depending on the PBL value. 0b - Disabled 1b - Enabled
15-14 —	Reserved.
13-0 —	Reserved.

72.18.246 DMA Channel Tx Control (DMA_CH0_Tx_Control)

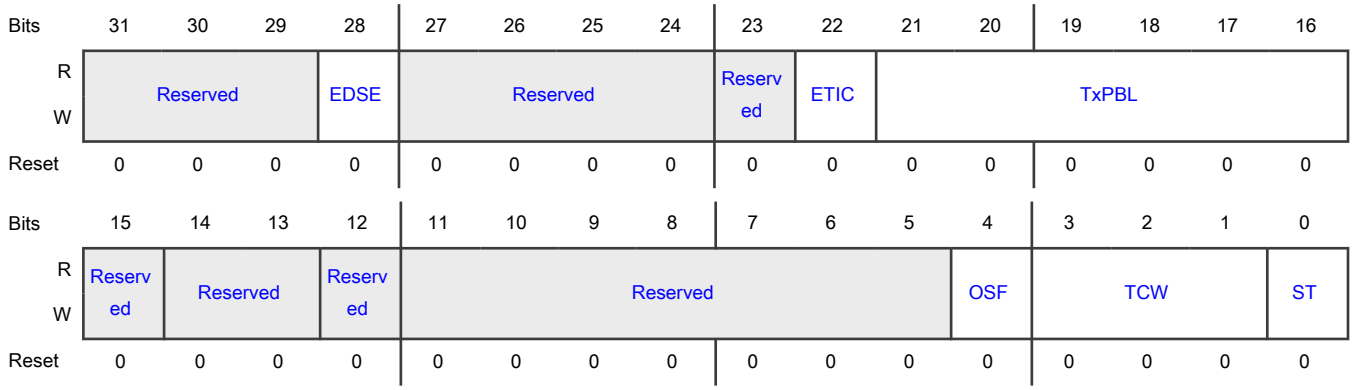
Offset

Register	Offset
DMA_CH0_Tx_Control	1104h

Function

Controls the transmit features such as PBL, TCP segmentation, and transmit channel weights.

Diagram



Fields

Field	Function
31-29 —	Reserved.
28 EDSE	Enhanced Descriptor Enable Indicates whether an enhanced descriptor is enabled. When this field is 1, it indicates that the corresponding channel uses 32 bytes enhanced descriptors for both normal and context descriptors. When this field becomes 0, it indicates that the corresponding channel uses the 16 bytes descriptors. 0b - Disabled 1b - Enabled
27-24 —	Reserved.
23 —	Reserved.
22 ETIC	Early Transmit Interrupt Control Indicates whether an early transmit interrupt is enabled. When this field is 1, it indicates that an early transmit interrupt (ETI) status = 1 after the data transfer from buffers of a transmit descriptor completes in which IOC bit (TDES2[31]) = 1. When this field becomes 1, it indicates that ETI = 1 only after a complete packet transfers to the MTL TX FIFO memory. 0b - Disabled 1b - Enabled
21-16 TxPBL	Transmit Programmable Burst Length

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Indicates the maximum number of beats to transfer in one DMA block data transfer. DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of these values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. Perform these steps to transfer more than 32 beats: 1. Set DMA_CH0_Control[PBLx8]. 2. Set the TxPBL. **NOTE** The maximum value of TxPBL must be less than or equal to half the transit queue size (TQS field of MTL_TxQ(#i)_Operation_Mode register) in terms of beats. This is required so that the transit queue has space to store at least another TxPBL worth of data while the MTL Tx queue controller transfers data to MAC. For example, in 64-bit data width configurations the total locations in transit queue of size 512 bytes is 64. You must program TxPBL and 8xPBL to less than or equal to 32.
15 —	Reserved.
14-13 —	Reserved.
12 —	Reserved.
11-5 —	Reserved.
4 OSF	Operate on Second Packet Indicates whether the operation on second packet is enabled. When this field is 1, it instructs DMA to process the second packet of the transmit data even before you receive the status for the first packet. 0b - Disabled 1b - Enabled
3-1 TCW	Transmit Channel Weight Indicates the weight assigned to the corresponding transmit channel. When reset completes, this field is 0 for all the channels by default, which results in equal weights to all channels.
0 ST	Start or Stop Transmission Command Indicates whether to start or stop the transmission command. When this field is 1, it indicates that the transmission is in the running state. DMA checks the transmit list at the current position for a packet to be transmitted.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	DMA tries to acquire descriptor from either of these positions: • The current position in the list. This is the base address of the transmit list to which DMA_CH0_TxDesc_List_Address sets. • The position at which the transmission was previously stopped. The transmission enters the suspended state and DMA_CH0_Status[TBU] = 1, if DMA does not own the current descriptor. The start transmission command is effective only when the transmission stops. If the command is issued before setting DMA_CH0_TxDesc_List_Address, you cannot predict the DMA behavior. When this field becomes 0, it indicates that the transmission process is placed in the stopped state when the transmission of the current packet completes . The next descriptor position in the transmit list is saved, and it becomes the current position when you restart the transmission. To change the list address, you must program DMA_CH0_TxDesc_List_Address with a new value when this field becomes 0.You can consider the new value when this field is 1 again. The stop transmission command is effective only when the transmission of the current packet completes or the transmission is in the suspended state. 0b - Stop 1b - Start

72.18.247 DMA Channel Rx Control (DMA_CH0_Rx_Control)

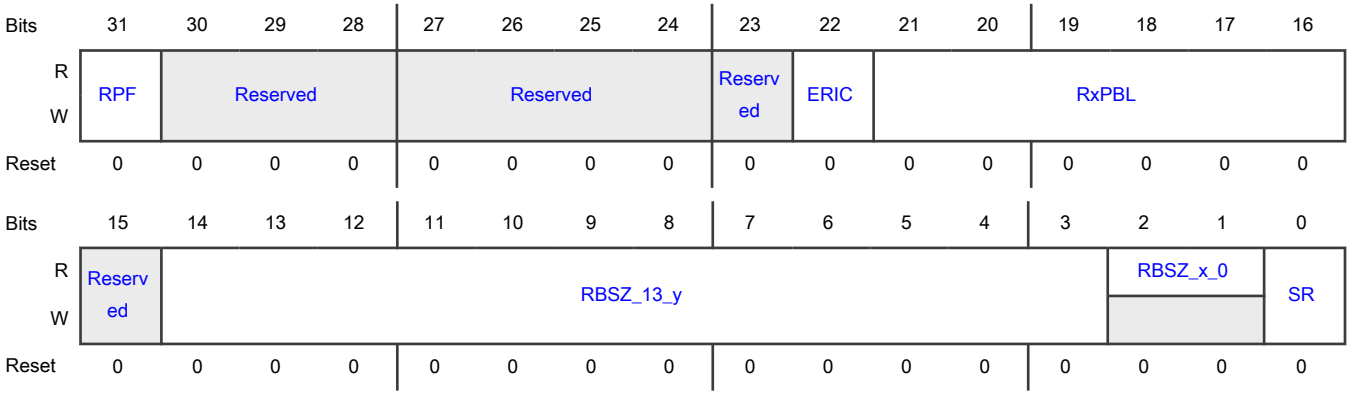
Offset

Register	Offset
DMA_CH0_Rx_Control	1108h

Function

Controls the receive features such as PBL, buffer size, and extended status.

Diagram



Fields

Field	Function
31 RPF	Rx Packet Flush Indicates whether the receive packet flush is enabled. When this field is 1, it indicates that the module automatically flushes the packet from the receive queues destined to this DMA receive channel, when it stops. When this field remains 1 and the software driver re-starts DMA, the packets residing in the receive queues that were received when this RxDMA stops and flushes out. The packets that MAC receives after the RxDMA re-starts, route to the RxDMA. The flushing takes place on the read side of the receive queue. When this field is 0, it indicates that the module do not flush the packet in the receive queue destined to this RxDMA channel when it is in STOP state. This may cause head-of-line blocking in the corresponding receive queue. **NOTE** The packet flow from a receive DMA channel to the application by writing 1 to this field stops, only when there is one-to-one mapping of receive queue to receive DMA channels. In Dynamic mapping mode, writing 1 to this field in any DMA_CH(#i)_Rx_Control register might flush packets from an unintended receive queues which are destined to the stopped receive DMA channel. 0b - Disabled 1b - Enabled
30-28 —	Reserved.
27-24 —	Reserved.
23 —	Reserved.
22 ERIC	Early Receive Interrupt Control Indicates whether an early receive interrupt is enabled. When this field is 1, it indicates that the early receive interrupt (ERI) status sets after every burst transfer of data from the Rx DMA to the buffer completes. When this field becomes 0, it indicates that ERI sets only after a complete buffer is filled by the RxDMA. 0b - Disabled 1b - Enabled
21-16 RxPBL	Receive Programmable Burst Length Indicates the maximum number of beats to be transferred in one DMA block data transfer. DMA always attempts max burst as specified in PBL every time it starts a burst transfer on the application bus. You can program PBL with any of these values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1. Set DMA_CH0_Control[PBLx8]. 2. Set the RxPBL. **NOTE** The maximum value of RxPBL must be less than or equal to half the receive queue size (RQS field of MTL_RxQ(#i)_Operation_Mode register) in terms of beats. This is required so that the receive queue has space to store at least another Rx PBL worth of data while the receive DMA transfers a block of data. For example, in 64-bit data width configurations the total locations in receive queue of size 512 bytes is 64. You must program RxPBL and 8xPBL to less than or equal to 32.
15 —	Reserved.
14-3 RBSZ_13_y	Receive Buffer size High RBSZ[13:0] splits into two fields, higher field is RBSZ_13_y and lower field is RBSZ_x_0. RBSZ[13:0] field indicates the receive buffers size specified in bytes. The maximum buffer size is limited to 16K bytes. The buffer size is applicable to payload buffers when split headers are enabled. **NOTE** The buffer size must be a multiple of 4, 8, or 16 depending on the data bus widths (32-bit, 64-bit, or 128-bit respectively). This is required even if the buffer address pointer value is not aligned with data bus width. Hence the lower RBSZ_x_0 fields are read-only and the value is considered as all-zero. Thus RBSZ_13_y field indicates the buffer size in terms of locations (with the width same as bus-width).
2-1 RBSZ_x_0	Receive Buffer size Low RBSZ[13:0] splits into two fields RBSZ_13_y and RBSZ_x_0. The RBSZ_x_0 is the lower field whose width is based on data bus width of the configuration. The field width is of 2, 3, or 4 bits for 32-bit, 64-bit, or 128-bit data bus width respectively. This field is read-only (RO).
0 SR	Start or Stop Receive Indicates whether to start or stop receive. When this field is 1, it indicates that the DMA tries to acquire the descriptor from the receive list and processes the incoming packets. DMA tries to acquire descriptor from either of these positions: • The current position in the list. This is the address which DMA_CH0_RxDesc_List_Address sets. • The position at which the receive process was previously stopped. If DMA does not own the current descriptor, the reception is suspended and DMA_CH0_Status[RBU] = 1. The start receive command is effective only when the reception stops. If the command is issued before setting DMA_CH0_RxDesc_List_Address, the DMA behavior is unpredictable.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When this field becomes 0, it indicates that the receive DMA operation stops after the transfer of the current packet. The next descriptor position in the receive list is saved, and it becomes the current position after the receive process restarts. The stop receive command is effective only when the receive process is in the running (waiting for receive packet) or suspended state. 0b - Stop 1b - Start

72.18.248 DMA Channel 0 Tx Descriptor List Address (DMA_CH0_TxDesc_List_Address)

Offset

Register	Offset
DMA_CH0_TxDesc_List_Address	1114h

Function

Specifies DMA to the start of transmit descriptor list. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). DMA internally converts it to bus width aligned address by making the corresponding LSB low.

You can write to this register only when the transit DMA stops, that is, DMA_CH0_Tx_Control[ST] = 0. When stopped, write this register with a new descriptor list address. When DMA_CH0_Tx_Control[ST] = 1, DMA uses the newly-programmed descriptor base address. If this register does not change when DMA_CH0_Tx_Control[ST] = 0, DMA uses the descriptor address where it was stopped earlier.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-2	Start of Transmit List

Table continues on the next page...

Table continued from the previous page...

Field	Function
TDESLA	Contains the base address of the first descriptor in the transmit descriptor list. DMA ignores the LSB bits (1:0, 2:0, or 3:0) for 32-bit, 64-bit, or 128-bit bus width and internally takes these bits as all-zero. Therefore, these LSB bits are read-only (RO). The field width depends on the configuration: 31:2 for 32-bit configuration 31:3 for 64-bit configuration 31:4 for 128-bit configuration
1-0 —	Reserved.

72.18.249 DMA Channel 0 Rx Descriptor List Address (DMA_CH0_RxDesc_List_Address)

Offset

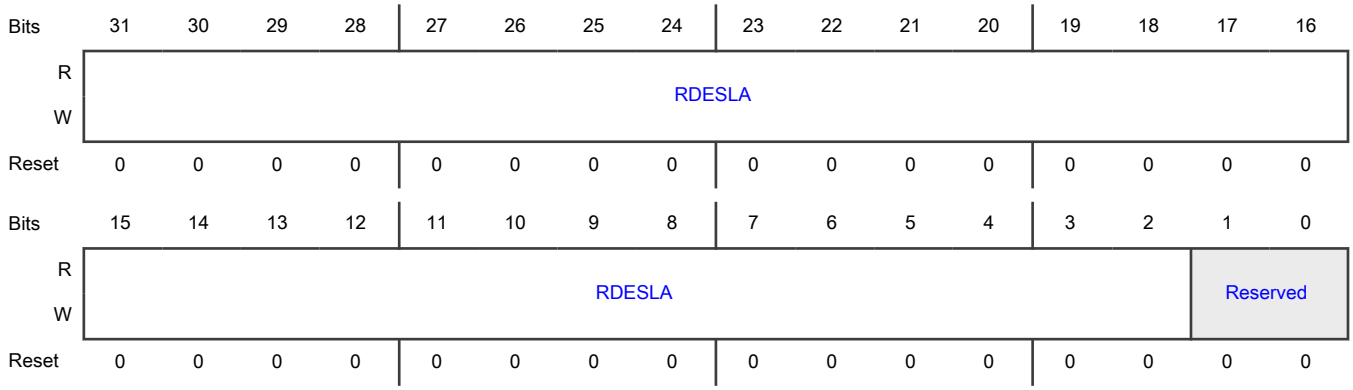
Register	Offset
DMA_CH0_RxDesc_List_Address	111Ch

Function

Specifies DMA to the start of receive descriptor list. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). DMA internally converts it to bus width aligned address by making the corresponding LS bits low. You can write to this register only when reception stops. When stopped, write this register before the receive start command is given. You can write to this register only when Rx DMA stops, that is, DMA_CH0_Rx_Control[SR] = 0. When stopped, write this register with a new descriptor list address.

When DMA_CH0_Rx_Control[SR] = 1, it indicates that DMA takes the newly programmed descriptor base address.

Diagram



Fields

Field	Function
31-2 RDESLA	Start of Receive List Contains the base address of the first descriptor in the receive descriptor list. DMA ignores the LSB bits (1:0, 2:0, or 3:0) for 32-bit, 64-bit, or 128-bit bus width and internally takes these bits as all-zero. Therefore, these LSB bits are read-only (RO). The field width depends on the configuration: 31:2 for 32-bit configuration 31:3 for 64-bit configuration 31:4 for 128-bit configuration
1-0 —	Reserved.

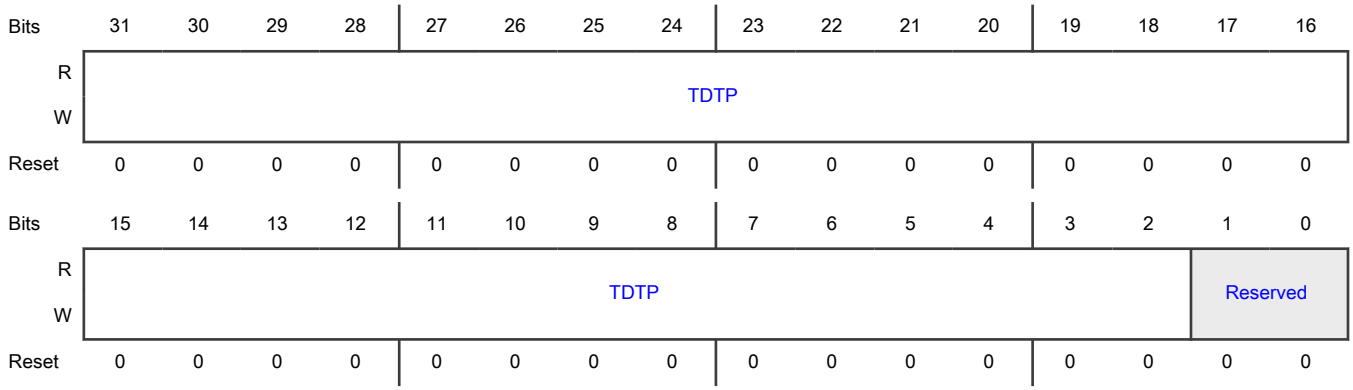
72.18.250 DMA Channel 0 Tx Descriptor Tail Pointer (DMA_CH0_TxDesc_Tail_Pointer)

Offset

Register	Offset
DMA_CH0_TxDesc_Tail_Pointer	1120h

Function
Points to an offset from the base and indicates the location of the last valid descriptor.

Diagram



Fields

Field	Function
31-2	Transmit Descriptor Tail Pointer

Table continues on the next page...

Table continued from the previous page...

Field	Function
TDTP	Contains the tail pointer for the transit descriptor ring. You must write the tail pointer to add more descriptors to the transit channel. The hardware tries to transmit all packets to the descriptors referenced between the head and the tail pointer registers. The field width depends on the configuration: 31:2 for 32-bit configuration 31:3 for 64-bit configuration 31:4 for 128-bit configuration
1-0 —	Reserved.

72.18.251 DMA Channeli 0 Rx Descriptor List Pointer (DMA_CH0_RxDesc_Tail_Pointer)

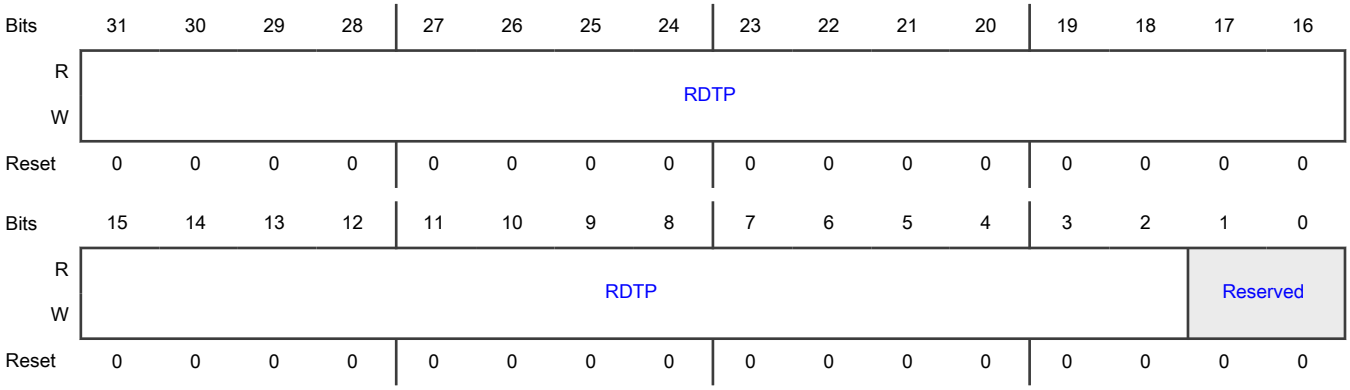
Offset

Register	Offset
DMA_CH0_RxDesc_Tail_Pointer	1128h

Function

Specifies an offset from the base and indicates the location of the last valid descriptor.

Diagram



Fields

Field	Function
31-2 RDTP	Receive Descriptor Tail Pointer

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Contains the tail pointer for the receive descriptor ring. You must write the tail pointer to add more descriptors to the receive channel. The hardware tries to write all received packets to the descriptors referenced between the head and the tail pointer registers. The field width depends on the configuration: 31:2 for 32-bit configuration 31:3 for 64-bit configuration 31:4 for 128-bit configuration
1-0 —	Reserved.

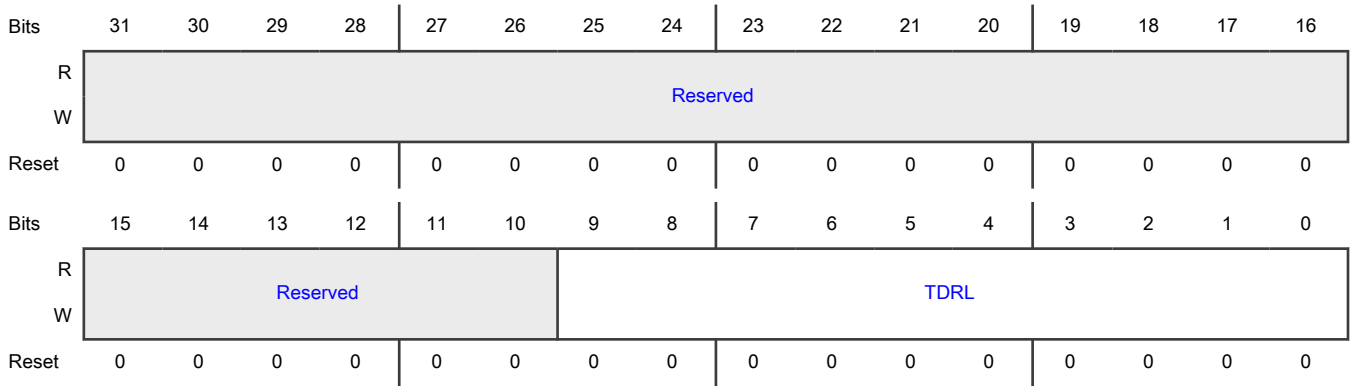
72.18.252 DMA Channel 0 Tx Descriptor Ring Length (DMA_CH0_TxDesc_Ring_Length)

Offset

Register	Offset
DMA_CH0_TxDesc_Ring_Length	112Ch

Function
Contains the length of the transmit descriptor ring.

Diagram



Fields

Field	Function
31-10 —	Reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
9-0 TDRL	Transmit Descriptor Ring Length Sets the maximum number of transmit descriptors in the circular descriptor ring. The maximum number of descriptors are limited to 1K descriptors. NXP recommends a minimum ring descriptor length of 4. For example, you can program any value up to 0x3FF in this field. This field is 10 bits wide, if you program 0x3FF, you can have 1024 descriptors. Program this field to a value of 0x9, if you want to have 10 descriptors.

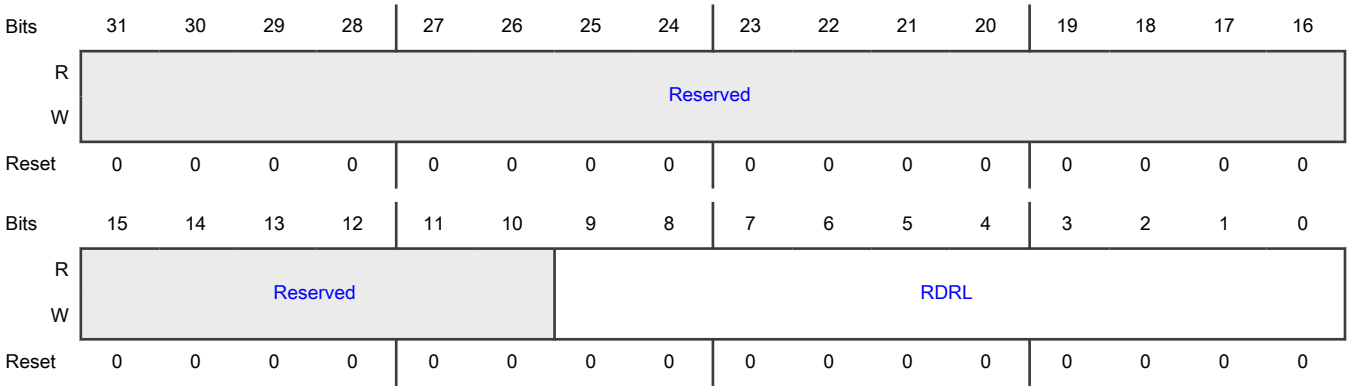
72.18.253 DMA Channel 0 Rx Descriptor Ring Length (DMA_CH0_RxDesc_Ring_Length)

Offset

Register	Offset
DMA_CH0_RxDesc_Ring_Length	1130h

Function
Contains the length of the receive descriptor circular ring.

Diagram



Fields

Field	Function
31-10 —	Reserved.
9-0 RDRL	Receive Descriptor Ring Length Sets the maximum number of receive descriptors in the circular descriptor ring. The maximum number of descriptors is limited to 1K descriptors. For example, you can program any value up to 0x3FF in this field. This field is 10 bits wide, if you program 0x3FF, you can have 1024 descriptors. Program this field to a value of 0x9, if you want to have 10 descriptors.

72.18.254 DMA Channel 0 Interrupt Enable (DMA_CH0_Interrupt_Enable)

Offset

Register	Offset
DMA_CH0_Interrupt_Enable	1134h

Function
Enables the interrupts which the status register report.

1 TXSE	Transmit Stopped Enable Enables or disables the transmit stopped interrupt. When this field is 1 along with DMA_CH0_Interrupt_Enable[AIE], it enables the transmission stopped interrupt. When this field becomes 0, it disables the transmission stopped interrupt. 0b - Disable 1b - Enable
0 TIE	Transmit Interrupt Enable Enables or disables the transmit interrupt. When this field is 1 along with DMA_CH0_Interrupt_Enable[NIE], it enables the transmit interrupt. When this field becomes 0, it disables the transmit interrupt. 0b - Disable 1b - Enable

72.18.255 DMA Channel 0 Rx Interrupt Watchdog Timer (DMA_CH0_Rx_Interrupt_Watchdog_Timer)

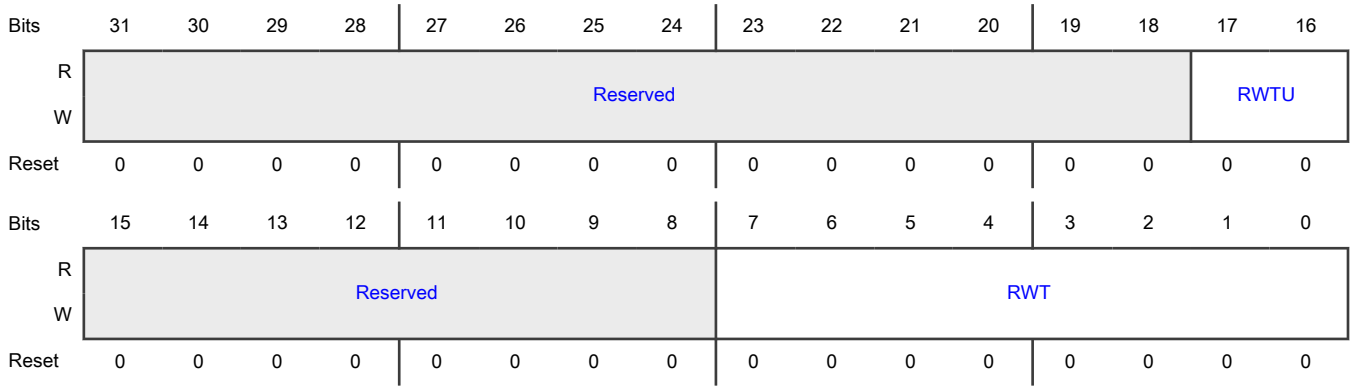
Offset

Register	Offset
DMA_CH0_Rx_Interrupt_Watchdog_Timer	1138h

Function

Indicates the watchdog timeout for receive interrupt (RI) from DMA. When you write this register with a non-zero value, it enables the watchdog timer for the RI bit of the DMA_CHi_Status register.

Diagram



Fields

Field	Function
31-18 —	Reserved.
17-16 RWTU	Receive Interrupt Watchdog Timer Count Units Indicates the system clock cycles number corresponding to one unit in DMA_CH0_Rx_Interrupt_Watchdog_Timer[RWT]. 2'b00 - 256 2'b01 - 512 2'b10 - 1024 2'b11 - 2048 For example, when DMA_CH0_Rx_Interrupt_Watchdog_Timer[RWT] = 2 and DMA_CH0_Rx_Interrupt_Watchdog_Timer[RWTU] = 1, the watchdog timer sets for 2*512=1024 system clock cycles.
15-8 —	Reserved.
7-0 RWT	Receive Interrupt Watchdog Timer Count Indicates the number of system clock cycles, multiplied by factor which DMA_CH0_Rx_Interrupt_Watchdog_Timer[RWTU] indicates, for which you set the watchdog timer. The watchdog timer triggers with the programmed value after the receive DMA completes the packet transfer for which the RI bit is not set in the DMA_CH(#i)_Status register, because of the setting of interrupt enable bit in the corresponding descriptor RDES3[30]. When the watchdog timer runs out, it indicates that the RI bit is 1 and the timer stops. The watchdog timer resets when the RI bit is 1 because of automatic setting of RI per the interrupt enable bit RDES3[30] of any received packet.

72.18.256 DMA Channel 0 Slot Function Control Status (DMA_CH0_Slot_Function_Control_Status)

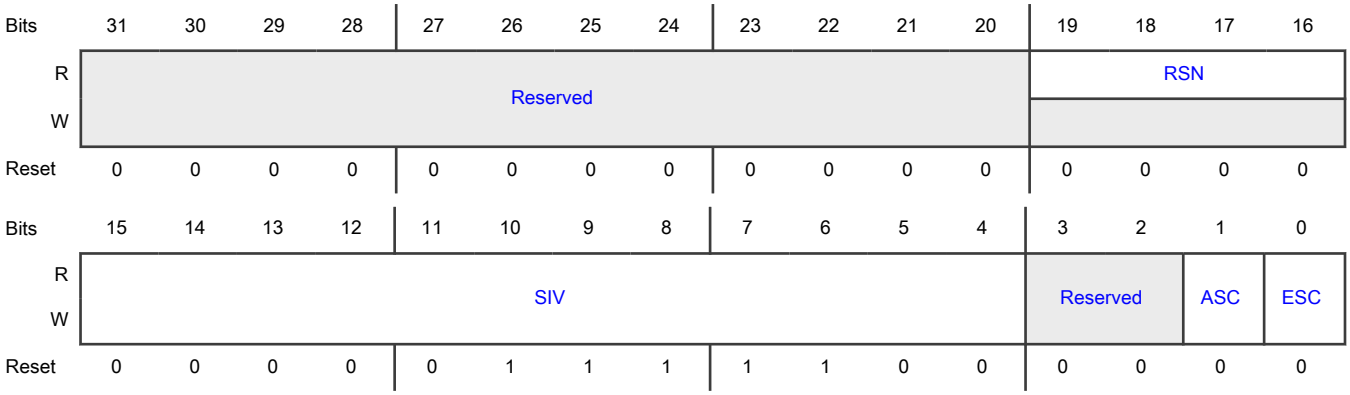
Offset

Register	Offset
DMA_CH0_Slot_Function_Control_Status	113Ch

Function

Contains the control bits for slot function and the status for transmit path.

Diagram



Fields

Field	Function
31-20 —	Reserved.
19-16 RSN	Reference Slot Number Provides the current value of the reference slot number in DMA. It is used for slot comparison.
15-4 SIV	Slot Interval Value Controls the period of the slot interval in which the TxDMA fetches the scheduled packets. A value of 0 specifies the slot interval of 1 us while the maximum value 4095 specifies the slot interval of 4096 us. The default or reset value is 0x07C which corresponds to slot interval of 125 us
3-2 —	Reserved.
1 ASC	Advance Slot Check Indicates whether the advance slot check is enabled. When this field is 1, it enables DMA to fetch the data from the buffer when the slot number (SLOTNUM) programmed in the transit descriptor is either:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Equal to the reference slot number given in DMA_CH0_Slot_Function_Control_Status[RSN], or Ahead of the reference slot number by up to two slots. This field is applicable only when DMA_CH0_Slot_Function_Control_Status[ESC] = 1. 0b - Disabled 1b - Enabled
0 ESC	Enable Slot Comparison Indicates whether the slot comparison is enabled. When this field is 1, it enables the checking of the slot numbers programmed in the transit descriptor with the current reference given in DMA_CH0_Slot_Function_Control_Status[RSN]. DMA fetches the data from the corresponding buffer only when the slot number is either: • Equal to the reference slot number, or • Ahead of the reference slot number by one slot. When this field becomes 0, it disables the checking of the slot numbers. DMA fetches the data immediately after you process the descriptor. **NOTE** You must not enable the UFO (UDP Fragmentation over IPv4)/TSO/USO along with TBS/AVB slot number check. The UFO/TSO/USO involves multiple packets/segments/ fragments transmission for single packet received from application and the slot number check are applicable for fetching only first segment/fragment. As a result it might be difficult for you to specify slot number for subsequent packets. 0b - Disabled 1b - Enabled

72.18.257 DMA Channel 0 Current Application Transmit Descriptor (DMA_CH0_Current_App_TxDesc)

Offset

Register	Offset
DMA_CH0_Current_App_TxDesc	1144h

Function
Specifies the current transmit descriptor which DMA reads.

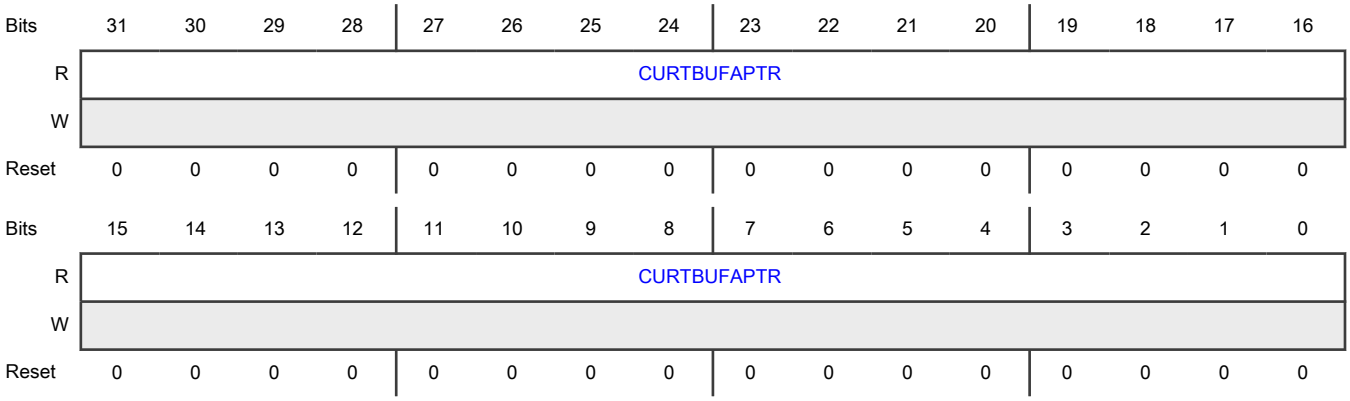
72.18.259 DMA Channel 0 Current Application Transmit Descriptor (DMA_CH0_Current_App_TxBuffer)

Offset

Register	Offset
DMA_CH0_Current_App_TxBuffer	1154h

Function
Specifies the current transit buffer address which DMA reads.

Diagram



Fields

Field	Function
31-0 CURTBUFAPTR	Application Transmit Buffer Address Pointer Indicates that DMA updates this pointer during the transit operation. This pointer clears when reset.

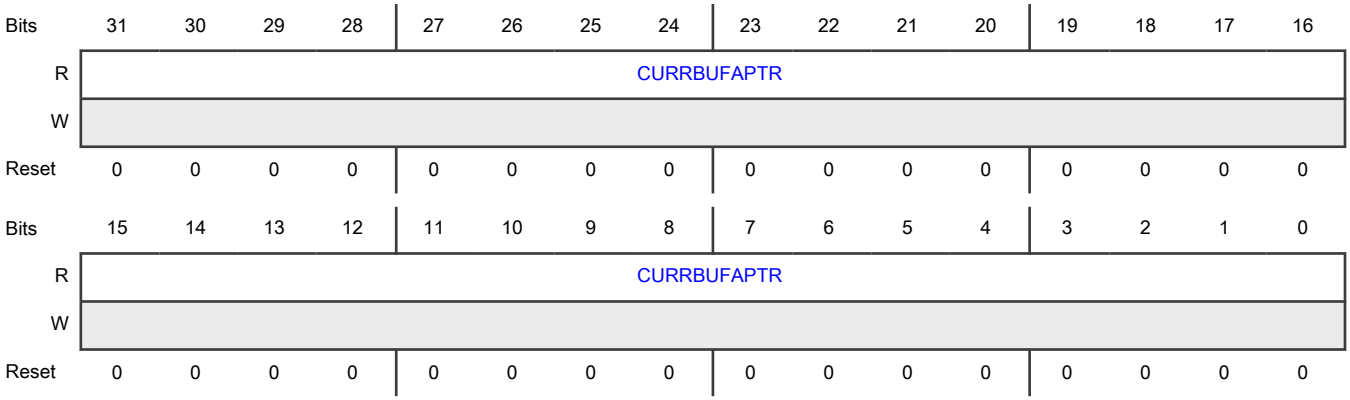
72.18.260 DMA Channel 0 Current Application Receive Buffer (DMA_CH0_Current_App_RxBuffer)

Offset

Register	Offset
DMA_CH0_Current_App_RxBuffer	115Ch

Function
Specifies the current receive buffer address which DMA read.

Diagram



Fields

Field	Function
31-0 CURRBUFAPTR	Application Receive Buffer Address Pointer Indicates that DMA updates this pointer during the receive operation. This pointer clears when reset.

72.18.261 DMA Channel 0 Status (DMA_CH0_Status)

Offset

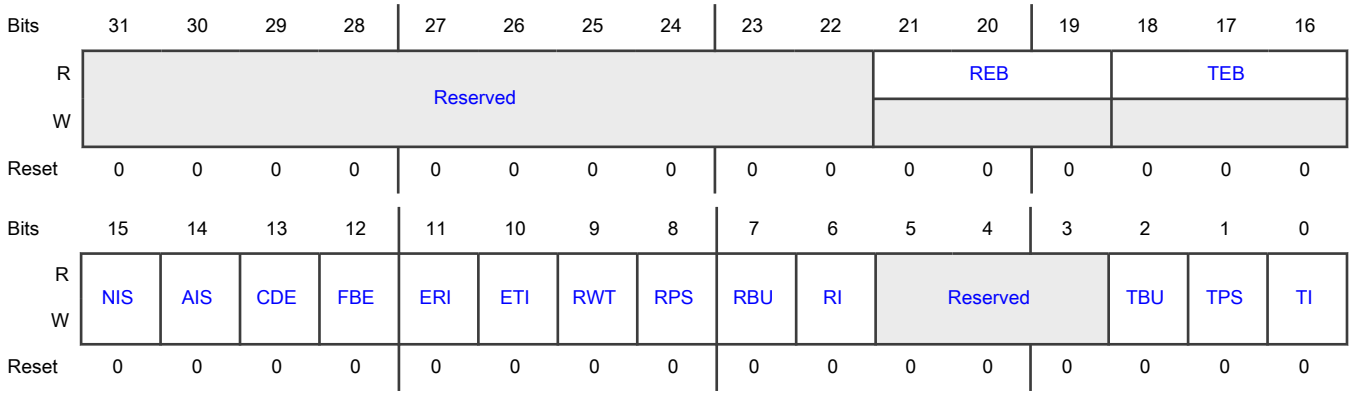
Register	Offset
DMA_CH0_Status	1160h

Function
Indicates that the software driver (application) reads the status register during an interrupt service routine or polling to determine the DMA status.

NOTE

The number of DMA_CH(#i)_Status register in the configuration is the higher of number of receive DMA channels and transit DMA channels.

Diagram



Fields

Field	Function
31-22 —	Reserved.
21-19 REB	Rx DMA Error Bits Indicates the type of error that causes a bus error. For example, error response on the AHB or AXI interface. Bit 21 1'b1 - Error during data transfer by Rx DMA 1'b0 - No Error during data transfer by Rx DMA Bit 20 1'b1 - Error during descriptor access 1'b0 - Error during data buffer access Bit 19 1'b1 - Error during read transfer 1'b0 - Error during write transfer This field is valid only when DMA_CH0_Status[FBE] = 1. This field does not generate an interrupt.
18-16 TEB	Tx DMA Error Bits Indicates the type of error that causes a bus error. For example, error response on the AHB or AXI interface. Bit 18 1'b1 - Error during data transfer by Tx DMA 1'b0 - No Error during data transfer by Tx DMA Bit 17 1'b1 - Error during descriptor access 1'b0 - Error during data buffer access

Table continued from the previous page...

Field	Function
	Bit 16 1'b1 - Error during read transfer 1'b0 - Error during write transfer This field is valid only when DMA_CH0_Status[FBE] = 1. This field does not generate an interrupt.
15 NIS	Normal Interrupt Summary Indicates whether the normal interrupt summary status is detected. This field is the logical OR of the following bits when you enables the corresponding interrupt bits in DMA_CH0_Interrupt_Enable: Bit 0 - Transmit interrupt Bit 2 - Transmit buffer unavailable Bit 6 - Receive interrupt Bit 11 - Early receive interrupt Only unmasked bits (interrupts for which interrupt enable sets in DMA_CH0_Interrupt_Enable) affect this field. This is a sticky bit. You must clear this field by writing 1 to it each time a corresponding field which sets this field clears. Access restriction apply to this field. It automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected
14 AIS	Abnormal Interrupt Summary Indicates whether an abnormal interrupt summary status is detected. This field is the logical OR of the following bits when you enables the corresponding interrupt bits in DMA_CH0_Interrupt_Enable: Bit 1 - Transmit process stopped Bit 7 - Receive buffer unavailable Bit 8 - Receive process stopped Bit 10 - Early transmit interrupt Bit 12 - Fatal bus error Bit 13 - Context descriptor error Only unmasked bits affect this field. This is a sticky bit. You must clear this field by writing 1 to it each time a corresponding field, which sets this field, clears. Access restriction apply to this field. It automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Not detected 1b - Detected
13 CDE	Context Descriptor Error Indicates whether the context descriptor error status is detected. This field indicates that the DMA Tx/Rx engine receives a descriptor error, which indicates an invalid context in the middle of packet flow (intermediate descriptor) or all one's descriptor in transit case and on receive side it indicates DMA has read a descriptor with either of the buffer address as ones which is considered to be invalid. Access restriction apply to this field. It automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected
12 FBE	Fatal Bus Error Indicates whether the fatal bus error status is detected. This field indicates that a bus error occurred (as described in the EB field). When this field is 1, it indicates that the corresponding DMA channel engine disables all bus accesses. Access restriction apply to this field. It automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected
11 ERI	Early Receive Interrupt Indicates whether an early receive interrupt status is detected. When this field is 1, it indicates that the RxDMA completes the packet data transfer to the memory. In configs supporting ERIC, this field is 1 only after the receive DMA fills a complete receive buffer with packet data, when DMA_CH0_Rx_Control[ERIC] = 0. This field is 1 after every burst transfer of data from the receive DMA to the buffer, when DMA_CH0_Rx_Control[ERIC] = 1. Writing 1 to RI field automatically clears this field. Access restriction apply to this field. It automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected
10 ETI	Early Transmit Interrupt Indicates whether an early transmit interrupt status is detected. When this field is 1, it indicates that the TxDMA completes the packet data transfer to the MTL TXFIFO memory.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	In configs supporting ERIC: this field is 1 only after the transit DMA transfers a complete packet to MTL, when DMA_CH0_Tx_Control[ETIC] = 0. This field is 1 after packet data transfers from buffer completes (partial) in the transmit descriptor in which IOC = 1, when DMA_CH0_Tx_Control[ETIC] = 1. Access restriction apply to this field. It automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected
9 RWT	Receive Watchdog Timeout Indicates whether the receive watchdog timeout status is detected. Asserts when you receives a packet with length greater than 2,048 bytes (10,240 bytes when Jumbo Packet mode is enabled). 0b - Not detected 1b - Detected
8 RPS	Receive Process Stopped Indicates whether the receive process stopped status is detected. Asserts when the receive process enters the stopped state. Access restriction apply to this field. It automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected
7 RBU	Receive Buffer Unavailable Indicates whether the receive buffer unavailable status is detected. This field indicates that the application owns the next descriptor in the receive list, and DMA cannot acquire it. The receive process is suspended. To resume processing receive descriptors, the application must change the ownership of the descriptor and issue a receive poll demand command. If this command is not issued, the receive process resumes when you receive the next recognized incoming packet. In ring mode, the application must advance the receive descriptor tail pointer register of a channel. This field is 1 only when DMA owns the previous receive descriptor. Access restriction apply to this field. It automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected
6 RI	Receive Interrupt Indicates that the receive interrupt status is detected.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field indicates that the packet reception is complete. When packet reception completes, bit 31 of RDES3 resets in the last descriptor, and you can update the specific packet status information in the descriptor. The reception remains in the running state. Access restriction apply to this field. It automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected
5-3 —	Reserved.
2 TBU	Transmit Buffer Unavailable Indicates whether the transmit buffer unavailable status is detected. This field indicates that the application owns the next descriptor in the transmit list, and the DMA cannot acquire it. Transmission is suspended. DMA_Debug_Status0[TPS0] explains the transmit process state transitions. To resume processing the transmit descriptors, the application must perform these steps: 1. Change the ownership of the descriptor by writing 1 to bit 31 of TDES3. 2. Issue a transmit poll demand command. For Ring mode, the application must advance the transmit descriptor tail pointer register of a channel. Access restriction apply to this field. It automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected
1 TPS	Transmit Process Stopped Indicates whether the transmit process stopped status is detected. This field is 1 when the transmission stops. Access restriction apply to this field. It automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected
0 TI	Transmit Interrupt Indicates whether the transmit interrupt status is detected. This field indicates that the packet transmission is complete. When transmission completes, Bit 31 of TDES3 resets in the last descriptor, and you can update the specific packet status information in the descriptor.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Access restriction apply to this field. It automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected

72.18.262 DMA Channel 0 Miss Frame Counter (DMA_CH0_Miss_Frame_Cnt)

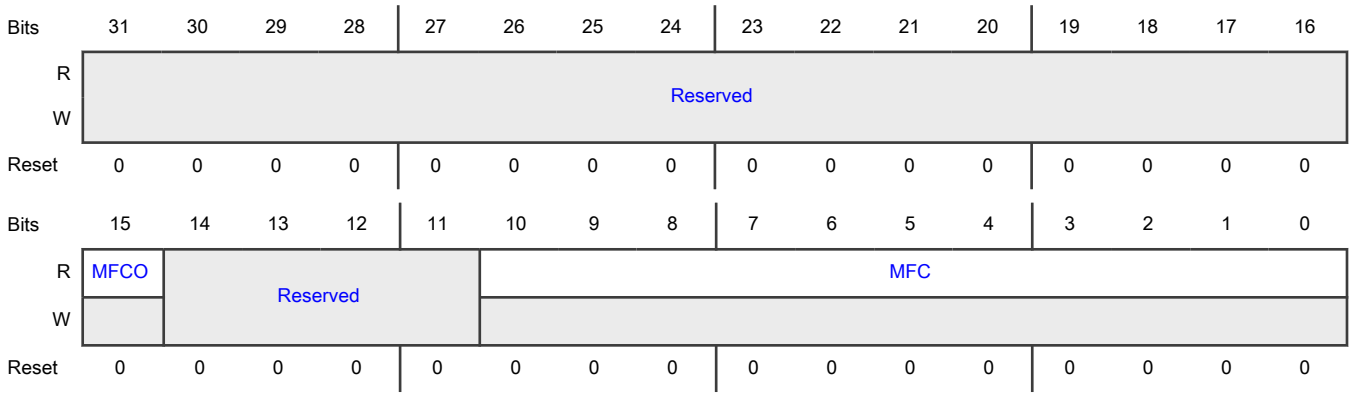
Offset

Register	Offset
DMA_CH0_Miss_Frame_Cnt	1164h

Function

Indicates the number of packet counter that DMA drops either due to bus error or due to programming RPF field in DMA_CH${i}_Rx_Control register.

Diagram



Fields

Field	Function
31-16 —	Reserved.
15 MFCO	Overflow status of the MFC Counter Indicates whether the miss frame counter overflow has occurred. When this field is 1, it indicates that the MFC counter does not increment further. This field is 0 when this register is read.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Access restriction apply to this field. It clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not occurred 1b - Occurred
14-11 —	Reserved.
10-0 MFC	Dropped Packet Counters Indicates the number of packet counters that DMA drops either because of bus error or because of programing RPF field in DMA_CH${i}_Rx_Control register. This field is 0 when this register is read. Access restriction apply to this field. It clears on read and automatically becomes 1 on an internal event occurrence.

72.18.263 DMA Channel 0 Rx Parser Accept Count (DMA_CH0_RXP_Accept_Cnt)

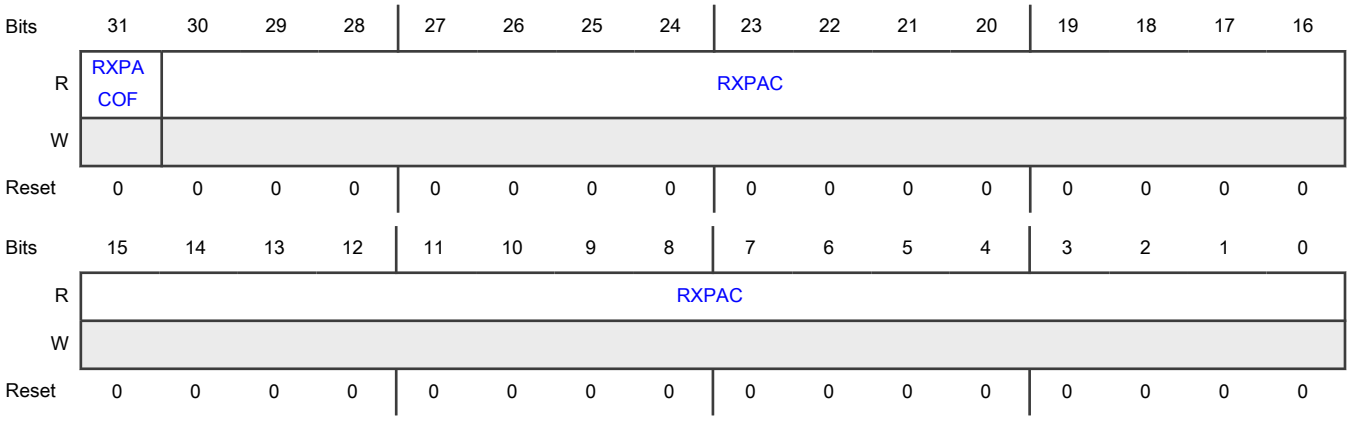
Offset

Register	Offset
DMA_CH0_RXP_Accept_Cnt	1168h

Function

Provides the count of the number of frames which the receive parser accept.

Diagram



Fields

Field	Function
31 RXPACOF	Rx Parser Accept Counter Overflow Bit Indicates whether the receive parser accept counter overflow has occurred. When this field is 1, it indicates that the RXPAC counter field has crossed the maximum limit. Access restriction apply to this field. It clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not occurred 1b - Occurred
30-0 RXPAC	Rx Parser Accept Counter Implements whenever a receive parser accept a packet because AF = 1. The counter clears when the register is read.

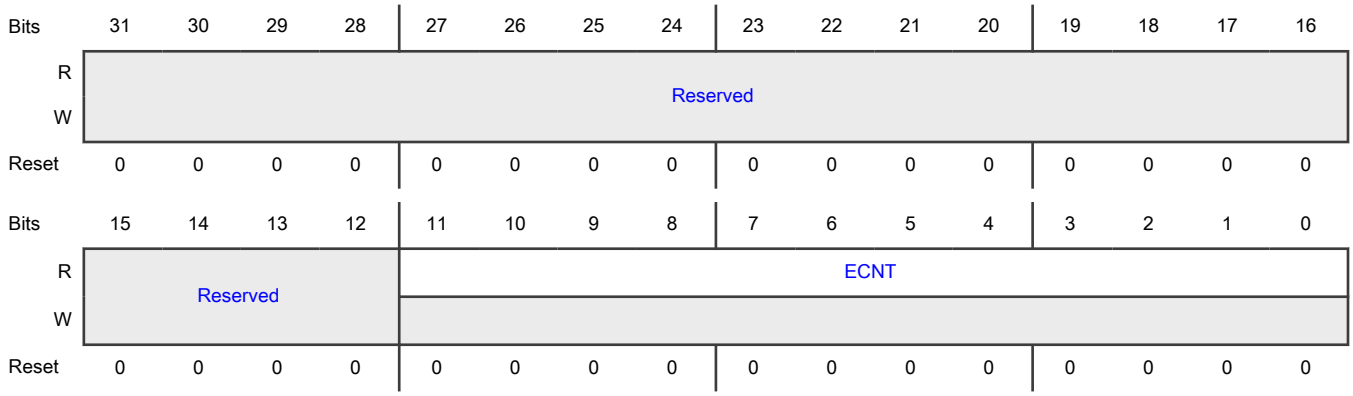
72.18.264 DMA Channel 0 Rx ERI Count (DMA_CH0_RX_ERI_Cnt)

Offset

Register	Offset
DMA_CH0_RX_ERI_Cnt	116Ch

Function
Provides the count of the number of times ERI is asserted.

Diagram



Fields

Field	Function
31-12	Reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
11-0 ECNT	ERI Counter Indicates that when ERIC bit of DMA_CH(#i)_RX_Control register is 1, this counter increments for burst transfer which the receive DMA completes from the start of packet transfer. This field becomes 0 at the start of new packet.

72.18.265 DMA Channel 1 Control (DMA_CH1_Control)

Offset

Register	Offset
DMA_CH1_Control	1180h

Function

Specifies the MSS value for segmentation, length to skip between two descriptors, and also the features such as header splitting and 8xPBL mode.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
20-18 DSL	Descriptor Skip Length Specifies the Word, Dword, or Lword number (depending on the 32-bit, 64-bit, or 128-bit bus) to skip between two unchained descriptors. The address skipping starts from the end of the current descriptor to the start of the next descriptor. When this field is 0, it indicates that DMA takes the descriptor table as contiguous.
17 —	Reserved.
16 PBLx8	8xPBL mode Indicates whether the 8xPBL mode is enabled. When this field is 1, it indicates that you must program the PBL value in Bits[21:16] in DMA_CH(#i)_Tx_Control and Bits[21:16] in DMA_CH(#i)_Rx_Control and multiply it eight times. Therefore, DMA transfers the data in 8, 16, 32, 64, 128, and 256 beats depending on the PBL value. 0b - Disabled 1b - Enabled
15-14 —	Reserved.
13-0 —	Reserved.

72.18.266 DMA Channel 1 Tx Control (DMA_CH1_Tx_Control)

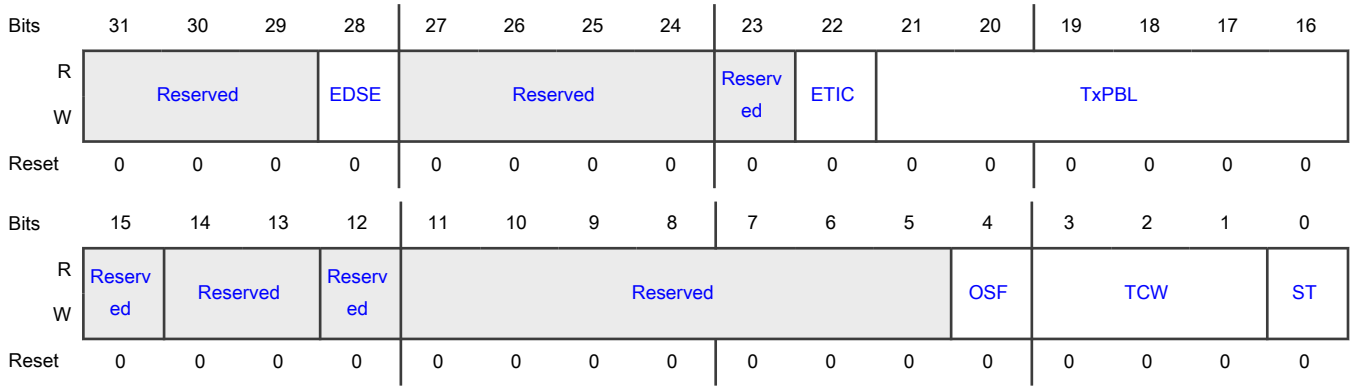
Offset

Register	Offset
DMA_CH1_Tx_Control	1184h

Function

Controls the transmit features such as PBL, TCP segmentation, and transmit channel weights.

Diagram



Fields

Field	Function
31-29 —	Reserved.
28 EDSE	Enhanced Descriptor Enable Indicates whether an enhanced descriptor is enabled. When this field is 1, it indicates that the corresponding channel uses enhanced descriptors that are 32 Bytes for both normal and context descriptors. When this field becomes 0, it indicates that the corresponding channel uses the descriptors that are 16 Bytes. 0b - Disabled 1b - Enabled
27-24 —	Reserved.
23 —	Reserved.
22 ETIC	Early Transmit Interrupt Control Indicates whether an early transmit interrupt is enabled. When this field is 1, it indicates that an early transmit interrupt (ETI) status sets after the data transfer completes from buffers of a transmit descriptor in which IOC bit (TDES2[31]) sets. When this field becomes 0, it indicates that the ETI sets only after a complete packet transfers to the MTL TX FIFO memory. 0b - Disabled 1b - Enabled
21-16	Transmit Programmable Burst Length

Table continues on the next page...

Table continued from the previous page...

Field	Function
TxPBL	Indicates the maximum number of beats to transfer in one DMA block data. DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of these values: 1, 2, 4, 8, 16, or 32. Any other value results in an undefined behavior. To transfer more than 32 beats, perform the following steps: 1. Write 1 to DMA_CH0_Control[PBLx8]. 2. Write 1 to this field. **NOTE** The maximum value of this field must be less than or equal to half the transit queue size (TQS field of MTL_TxQ(#i)_Operation_Mode register) in terms of beats. This is required so that the transit queue has space to store at least another Tx PBL worth of data while the MTL Tx Queue controller transfers data to MAC. For example, in 64-bit data width configurations the total locations in transit queue of size 512 bytes is 64. You must program TxPBL and 8xPBL to less than or equal to 32.
15 —	Reserved.
14-13 —	Reserved.
12 —	Reserved.
11-5 —	Reserved.
4 OSF	Operate on Second Packet Indicates whether an operation on second packet is enabled. When this field is 1, it instructs DMA to process the second packet of the transmit data even before the first packet status is obtained. 0b - Disabled 1b - Enabled
3-1 TCW	Transmit Channel Weight Indicates the weight assigned to the corresponding transmit channel. When reset completes, this field becomes 0 for all channels by default, resulting in equal weights to all channels.
0 ST	Start or Stop Transmission Command Indicates whether to start or stop transmission command. When this field is 1, it indicates that the transmission is placed in the running state. DMA checks the transmit list at the current position to transmit a packet.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	DMA tries to acquire descriptor from either of the following positions: • The current position in the list. This is the base address of the transmit list which DMA_CH0_TxDesc_List_Address sets. • The position at which the transmission was previously stopped If DMA does not own the current descriptor, the transmission enters the suspended state and DMA_CH0_Status[TBU] = 1. The start transmission command is effective only when the transmission stops. If you issue the command before writing 1 to DMA_CH0_TxDesc_List_Address, then DMA behavior is unpredictable. When this field becomes 0, it indicates that the transmission process is placed in the stopped state after the transmission of the current packet completes. The next descriptor position in the transmit list is saved, and it becomes the current position when the transmission restarts. To change the list address, you must program DMA_CH0_TxDesc_List_Address with a new value when this field becomes 0. The new value is considered when this field is 1 again. The stop transmission command is effective only when the transmission of the current packet completes or the transmission is in the suspended state. 0b - Stop 1b - Start

72.18.267 DMA Channel 1 Rx Control (DMA_CH1_Rx_Control)

Offset

Register	Offset
DMA_CH1_Rx_Control	1188h

Function

Controls the receive features such as PBL, buffer size, and extended status.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	Reserved	RBSZ_13_y												RBSZ_x_0		SR
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31 RPF	Rx Packet Flush Indicates whether the receive packet flush is enabled. When this field is 1, it indicates that the module automatically flushes the packet from the receive queues destined to this DMA receive channel, when it stops. When this field remains 1 and the software driver re-starts DMA, the packets residing in the receive queues that were received when this RxDMA was stopped, flushes out. Route the packets to the RxDMA that the MAC receives after the RxDMA re-starts. The flushing takes place on the read side of the receive queue. When this field is 0, it indicates that the module do not flush the packet in the receive queue destined to this RxDMA channel when it is in stop state. This might in turn cause head-of-line blocking in the corresponding RxQueue. **NOTE** The stopping of packet flow from a Rx DMA Channel to the application by writing 1 to this field works only when there is one-to-one mapping of receive queue to the receive DMA channels. In Dynamic mapping mode, writing 1 to this field in any DMA_CH(#i)_Rx_Control register might flush packets from unintended receive queues which are destined to the stopped Rx DMA Channel. 0b - Disabled 1b - Enabled
30-28 —	Reserved.
27-24 —	Reserved.
23 —	Reserved.
22 ERIC	Early Receive Interrupt Control Indicates whether an early receive interrupt control status is enabled. When this field is 1, it indicates that an early receive interrupt (ERI) status sets after every burst transfer of data from the receive DMA to the buffer completes. When this field becomes 0, it indicates that ERI sets only after the RxDMA fills the complete buffer is filled. 0b - Disabled 1b - Enabled
21-16 RxPBL	Receive Programmable Burst Length Indicates the maximum number of beats to transfer in one DMA block data. DMA always attempts max burst as specified in PBL, each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in an undefined behavior. To transfer more than 32 beats, perform the following steps:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1. Write 1 to DMA_CH0_Control[PBLx8]. 2. Write 1 to RxPBL. **NOTE** The maximum value of RxPBL must be less than or equal to half the receive queue size (RQS field of MTL_RxQ(#i)_Operation_Mode register) in terms of beats. This is required so that the receive queue has space to store at least another Rx PBL worth of data when the receive DMA transfers a block of data. For example, in 64-bit data width configurations the total locations in receive queue of size 512 bytes is 64, so you must program RxPBL and 8xPBL to less than or equal to 32.
15 —	Reserved.
14-3 RBSZ_13_y	Receive Buffer size High Indicates that RBSZ[13:0] splits into two fields higher RBSZ_13_y and lower RBSZ_x_0. RBSZ[13:0] field indicates the size of the receive buffers specified in bytes. The maximum buffer size is limited to 16K bytes. The buffer size is applicable to payload buffers when you enable split headers. **NOTE** The buffer size must be a multiple of 4, 8, or 16 depending on the data bus widths (32-bit, 64-bit, or 128-bit respectively). This is required even if the value of buffer address pointer is not aligned to data bus width. Hence the lower RBSZ_x_0 bits are read-only and the value is considered as all-zero. Thus RBSZ_13_y indicates the buffer size in terms of locations (with the width same as bus-width).
2-1 RBSZ_x_0	Receive Buffer size Low Indicates that RBSZ[13:0] splits into two fields RBSZ_13_y and RBSZ_x_0. RBSZ_x_0 is the lower field whose width is based on data bus width of the configuration. This field width is of 2, 3, or 4 bits for 32-bit, 64-bit, or 128-bit data bus width respectively. This field is read-only (RO).
0 SR	Start or Stop Receive Indicates whether to start or stop receive. When this field is 1, it indicates that DMA tries to acquire the descriptor from the receive list and processes the incoming packets. DMA tries to acquire descriptor from either of the following positions: • The current position in the list. This is the address that DMA_CH0_RxDesc_List_Address sets. • The position at which the receive process was previously stopped If DMA does not own the current descriptor, the reception suspends and DMA_CH0_Status[RBU] = 1. The start receive command is effective only when the reception stops. If the command is issued before writing 1 to DMA_CH0_RxDesc_List_Address, DMA behavior is unpredictable.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When this field becomes 0, it indicates that the receive DMA operation stops after the transfer of the current packet. The next descriptor position in the receive list is saved, and it becomes the current position after the receive process restarts. The stop receive command is effective only when the receive process is in the running (waiting for Rx packet) or suspended state. 0b - Stop 1b - Start

72.18.268 DMA Channel 1 Tx Descriptor List Address (DMA_CH1_TxDesc_List_Address)

Offset

Register	Offset
DMA_CH1_TxDesc_List_Address	1194h

Function

Specifies DMA to the start of transmit descriptor list. The descriptor lists reside in the application's physical memory space and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA converts the corresponding LSB bits to low to internally convert the descriptor lists to bus width aligned address.

You can write to this register only when the transmit DMA stops, that is, DMA_CH0_Tx_Control[ST] = 0. When stopped, you can write this register with a new descriptor list address. When DMA_CH0_Tx_Control[ST] = 1, the DMA takes the newly-programmed descriptor base address. If this register do not change when DMA_CH0_Tx_Control[ST] = 0, DMA takes the descriptor address where it was stopped earlier.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-2	Start of Transmit List

Table continues on the next page...

Table continued from the previous page...

Field	Function
TDESLA	Contains the first descriptor base address in the transmit descriptor list. DMA ignores the LSB bits (1:0, 2:0, or 3:0) for 32-bit, 64-bit, or 128-bit bus width and internally assumes these bits as all-zero. Therefore, these LSB bits are read-only (RO). The field width depends on the configuration: 31:2 for 32-bit configuration 31:3 for 64-bit configuration 31:4 for 128-bit configuration
1-0 —	Reserved.

72.18.269 DMA Channel 1 Rx Descriptor List Address (DMA_CH1_RxDesc_List_Address)

Offset

Register	Offset
DMA_CH1_RxDesc_List_Address	119Ch

Function

Specifies DMA to the start of receive descriptor list. The descriptor lists resides in the application's physical memory space and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). DMA converts the correspondong LS bits low to internally convert the descriptor lists to bus width aligned address. You can write to this register only when reception stops. When stopped, you must write this register before the receive start command is given.

You can write to this register when receive DMA has stopped, that is, DMA_CH0_Rx_Control[SR] = 0. When stopped, you can this register with a new descriptor list address.

When DMA_CH0_Rx_Control[SR] = 1, DMA takes the newly programmed descriptor base address.

Table continues on the next page...

Table continued from the previous page...

Field	Function
9-0 TDRL	Transmit Descriptor Ring Length Sets the maximum number of transmit descriptors in the circular descriptor ring. The maximum number of descriptors is limited to 1 K descriptors. NXP recommends a minimum ring descriptor length of 4. For example, you can program any value up to 0x3FF in this field. This field is 10 bits wide, if you program 0x3FF, you can have 1024 descriptors. Program it to a value of 0x9 if you want to have 10 descriptors.

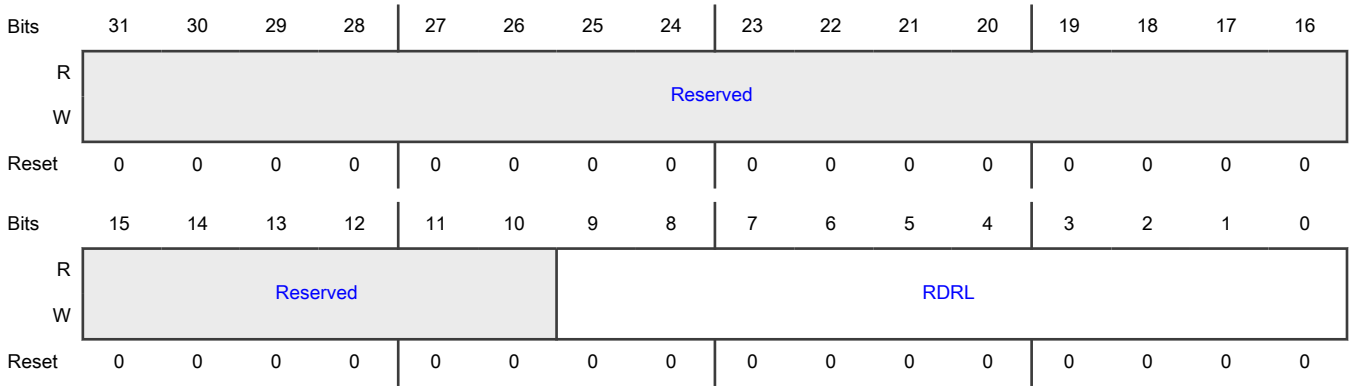
72.18.273 DMA Channel 1 Rx Descriptor Ring Length (DMA_CH1_RxDesc_Ring_Length)

Offset

Register	Offset
DMA_CH1_RxDesc_Ring_Length	11B0h

Function
Contains the length of the receive descriptor circular ring.

Diagram



Fields

Field	Function
31-10 —	Reserved.
9-0 RDRL	Receive Descriptor Ring Length Sets the maximum number of receive descriptors in the circular descriptor ring. The maximum number of descriptors are limited to 1 K descriptors. For example, you can program any value up to 0x3FF in this field. This field is 10 bits wide, if you program 0x3FF, you can have 1024 descriptors. Program it to a value of 0x9 if you want to have 10 descriptors.

72.18.274 DMA Channel 1 Interrupt Enable (DMA_CH1_Interrupt_Enable)

Offset

Register	Offset
DMA_CH1_Interrupt_Enable	11B4h

Function
Enables the interrupts which the status register reports.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-16 —	Reserved.
15 NIE	Normal Interrupt Summary Enable Enables or disables the normal interrupt summary. When this field is 1, it enables the normal interrupt summary. This field also enables the following interrupts in DMA_CH0_Status: Bit 0 - Transmit interrupt Bit 2 - Transmit buffer unavailable Bit 6 - Receive interrupt Bit 11 - Early receive interrupt When this field becomes 0, it disables the normal interrupt summary. 0b - Disable 1b - Enable
14	Abnormal Interrupt Summary Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
AIE	Enables or disables the abnormal interrupt summary. When this field is 1, it enables the abnormal interrupt summary. This field also enables the following interrupts in DMA_CH0_Status: Bit 1 - Transmit process stopped Bit 7 - Rx buffer unavailable Bit 8 - Receive process stopped Bit 9 - Receive watchdog timeout Bit 10 - Early transmit interrupt Bit 12 - Fatal bus error Bit 13 - Context descriptor error When this field becomes 0, it disables the abnormal interrupt summary. 0b - Disable 1b - Enable
13 CDEE	Context Descriptor Error Enable Enables or disables the context descriptor error. When this field is 1 along with DMA_CH0_Interrupt_Enable[AIE], it enables the descriptor error interrupt. When this field becomes 0, it disables the descriptor error interrupt. 0b - Disable 1b - Enable
12 FBEE	Fatal Bus Error Enable Enables or disables fatal bus error. When this field is 1 along with DMA_CH0_Interrupt_Enable[AIE], it enables the fatal bus error interrupt. When this field becomes 0, it disables the fatal bus error interrupt. 0b - Disable 1b - Enable
11 ERIE	Early Receive Interrupt Enable Enables or disables the early receive interrupt. When this field is 1 along with DMA_CH0_Interrupt_Enable[NIE], it enables the early receive interrupt. When this field becomes 0, it disables the early receive interrupt. 0b - Disable 1b - Enable
10 ETIE	Early Transmit Interrupt Enable Enables or disables the early transmit interrupt.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When this field is 1 along with DMA_CH0_Interrupt_Enable[AIE], it enables the early transmit interrupt. When this field becomes 0, it disables the early transmit interrupt. 0b - Disable 1b - Enable
9 RWTE	Receive Watchdog Timeout Enable Enables or disables the receive watchdog timeout interrupt. When this field is 1 along with DMA_CH0_Interrupt_Enable[AIE], it enables the receive watchdog timeout interrupt. When this field becomes 0, it disables the receive watchdog timeout interrupt. 0b - Disable 1b - Enable
8 RSE	Receive Stopped Enable Enables or disables the receive stopped interrupt. When this field is 1 along with DMA_CH0_Interrupt_Enable[AIE], It enables the receive stopped interrupt. When this field becomes 0, it disables the receive stopped interrupt. 0b - Disable 1b - Enable
7 RBUE	Receive Buffer Unavailable Enable Enables or disables the receive buffer unavailable interrupt. When this field is 1 along with DMA_CH0_Interrupt_Enable[AIE], it enables the receive buffer unavailable interrupt. When this field becomes 0, it disables the receive buffer unavailable interrupt. 0b - Disable 1b - Enable
6 RIE	Receive Interrupt Enable Enables or disables the receive interrupt. When this field is 1 along with DMA_CH0_Interrupt_Enable[NIE], it enables the receive interrupt. When this field becomes 0, it disables the receive interrupt. 0b - Disable 1b - Enable
5-3 —	Reserved.
2 TBUE	Transmit Buffer Unavailable Enable Enables or disables the transmit buffer unavailable interrupt.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When this field is 1 along with DMA_CH0_Interrupt_Enable[NIE], it enables the transmit buffer unavailable interrupt. When this field becomes 0, it disables the transmit buffer unavailable interrupt. 0b - Disable 1b - Enable
1 TXSE	Transmit Stopped Enable Enables or disables the transmit stopped interrupt. When this field is 1 along with DMA_CH0_Interrupt_Enable[AIE], it enables the transmission stopped interrupt. When this field becomes 0, it disables the transmission Stopped interrupt. 0b - Disable 1b - Enable
0 TIE	Transmit Interrupt Enable Enables or disables the transmit interrupt. When this field is 1 along with DMA_CH0_Interrupt_Enable[NIE], it enables the transmit interrupt. When this field becomes 0, it disables the transmit interrupt. 0b - Disable 1b - Enable

72.18.275 DMA Channel 1 Rx Interrupt Watchdog Timer (DMA_CH1_Rx_Interrupt_Watchdog_Timer)

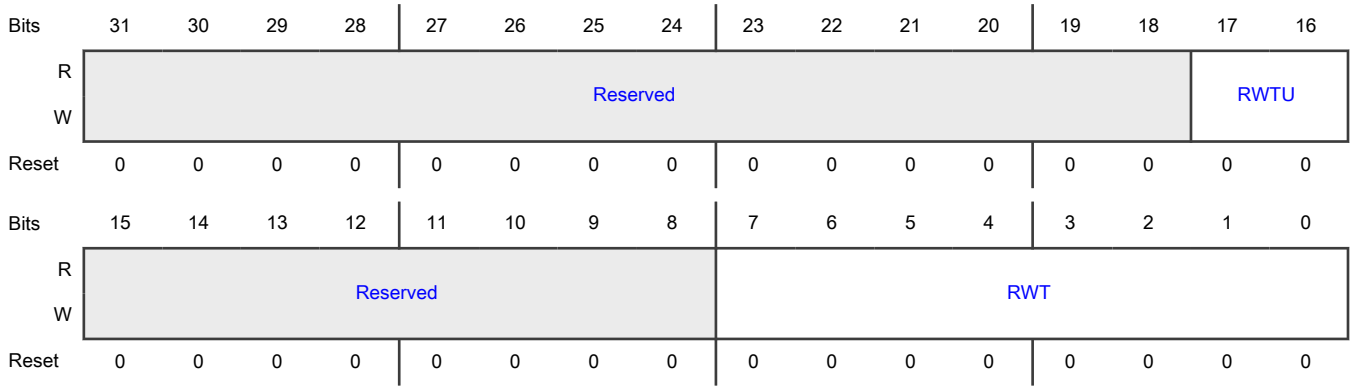
Offset

Register	Offset
DMA_CH1_Rx_Interrupt_Watchdog_Timer	11B8h

Function

Indicates the watchdog timeout for receive interrupt (RI) from DMA. When you write this register with a non-zero value, it enables the watchdog timer for the RI bit of the DMA_CHi_Status register.

Diagram



Fields

Field	Function
31-18 —	Reserved.
17-16 RWTU	Receive Interrupt Watchdog Timer Count Units Indicates the number of system clock cycles corresponding to one unit in DMA_CH1_Rx_Interrupt_Watchdog_Timer[RWT]. 2'b00 - 256 2'b01 - 512 2'b10 - 1024 2'b11 - 2048 For example, the watchdog timer sets for 2*512=1024 system clock cycles, when DMA_CH1_Rx_Interrupt_Watchdog_Timer[RWT] = 2 and DMA_CH1_Rx_Interrupt_Watchdog_Timer[RWTU] = 1.
15-8 —	Reserved.
7-0 RWT	Receive Interrupt Watchdog Timer Count Indicates the number of system clock cycles, multiplied by factor indicated in DMA_CH1_Rx_Interrupt_Watchdog_Timer[RWTU], for which the watchdog timer sets. The watchdog timer triggers with the programmed value after the receive DMA completes the packet transfer for which the RI bit is not 1 in DMA_CH(#i)_Status register, because of the setting of interrupt enable bit in the corresponding descriptor RDES3[30]. RI bit is 1 and the timer stops when the watchdog timer runs out. The watchdog timer becomes 0 when RI bit is 1 because RI sets automatically per the interrupt enable bit RDES3[30] of any received packet.

72.18.276 DMA Channel 1 Slot Function Control Status (DMA_CH1_Slot_Function_Control_Status)

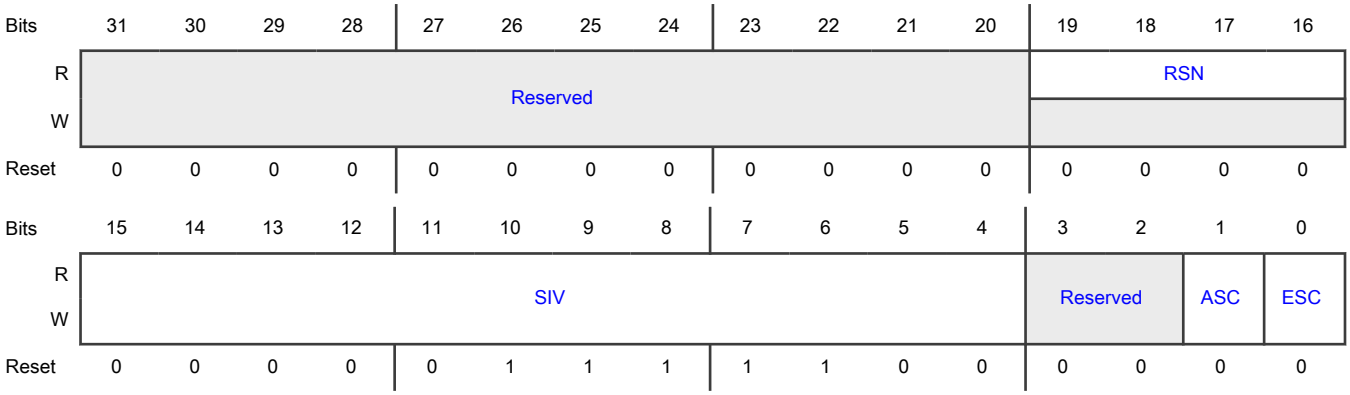
Offset

Register	Offset
DMA_CH1_Slot_Function_Control_Status	11BCh

Function

Contains the control field for slot function and the status for transmit path.

Diagram



Fields

Field	Function
31-20 —	Reserved.
19-16 RSN	Reference Slot Number Provides the current value of the reference slot number in DMA. It is used for slot comparison.
15-4 SIV	Slot Interval Value Controls the period of the slot interval in which the TxDMA fetches the scheduled packets. A value of 0 specifies the slot interval of 1 us while the maximum value 4095 specifies the slot interval of 4096 us. The default or reset value is 0x07C which corresponds to slot interval of 125 us.
3-2 —	Reserved.
1 ASC	Advance Slot Check Indicates whether an advance slot check is enabled. When this field is 1, it enables DMA to fetch the data from the buffer when the slot number (SLOTNUM) programmed in the transmit descriptor is:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• Equal to the reference slot number given in DMA_CH1_Slot_Function_Control_Status[RSN], or • Ahead of the reference slot number by up to two slots. This field is applicable only when DMA_CH1_Slot_Function_Control_Status[ESC] = 1. 0b - Disabled 1b - Enabled
0 ESC	Enable Slot Comparison Enables slot comparison. When this field is 1, it enables the checking of the slot numbers programmed in the transmit descriptor with the current reference given in DMA_CH1_Slot_Function_Control_Status[RSN]. DMA fetches the data from the corresponding buffer only when the slot number is: • Equal to the reference slot number, or • Ahead of the reference slot number by one slot. When this field becomes 0, it disables the checking of the slot numbers. DMA fetches the data immediately after you process the descriptor. **NOTE** You must not enable the UFO (UDP Fragmentation over IPv4)/TSO/USO along with TBS/AVB slot number check. The UFO/TSO/USO involves multiple packets or segments or fragments transmission for single packet received from application and the slot number check are applicable for fetching only first segment/fragment. As a result it might be difficult for you to specify slot number for subsequent packets. 0b - Disable 1b - Enable

72.18.277 DMA Channel 1 Current Application Transmit Descriptor (DMA_CH1_Current_App_TxDesc)

Offset

Register	Offset
DMA_CH1_Current_App_TxDesc	11C4h

Function

Specifies the current transmit descriptor which DMA reads.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-0 CURRDESAPTR	Application Receive Descriptor Address Pointer Indicates that DMA updates this pointer during the receive operation. This pointer is 0 on reset.

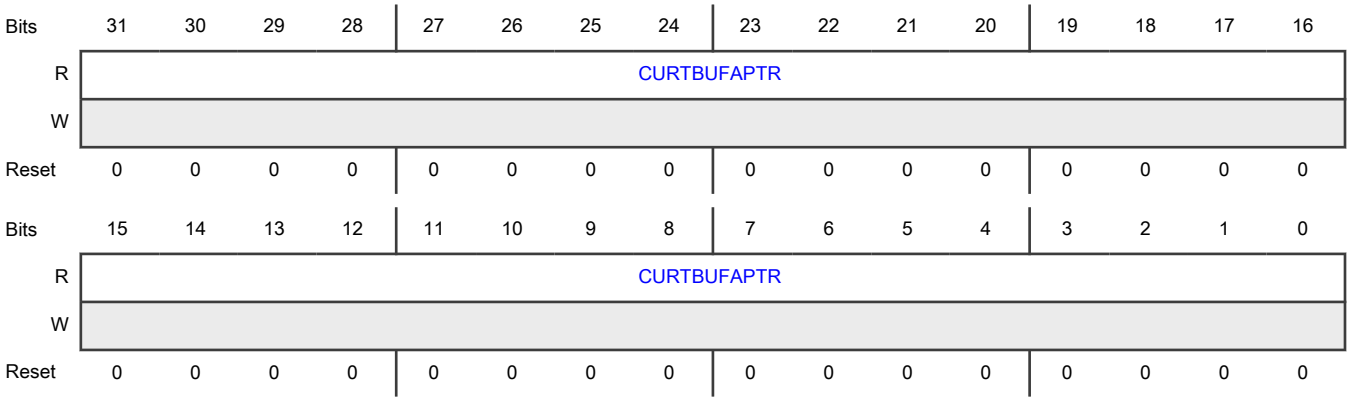
72.18.279 DMA Channel 1 Current Application Transmit Buffer (DMA_CH1_Current_App_TxBuffer)

Offset

Register	Offset
DMA_CH1_Current_App_TxBuffer	11D4h

Function
Specifies the current transmit buffer address which DMA reads.

Diagram



Fields

Field	Function
31-0 CURTBUFAPTR	Application Transmit Buffer Address Pointer Indicates that DMA updates this pointer during the transmit operation. This pointer is 0 on reset.

72.18.280 DMA Channel 1 Current Application Receive Buffer (DMA_CH1_Current_App_RxBuffer)

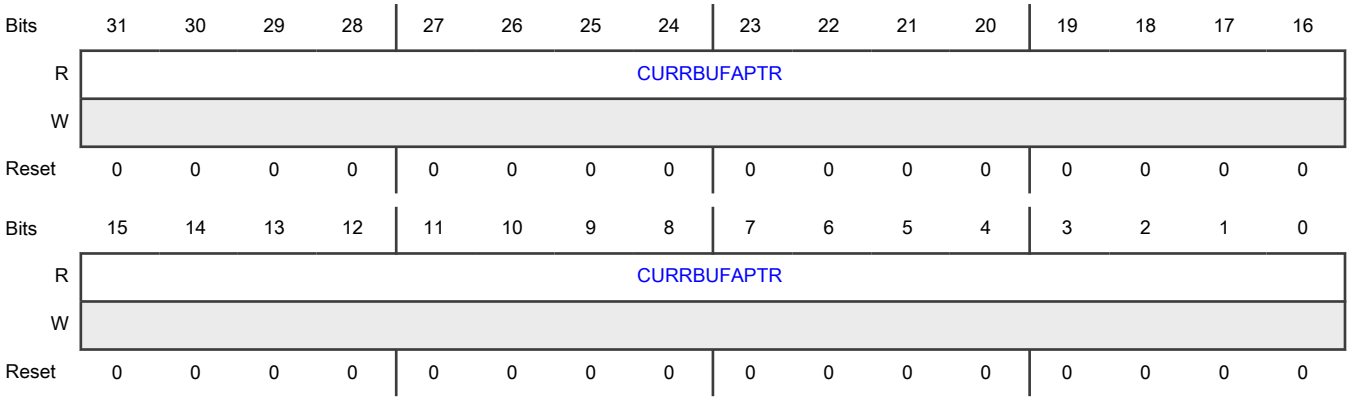
Offset

Register	Offset
DMA_CH1_Current_App_RxBuffer	11DCh

Function

Indicates that DMA_CH0_Current_App_RxBuffer points to the current receive buffer address which the DMA reads.

Diagram



Fields

Field	Function
31-0 CURRBUFAPTR	Application Receive Buffer Address Pointer Indicates that DMA update this pointer during the receive operation. This pointer is 0 on reset.

72.18.281 DMA Channel 1 Status (DMA_CH1_Status)

Offset

Register	Offset
DMA_CH1_Status	11E0h

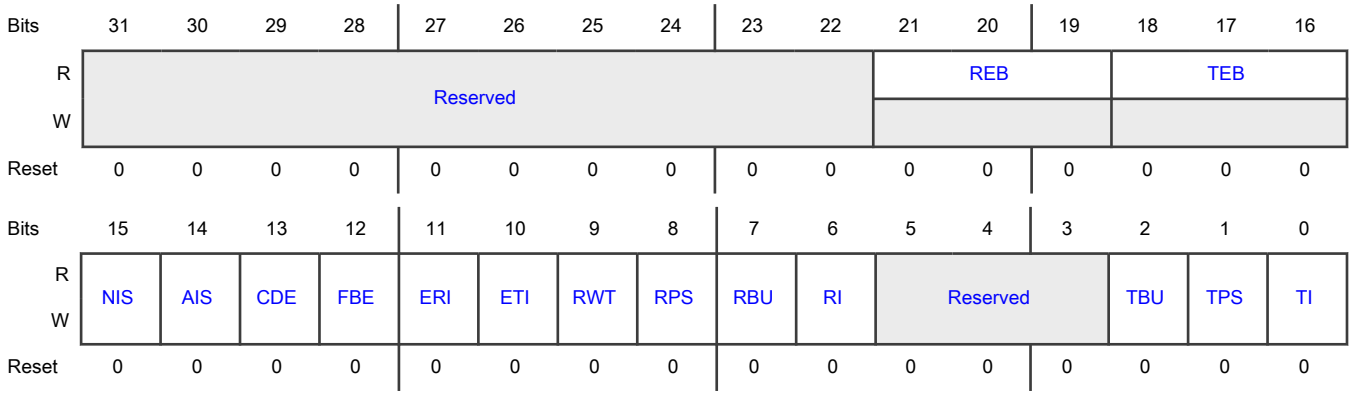
Function

Indicates that to determine the status of DMA, the application reads the status register during an interrupt service routine or polling.

NOTE

The number of DMA_CH(#i)_Status register in the configuration is the higher of number of receive DMA Channels and transmit DMA Channels.

Diagram



Fields

Field	Function
31-22 —	Reserved.
21-19 REB	Rx DMA Error Bits Indicates the type of error that causes a bus error. For example, an error response on the AHB or AXI interface. Bit 21 1'b1 - Error during data transfer by Rx DMA 1'b0 - No Error during data transfer by Rx DMA Bit 20 1'b1 - Error during descriptor access 1'b0 - Error during data buffer access Bit 19 1'b1 - Error during read transfer 1'b0 - Error during write transfer This field is valid only when DMA_CH1_Status[FBE] = 1. It does not generate an interrupt.
18-16 TEB	Tx DMA Error Bits Indicates the type of error that causes a bus error. For example, error response on the AHB or AXI interface. Bit 18 1'b1 - Error during data transfer by Tx DMA 1'b0 - No Error during data transfer by Tx DMA Bit 17 1'b1 - Error during descriptor access

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1'b0 - Error during data buffer access Bit 16 1'b1 - Error during read transfer 1'b0 - Error during write transfer This field is valid only when DMA_CH1_Status[FBE] = 1. It does not generate an interrupt.
15 NIS	Normal Interrupt Summary Indicates whether the normal interrupt summary status is detected. The field value is the logical OR of the following bits when the corresponding interrupt bits enable in DMA_CH0_Interrupt_Enable: Bit 0 - Transmit interrupt Bit 2 - Transmit buffer unavailable Bit 6 - Receive interrupt Bit 11 - Early receive interrupt Only unmasked bits (interrupts for which interrupt enable sets in DMA_CH0_Interrupt_Enable) affect this field. This is a sticky field. You must clear this field (by writing 1 to this field) each time a corresponding bit which sets it, clears. Access restriction apply to this field. Automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected
14 AIS	Abnormal Interrupt Summary Indicates whether an abnormal interrupt summary status is detected. The field value is the logical OR of the following bits when the corresponding interrupt bits enable in DMA_CH0_Interrupt_Enable: Bit 1 - Transmit process stopped Bit 7 - Receive buffer unavailable Bit 8 - Receive process stopped Bit 10 - Early transmit interrupt Bit 12 - Fatal bus error Bit 13 - Context descriptor error Only unmasked bits affect this field. This is a sticky bit. You must clear this field (by writing 1 to this bit) each time a corresponding bit, which sets it, clears.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Access restriction apply to this field. Automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected
13 CDE	Context Descriptor Error Indicates whether the context descriptor error status is detected. This field indicates that the DMA Tx/Rx engine receive a descriptor error, which indicates an invalid context in the middle of packet flow (intermediate descriptor) or all one's descriptor in transmit case and on receive side. It indicates that DMA has read a descriptor with either of the buffer address as ones which you can consider invalid. Access restriction apply to this field. Automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected
12 FBE	Fatal Bus Error Indicates whether the fatal bus error status is detected. This field indicates that a bus error has occurred (as described in the EB field). When this field is 1, it indicates that the corresponding DMA channel engine disables all bus accesses. Access restriction apply to this field. Automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected
11 ERI	Early Receive Interrupt Indicates whether an early receive interrupt status is detected. When this field is 1, it indicates that the RxDMA has completed the packet data transfer to the memory. In configs supporting ERIC, When DMA_CH1_Rx_Control[ERIC] = 0, this field is 1 only after the Rx DMA fills a complete receive buffer with packet data. When DMA_CH1_Rx_Control[ERIC] = 1, this field is 1 after every burst data transfer from the receive DMA to the buffer. If DMA_CH1_Status[RI] = 1, this field clears automatically. Access restriction apply to this field. Automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected
10 ETI	Early Transmit Interrupt Indicates whether an early transmit interrupt status is detected.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When this field is 1, it indicates that the TxDMA has completed the packet data transfer to the MTL TXFIFO memory. In configs supporting ERIC: When DMA_CH1_Tx_Control[ETIC] = 0, this fied is 1 only after the Tx DMA transfers a complete packet to MTL. When DMA_CH1_Tx_Control[ETIC] = 1, this field is 1 after the packet data transfer completes (partial) from buffers in the Transmit descriptor in which IOC=1. Access restriction apply to this field. Automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected
9 RWT	Receive Watchdog Timeout Indicates whether a receive watchdog timeout status is detected. This field asserts when it receives a packet with length greater than 2,048 bytes (10,240 bytes when Jumbo Packet mode is enabled). 0b - Not detected 1b - Detected
8 RPS	Receive Process Stopped Indicates whether a receive process stopped status is detected. This field asserts when the receive process enters the stopped state. Access restriction apply to this field. Automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected
7 RBU	Receive Buffer Unavailable Indicates whether a receive buffer unavailable status is detected. This field indicates that the application owns the next descriptor in the receive list, and the DMA cannot acquire it. The receive process is suspended. To resume processing receive descriptors, the application must change the ownership of the descriptor and issue a receive poll demand command. If this command is not issued, the receive process resumes when you receives the next recognized incoming packet. In Ring mode, the application must advance the receive descriptor tail pointer register of a channel. This field is 1 only when the DMA owns the previous receive descriptor. Access restriction apply to this field. Automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected
6 RI	Receive Interrupt Indicates whether the receive interrupt status is detected.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field indicates that the packet reception is complete. Bit 31 of RDES3 resets in the last descriptor, and updates the specific packet status information in the descriptor, when the packet reception is complete. The reception remains in the running state. Access restriction apply to this field. Automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected
5-3 —	Reserved.
2 TBU	Transmit Buffer Unavailable Indicates whether the transmit buffer unavailable status is detected. This field indicates that the application owns the next descriptor in the transmit list, and the DMA cannot acquire it. Transmission is suspended. DMA_Debug_Status0[TPS0] explains the transmit process state transitions. The application must perform these actions, to resume the processing of transmit descriptors: 1. Write 1 to bit 31 of TDES3 to change the ownership of the descriptor. 2. Issue a transmit poll demand command. For Ring mode, the application must advance the transmit descriptor tail pointer register of a channel. Access restriction apply to this field. Automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected
1 TPS	Transmit Process Stopped Indicates that the transmit process stopped status is detected. This field is 1 when the transmission stops. Access restriction apply to this field. Automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. 0b - Not detected 1b - Detected
0 TI	Transmit Interrupt Indicates whether the transmit interrupt status is detected. This field indicates that the packet transmission is complete. When transmission completes, bit 31 of TDES3 resets in the last descriptor, and the specific packet status information is updated in the descriptor. Access restriction apply to this field. Automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect.

72.18.282 DMA Channel 1 Miss Frame Counter (DMA_CH1_Miss_Frame_Cnt)

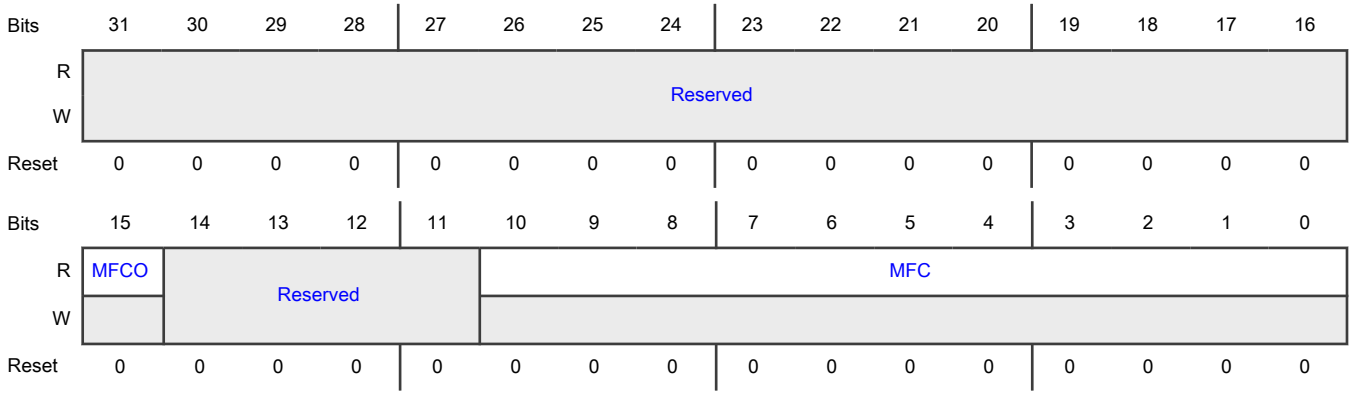
Offset

Register	Offset
DMA_CH1_Miss_Frame_Cnt	11E4h

Function

Provides the number of packet counter that the DMA drops either because of bus error or programming RPF field in DMA_CH${i}_Rx_Control register.

Diagram



Fields

Field	Function
31-16 —	Reserved.
15 MFCO	Overflow status of the MFC Counter Indicates whether the miss frame counter overflow has occurred. When this field is 1, it indicates that the MFC counter does not increments further. This field becomes 0 when this register is read. Access restriction apply to this field. It clears on read and automatically becomes 1 on an internal event occurrence.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Not occurred 1b - Occurred
14-11 —	Reserved.
10-0 MFC	Dropped Packet Counters Indicates the number of packet counters that DMA drops either because of bus error or programing RPF field in DMA_CH${i}_Rx_Control register. This counter is 0 when this register is read. Access restriction apply to this field. It clears on read and automatically becomes 1 on an internal event occurrence.

72.18.283 DMA Channel 1 Rx Parser Accept Count (DMA_CH1_RXP_Accept_Cnt)

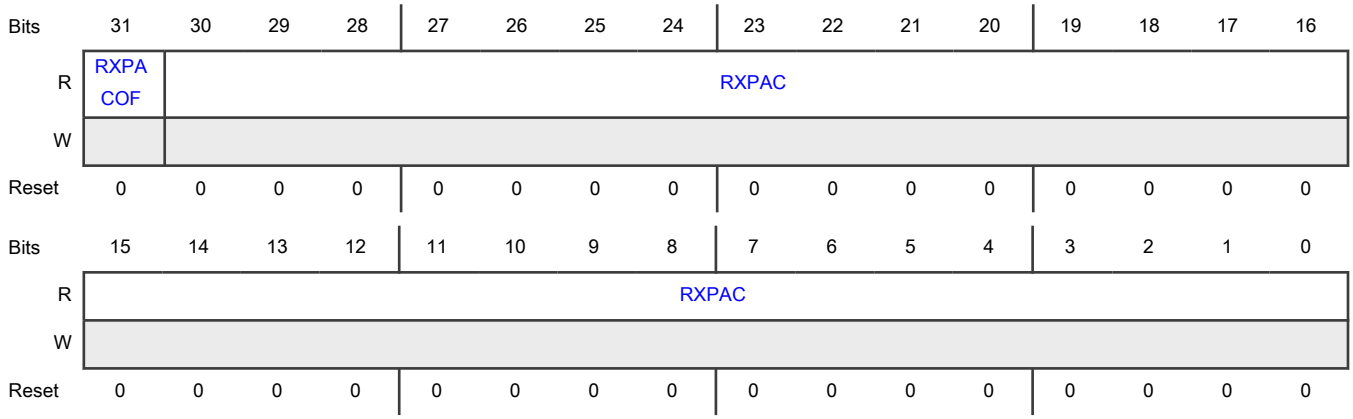
Offset

Register	Offset
DMA_CH1_RXP_Accept_Cnt	11E8h

Function

Provides the count of the number of frames which the receive parser accepts.

Diagram



Fields

Field	Function
31	Rx Parser Accept Counter Overflow Bit

Table continues on the next page...

Table continued from the previous page...

Field	Function
RXPACOF	Indicates whether the receive parser accept counter overflow have occurred. When this field is 1, it indicates that the DMA_CH1_RXP_Accept_Cnt[RXPAC] has crossed the maximum limit. Access restriction apply to this field. It clears on read and automatically becomes 1 on an internal event occurrence. 0b - Not occurred 1b - Occurred
30-0 RXPAC	Rx Parser Accept Counter Implements whenever a receive parser accept a packet because AF = 1. The counter clears when the register is read.

72.18.284 DMA Channel 1 Rx ERI Count (DMA_CH1_RX_ERI_Cnt)

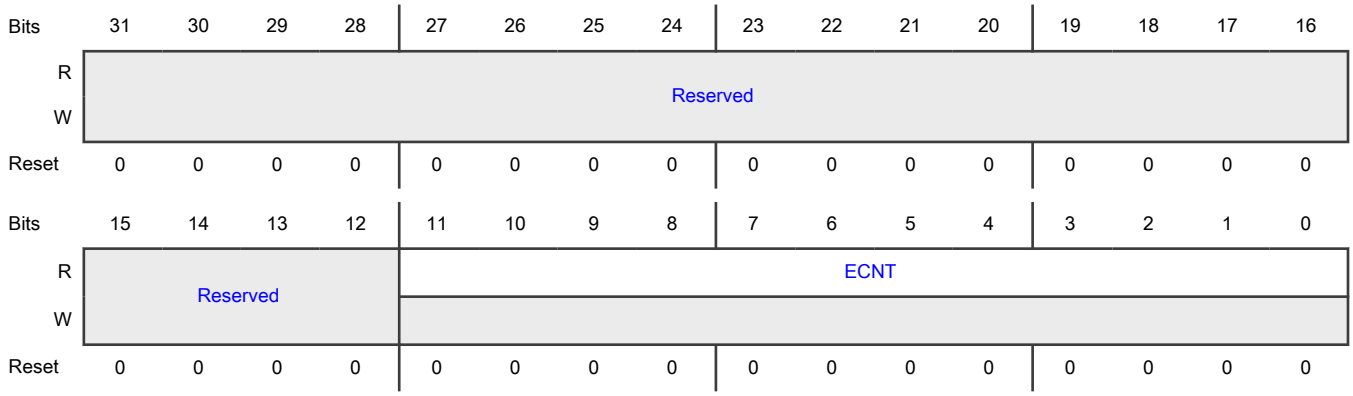
Offset

Register	Offset
DMA_CH1_RX_ERI_Cnt	11ECh

Function

Provides the count of the number of times ERI asserts.

Diagram



Fields

Field	Function
31-12	Reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
11-0 ECNT	ERI Counter ERI Counter When ERIC bit of DMA_CH(#i)_RX_Control register is 1, it indicates that this counter increments for burst transfer which the Rx DMA completes from the start of packet transfer. This counter resets at the start of new packet.

Table 530. LPUART Configuration (continued)

Feature	Configuration	
Functionality supported	Standard LPUART functionality with MODEM/IrDA	• Standard LPUART functionality with MODEM/IrDA • MODBUS and PPROFIBUS support[1]
	LIN master and slave operation	

1. Only supported for instance LPUART_0 and LPUART_1.

NOTE

LPUART instances are not available during Standby.

LPUART[0:2]_trg_input is coming from TRGMUX and you should take care of the pulse width of trigger. It should follow the requirement mentioned in section "Peripheral Triggers". These triggers are not present in MWCT2D17S.

73.2 Overview

The Low Power Universal Asynchronous Receiver/Transmitter (LPUART) module provides asynchronous, serial communication capability with external devices. LPUART supports non-return-to-zero (NRZ) encoding format and IrDA compatible infrared (low-speed) SIR format. The LPUART can continue operating while the processor is in low-power mode if an appropriate peripheral clock is available.

73.2.1 Block diagram

The following figure shows the transmitter portion of the LPUART.

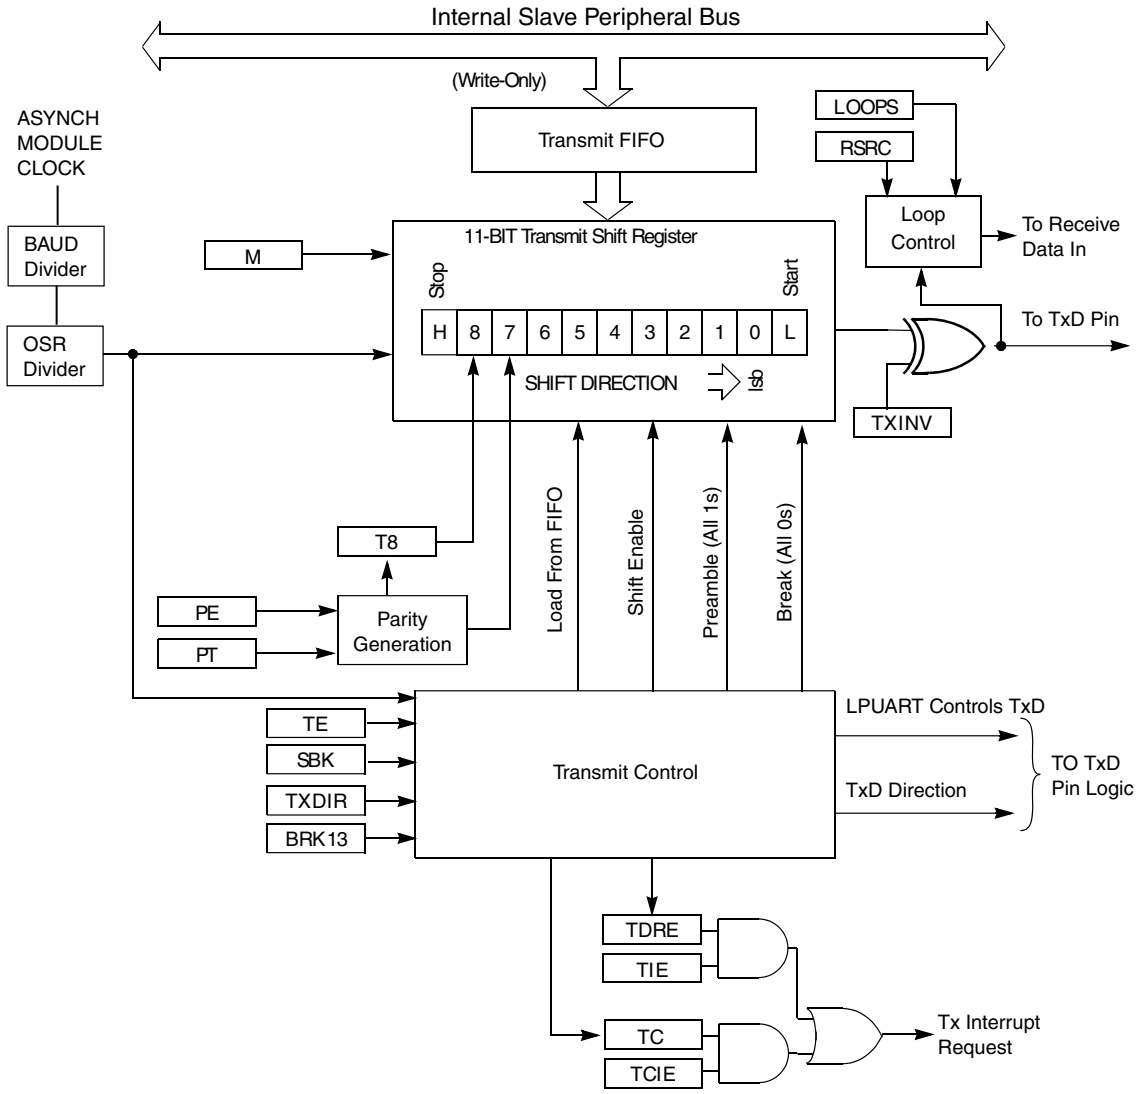

Figure 423. LPUART transmitter block diagram

The following figure shows the receiver portion of the LPUART.

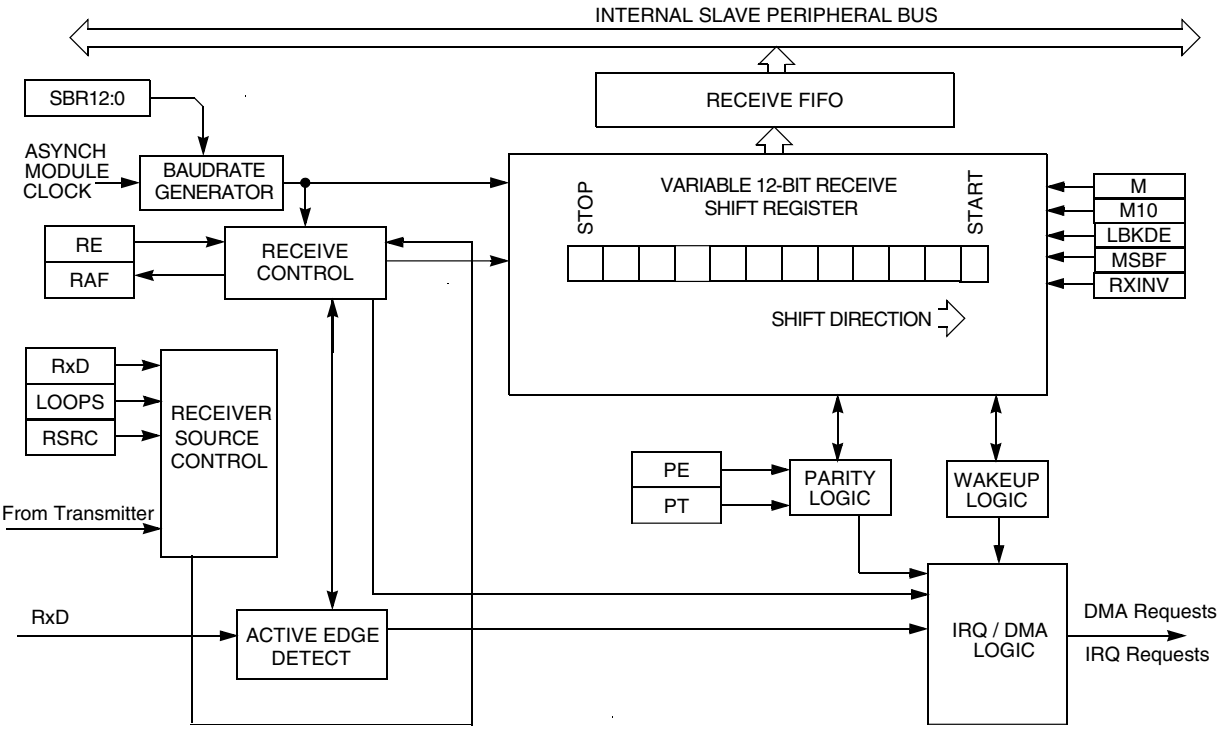

Figure 424. LPUART receiver block diagram

73.2.2 Features

Following are the features of the LPUART module.

- Full-duplex, standard non-return-to-zero (NRZ) format
- Programmable baud rates(13-bit modulo divider) with configurable oversampling ratio from 4x to 32x
- Asynchronous operation of transmit and receive baud rate with respect to the bus clock:
  - Baud rate can be configured independently of the bus clock frequency
  - Supports operation in low-power modes
- Interrupt, DMA or polled operation:
  - Transmit data register empty and transmission complete
  - Receive data register full
  - Receive overrun, parity error, framing error, and noise error
  - Idle receiver detect
  - Active edge on receive pin
  - Break detect supporting LIN
  - Receive data match
- Hardware parity generation and checking
- Programmable 7-bit, 8-bit, 9-bit or 10-bit character length
- Programmable 1-bit or 2-bit stop bits
- Support for three receiver wakeup methods:
  - Idle line wakeup

  - Address mark wakeup
  - Receive data match
- Automatic address matching to reduce ISR overhead:
  - Address mark matching
  - Idle line address matching
  - Address match start, address match end
- Optional 13-bit/11-bit break character generation
- Configurable idle length detection supporting 1, 2, 4, 8, 16, 32, 64, or 128 idle characters
- Selectable transmitter output and receiver input polarity
- Hardware flow control support for request to send (RTS) and clear to send (CTS) signals
- Selectable IrDA 1.4 return-to-zero-inverted (RZI) format with programmable pulse width
- Independent FIFO structure for transmit and receive
  - Separate configurable watermark for receive and transmit requests
  - Option for receiver to assert request after a configurable number of idle characters if receive FIFO is not empty

73.3 Functional description

The LPUART supports full-duplex, asynchronous, NRZ serial communication and comprises a baud rate generator, transmitter, and receiver block. The transmitter and receiver operate independently, although they use the same baud rate generator. The following describes each of the blocks of the LPUART.

73.3.1 Low-power modes

The LPUART remains functional during low power modes, provided the CTRL[DOZEEN] bit is clear and the LPUART functional clock remain enabled. The LPUART can generate an interrupt or DMA request to cause a wakeup from low power modes.

The LPUART can be configured to be disabled in low power modes, when the CTRL[DOZEEN] bit is set. In this case the transmitter and receiver finish transmitting/receiving the current word.

If the LPUART is disabled in low power modes, then it can generate a wakeup via the STAT[RXEDGIF] flag if the receiver detects an active edge.

NOTE

See the chip-specific information to know the specific low-power modes available on your device.

73.3.2 Debug mode

The LPUART remains functional in debug mode.

73.3.3 Baud rate generation

A 13-bit modulus counter in the baud rate generator derives the baud rate for both the receiver and the transmitter. The value from 1 to 8191 written to BAUD[SBR] determines the baud clock divisor for the asynchronous LPUART baud clock. The baud rate clock drives the receiver, while the transmitter is driven by a bit clock which is generated from baud rate clock divided by the over sampling ratio (OSR). Depending on the over sampling ratio, the receiver has an acquisition rate of 4 to 32 samples per bit time.

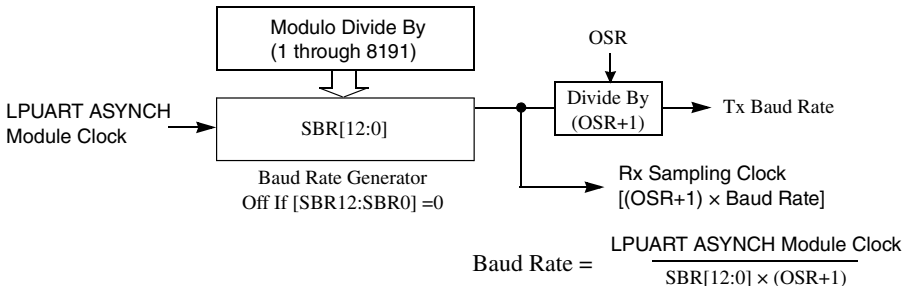

Figure 425. LPUART baud rate generation

Baud rate generation is subject to two sources of error:

- Integer division of the asynchronous LPUART baud clock may not give the exact target frequency.
- Synchronization with the asynchronous LPUART baud clock can cause phase shift.

The baud rate generation is a free-running counter that continues whenever the transmitter or receiver is enabled. The transmitter bit clock continues whenever the transmitter is enabled; each transmitted character aligns to the next edge of the transmit bit clock.

In general, configuring OSR for a higher oversampling ratio and/or sampling on both edges of the clock slightly improves the LPUART tolerance to baud rate mismatch between the received data and the LPUART configured baud rate. However, the three data samples in each bit will also be closer together which may impact noise sensitivity.

73.3.4 Transmitter functional description

This section describes the overall block diagram for the LPUART transmitter, as well as specialized functions for sending break and idle characters.

The transmitter output (TXD) idle state defaults to logic high; the transmitter output is inverted by setting CTRL[TXINV]. CTRL[TXINV] is cleared following reset. The transmitter is enabled by setting the CTRL[TE] bit. This queues a preamble character that is one full character frame of the idle state. The transmitter then remains idle until data is available in the transmit FIFO. Programs store data into the transmit FIFO by writing to the DATA register.

The central element of the LPUART transmitter is the transmit shift register that is 9-bit to 13-bit long depending on the setting in the CTRL[M], CTRL[M7], BAUD[M10] and BAUD[SBNS] control bits. For the remainder of this section, assume CTRL[M], CTRL[M7], BAUD[M10] and BAUD[SBNS] are cleared, selecting the normal 8-bit data mode. In 8-bit data mode, the shift register holds a start bit, eight data bits, and a stop bit. When the transmit shift register is available for a new character, the value waiting in the transmit data register is transferred to the transmit shift register, synchronized with the baud rate clock, and the transmit data register empty (STAT[TDRE]) status flag is set to indicate another character may be written to the transmit FIFO at the DATA register.

If no new character is waiting in the transmit FIFO after a stop bit is shifted out of the TXD pin, the transmitter sets the transmit complete flag and enters an idle mode, with TXD high, waiting for more characters to transmit.

Writing 0 to CTRL[TE] does not immediately disable the transmitter. The current transmit activity in progress must first be completed (that could include a data character, idle character or break character), although the transmitter does not start transmitting another character.

73.3.4.1 Send break and queued idle

The CTRL[SBK] bit sends break characters originally used to gain the attention of old teletype receivers. Break characters are a full character time of logic 0, 9-bit to 12-bit times including the start and stop bits. A longer break of 13-bit times can be enabled by setting STAT[BRK13]. Normally, a program waits for STAT[TDRE] to become set to indicate the last character of a message has moved to the transmit shifter, write 1, and then write 0 to the CTRL[SBK] bit. This action queues a break character to be sent as soon as the shifter is available. If CTRL[SBK] remains 1 when the queued break moves into the shifter, synchronized to the baud rate clock, an additional break character is queued. When the LPUART is the receiving device, a break character is received as 0s in all data bits and a framing error (STAT[FE] = 1) is detected.

A break character can also be transmitted by writing to the DATA register with DATA[FRETSC] set and the data bits clear. This supports transmitting the break character as part of the normal data stream and also allows the DMA to transmit a break character.

When idle-line wakeup is used, a full character time of idle (logic 1) is needed between messages to wake up any sleeping receivers. Normally, a program waits for STAT[TDRE] to become set to indicate the last character of a message has moved to the transmit shifter, write 0, and then write 1 to the CTRL[TE] bit. This action queues an idle character to be sent as soon as the shifter is available. As long as the character in the shifter does not finish while CTRL[TE] is cleared, the LPUART transmitter never actually releases control of the TXD pin.

An idle character can also be transmitted by writing to the DATA register with DATA[FRETSC] and DATA[T9] set, and all other bits cleared. This supports transmitting the idle character as part of the normal data stream and also allows the DMA to transmit a idle character.

The length of the break character is affected by the STAT[BRK13], CTRL[M], CTRL[M7], BAUD[M10] and BAUD[SNBS] bits as shown below.

Table 531. Break character length

BRK13	M	M10	M7	SBNS	Break character length
0	0	0	0	0	10 bit times
0	0	0	0	1	11 bit times
0	0	0	1	0	9 bit times
0	0	0	1	1	10 bit times
0	1	0	X	0	11 bit times
0	1	0	X	1	12 bit times
0	X	1	X	0	12 bit times
0	X	1	X	1	13 bit times
1	0	0	0	0	13 bit times
1	0	0	0	1	13 bit times
1	0	0	1	0	12 bit times
1	0	0	1	1	12 bit times
1	1	0	X	0	14 bit times
1	1	0	X	1	14 bit times
1	X	1	X	0	15 bit times
1	X	1	X	1	15 bit times

73.3.4.2 Hardware flow control

The transmitter supports hardware flow control by gating the transmission with the value of CTS_B. If the clear-to-send operation is enabled, the character is transmitted when CTS_B is asserted. If CTS_B is deasserted in the middle of a transmission with characters remaining in the transmitter FIFO, the character in the transmit shift register will be complete; any characters in the FIFO will wait for the CTS_B to assert again and TXD remains in the mark state (idle state) until CTS_B is reasserted. The CTS_B pin must assert for longer than one bit period to guarantee a new transmission is started when the transmitter is idle with data to send.

If the clear-to-send operation is disabled, the transmitter ignores the state of CTS_B.

The transmitter's CTS_B signal can be enabled even if the same LPUART receiver's RTS_B signal is disabled.

73.3.4.3 Transceiver driver enable

The transmitter can use RTS_B as an enable signal for the driver of an external transceiver. See Transceiver driver enable using RTS_B for details. If the request-to-send operation is enabled, when a character is placed into an empty transmit shift register, RTS_B asserts one bit time before the start bit is transmitted. RTS_B remains asserted for the whole time that the transmit shift register has any characters. RTS_B deasserts one bit time after all characters in the transmit FIFO and shift register are completely sent, including the last stop bit. In other words, when RTS_B is used as a transceiver enable, the RTS_B asserts 1 bit time before the transmitter starts transmitting and negates 1 bit time after the transmitter goes idle.

Transmitting a break character also asserts RTS_B, with the same assertion and deassertion timing as having a character in the transmit shift register.

The transmitter's RTS_B signal asserts only when the transmitter is enabled. However, the transmitter's RTS_B signal is unaffected by its CTS_B signal. RTS_B remains asserted until the transfer is completed, even if the transmitter is disabled mid-way through a data transfer.

73.3.4.4 Transceiver driver enable using RTS_B

RS-485 is a multiple drop communication protocol in which the LPUART transceiver's driver is 3-stated unless the LPUART is driving. The RTS_B signal can be used by the transmitter to enable the driver of a transceiver. The polarity of RTS_B can be matched to the polarity of the transceiver's driver enable signal.

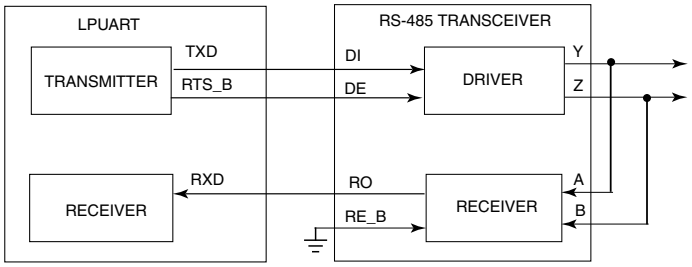

Figure 426. Transceiver driver enable using RTS_B

In the figure, the receiver enable signal is asserted. Another option for this connection is to connect RTS_B to both DE and RE_B. The transceiver's receiver is disabled while driving. A pullup can pull RXD to a non-floating value during this time. This option can be refined further by operating the LPUART in single wire mode, freeing the RXD pin for other uses.

73.3.5 Receiver functional description

In this section, the receiver block diagram is a guide for the overall receiver functional description. Next, the data sampling technique used to reconstruct receiver data is described in more detail. Finally, different variations of the receiver wakeup function are explained.

The receiver input is inverted by setting STAT[RXINV]. The receiver is enabled by setting the CTRL[RE] bit. Character frames consist of a start bit of logic 0, seven to ten data bits (msb or lsb first), and one or two stop bits of logic 1. For information about 7-bit, 9-bit or 10-bit data mode, refer to Data Modes. For the remainder of this discussion, assume the LPUART is configured for normal 8-bit data mode.

After receiving the stop bit into the receive shifter, and provided the receive data register is not already full, the data character is transferred to the receive data register and the receive data register full (STAT[RDRF]) status flag is set. If [RDRF] was already set indicating the receive data register (buffer) was already full, the overrun (OR) status flag is set and the new data is lost.

Since the LPUART receiver is separate from the receive FIFO, the receive shift register can be receiving the next word when the receive FIFO is full and it is only at the end of the character that the next data is written into the receive FIFO, potentially triggering the overrun flag if FIFO is full.

When a program detects that the receive data register is full (STAT[RDRF] = 1), it gets the data from the receive data register by reading the DATA register. Refer to Interrupts and status flags for details about flag clearing.

73.3.5.1 Data sampling technique

The LPUART receiver supports a configurable oversampling rate of between 4× and 32× of the baud rate clock for sampling. The receiver starts by taking logic level samples at the oversampling rate times the baud rate to search for a falling edge on the RXD serial data input pin. A falling edge is defined as a logic 0 sample after three consecutive logic 1 samples. The oversampling baud rate clock divides the bit time into 4 to 32 segments from 1 to OSR (where OSR is the configured oversampling ratio). When a falling edge is located, three more samples are taken at (OSR/2), (OSR/2)+1, and (OSR/2)+2 to make sure this was a real start bit and not merely noise. If at least two of these three samples are 0, the receiver assumes it is synchronized to a received character. If another falling edge is detected before the receiver is considered synchronized, the receiver restarts the sampling from the first segment.

The receiver then samples each bit time, including the start and stop bits, at (OSR/2), (OSR/2)+1, and (OSR/2)+2 to determine the logic level for that bit. The logic level is interpreted to be that of the majority of the samples taken during the bit time. If any sample in any bit time, including the start and stop bits, in a character frame fails to agree with the logic level for that bit, the noise flag (STAT[NF]) is set when the received character is transferred to the receive FIFO.

When the LPUART receiver is configured to sample on both edges of the baud rate clock (that is, when BAUD[BOTHEDGE]=1), the number of segments in each received bit is effectively doubled (from 1 to OSR×2). The start and data bits are then sampled at OSR, OSR+1 and OSR+2. Sampling on both edges of the clock must be enabled for oversampling rates of 4× to 7× and is optional for higher oversampling rates.

The "synchronization" is a feature of the LPUART module to synchronize the internal oversampling counter with detected falling edge on Rx signal, and to adjust the data sampling window. The falling edge detection needs three consecutive '1' prior to '1'->'0' transition. After the initial falling edge detection for the start bit, the circuit continuously monitors the next falling edge, and resets the counter once another falling edge is detected. This is called "resynchronization".

- When LPUART_BAUD[RESYNCDIS] = 0, this falling edge detection and resynchronization is performed not only for the start bit but also for the rest of character reception after the start bit.
- When LPUART_BAUD[RESYNCDIS] = 1, the falling edge detection and resynchronization is performed only for the start bit. The use case for disabling the resynchronization is protocols that require this (for example, LIN 2.1 prohibits resynchronization within a byte).

  See the following table and figure.

Table 532. LPUART resynchronization

Resynchronization	LPUART_BAUD[RESYNCDIS]=0	LPUART_BAUD[RESYNCDIS]=1
For the starting bit falling edge	Yes	Yes
For every falling edges after the start bit	Yes	No

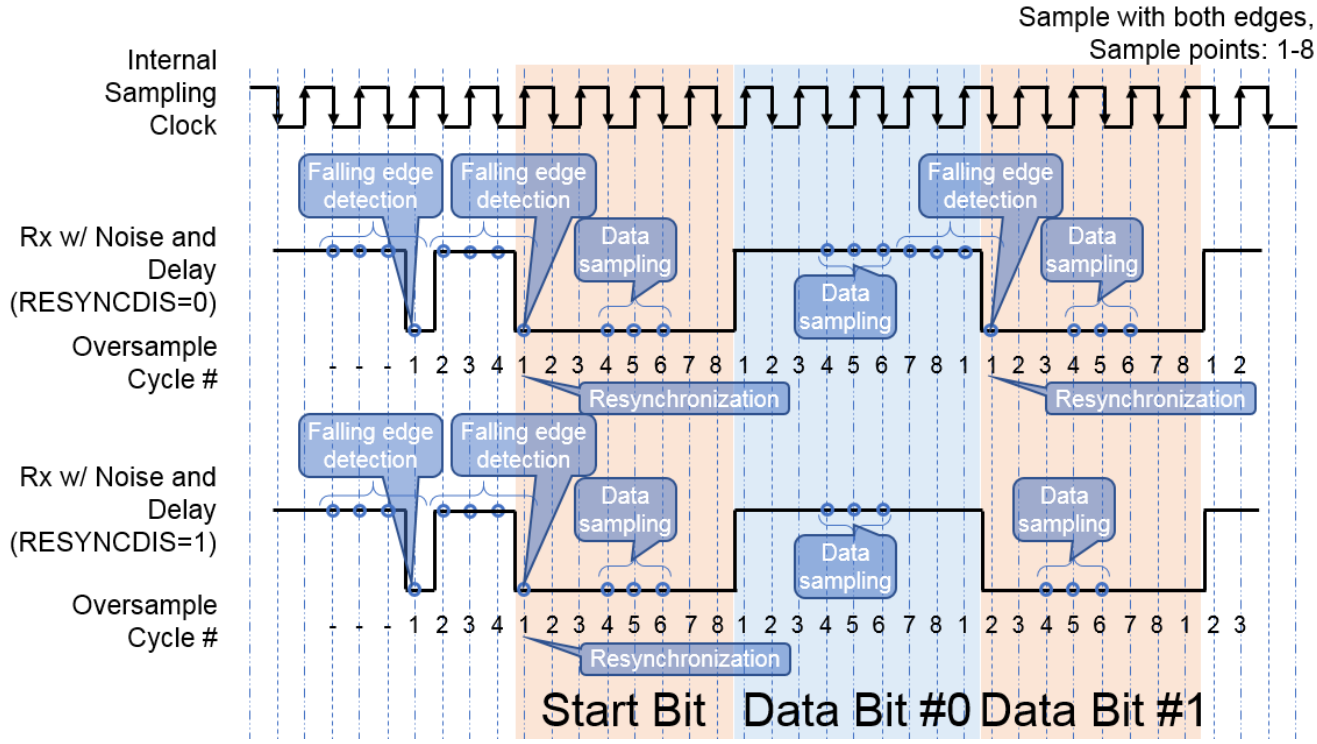

Figure 427. LPUART resynchronization

73.3.5.2 Receiver wakeup operation

Receiver wakeup and receiver address matching is a hardware mechanism that allows an LPUART receiver to ignore the characters in a message intended for a different receiver.

During receiver wakeup, all receivers evaluate the first character(s) of each message, and as soon as they determine the message is intended for a different receiver, they write logic 1 to the receiver wake up control bit (CTRL[RWU]). When CTRL[RWU] and STAT[RWUID] bit are set, the status flags associated with the receiver, with the exception of the idle bit, STAT[IDLE], are inhibited from setting, thus eliminating the software overhead for handling the unimportant message characters. At the end of a message, all receivers automatically force CTRL[RWU] to 0 so all receivers wake up in time to look at the first character(s) of the next message.

During receiver address matching, the address matching is performed in hardware and the LPUART receiver ignores all characters that do not meet the address match requirements.

Table 533. Receiver Wakeup Options

RWU	MA1 | MA2	MATCFG	WAKE:RWUID	Receiver Wakeup
0	0	X	X	Normal operation
1	0	00	00	Receiver wakeup on idle line, IDLE flag not set
1	0	00	01	Receiver wakeup on idle line, IDLE flag set
1	0	00	10	Receiver wakeup on address mark

Table continues on the next page...

Table 533. Receiver Wakeup Options (continued)

RWU	MA1 | MA2	MATCFG	WAKE:RWUID	Receiver Wakeup
1	1	11	10	Receiver wakeup on data match
0	1	00	X0	Address mark address match, IDLE flag not set for discarded characters
0	1	00	X1	Address mark address match, IDLE flag set for discarded characters
0	1	01	X0	Idle line address match
0	1	10	X0	Match On and Match Off, IDLE flag not set for discarded characters
0	1	10	X1	Match On and Match Off, IDLE flag set for discarded characters

73.3.5.2.1 Idle-line wakeup

When CTRL[WAKE] is cleared, the receiver is configured for idle-line wakeup. In this mode, CTRL[RWU] is cleared automatically when the receiver detects a full character time of the idle-line level. The CTRL[M], CTRL[M7], and BAUD[M10] control bits select 7-bit to 10-bit data mode and the BAUD[SBNS] bit selects 1-bit or 2-bit stop bit number that determines how many bit times of idle are needed to constitute a full character time, 9 to 13 bit times because of the start and stop bits.

When CTRL[RWU] is 1 and STAT[RWUID] is 0, the idle condition that wakes up the receiver does not set the STAT[IDLE] flag. The receiver wakes up and waits for the first data character of the next message that sets the STAT[RDRF] flag and generates an interrupt if enabled. When STAT[RWUID] is 1, any idle condition sets the STAT[IDLE] flag and generates an interrupt if enabled, regardless of whether CTRL[RWU] is 0 or 1.

The idle-line type (CTRL[ILT]) control bit selects one of two ways to detect an idle line.

- When CTRL[ILT] is cleared, the idle bit counter starts after the start bit so the stop bit and any logic 1s at the end of a character count toward the full character time of idle.
- When CTRL[ILT] is set, the idle bit counter does not start until after the stop bit time, so the idle detection is not affected by the data in the last character of the previous message.

73.3.5.2.2 Address-mark wakeup

When CTRL[WAKE] is set, the receiver is configured for address-mark wakeup. In this mode, CTRL[RWU] is cleared automatically when the receiver detects a logic 1 in the most significant bit of the received character. When parity is enabled, the second most significant bit is used for address-mark wakeup.

Address-mark wakeup allows messages to contain idle characters, but requires one bit be reserved for use in address frames. The logic 1 in the most significant bit (or second most significant bit when parity is enabled) of an address frame clears the CTRL[RWU] bit and sets the STAT[RDRF] flag. In this case, the character with the address-mark bit is received even though the receiver was sleeping during most of this character time.

73.3.5.2.3 Data match wakeup

When CTRL[RWU] is set, CTRL[WAKE] is set and BAUD[MATCFG] equals 11, the receiver is configured for data match wakeup. In this mode, CTRL[RWU] is cleared automatically when the receiver detects a character that matches MATCH[MA1] field when BAUD[MAEN1] is set, or that matches MATCH[MA2] when BAUD[MAEN2] is set.

73.3.5.2.4 Address Match operation

Address match operation is enabled when the BAUD[MAEN1] or BAUD[MAEN2] bit is set and BAUD[MATCFG] is equal to 00. In this function, a character received by the RXD pin with a logic 1 in the most significant bit (or second most significant bit when parity is enabled) is considered an address and is compared with the associated MATCH[MA1] or MATCH[MA2] field. The character is only transferred to the receive buffer, and STAT[RDRF] is set, if the comparison matches. All subsequent characters received with a logic 0 in the most significant bit (or second most significant bit when parity is enabled) are considered to be data associated with the address and are transferred to the receive FIFO. If no marked address match occurs then no transfer is made to the receive FIFO, and all following characters with logic zero in the most significant bit (or second most significant bit when parity is enabled) are also discarded. If both the BAUD[MAEN1] and BAUD[MAEN2] bits are negated, the receiver operates normally and all data received is transferred to the receive FIFO.

Address match operation functions in the same way for both MATCH[MA1] and MATCH[MA2] fields.

- If only one of BAUD[MAEN1] and BAUD[MAEN2] is asserted, a marked address is compared only with the associated match register field and data is transferred to the receive FIFO only on a match.
- If BAUD[MAEN1] and BAUD[MAEN2] are asserted, a marked address is compared with both match registers and data is transferred only on a match with either of the MATCH[MA1] or MATCH[MA2] fields.

73.3.5.2.5 Idle Match operation

Idle match operation is enabled when the BAUD[MAEN1] or BAUD[MAEN2] bit is set and BAUD[MATCFG] is equal to 01. In this function, the first character received by the RXD pin after an idle line condition is considered an address and is compared with the associated MATCH[MA1] or MATCH[MA2] field. The character is transferred only to the receive buffer, and STAT[RDRF] is set, if the comparison matches. All subsequent characters are considered to be data associated with the address and are transferred to the receive FIFO until the next idle line condition is detected. If no address match occurs then no transfer is made to the receive FIFO, and all following frames until the next idle condition are also discarded. If both the BAUD[MAEN1] and BAUD[MAEN2] bits are negated, the receiver operates normally and all data received is transferred to the receive FIFO.

Idle match operation functions in the same way for both MATCH[MA1] or MATCH[MA2] fields.

- If only one of BAUD[MAEN1] and BAUD[MAEN2] is asserted, the first character after an idle line is compared only with the associated match register and data is transferred to the receive FIFO only on a match.
- If BAUD[MAEN1] and BAUD[MAEN2] are asserted, the first character after an idle line is compared with both MATCH[MA1] or MATCH[MA2] fields and data is transferred only on a match with either of the fields.

73.3.5.2.6 Match On Match Off operation

Match on, match off operation is enabled when both BAUD[MAEN1] and BAUD[MAEN2] are set and BAUD[MATCFG] is equal to 10. In this function, a character received by the RXD pin that matches MATCH[MA1] is received and transferred to the receive buffer, and STAT[RDRF] is set. All subsequent characters are considered to be data and are also transferred to the receive FIFO, until a character is received that matches MATCH[MA2] field. The character that matches MATCH[MA2] and all following characters are discarded; this continues until another character that matches MATCH[MA1] is received. If both the BAUD[MAEN1] and BAUD[MAEN2] bits are negated, the receiver operates normally and all data received is transferred to the receive FIFO.

NOTE

Match on, match off operation requires both BAUD[MAEN1] and BAUD[MAEN2] to be asserted.

73.3.5.3 Hardware flow control

To support hardware flow control, the receiver can be programmed to automatically deassert and assert RTS_B.

- RTS_B remains asserted until the transfer is complete, even if the transmitter is disabled midway through a data transfer. See Transceiver driver enable using RTS_B for more details.
- If the receiver request-to-send functionality is enabled, the receiver automatically deasserts RTS_B if the number of characters in the receiver data register is full or a start bit is detected that causes the receiver data register to be full.
- The receiver asserts RTS_B when the number of characters in the receiver data register is not full and has not detected a start bit that causes the receiver data register to be full. It is not affected if STAT[RDRF] is asserted.
- Even if RTS_B is deasserted, the receiver continues to receive characters until the receive FIFO is overrun.
- If the receiver request-to-send functionality is disabled, the receiver RTS_B remains deasserted.

73.3.6 Additional LPUART functions

The following sections describe additional LPUART functions.

73.3.6.1 Data Modes

The LPUART transmitter and receiver can be configured to operate in 7-bit data mode by setting CTRL[M7], 9-bit data mode by setting the CTRL[M] or 10-bit data mode by setting BAUD[M10]. In 9-bit mode, there is a ninth data bit and in 10-bit mode, there is a tenth data bit.

When performing 8-bit writes to the transmit FIFO, the 9th and 10th bit are pushed into the FIFO from CTRL[T8] and CTRL[T9]. For coherent 8-bit writes, write to CTRL[T8] and CTRL[T9] before writing to DATA[7:0], but if values in CTRL[T8] or CTRL[T9] do not need to change then it is not necessary to update CTRL[T8] and CTRL[T9] before every 8-bit write to the DATA register.

When performing 16-bit or 32-bit writes to the transmit FIFO, all 10-bits are pushed into the transmit FIFO from the write data.

When performing 8-bit reads of the receive FIFO, the 9th and 10th bit are held in CTRL[R8] and CTRL[R9] but should be read before reading the DATA register. A 16-bit or 32-bit read of the receive FIFO will return all 10-bits in the DATA register.

The 9-bit data mode is typically used with parity to allow eight bits of data plus the parity in the ninth bit, or it is used with address-mark wakeup so the ninth data bit can serve as the wakeup bit. The 10-bit data mode is typically used with parity and address-mark wakeup so the ninth data bit can serve as the wakeup bit and the tenth bit as the parity bit. In custom protocols, the ninth and/or tenth bits can also serve as software-controlled markers.

73.3.6.2 Idle length

An idle character is a character where the start bit, all data bits and stop bits are in the mark position (idle state, generally logic 1). The CTRL[ILT] bit can be configured to start detecting an idle character from the previous start bit (any data bits and stop bits count towards the idle character detection) or from the previous stop bit.

The number of idle characters that must be received before an idle line condition is detected can also be configured using the CTRL[IDLECFG] field. This field configures the number of idle characters that must be received before the STAT[IDLE] flag is set, the STAT[RAF] flag is cleared and the DATA[IDLINE] flag is set with the next received character.

Idle-line wakeup and idle match operation are also affected by the CTRL[IDLECFG] field. When address match or match on/off operation is enabled, setting the STAT[RWUID] bit causes any discarded characters to be treated as if they were idle characters.

73.3.6.3 Loop mode

When CTRL[LOOPS] is set, the CTRL[RSRC] bit chooses between loop mode (CTRL[RSRC] = 0) or single-wire mode (CTRL[RSRC] = 1). Loop mode is sometimes used to check software, independent of connections in the external system, to help isolate system problems. In this mode, the transmitter output is internally connected to the receiver input and the RXD pin is not used by the LPUART.

73.3.6.4 Single-wire operation

When CTRL[LOOPS] is set, the CTRL[RSRC] bit chooses between loop mode (CTRL[RSRC] = 0) or single-wire mode (CTRL[RSRC] = 1). Single-wire mode implements a half-duplex serial connection. The receiver is internally connected to the transmitter output and to the TXD pin (the RXD pin is not used).

In single-wire mode, the CTRL[TXDIR] bit controls the direction of serial data on the TXD pin. When CTRL[TXDIR] is cleared, the TXD pin is an input to the receiver and the transmitter is temporarily disconnected from the TXD pin so an external device can send serial data to the receiver. When CTRL[TXDIR] is set, the TXD pin is an output driven by the transmitter, the internal loop back connection is disabled, and as a result the receiver cannot receive characters that are sent out by the transmitter.

73.3.7 Infrared interface

The LPUART provides the capability of transmitting narrow pulses to an IR LED and receiving narrow pulses and transforming them to serial bits, which are sent to the LPUART. The IrDA physical layer specification defines a half-duplex infrared communication link for exchanging data. The full standard includes data rates up to 16 Mbits/s. The LPUART IrDA support is limited to SIR mode which supports data rates only between 2.4 kbits/s and 115.2 kbits/s.

The LPUART has an infrared transmit encoder and receive decoder. The infrared decoder converts the received character from the IrDA format to the NRZ format used by the receiver. It also has a OSR oversampling baud rate clock counter that filters noise and indicates when a 1 is received. The LPUART transmits serial bits of data that are encoded by the infrared submodule to transmit a narrow pulse for every zero bit. No pulse is transmitted for every one bit. When receiving data, the IR pulses are detected using an IR photo diode (external to LPUART) and transformed to CMOS levels by the IR receive decoder. The narrow pulses are then stretched by the infrared receive decoder to get back to a serial bit stream to be received by the LPUART. The polarity of transmitted pulses and expected receive pulses can be inverted so that a direct connection can be made to external IrDA transceiver modules that use active high pulses.

The infrared submodule receives its clock sources from the LPUART. One of these two clocks are selected in the infrared submodule to generate either 1/OSR, 2/OSR, 3/OSR, or 4/OSR narrow pulses during transmission.

73.3.7.1 Infrared transmit encoder

The infrared transmit encoder converts serial bits of data from transmit shift register to the TXD signal. A narrow pulse is transmitted for a 0 bit and no pulse for a 1 bit. The narrow pulse is sent at the start of the bit with a duration of 1/OSR, 2/OSR, 3/OSR, or 4/OSR of a bit time. A narrow low pulse is transmitted for a 0 bit when CTRL[TXINV] is cleared, while a narrow high pulse is transmitted for a 0 bit when CTRL[TXINV] is set.

73.3.7.2 Infrared receive decoder

The infrared receive block converts data from the RXD signal to the receive shift register. A narrow pulse is expected for each 0 received and no pulse is expected for each 1 received. A narrow low pulse is expected for a 0 bit when STAT[RXINV] is cleared, while a narrow high pulse is expected for a 0 bit when STAT[RXINV] is set. This receive decoder meets the edge jitter requirement as defined by the IrDA serial infrared physical layer specification.

73.3.7.3 Start bit detection

When STAT[RXINV] is cleared, the first falling edge of the received character corresponds to the start bit. The infrared decoder resets its counter. At this time, the receiver also begins its start bit detection process. After the start bit is detected, the receiver synchronizes its bit times to this start bit time. For the rest of the character reception, the infrared decoder's counter and the receiver's bit time counter count independently from each other.

73.3.7.4 Noise filtering

Any further rising edges detected during the first half of the infrared decoder counter are ignored by the decoder. Any pulses less than one oversampling baud clock can be undetected by it regardless of whether it is seen in the first or second half of the count.

73.3.7.5 Low-bit detection

During the second half of the decoder count, a rising edge is decoded as a 0, which is sent to the receiver. The decoder counter is also reset.

73.3.7.6 High-bit detection

At OSR oversampling baud rate clocks after the previous rising edge, if a rising edge is not seen, then the decoder sends a 1 to the receiver.

If the next bit is a 0, which arrives late, then a low-bit is detected according to Low-bit detection. The value sent to the receiver is changed from 1 to a 0. Then, if a noise pulse occurs outside the receiver's bit time sampling period, then the delay of a 0 is not recorded as noise.

73.3.8 Interrupts and status flags

The LPUART transmitter has two status flags that can optionally generate hardware interrupt requests. Transmit Data Register Empty (STAT[TDRE]) indicates when there is room in the transmit FIFO to write another transmit character to the DATA register. If the Transmit Interrupt Enable (CTRL[TIE]) bit is set, a hardware interrupt is requested when STAT[TDRE] is set. Transmit complete (STAT[TC]) indicates that the transmitter is finished transmitting all data, preamble, and break characters and is idle with TXD at the inactive level. This flag is often used in systems with modems to determine when it is safe to turn off the modem. If the transmit complete interrupt enable (CTRL[TCIE]) bit is set, a hardware interrupt is requested when STAT[TC] is set. Instead of hardware interrupts, software polling may be used to monitor the STAT[TDRE] and STAT[TC] status flags if the corresponding CTRL[TIE] or CTRL[TCIE] local interrupt masks are cleared.

When a program detects that the receive data register is full (STAT[RDRF] = 1), it gets the data from the receive data register by reading the DATA register. The STAT[RDRF] flag is cleared by reading the DATA register.

The IDLE status flag includes logic that prevents it from getting set repeatedly when the RXD line remains idle for an extended period of time. IDLE is cleared by writing 1 to the STAT[IDLE] flag. After STAT[IDLE] has been cleared, it cannot become set again until the receiver has received at least one new character and has set STAT[RDRF].

If the associated error is detected in the received character that caused STAT[RDRF] to be set, the error flags — noise flag (STAT[NF]), framing error (STAT[FE]), and parity error flag (STAT[PF]) — are set at the same time as STAT[RDRF]. These flags are not set in overrun cases.

If STAT[RDRF] is already set when a new character is ready to be transferred from the receive shifter to the receive FIFO, the overrun (STAT[OR]) flag is set instead of the data along with any associated STAT[NF], STAT[FE], or STAT[PF] condition is lost.

If the received character matches the contents of MATCH[MA1] and/or MATCH[MA2] then the STAT[MA1F] and/or STAT[MA2F] flags are set at the same time that STAT[RDRF] is set.

At any time, an active edge on the RXD serial data input pin causes the STAT[RXEDGIF] flag to set. The STAT[RXEDGIF] flag is cleared by writing a 1 to it. This function depends on the receiver being enabled (CTRL[RE] = 1).

73.3.9 Peripheral Triggers

The connection of the LPUART peripheral triggers with other peripherals are device specific.

Output Triggers

The LPUART generates the following output triggers that can be connected to other peripherals on the device.

- The transmit word trigger asserts at the end of each transmitted word, it negates after one bit period.
- The transmit data trigger is identical to the TXD pin output, but without support for input trigger modulation.
- The receive word trigger asserts at the end of each received word that is written to the receive FIFO, for one oversampling clock period.
- The receive idle trigger asserts when the idle flag would set, for one oversampling clock period.

Input Trigger

The LPUART supports one peripheral input trigger, that can be configured in one of the following ways.

- The CTS function must be enabled. The input trigger can be connected in place of the CTS_B pin input. The input trigger must assert for longer than one bit clock period when the transmitter is idle with data to send to guarantee a new transmission.
- The input trigger can modulate the transmit data output (trigger is logically ANDed with the TXD output). The input trigger is expected to be a free running clock (carrier signal) generated from a timer or PWM source with a frequency that is greater than the bit clock frequency. The carrier signal must not toggle faster than the maximum supported bit time.
- The input trigger can be connected in place of the RXD pin input. The input trigger is expected to be generated from a receive data source, such as analog comparator or external pin.

73.4 Clocking and Resets

Table 534. Clocks

LPUART Functional clock	The LPUART functional clock is asynchronous to the bus clock and can remain enabled in low power modes to support transmit and/or receive, including low power wakeups.
Bus clock	The bus clock is only used for bus accesses to the control and configuration registers. The bus clock frequency must be sufficient to support the data bandwidth requirements of the LPUART transmit and receive registers, including the FIFOs.

Table 535. Resets

Chip reset	The logic and registers for the LPUART transmitter and receiver are reset to their default state on a chip reset.
Software reset	Resets the LPUART logic and registers to their default state, except for the Global Register. The LPUART software reset is in the Global Register GLOBAL[RST].
FIFO reset	The LPUART implements write-only control bits that reset the transmit FIFO (FIFO[TXFLUSH]) and receive FIFO (FIFO[RXFLUSH]). After a FIFO is reset, that FIFO is empty.

73.5 External signals

Table 536.

Signal	Description	I/O
TXD	Transmit data. This pin is normally an output, but is an input (tristated) in single wire mode whenever the transmitter is disabled or transmit direction is configured for receive data.	I/O
RXD	Receive data.	I
CTS_B	Clear to send.	I
RTS_B	Request to send.	O

73.6 Register definition

The LPUART includes registers to control baud rate, select options, report status, and store transmit/receive data. Access to an address outside the valid memory map generates a bus error.

NOTE

Writing a Read-Only (RO) register or reading a Write-Only (WO) register can cause bus errors. This module does not check if programmed values in the registers are correct; the application software must ensure that valid programmed values are being written.

23 TDMAE	Transmitter DMA Enable TDMAE configures the transmit data register empty flag, STAT[TDRE], to generate a DMA request. 0b - DMA request disabled. 1b - DMA request enabled.
22 —	Reserved
21 RDMAE	Receiver Full DMA Enable RDMAE configures the receiver data register full flag, STAT[RDRF], to generate a DMA request.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - DMA request disabled. 1b - DMA request enabled.
20 —	Reserved
19-18 MATCFG	Match Configuration Configures the match addressing mode used. This field should be changed only when the transmitter and receiver are both disabled. 00b - Address Match Wakeup 01b - Idle Match Wakeup 10b - Match On and Match Off 11b - Enables RWU on Data Match and Match On/Off for transmitter CTS input
17 BOTHEDGE	Both Edge Sampling Enables sampling of the received data on both edges of the baud rate clock, effectively doubling the number of times the receiver samples the input data for a given oversampling ratio. This bit must be set for oversampling ratios between x4 and x7 and is optional for higher oversampling ratios. This bit should be changed only when the receiver is disabled. 0b - Receiver samples input data using the rising edge of the baud rate clock. 1b - Receiver samples input data using the rising and falling edge of the baud rate clock.
16 RESYNCDIS	Resynchronization Disable When set, this field disables the resynchronization of the received data word when a data one followed by data zero transition is detected. This bit should be changed only when the receiver is disabled. 0b - Resynchronization during received data word is supported. 1b - Resynchronization during received data word is disabled.
15 LBKDIE	LIN Break Detect Interrupt Enable LBKDIE enables the LIN break detect flag, STAT[LBKDIF], to generate interrupt requests. 0b - Hardware interrupts from STAT[LBKDIF] flag are disabled (use polling). 1b - Hardware interrupt is requested when STAT[LBKDIF] flag is 1.
14 RXEDGIE	RX Input Active Edge Interrupt Enable Enables the receive input active edge, STAT[RXEDGIF], to generate interrupt requests. Changing CTRL[LOOPS] or CTRL[RSRC] when RXEDGIE is set can cause the STAT[RXEDGIF] flag to set. 0b - Hardware interrupts from STAT[RXEDGIF] are disabled. 1b - Hardware interrupt is requested when STAT[RXEDGIF] flag is 1.
13	Stop Bit Number Select

Table continues on the next page...

Table continued from the previous page...

Field	Function
SBNS	SBNS determines whether data characters have one or two stop bits. This bit should be changed only when the transmitter and receiver are both disabled. 0b - One stop bit. 1b - Two stop bits.
12-0 SBR	Baud Rate Modulo Divisor. The 13 bits in SBR[12:0] set the modulo divide rate for the baud rate generator. When SBR is 1 - 8191, the baud rate equals "baud clock / ((OSR+1) * SBR)". The 13-bit baud rate setting [SBR12:SBR0] must be updated only when the transmitter and receiver are both disabled (CTRL[RE] and CTRL[TE] are both 0).

73.6.1.7 LPUART Status Register (STAT)

Offset

Register	Offset
STAT	14h

Fields

Field	Function
31 LBKDIF	LIN Break Detect Interrupt Flag LBKDIF is set when the LIN break detect circuitry is enabled and a LIN break character is detected. Writing a 1 clears the LBKDIF field. 0b - No LIN break character has been detected. 1b - LIN break character has been detected.

Table continues on the next page...

Table continued from the previous page...

Field	Function
30 RXEDGIF	RXD Pin Active Edge Interrupt Flag RXEDGIF is set whenever the receiver is enabled and an active edge (falling if RXINV = 0, rising if RXINV=1,) on the RXD pin occurs. To clear RXEDGIF, write a 1 to the RXEDGIF field. 0b - No active edge on the receive pin has occurred. 1b - An active edge on the receive pin has occurred.
29 MSBF	MSB First Setting this bit reverses the order of the bits that are transmitted and received on the wire. This bit does not affect the polarity of the bits, the location of the parity bit, or the location of the start or stop bits. This bit should be changed only when the transmitter and receiver are both disabled. 0b - LSB (bit0) is the first bit that is transmitted following the start bit. Further, the first bit received after the start bit is identified as bit0. 1b - MSB (identified as bit9, bit8, bit7 or bit6) is the first bit that is transmitted following the start bit depending on the setting of CTRL[M], CTRL[PE] and BAUD[M10]. .
28 RXINV	Receive Data Inversion Setting this bit reverses the polarity of the received data input. This bit should be changed only when the receiver is disabled. **NOTE** Setting RXINV inverts the RXD input for all cases: data bits, start and stop bits, break, and idle. 0b - Receive data not inverted. 1b - Receive data inverted.
27 RWUID	Receive Wake Up Idle Detect For RWU on idle character, RWUID controls whether the idle character that wakes up the receiver sets the IDLE bit. For address match wakeup, RWUID controls if the IDLE bit is set when the address does not match. This bit should be changed only when the receiver is disabled. 0b - During receive standby state (RWU = 1), the IDLE bit does not get set upon detection of an idle character. During address match wakeup, the IDLE bit does not set when an address does not match. 1b - During receive standby state (RWU = 1), the IDLE bit gets set upon detection of an idle character. During address match wakeup, the IDLE bit does set when an address does not match.
26 BRK13	Break Character Generation Length BRK13 selects a longer transmitted break character length. The state of this bit does not affect the detection of a framing error. This bit should be changed only when the transmitter is disabled. A break character can be sent by setting CTRL[SBK] or by writing the transmit FIFO with DATA[FRETSC] set and DATA[R9T9] clear.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Break character is transmitted with length of 9 to 13 bit times. 1b - Break character is transmitted with length of 12 to 15 bit times.
25 LBKDE	LIN Break Detection Enable LBKDE selects a longer break character detection length. While LBKDE is set, receive data is not stored in the receive FIFO. **NOTE** The LBKDE bit enables the LIN break detect circuit and disables writing receive data to FIFO. So it essentially ignores all characters except a LIN break. 0b - LIN break detect is disabled, normal break character can be detected. 1b - LIN break detect is enabled. LIN break character is detected at length of 11 bit times (if M = 0) or 12 (if M = 1) or 13 (M10 = 1).
24 RAF	Receiver Active Flag RAF is set when the receiver detects the beginning of a valid start bit, and RAF is cleared automatically when the receiver detects an idle line. 0b - LPUART receiver idle waiting for a start bit. 1b - LPUART receiver active (RXD input not idle).
23 TDRE	Transmit Data Register Empty Flag When the transmit FIFO is enabled, TDRE is set when the number of datawords in the transmit FIFO is equal to or less than the number indicated by WATER[TXWATER]. To clear TDRE, write to the DATA register until the number of words in the transmit FIFO is greater than the number indicated by WATER[TXWATER]. When the transmit FIFO is disabled, TDRE is set when the transmit DATA register is empty. To clear TDRE, write to the DATA register. TDRE is not affected by a character that is in the process of being transmitted; it is updated at the start of each transmitted character. 0b - Transmit FIFO level is greater than watermark. 1b - Transmit FIFO level is equal or less than watermark.
22 TC	Transmission Complete Flag TC is cleared when there is a transmission in progress or when a preamble or break character is loaded. TC is set when the transmit buffer is empty and no data, preamble, or break character is being transmitted. When TC is set, the transmit data output signal becomes idle (logic 1). TC is cleared by writing to the DATA register to transmit new data, queuing a preamble by clearing and then setting CTRL[TE], queuing a break character by writing 1 to CTRL[SBK]. 0b - Transmitter active (sending data, a preamble, or a break). 1b - Transmitter idle (transmission activity complete).
21 RDRF	Receive Data Register Full Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When the receive FIFO is enabled, RDRF is set when the number of datawords in the receive buffer is greater than the number indicated by WATER[RXWATER]. To clear RDRF, read the DATA register until the number of datawords in the receive FIFO is equal to or less than the number indicated by WATER[RXWATER]. When the receive FIFO is disabled, RDRF is set when the receive buffer (the DATA register) is full. To clear RDRF, read the DATA register. A character that is in the process of being received does not cause a change in RDRF until the entire character is received. Even if RDRF is set, the character continues to be received until an overrun condition occurs once the entire character is received. 0b - Receive FIFO level is less than watermark. 1b - Receive FIFO level is equal or greater than watermark.
20 IDLE	Idle Line Flag IDLE is set when the LPUART receive line becomes idle for a full character time after a period of activity. When CTRL[ILT] is cleared, the receiver starts counting idle bit times after the start bit. If the receive character is all 1s, these bit times and the stop bits time count toward the full character time of logic high, 10 to 13 bit times, needed for the receiver to detect an idle line. When CTRL[ILT] is set, the receiver doesn't start counting idle bit times until after the stop bits. The stop bits and any logic high bit times at the end of the previous character do not count toward the full character time of logic high needed for the receiver to detect an idle line. To clear IDLE, write logic 1 to the IDLE flag. After IDLE has been cleared, it cannot be set again until after a new character is stored in the receive buffer or a LIN break character has set the LBKDIF flag . IDLE is set only once even if the receive line remains idle for an extended period. 0b - No idle line detected. 1b - Idle line is detected.
19 OR	Receiver Overrun Flag OR is set when software fails to prevent the receive data register from overflowing with data. The OR bit is set immediately after the stop bit has been completely received for the dataword that overflows the buffer and all the other error flags (FE, NF, and PF) are prevented from setting. The data in the shift register is lost, but the data already in the LPUART data registers is not affected. If LBKDE is enabled and a LIN Break is detected, the OR field asserts if LBKDIF is not cleared before the next data character is received. While the OR flag is set, no additional data is stored in the receive FIFO even if sufficient room exists. To clear OR, write logic 1 to the OR flag. 0b - No overrun. 1b - Receive overrun (new LPUART data lost).
18 NF	Noise Flag The advanced sampling technique used in the receiver takes three samples in each of the received bits. If any of these samples disagrees with the rest of the samples within any bit time in the frame then noise is detected for that character. NF is set whenever the next character to be read from the DATA register is received with noise detected within the character. To clear NF, write logic 1 to the NF field. 0b - No noise detected.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Noise detected in the received character in the DATA register.
17 FE	Framing Error Flag FE is set whenever the next character to be read from the DATA register is received with logic 0 detected where a stop bit was expected. To clear FE, write logic 1 to the FE field. 0b - No framing error detected. This does not guarantee the framing is correct. 1b - Framing error.
16 PF	Parity Error Flag PF is set whenever the next character to be read from the DATA register is received when parity is enabled (PE = 1) and the parity bit in the received character does not agree with the expected parity value. To clear PF, write a logic 1 to the PF field. 0b - No parity error. 1b - Parity error.
15 MA1F	Match 1 Flag MA1F is set whenever the next character to be read from the DATA register matches MA1. To clear MA1F, write a logic 1 to the MA1F field. 0b - Received data is not equal to MA1 1b - Received data is equal to MA1
14 MA2F	Match 2 Flag MA2F is set whenever the next character to be read from the DATA register matches MA2. To clear MA2F, write a logic 1 to the MA2F field. 0b - Received data is not equal to MA2 1b - Received data is equal to MA2
13-10 —	Reserved
9-8 —	Reserved
7-2 —	Reserved
1 AME	Address Mark Enable Configures the location of the address mark when configured for MSB first transfers. This bit has no effect when configured for LSB first. This bit should be changed only when the transmitter and receiver are both disabled. 0b - Address mark in character is MSB.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Address mark in character is last bit before stop bit (or parity bit when enabled) and stored in DATA register at MSB (or MSB-1 when parity bit enabled).
0 LBKFE	LIN Break Flag Enable Enables the LIN Break Flag to assert whenever a LIN break character is detected. Unlike LBKDE, this does not impact data being stored in the receive data buffer, but does cause LBKDIF to assert whenever a LIN break is detected. Since a LIN break is longer than a normal character, the LIN break will trigger a write to the receive data register with the data bits clear and the Framing Error set. The character following the LIN break has the LINBRK flag set to indicate the previous character was a LIN break. This bit should be changed only when the transmitter and receiver are both disabled. 0b - LIN break detect is disabled. 1b - LIN break detect is enabled. LIN break character is detected at length of 11 bit times (if M = 0) or 12 (if M = 1) or 13 (M10 = 1).

73.6.1.8 LPUART Control Register (CTRL)

Offset

Register	Offset
CTRL	18h

Function

This read/write register controls various optional features of the LPUART system. This register should only be altered when the transmitter and receiver are both disabled.

Fields

Field	Function
31 R8T9	Receive Bit 8 / Transmit Bit 9 R8 is the ninth data bit received when the LPUART is configured for 9-bit or 10-bit data formats. When reading 9-bit or 10-bit data, read R8 before reading the DATA register. T9 is the tenth data bit transmitted when the LPUART is configured for 10-bit data formats. When writing 10-bit data, write T9 before writing the DATA register. If T9 does not need to change from its previous value, such as when it is used to generate address mark or parity, then it need not be written each time the DATA register is written. **NOTE** R8 is a read-only bit and T9 is a write-only bit, the value read is different from the value written.
30 R9T8	Receive Bit 9 / Transmit Bit 8 R9 is the tenth data bit received when the LPUART is configured for 10-bit data formats. When reading 10-bit data, read R9 before reading the DATA register T8 is the ninth data bit transmitted when the LPUART is configured for 9-bit or 10-bit data formats. When writing 9-bit or 10-bit data, write T8 before writing the DATA register. If T8 does not need to change from its previous value, such as when it is used to generate address mark or parity, then it need not be written each time the DATA register is written. **NOTE** R9 is a read-only bit and T8 is a write-only bit, the value read is different from the value written.
29 TXDIR	TXD Pin Direction in Single-Wire Mode When the LPUART is configured for single-wire half-duplex operation (LOOPS = RSRC = 1), this bit determines the direction of data at the TXD pin. When clearing TXDIR, the transmitter finishes receiving the current character (if any) before the receiver starts receiving data from the TXD pin. 0b - TXD pin is an input in single-wire mode. 1b - TXD pin is an output in single-wire mode.
28 TXINV	Transmit Data Inversion Setting this bit reverses the polarity of the transmitted data output. **NOTE** Setting TXINV inverts the TXD output for all cases: data bits, start and stop bits, break, and idle. 0b - Transmit data not inverted. 1b - Transmit data inverted.
27 ORIE	Overrun Interrupt Enable This bit enables the overrun flag (OR) to generate hardware interrupt requests.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - OR interrupts disabled; use polling. 1b - Hardware interrupt is requested when OR is set.
26 NEIE	Noise Error Interrupt Enable This bit enables the noise flag (NF) to generate hardware interrupt requests. 0b - NF interrupts disabled; use polling. 1b - Hardware interrupt is requested when NF is set.
25 FEIE	Framing Error Interrupt Enable This bit enables the framing error flag (FE) to generate hardware interrupt requests. 0b - FE interrupts disabled; use polling. 1b - Hardware interrupt is requested when FE is set.
24 PEIE	Parity Error Interrupt Enable This bit enables the parity error flag (PF) to generate hardware interrupt requests. 0b - PF interrupts disabled; use polling). 1b - Hardware interrupt is requested when PF is set.
23 TIE	Transmit Interrupt Enable Enables STAT[TDRE] to generate interrupt requests. 0b - Hardware interrupts from TDRE disabled. 1b - Hardware interrupt is requested when TDRE flag is 1.
22 TCIE	Transmission Complete Interrupt Enable for TCIE enables the transmission complete flag, TC, to generate interrupt requests. 0b - Hardware interrupts from TC disabled. 1b - Hardware interrupt is requested when TC flag is 1.
21 RIE	Receiver Interrupt Enable Enables STAT[RDRF] to generate interrupt requests. 0b - Hardware interrupts from RDRF disabled. 1b - Hardware interrupt is requested when RDRF flag is 1.
20 ILIE	Idle Line Interrupt Enable ILIE enables the idle line flag, STAT[IDLE], to generate interrupt requests. 0b - Hardware interrupts from IDLE disabled; use polling. 1b - Hardware interrupt is requested when IDLE flag is 1.
19	Transmitter Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
TE	Enables the LPUART transmitter. TE can also be used to queue an idle preamble by clearing and then setting TE. When TE is cleared, this register bit reads as 1 until the transmitter has completed the current character and the TXD pin is tristated. A single idle character can also be queued by writing to the transmit FIFO with DATA[FRETSC] set and DATA[R9T9] set. 0b - Transmitter disabled. 1b - Transmitter enabled.
18 RE	Receiver Enable Enables the LPUART receiver. When RE is written to 0, this register bit reads as 1 until the receiver finishes receiving the current character (if any). 0b - Receiver disabled. 1b - Receiver enabled.
17 RWU	Receiver Wakeup Control This field can be set to place the LPUART receiver in a standby state. RWU automatically clears when an RWU event occurs, that is, an IDLE event when CTRL[WAKE] is clear or an address match when CTRL[WAKE] is set and STAT[RWUID] is clear. **NOTE** RWU must be set only with CTRL[WAKE] = 0 (wakeup on idle) if the channel is currently not idle. This can be determined by STAT[RAF]. If the flag is set to wake up an IDLE event and the channel is already idle, it is possible that the LPUART will discard data. This is because the data must be received or a LIN break detected after an IDLE is detected before IDLE is allowed to be reasserted. 0b - Normal receiver operation. 1b - LPUART receiver in standby waiting for wakeup condition.
16 SBK	Send Break Writing a 1 and then a 0 to SBK queues a break character in the transmit data stream. Additional break characters of 9 to 13 bits, or 12 to 15 bits if STAT[BRK13] is set, bit times of logic 0 are queued as long as SBK is set. Depending on the timing of the set and clear of SBK relative to the character currently being transmitted, a second break character may be queued before software clears SBK. If software takes too long to clear SBK (for example, it is not cleared by the end of the 1st break character), then a 2nd break character is sent. This is compared to queuing a break character through the transmit FIFO which guarantees only one is sent. A single break character can also be queued by writing to the transmit FIFO with DATA[FRETSC] set and DATA[R9T9] clear. 0b - Normal transmitter operation. 1b - Queue break character(s) to be sent.
15	Match 1 Interrupt Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
MA1IE	0b - MA1F interrupt disabled 1b - MA1F interrupt enabled
14 MA2IE	Match 2 Interrupt Enable 0b - MA2F interrupt disabled 1b - MA2F interrupt enabled
13-12 —	Reserved
11 M7	7-Bit Mode Select This bit should be changed only when the transmitter and receiver are both disabled. 0b - Receiver and transmitter use 8-bit to 10-bit data characters. 1b - Receiver and transmitter use 7-bit data characters.
10-8 IDLECFG	Idle Configuration Configures the number of idle characters that must be received before the IDLE flag is set. 000b - 1 idle character 001b - 2 idle characters 010b - 4 idle characters 011b - 8 idle characters 100b - 16 idle characters 101b - 32 idle characters 110b - 64 idle characters 111b - 128 idle characters
7 LOOPS	Loop Mode Select When LOOPS is set, the RXD pin is disconnected from the LPUART and the transmitter output is internally connected to the receiver input. The transmitter and the receiver must be enabled to use the loop function. 0b - Normal operation - RXD and TXD use separate pins. 1b - Loop mode or single-wire mode where transmitter outputs are internally connected to receiver input (see RSRC bit).
6 DOZEEN	Doze Enable 0b - LPUART is enabled in Doze mode. 1b - LPUART is disabled in Doze mode , but remains active when not in Doze mode .
5	Receiver Source Select

Table continues on the next page...

Table continued from the previous page...

Field	Function
RSRC	This field has no meaning or effect unless the LOOPS field is set. When LOOPS is set, the RSRC field determines the source for the receiver shift register input. 0b - Provided LOOPS is set, RSRC is cleared, selects internal loop back mode and the LPUART does not use the RXD pin. 1b - Single-wire LPUART mode where the TXD pin is connected to the transmitter output and receiver input.
4 M	9-Bit or 8-Bit Mode Select 0b - Receiver and transmitter use 8-bit data characters. 1b - Receiver and transmitter use 9-bit data characters.
3 WAKE	Receiver Wakeup Method Select Determines which condition wakes the LPUART when RWU=1 and MATCFG=00 (WAKE must be set when MATCFG=11): • Address mark in the bit preceding the stop bit (or bit preceding the parity bit when parity is enabled) of the received data character. • An idle condition on the receive pin input signal. 0b - Configures RWU for idle-line wakeup. 1b - Configures RWU with address-mark wakeup.
2 ILT	Idle Line Type Select Determines when the receiver starts counting logic 1s as idle character bits. The count begins either after a valid start bit or after the stop bit. If the count begins after the start bit, then a string of logic 1s preceding the stop bit can cause false recognition of an idle character. Beginning the count after the stop bit avoids false idle character recognition, but requires properly synchronized transmissions. **NOTE** In case the LPUART is programmed with ILT = 1, a logic 0 is automatically shifted after a received stop bit, therefore resetting the idle count. 0b - Idle character bit count starts after start bit. 1b - Idle character bit count starts after stop bit.
1 PE	Parity Enable Enables hardware parity generation and checking. When parity is enabled, the bit immediately before the stop bit is treated as the parity bit. 0b - No hardware parity generation or checking. 1b - Parity enabled.
0 PT	Parity Type Provided parity is enabled (PE = 1), this bit selects even or odd parity. Odd parity means the total number of logic 1 bits in the data character, including the parity bit, is odd. Even parity means the total number of 1s in the data character, including the parity bit, is even.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Even parity. 1b - Odd parity.

73.6.1.9 LPUART Data Register (DATA)

Offset

Register	Offset
DATA	1Ch

Function

NOTE

This register is two separate registers. Reads return the contents of the read-only receive FIFO and writes go to the write-only transmit FIFO.

Reads and writes of this register are also involved in the automatic flag clearing mechanisms for some of the LPUART status flags. This register can be written using 8-bit, 16-bit or 32-bit writes. An 8-bit write to DATA[7:0] will push { R8T9, R9T8, DATA[7:0] } the transmit FIFO with TSC clear. A 16-bit or 32-bit write will push the data written into the FIFO and does not update the value in R8T9 or R9T8.

Fields

Field	Function
31-16 —	Reserved
15	Noisy Data Received

Table continues on the next page...

Table continued from the previous page...

Field	Function
NOISY	The current received dataword contained in DATA[R9:R0] is received with noise. 0b - The dataword is received without noise. 1b - The data is received with noise.
14 PARITYE	Parity Error The current received dataword contained in DATA[R9:R0] is received with a parity error. 0b - The dataword is received without a parity error. 1b - The dataword is received with a parity error.
13 FRETSC	Frame Error / Transmit Special Character For reads, indicates the current received dataword contained in DATA[R9:R0] was received with a frame error. For writes, indicates a break or idle character is to be transmitted instead of the contents in DATA[T9:T0]. T9 is used to indicate a break character when 0 and a idle character when 1, the contents of DATA[T8:T0] should be zero. 0b - The dataword is received without a frame error on read, or transmit a normal character on write. 1b - The dataword is received with a frame error, or transmit an idle or break character on transmit.
12 RXEMPT	Receive Buffer Empty Asserts when there is no data in the receive buffer. This field does not take into account data that is in the receive shift register. 0b - Receive buffer contains valid data. 1b - Receive buffer is empty, data returned on read is not valid.
11 IDLINE	Idle Line Indicates the receiver line was idle before receiving the character in DATA[9:0]. Unlike the IDLE flag, this bit can set for the first character received when the receiver is first enabled. 0b - Receiver was not idle before receiving this character. 1b - Receiver was idle before receiving this character.
10 LINBRK	LIN Break Indicates the receiver line detected a LIN break before receiving the character in DATA[9:0]. This flag requires LBKDF to be set. 0b - Receiver did not detect LIN break before this character, or LIN break detect circuitry disabled. 1b - Receiver detected a LIN break before receiving this character.
9 R9T9	R9T9 Read receive FIFO bit 9 or write transmit FIFO bit 9.
8	R8T8

Table continues on the next page...

Table continued from the previous page...

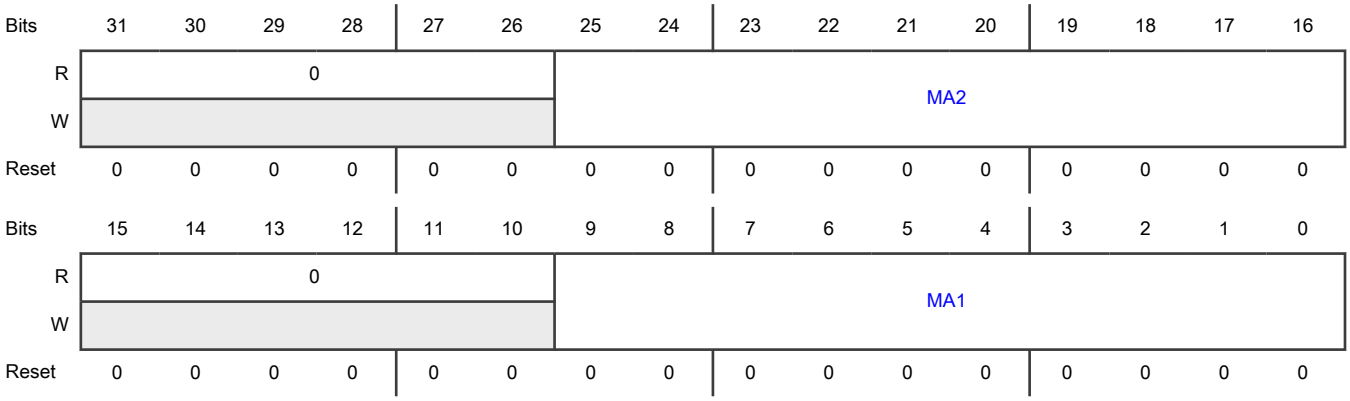
Field	Function
R8T8	Read receive FIFO bit 8 or write transmit FIFO bit 8.
7 R7T7	R7T7 Read receive FIFO bit 7 or write transmit FIFO bit 7.
6 R6T6	R6T6 Read receive FIFO bit 6 or write transmit FIFO bit 6.
5 R5T5	R5T5 Read receive FIFO bit 5 or write transmit FIFO bit 5.
4 R4T4	R4T4 Read receive FIFO bit 4 or write transmit FIFO bit 4.
3 R3T3	R3T3 Read receive FIFO bit 3 or write transmit FIFO bit 3.
2 R2T2	R2T2 Read receive FIFO bit 2 or write transmit FIFO bit 2.
1 R1T1	R1T1 Read receive FIFO bit 1 or write transmit FIFO bit 1.
0 R0T0	R0T0 Read receive FIFO bit 0 or write transmit FIFO bit 0.

73.6.1.10 LPUART Match Address Register (MATCH)

Offset

Register	Offset
MATCH	20h

Diagram



Fields

Field	Function
31-26 —	Reserved
25-16 MA2	Match Address 2 The MA1 and MA2 fields are compared to input data addresses when the most significant bit is set and the associated BAUD[MAEN] bit is set. If a match occurs, the following data is transferred to the DATA register. If a match fails, the following data is discarded. Software should only write a MAx field when the associated BAUD[MAEN] bit is clear.
15-10 —	Reserved
9-0 MA1	Match Address 1 The MA1 and MA2 fields are compared to input data addresses when the most significant bit is set and the associated BAUD[MAEN] bit is set. If a match occurs, the following data is transferred to the DATA register. If a match fails, the following data is discarded. Software should only write a MAx field when the associated BAUD[MAEN] bit is clear.

73.6.1.11 LPUART Modem IrDA Register (MODIR)

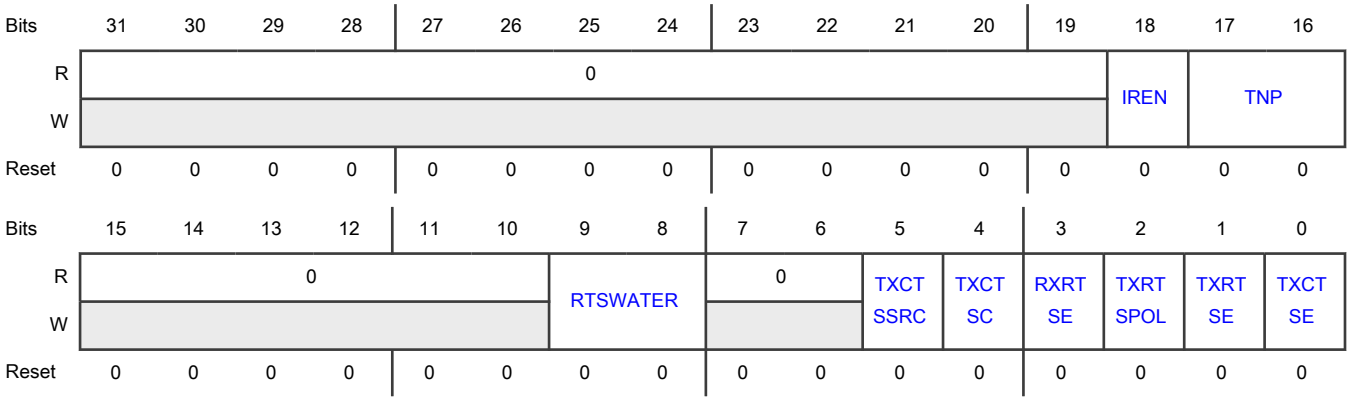
Offset

Register	Offset
MODIR	24h

Function

The MODIR register controls options for setting the modem configuration.

Diagram



Fields

Field	Function
31-19 —	Reserved
18 IREN	Infrared enable Enables/disables the infrared modulation/demodulation. This bit should be changed only when the transmitter and receiver are both disabled. 0b - IR disabled. 1b - IR enabled.
17-16 TNP	Transmitter narrow pulse Configures whether the LPUART transmits a 1/OSR, 2/OSR, 3/OSR or 4/OSR narrow pulse when IR is enabled. This bit should be changed only when the transmitter and receiver are both disabled. The IR pulse width should be configured to less than half of the oversampling ratio. Common pulse widths are 3/16, 1/16, 1/32 or 1/4 of the bit length. These can be configured by selecting the appropriate oversample ratio and pulse width. 00b - 1/OSR. 01b - 2/OSR. 10b - 3/OSR. 11b - 4/OSR.
15-10 —	Reserved
9-8 RTSWATER	Receive RTS Configuration Configures the assertion and negation of the RX RTS_B output. The RX RTS_B output negates when the number of empty words in the receive FIFO is greater or equal to RTSWATER. If RTSWATER is configured to zero, RTS_B negates when the receive FIFO is full. For the purpose of RX RTS_B generation, the number of words in the receive FIFO updates when a start bit is detected. This supports additional latency between

Table continues on the next page...

Table continued from the previous page...

Field	Function
	RTS_B negation and the external transmitter ceasing transmission. If both RX RTS_B and address/data matching is enabled, then RTS_B could assert at the end of a character if there is not a match. This field should be changed only when the receiver is disabled.
7-6 —	Reserved
5 TXCTSSRC	Transmit CTS Source Configures the source of the CTS input. 0b - CTS input is the CTS_B pin. 1b - CTS input is an internal connection to the receiver address match result.
4 TXCTSC	Transmit CTS Configuration Configures if the CTS state is checked at the start of each character or only when the transmitter is idle. 0b - CTS input is sampled at the start of each character. 1b - CTS input is sampled when the transmitter is idle.
3 RXRTSE	Receiver request-to-send enable Allows the RTS output to control the CTS input of the transmitting device to prevent receiver overrun. This bit should be changed only when the receiver is disabled. **NOTE** Do not set both RXRTSE and TXRTSE. 0b - The receiver has no effect on RTS. 1b - RTS is deasserted if the receiver data register is full or a start bit has been detected that would cause the receiver data register to become full. RTS is asserted if the receiver data register is not full and has not detected a start bit that would cause the receiver data register to become full.
2 TXRTSPOL	Transmitter request-to-send polarity Controls the polarity of the transmitter RTS. TXRTSPOL does not affect the polarity of the receiver RTS. RTS remains negated in the active low state unless TXRTSE is set. This bit should be changed only when the transmitter is disabled. 0b - Transmitter RTS is active low. 1b - Transmitter RTS is active high.
1 TXRTSE	Transmitter request-to-send enable Controls RTS before and after a transmission. This bit should be changed only when the transmitter is disabled. 0b - The transmitter has no effect on RTS.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - When a character is placed into an empty transmit shift register, RTS asserts one bit time before the start bit is transmitted. RTS deasserts one bit time after all characters in the transmitter FIFO and shift register are completely sent, including the last stop bit.
0 TXCTSE	Transmitter clear-to-send enable TXCTSE controls the operation of the transmitter. TXCTSE can be set independently from the state of TXRTSE and RXRTSE. 0b - CTS has no effect on the transmitter. 1b - Enables clear-to-send operation. The transmitter checks the state of CTS each time it is ready to send a character. If CTS is asserted, the character is sent. If CTS is deasserted, the signal TXD remains in the mark state and transmission is delayed until CTS is asserted. Changes in CTS as a character is being sent do not affect its transmission.

73.6.1.12 LPUART FIFO Register (FIFO)

Offset

Register	Offset
FIFO	28h

Function

This register provides the ability for the programmer to turn on and off FIFO functionality. It also provides the size of the FIFO that has been implemented. This register may be read at any time. This register must be written only when CTRL[RE] and CTRL[TE] are cleared/not set and when the FIFO is empty.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W	TXFLUSH	RXFLUSH														
Reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	1

Fields

Field	Function
31-24 —	Reserved
23 TXEMPT	Transmit FIFO/Buffer Empty Asserts when there is no data in the Transmit FIFO/Buffer. This field does not take into account data that is in the transmit shift register. 0b - Transmit buffer is not empty. 1b - Transmit buffer is empty.
22 RXEMPT	Receive FIFO/Buffer Empty Asserts when there is no data in the Receive FIFO/Buffer. This field does not take into account data that is in the receive shift register. 0b - Receive buffer is not empty. 1b - Receive buffer is empty.
21-18 —	Reserved
17 TXOF	Transmitter FIFO Overflow Flag Indicates that more data has been written to the transmit FIFO than it can hold. This field asserts regardless of the value of TXOFE. However, an interrupt is issued to the host only if TXOFE is set. Write 1 to clear this flag. 0b - No transmit FIFO overflow has occurred since the last time the flag was cleared. 1b - At least one transmit FIFO overflow has occurred since the last time the flag was cleared.
16 RXUF	Receiver FIFO Underflow Flag Indicates that more data has been read from the receive FIFO than was present. This field asserts regardless of the value of RXUFE. However, an interrupt is issued to the host only if RXUFE is set. Write a logic 1 to clear RXUF. 0b - No receive FIFO underflow has occurred since the last time the flag was cleared. 1b - At least one receive FIFO underflow has occurred since the last time the flag was cleared.
15 TXFLUSH	Transmit FIFO Flush Writing to this field causes all data that is stored in the transmit FIFO to be flushed. This does not affect data that is in the transmit shift register. 0b - No flush operation occurs. 1b - All data in the transmit FIFO is cleared out.
14 RXFLUSH	Receive FIFO Flush Writing to this field causes all data that is stored in the receive FIFO to be flushed. This does not affect data that is in the receive shift register.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No flush operation occurs. 1b - All data in the receive FIFO/buffer is cleared out.
13 —	Reserved
12-10 RXIDEN	Receiver Idle Empty Enable When set, enables the assertion of RDRF when the receiver is idle for a number of idle characters and the FIFO is not empty. 000b - Disable RDRF assertion due to partially filled FIFO when receiver is idle. 001b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 1 character. 010b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 2 characters. 011b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 4 characters. 100b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 8 characters. 101b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 16 characters. 110b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 32 characters. 111b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 64 characters.
9 TXOFE	Transmit FIFO Overflow Interrupt Enable When this field is set, the TXOF flag generates an interrupt to the host. 0b - TXOF flag does not generate an interrupt to the host. 1b - TXOF flag generates an interrupt to the host.
8 RXUFE	Receive FIFO Underflow Interrupt Enable When this field is set, the RXUF flag generates an interrupt to the host. 0b - RXUF flag does not generate an interrupt to the host. 1b - RXUF flag generates an interrupt to the host.
7 TXFE	Transmit FIFO Enable When this field is set, the built-in FIFO structure for the transmit buffer is enabled. The size of the FIFO structure is indicated by TXFIFOSIZE. If this field is not set, the transmit buffer operates as a FIFO of depth one dataword regardless of the value in TXFIFOSIZE. Both CTRL[TE] and CTRL[RE] must be cleared prior to changing this field. 0b - Transmit FIFO is not enabled. Buffer depth is 1. 1b - Transmit FIFO is enabled. Buffer depth is indicated by TXFIFOSIZE.
6-4 TXFIFOSIZE	Transmit FIFO Buffer Depth The maximum number of transmit datawords that can be stored in the transmit buffer. This field is read-only.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	000b - Transmit FIFO/Buffer depth = 1 dataword. 001b - Transmit FIFO/Buffer depth = 4 datawords. 010b - Transmit FIFO/Buffer depth = 8 datawords. 011b - Transmit FIFO/Buffer depth = 16 datawords. 100b - Transmit FIFO/Buffer depth = 32 datawords. 101b - Transmit FIFO/Buffer depth = 64 datawords. 110b - Transmit FIFO/Buffer depth = 128 datawords. 111b - Transmit FIFO/Buffer depth = 256 datawords
3 RXFE	Receive FIFO Enable When this field is set, the built-in FIFO structure for the receive buffer is enabled. The size of the FIFO structure is indicated by the RXFIFOSIZE field. If this field is not set, the receive buffer operates as a FIFO of depth one dataword regardless of the value in RXFIFOSIZE. Both CTRL[TE] and CTRL[RE] must be cleared prior to changing this field. 0b - Receive FIFO is not enabled. Buffer depth is 1. 1b - Receive FIFO is enabled. Buffer depth is indicted by RXFIFOSIZE.
2-0 RXFIFOSIZE	Receive FIFO Buffer Depth The maximum number of receive datawords that can be stored in the receive buffer before an overrun occurs. This field is read-only. 000b - Receive FIFO/Buffer depth = 1 dataword. 001b - Receive FIFO/Buffer depth = 4 datawords. 010b - Receive FIFO/Buffer depth = 8 datawords. 011b - Receive FIFO/Buffer depth = 16 datawords. 100b - Receive FIFO/Buffer depth = 32 datawords. 101b - Receive FIFO/Buffer depth = 64 datawords. 110b - Receive FIFO/Buffer depth = 128 datawords. 111b - Receive FIFO/Buffer depth = 256 datawords.

73.6.1.13 LPUART Watermark Register (WATER)

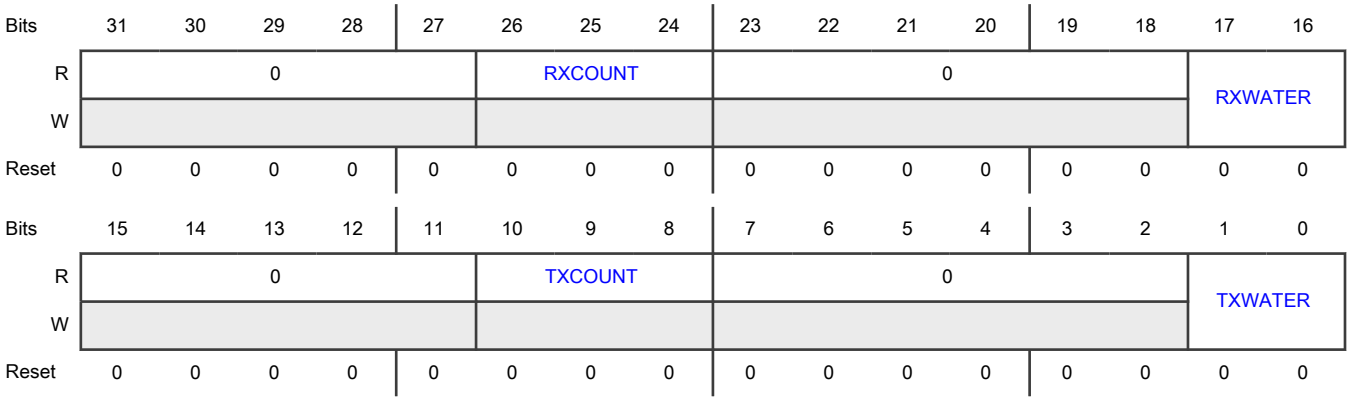
Offset

Register	Offset
WATER	2Ch

Function

This register provides the ability to set a programmable threshold for notification of needing additional transmit data. This register may be read at any time but must be written only when CTRL[TE] is not set.

Diagram



Fields

Field	Function
31-27 —	Reserved
26-24 RXCOUNT	Receive Counter The value in this register indicates the number of datawords that are in the receive FIFO/buffer. If a dataword is being received, that is, in the receive shift register, it is not included in the count. This value may be used in conjunction with FIFO[RXFIFOSIZE] to calculate how much room is left in the receive FIFO/buffer.
23-18 —	Reserved
17-16 RXWATER	Receive Watermark When the number of datawords in the receive FIFO/buffer is greater than the value in this register field, an interrupt or a DMA request is generated. For proper operation, the value in RXWATER must be set to be less than the receive FIFO/buffer size as indicated by FIFO[RXFIFOSIZE] and FIFO[RXFE].
15-11 —	Reserved
10-8 TXCOUNT	Transmit Counter The value in this register indicates the number of datawords that are in the transmit FIFO/buffer. If a dataword is being transmitted, that is, in the transmit shift register, it is not included in the count. This value may be used in conjunction with FIFO[TXFIFOSIZE] to calculate how much room is left in the transmit FIFO/buffer.
7-2 —	Reserved
1-0 TXWATER	Transmit Watermark

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When the number of datawords in the transmit FIFO/buffer is equal to or less than the value in this register field, an interrupt or a DMA request is generated. For proper operation, the value in TXWATER must be set to be less than the size of the transmit buffer/FIFO size as indicated by FIFO[TXFIFOSIZE] and FIFO[TXFE].

73.6.1.14 Data read-only Register (DATARO)

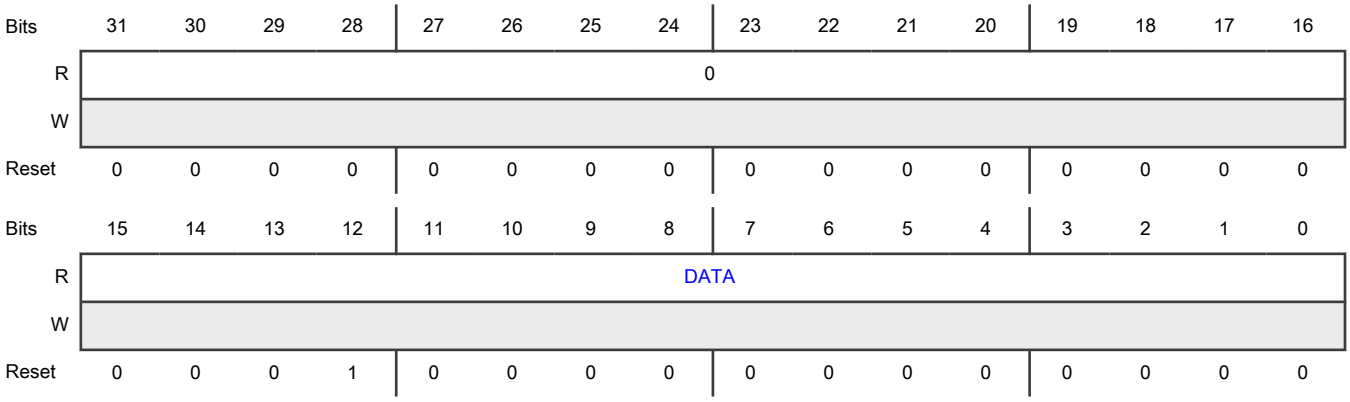
Offset

Register	Offset
DATARO	30h

Function

Returns the first entry in the receive FIFO, but does not pull the data from the FIFO.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 DATA	Receive Data Returns first entry from the receive FIFO, the bit definition is the same as the DATA register.

73.7 Glossary

Baud rate Number of bits transmitted or received per second by the LPUART

Break character Break character is generated when the transmitter is holding the data line at the space level for at least 1 character time

Oversampling	Number of times the receive circuitry samples the receive input per baud period (i.e. per data bit)

Chapter 74
Quad Serial Peripheral Interface (QuadSPI)

74.1 Chip-specific QuadSPI information

74.1.1 QuadSPI configuration

Table 537. QuadSPI instances

Instance	MWCT2D16S/MWCT2D17S	MWCT2015S/MWCT2016S
QuadSPI	Yes	No

Table 538. QuadSPI configuration details

Configuration	MWCT2x16S/MWCT2D17S
QuadSPI Tx FIFO size	32 words
QuadSPI Rx FIFO size	32 words
Look Up Table Size	4 words
AHB Buffer Size	256 Bytes

Table 539. Supported data rates at different frequencies

Supported data rates	80 MHz	120 MHz
4 pin SDR	Yes	Yes
4 pin DDR	No	No

NOTE

Boot from QuadSPI is not supported but execution from external memory is supported.

Table 540. Features supported

Feature	MWCT2x16S/MWCT2D17S
AHB Write	No
Data learning feature	No
OTFAD (On-the-fly-AES-decryption engine)	No
DDR mode	No
HyperRAM	No
HyperFlash	No
External DQS (Data Strobe)	No
Boot from QuadSPI interface	No

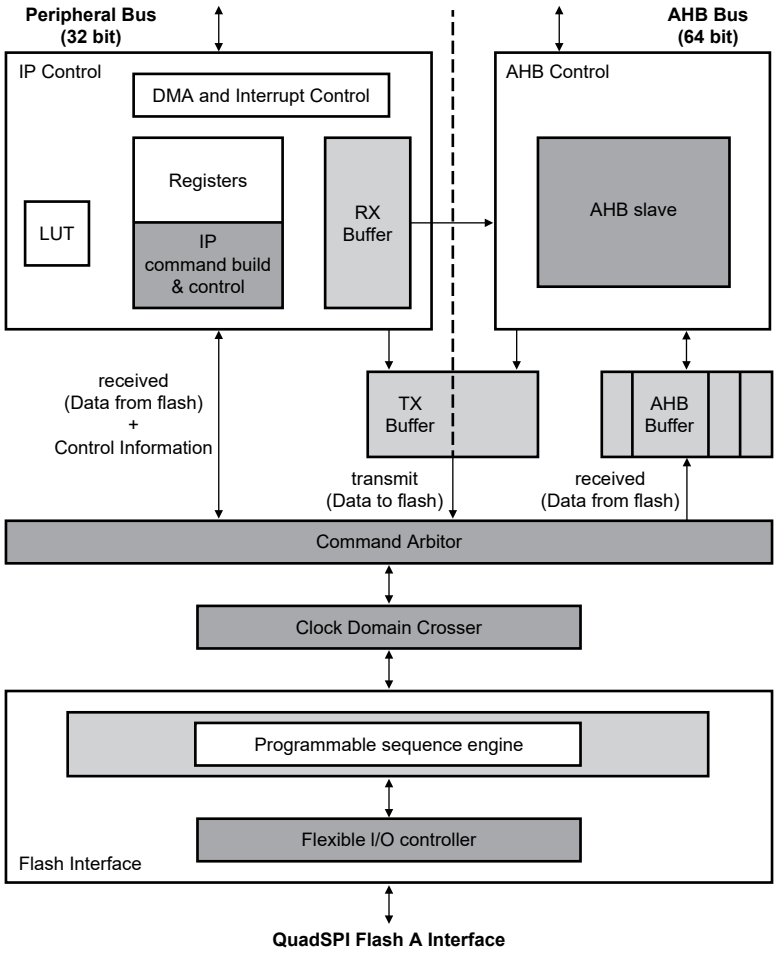


Figure 428. Block diagram

74.1.2 Supported read modes

The table below provides an overview of the QuadSPI read modes.

Table 541. QuadSPI read modes

Read modes		SDR support (QuadSPI_MCR [DDR_EN]=0)	QuadSPI_MCR [DQS_EN]	QuadSPI_MCR [DQS_FA_SEL]	DLL/Data learning support
DQS sampling method	Pad loopback	Yes	1	01	No

74.1.3 QuadSPI initialization sequence

Following initialization sequence should be followed for proper QuadSPI operation:

- Enable QuadSPI module by MC_ME peripheral clock enable (register PRTNx_COFBy_CLKEN present within MC_ME). Refer MC_ME chapter for peripheral mapping.
- Configure the SIUL2 registers MSCR[OBE] as 1 and MSCR[SSS] as 0 for QuadSPI_SCKFA pin.
- Initialize QuadSPI SCKFA by writing a sequence of 1010 to the SIUL2 register GPDO[PDO_a] for QuadSPI_SCKFA pin.
- Configure the SIUL2 register MSCR[OBE] back as 0 for the pins.

- Initiate a dummy flash read to reset all DQS flops by itself and any crossing from DQS domain to IPS/AHB is taken care by CDC logic.
- Initiate a peripheral software reset to QuadSPI controller by writing to QuadSPI controller's MCR.
- Post this initialization sequence, the QuadSPI will work in intended deterministic manner.

NOTE

QuadSPI initialization is to be done before using QuadSPI after each functional reset.

74.1.4 Pad clock loopback

This chip supports pad clock loopback. The QuadSPI can be configured to use clock loopback to sample input data. SCK is delayed by the SCK pin output delay, plus the SCK pin input delay using pad loopback, and is configured by setting QuadSPI config registers SOCCR[SOCCFG] and MCR[DQS_FA_SEL]. Enabling the loopback version of SCK can improve the setup time of the input data from the Flash.

For details of these register, see QuadSPI register descriptions.

74.1.5 QuadSPI SOC Configuration register SOCCR[SOCCFG] implementation

The QuadSPI SOC Configuration register QuadSPI_SOCCR[SOCCFG] register is used to control dummy loopback pads and obe_pull_timing_relax_b. Below is the description of it's bits:

Table 542. SOCCR[SOCCFG] implementation

Bit	Description
Bit[0]	obe_pull_timing_relax_b : enables the timing relaxation by pulling obe for pad 1 for half cycle, if 0 then enabled else disabled.
Bit[1]	ibe of QSPIA_SCK_DUMMY pad. 0: Disable input reciever 1: Enable input reciever.
Bit[2]	obe of QSPIA_SCK_DUMMY pad. 0: Disable output driver 1: Enable output driver.
Bit[3]	dse of QSPIA_SCK_DUMMY pad. 0: Disable drive strength 1: Enable drive strength.
Bit[4]	pue of QSPIA_SCK_DUMMY pad. 0: Disable internal pullup or pulldown resistor 1: Enable internal pullup or pulldown resistor.
Bit[5]	pus of QSPIA_SCK_DUMMYpad. 0: Enable internal pulldown resistor if pue is set 1: Enable internal pullup resistor if pue is set.
Bit[6]	sre of QSPIA_SCK_DUMMY pad. 0: Disable slew rate control 1: Enable slew rate control.
Bit[31:7]	Reserved

To Enable the Quadspi dummy PAD loopback use following settings

For Flash-A: MCR[DQS_FB_SEL] = 0x2

SOCCR[SOCCFG] = 0x0000000E (ibe=1, obe=1, dse=1 and sre=0)

74.1.6 QuadSPI AHB Buffer write access control

In MWCT2D17S and MWCT2x16S devices, the QuadSPI AHB buffer does not support writes. A write to QuadSPI AHB buffer results in error response from QuadSPI.

QuadSPI might behave unexpectedly in case if its AHB buffer is written with QuadSPI MCR[MDIS] =1. In cases wherein QuadSPI is disabled with above MDIS control bit, XRDC must also be appropriately configured to block the accesses to QSPI AHB buffer and indicate an error response.

74.2 Introduction

The QuadSPI module acts as an interface to a single serial flash memory device, with up to four bidirectional data lines.

74.2.1 Features

QuadSPI supports the following features:

- Flexible sequence engine to support various flash memory vendor devices. As there is no specific standard, the module supports various kinds of flash memories from different vendors. See Serial flash memory devices for example sequences.
- Single, dual, and quad modes of operation supported for Quad flash memories
- AHB master to read RX buffer data through AMBA AHB (64-bit width interface) or IPS registers space (32-bit access) and fill TX buffer via IPS registers space (32-bit access)
  - AHB master can be a DMA with a configurable inner loop size
- Multi-master accesses are allowed
  - Flexible and configurable buffer for each master—total available buffer size is 256 bytes.
- All AHB accesses to flash memory devices are directly memory mapped to the chip system memory
- Programmable sequence engine to cater to future command/protocol changes and ability to support all existing vendor commands and operations. The software needs to select the corresponding sequence according to the connected flash memory device.
  - Support for 3-byte and 4-byte addressing

74.2.2 RX buffer push event

To add the valid entries into the RX buffer

By default, each buffer push event adds two entries to the RX buffer because the interface to the serial clock domain is 64 bits in width. Depending on the number of bytes read from the serial flash memory device, it is possible for the very last buffer push event that only one entry is added.

RBSR[RDBFL] is incremented by the number of entries added to the RX buffer.

74.2.3 RX buffer POP event

To remove valid entries from the RX buffer

Each buffer POP event removes (RBCT[WMRK] + 1) valid entries from the buffer. BSR[RDBFL] is decremented by the same number and RBSR[RDCTR] is incremented accordingly.

74.2.4 Block diagram

The following figure shows a block diagram of the QuadSPI module.

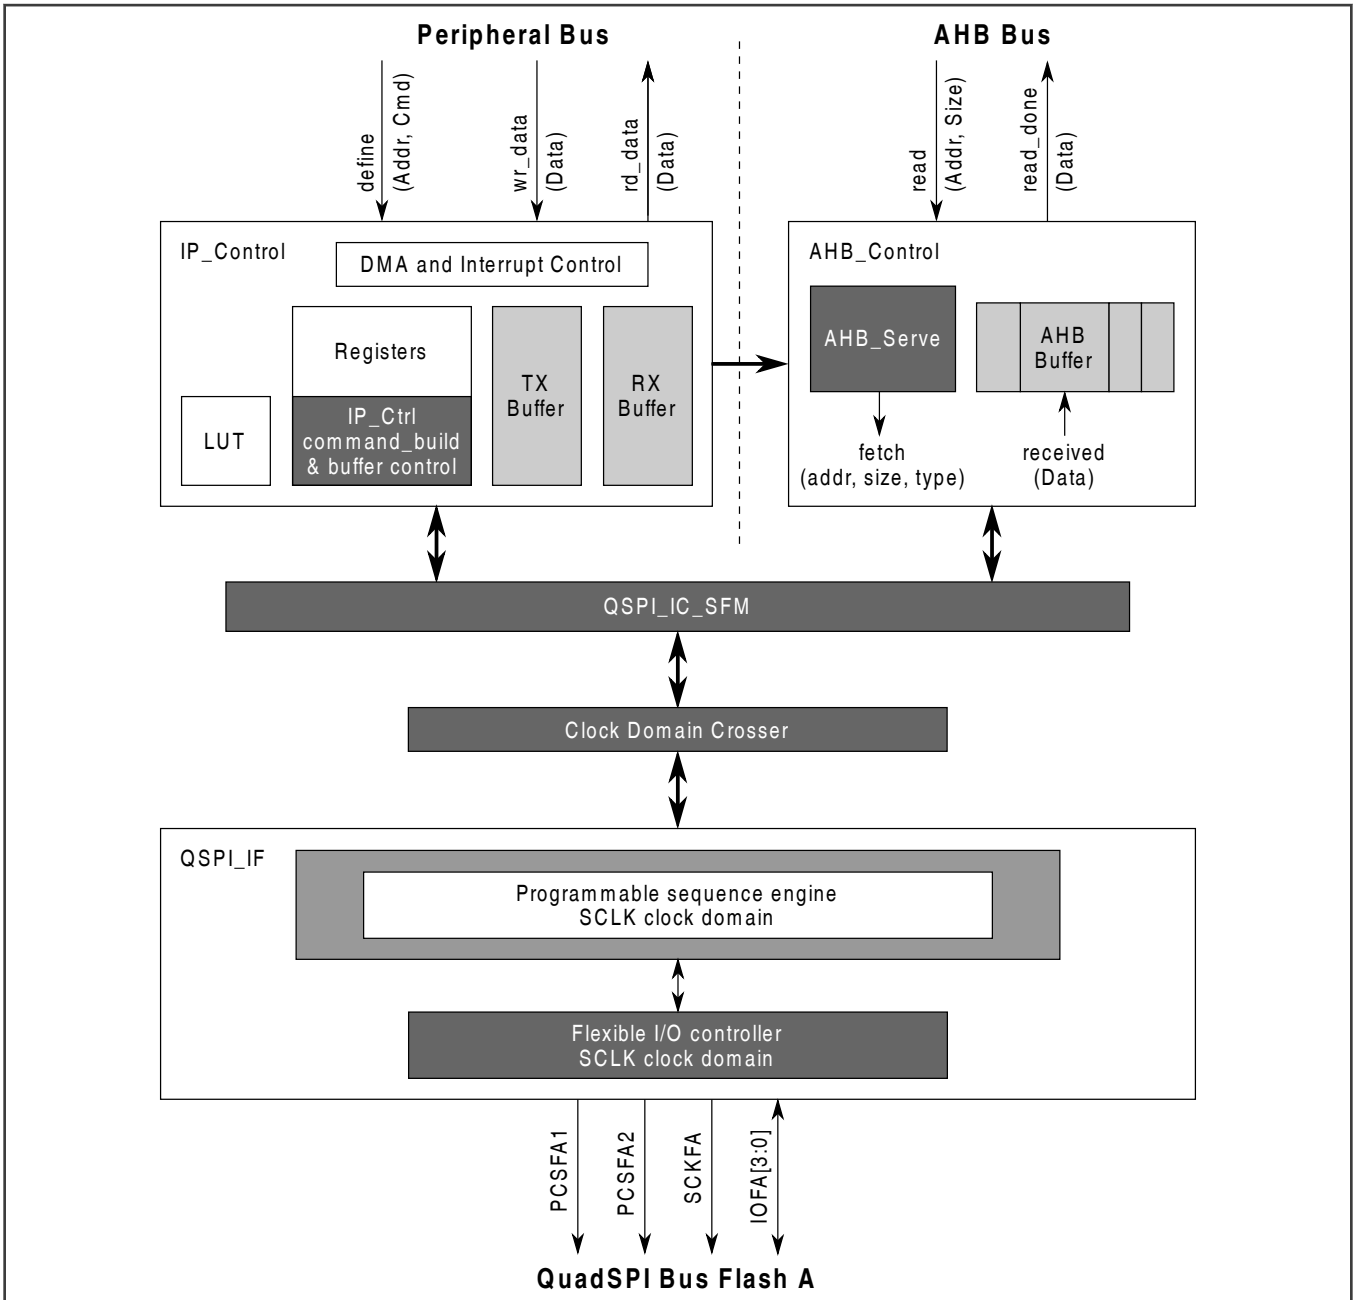

Figure 429. QuadSPI Block Diagram

74.2.5 QuadSPI modes of operation

QuadSPI supports the following modes of operation:

- Normal mode: You can use this mode for write or read accesses to an external serial flash memory device. See Normal mode for details.
  - Serial flash memory write: You can program data into the flash memory through the IP interface only. See Flash memory programming for details.
  - Serial flash memory read: Read the contents of the serial flash memory device. Two separate read channels are available through the RX buffer and AHB buffer. See Flash memory read for details.

- Module Disable mode: You can use this mode for disabling serial flash memory clock and AHB command. The clock to the non-memory mapped logic in QuadSPI can be stopped in the Module Disable mode. The module enters the mode by setting MCR[MDIS].

74.3 External signal description

This section provides the external signal information for the QuadSPI module.

The following table lists the external signals belonging to the module in conjunction with the different modes of operation.

Table 543. Signal properties

Signal name	Function	Direction	Description
PCSFA1	Peripheral Chip Select Flash Memory A1	O	This signal is the chip select for the serial flash memory device A1 that represents the first of the two flash memory devices that share IOFA.
PCSFA2	Peripheral Chip Select Flash Memory A2	O	This signal is the chip select for the serial flash memory device A2 that represents the the second of the two flash memory devices that share IOFA.
SCKFA	Serial Clock Flash Memory A	O	This signal is the serial clock output to the serial flash memory device A.
IOFA[3:0]	Serial I/O Flash memory A	I/O	These signals are the data I/O lines to/from the serial flash memory device A. See Driving external signals for details about the signal drive and timing behavior. Note that the signal pins of the serial flash memory device may change their function according to the SFM Command executed, leaving them as control inputs when single and dual instructions are executed. The module supports driving these inputs to dedicated values. In single I/O mode, QuadSPI drives data on IOFA[0] and expects data on IOFA[1].

74.3.1 Driving external signals

Single/dual/quad instructions

Depending on the serial flash memory device connected to the QuadSPI module, there are instructions using a different number of data lines:

- Single pad: Single line I/O with one data out and one data in line to/from the serial flash memory device
- Dual pad: Dual line I/O with two bidirectional I/O lines, driven alternatively by the serial flash memory device or the QuadSPI module
- Quad pad: Quad line I/O with four bidirectional I/O lines, driven alternatively by the serial flash memory device or the QuadSPImodule

The different phases of the serial flash memory access scheme are shown in the following figure.

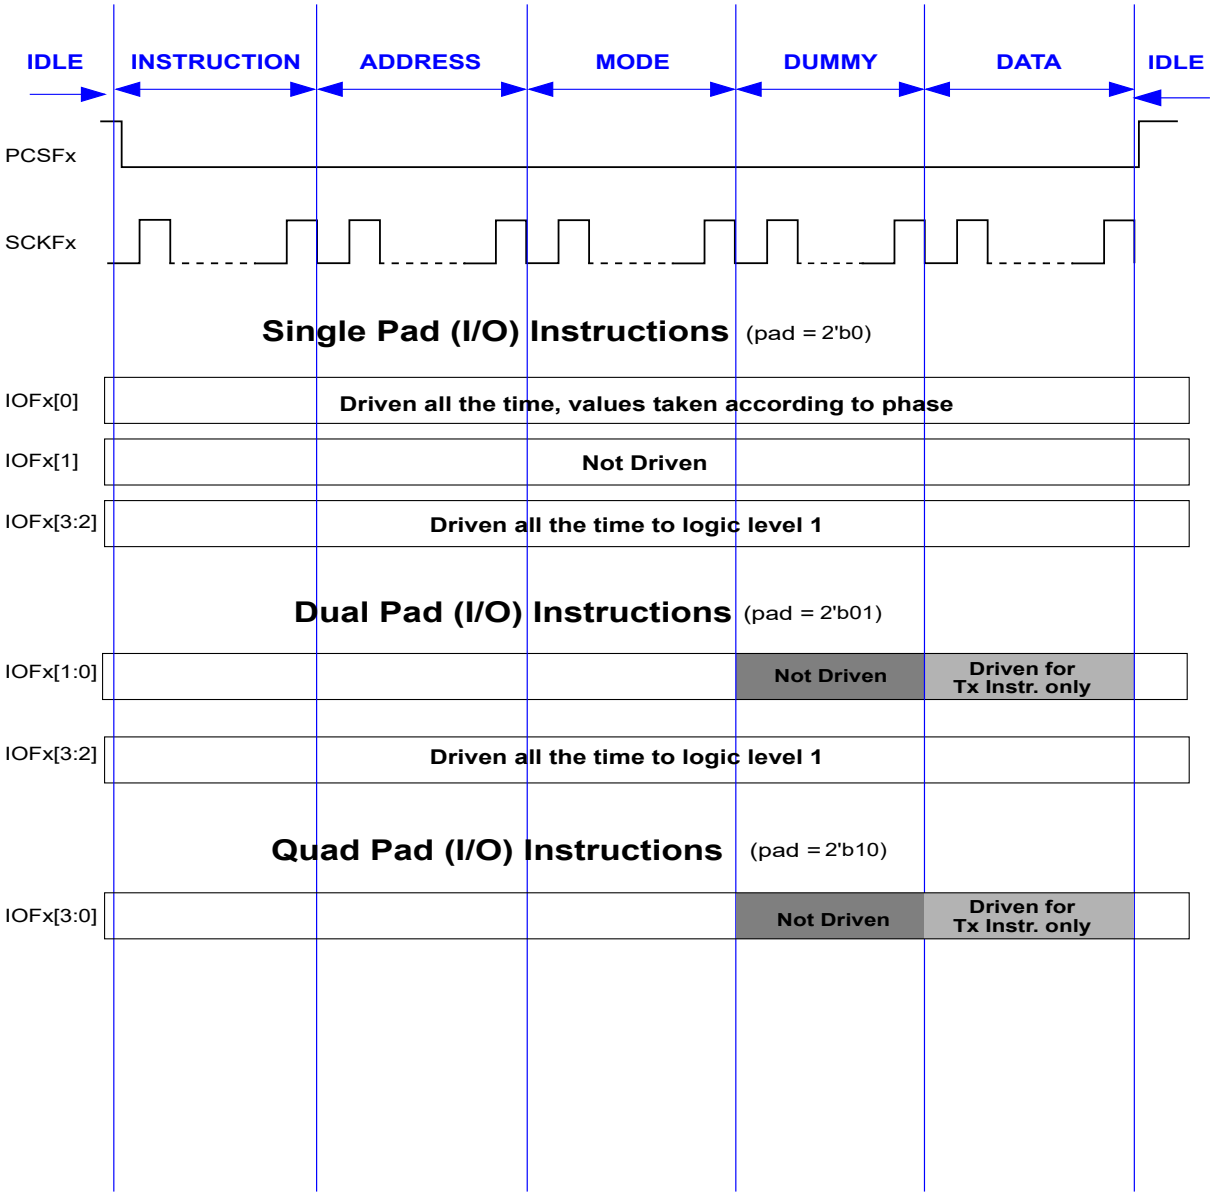

Figure 430. Serial flash memory access scheme

Following are the different phases and the I/O driving characteristics of the QuadSPI module:

- Idle: Serial flash memory device not selected – no interaction with the serial flash memory device and the IOFx signals are driven.
- Instruction: Serial flash memory device selected – the instruction is sent to the serial device and all the IOFx signals are driven.
- Address: Serial flash memory address is sent to the device – all the IOFx signals are driven and this phase is not applicable for all SFM commands.
- Mode: Mode bytes are sent to the serial flash memory device – all the IOFx signals are driven and this phase is not applicable for all SFM commands.
- Dummy: Dummy clocks are provided to the serial flash memory device. See Figure 430 for the IOFx signals driven. The actual data lines required for the SFM command executed are not driven for data read commands.

NOTE

— This phase is not applicable for all the SFM commands.

— All read commands in Dual pad, Quad pad or Octal pad modes must use dummy phase before read phase. Note that this restriction is not applicable to Single-pad mode.

- Data: Serial flash memory data are sent to or received from the serial flash memory device. See the preceding figure for the IOFx signals driven. The actual data lines required for the SFM command executed are not driven for data read commands.

NOTE

This phase is not applicable for all the SFM commands.

The PCSFx and SCKFx signals are driven permanently throughout all the phases. In the individual flash memory mode, this applies to the selected flash memory device.

Access to a single, individual serial flash memory device

See Serial flash memory access schemes for details.

Read access to two serial flash memory devices attached to the QuadSPI module in parallel. See Serial flash memory access schemes for details.

74.4 Functional description

This section provides a functional description of the QuadSPI module.

74.4.1 Serial flash memory access schemes

In the individual flash memory mode, all supported commands are available.

74.4.2 Normal mode

This mode allows communication with an external serial flash memory device. Compared to the standard SPI protocol, this communication method uses up to four bidirectional data lines operating at high-data rates. The communication to the external serial flash memory device consists of an instruction code and optional address, mode, dummy, and data transfers. The flexible programmable core engine described below is immune to a wide variety of command or protocol differences in the serial flash memory devices provided by various flash memory vendors.

74.4.2.1 Programmable sequence engine

The core of the QuadSPI module is a programmable sequence engine that works on "instruction-operand" pairs. The core controller executes each programmed instruction sequentially. The complete list of instructions and the corresponding operands are provided in the following table.

Table 544. Instruction set

Instruction	Instruction encoding	Pins	Operand	Action on serial flash memories
CMD	1d	N={0,1,2}d 0d - One pad 1d - Two pads 2d - Four pads	8-bit command value	Provide the serial flash memory with operand on the number of pads specified
ADDR	2d		Number of address bits to be sent (for example, 24d	Provide the serial flash memory with address cycles according to the operand on the number of pads specified

Table continues on the next page...

Table 544. Instruction set (continued)

Instruction	Instruction encoding	Pins	Operand	Action on serial flash memories
			=> 24 address bits required)	The actual address to be provided is derived from the incoming address in case of AHB-initiated transactions and the value of SFAR in case of IPS-initiated transactions.
DUMMY	3d		Number of dummy clock cycles (should be <= 64 and > 2 cycles)	Provide the serial flash memory with dummy cycles according the operand The PAD information defines the number of pads in input mode. For example, one pad implies that pad 1 is not driven, rest all are driven.
MODE	4d		8-bit mode value	Provide the serial flash memory with 8-bit operand on the number of pads specified
MODE2	5d	N={0,1}d	2-bit mode value	Provide the serial flash memory with 2-bit operand on the number of pads[1] specified
MODE4	6d	N={0,1,2}d	4-bit mode value	Provide the serial flash memory with 4-bit operand on the number of pads[2] specified
READ	7d	N={0,1,2}d 0d - One pad 1d - Two pads 2d - Four pads	Read data size in bytes (for AHB transactions, your application should ensure that data size is a multiple of 8 bytes)	Read data from flash memory on the number of pads specified The data size can be overwritten by writing to the ADATSZ field of the BUFxCR registers for AHB-initiated transactions and to the IDATSZ field of the IP Configuration Register (IPCR) for IPS-initiated transactions.
WRITE	8		Write data size in bytes	Write data on the number of pads specified The data size can be overwritten by writing to the IDATSZ field of IP Configuration Register (IPCR).
JMP_ON_CS	9d	NA	Instruction number	Every time the CS is deasserted, jump to the instruction pointed to by the operand. This instruction allows the programmer to specify the behavior of the controller when a new read transaction is initiated following a CS deassertion.
STOP	0d	NA	NA	Stop execution; deassert CS

1. For a one-pad instruction, MODE2 takes two serial flash memory clock cycles on the flash memory interface.
2. For a one-pad instruction, MODE4 takes four serial flash memory clock cycles on the flash memory interface. For a four-pad instruction, MODE4 takes one serial flash memory clock cycle on the flash memory interface.

The programmable sequence engine allows you to configure the QuadSPI module according to the serial flash memory connected on board. This flexible structure is compatible with new command or protocol changes from different vendors.

74.4.2.2 Flexible read xAHB buffers

To reduce the latency of the reads for AHB masters, the data read from serial flash memory is buffered in flexible AHB buffers. There are four such flexible buffers. The size of each of these buffers is configurable with the minimum size being 0 bytes and maximum size being the size of the complete buffer instantiated (256 bytes). The size of buffer 0 ranges from 0 to BUF0IND. The size of buffer 1 ranges from BUF0IND to BUF1IND, buffer2 from BUF1IND to BUF2IND and, buffer 3 ranges from BUF2IND to the size of the complete buffer (256 bytes).

Each flexible AHB buffer is associated with the following:

- An AHB master: Optionally, buffer3 may be configured as an "all master" buffer by writing 1 to BUF3CR[ALLMST]. When buffer3 is configured in such a way, any access from a master not associated with any other buffer is routed to buffer3.
- A datasize field representing the amount of data to be fetched from the flash memory on every missed access.

The master port number of every incoming request is checked and the data is returned or fetched into the corresponding associated buffer. Every missed access to the buffer causes the controller to clear the buffer and fetch the BUFxCR[ADATSZ] amount of data from the serial flash memory. As such, you need not configure the buffer size to be greater than ADATSZ because the locations greater than ADATSZ are never used. For any AHB access, the sequence pointed to by BFGENCR[SEQID] is used for the initiated flash memory transaction. The data is returned to the master as soon as the requested amount is read from the serial flash memory. The controller; however, continues to prefetch the rest of the data in anticipation of a next consecutive request. See Figure 431 that shows flexible AHB buffers.

BFGENCR[SEQID] points to an index of the LUT. See LUT for details.

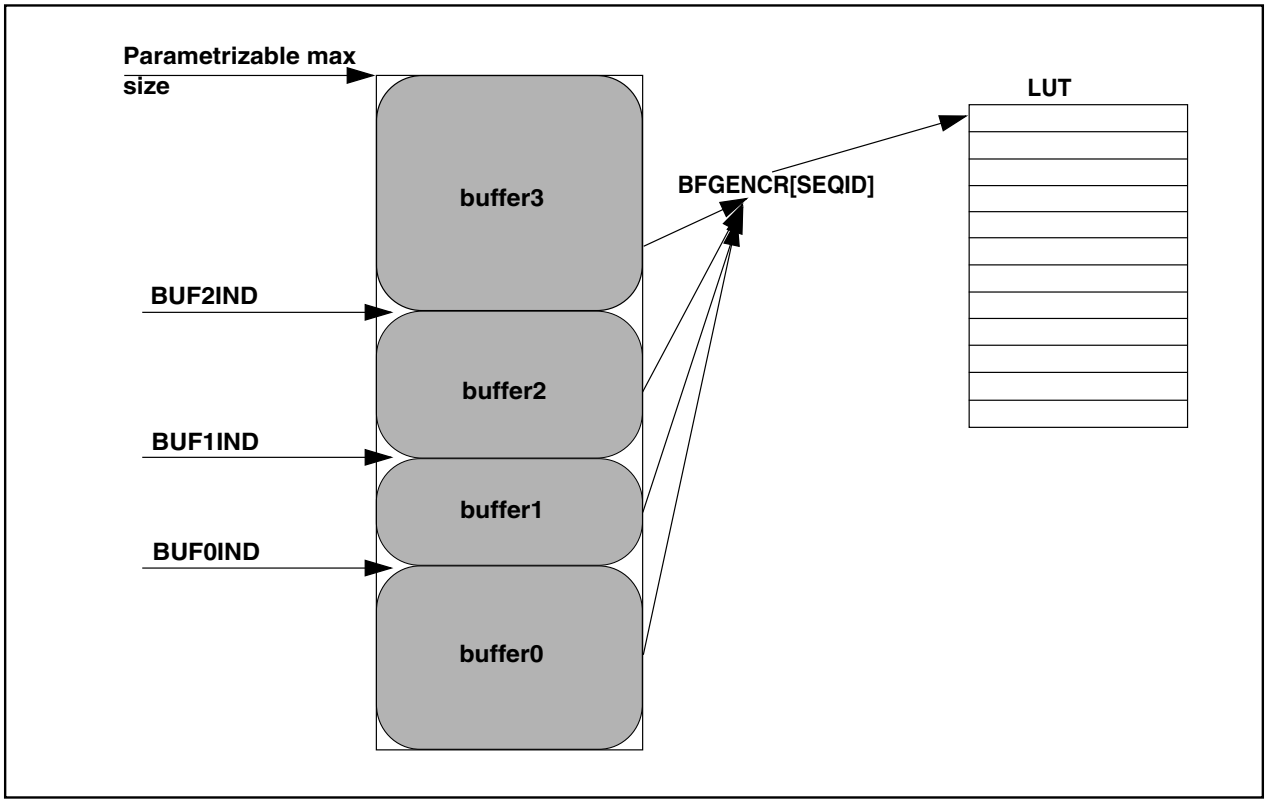

Figure 431. Flexible read AHB buffers

74.4.2.3 Abort mechanism during AHB read

Any ongoing read transaction is aborted if a request from the same master arrives for a location other than the location at which the transaction is going on. The abort can happen at any point of time.

74.4.2.4 HBURST support with AHB read

QuadSPI controller supports HBURST and HSIZE on the AHB read interface. HBURST indicates if the transfer forms part of a burst. Four, eight, and sixteen beat bursts are supported and the bursts might either be incrementing or wrapping. HSIZE indicates the size of the transfer, and supports 8-, 16-, 32-, and 64-bit data sizes. In case of WRAP accesses, QuadSPI generates aligned accesses to serial flash memory if there is no buffer hit for any incoming, non-sequential AHB read access. In case there is a buffer hit, the incoming address in the haddr line is latched as it is. If the total burst size is more than the data prefetch size, an error response is generated and the value of FR[AIBSEF] is configured as 1. The data prefetch size can be defined by BUFxCR[ADATSZ] or data size mentioned in the sequence pointed to by the SEQID field when ADATSZ is programmed as 0. In case of wrap burst, data prefetch size must be greater than or equal to the wrap burst size + 32 bytes. A few examples are shown in the figure below:

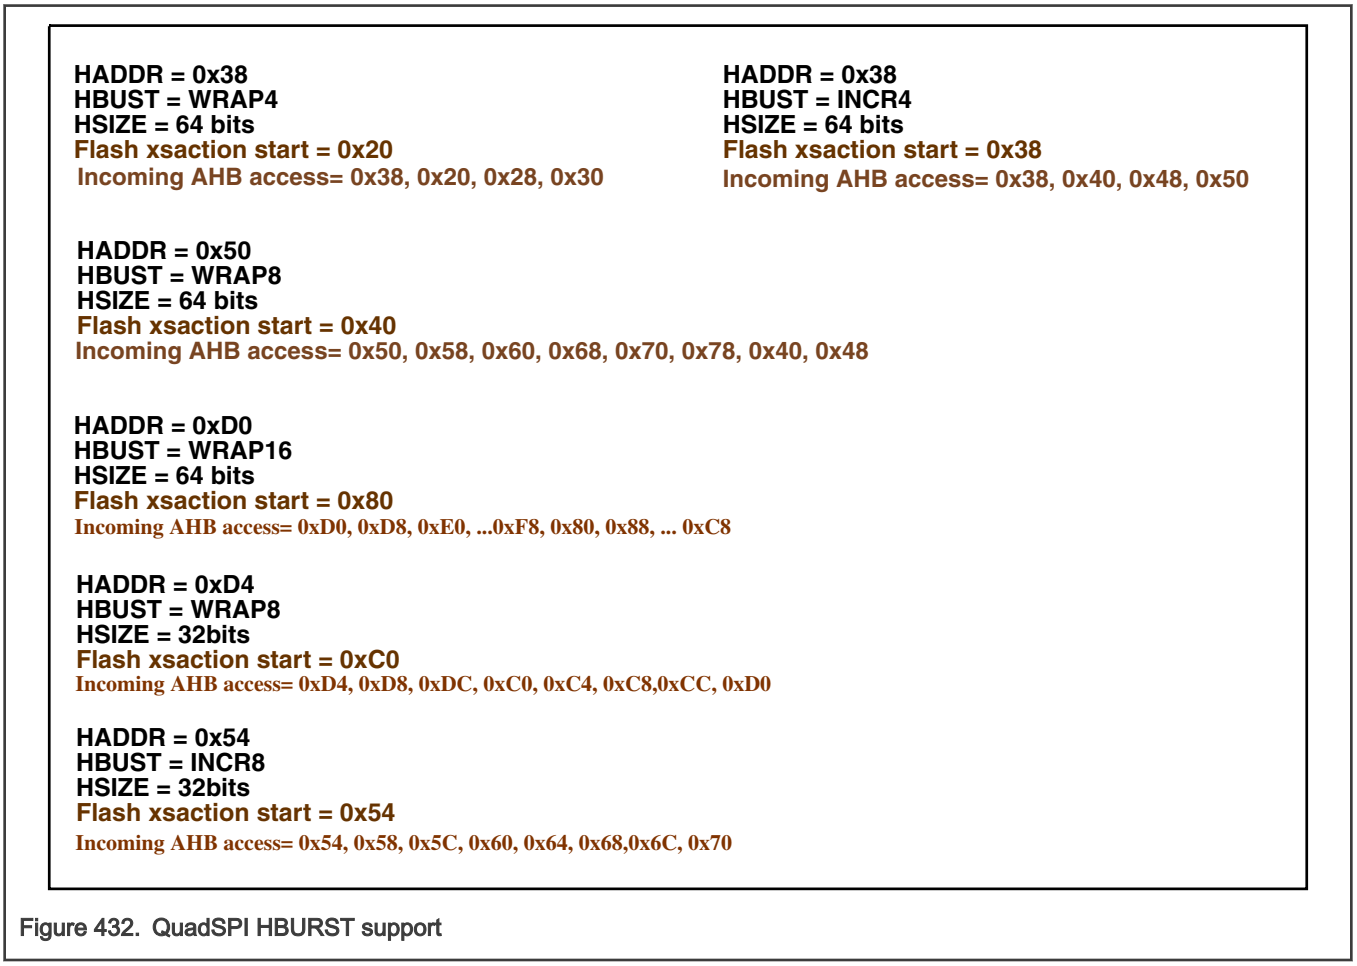

Figure 432. QuadSPI HBURST support

NOTE

The software must take care that the prefetch size should never be set less than the minimum data needed by any external interface to start processing.

NOTE

Whenever a core accesses QuadSPI memory with cache enabled, the prefetch size must be configured as equal or more than the cache line size; otherwise, FR[AIBSEF] error appears.

74.4.2.5 LUT

The LUT consists of a number of pre-programmed sequences. Each sequence is basically a sequence of instruction-operand pairs, which when executed sequentially, generate a valid serial flash memory transaction. Each sequence can have a maximum

of 10 instruction-operand pairs. The LUT can hold a maximum of sequences. The figure below shows the basic structure of the sequence in the LUT.

At reset, the index 0 of the LUT[0..4] is programmed with a basic read sequence as described in Reset sequence. After reset, the complete LUT may be reprogrammed according to the chip connected on board. To protect its contents, during a code runover, the LUT might be locked, after which a write to the LUT will not be successful until it has been unlocked again. The key for locking or unlocking the LUT is 5AF05AF0h, and the associated processes are as follows:

Locking the LUT

1. Write the key 5AF05AF0h into the LUT Key Register (LUTKEY).
2. Write 0b01 to the LUT Lock Configuration Register (LCKCR). Note that this IPS transaction should immediately follow the above IPS transaction (no other IPS transaction can be issued). A successful write to this register locks the LUT.

Unlocking the LUT

1. Write the key 5AF05AF0h into the LUT Key Register (LUTKEY).
2. Write 0b10 to the LUT Lock Configuration Register (LCKCR). Note that this IPS transaction should immediately follow the above IPS transaction (no other IPS transaction can be issued in between). A successful write to this register unlocks the LUT.

The lock status of the LUT can be read from the LCKCR[UNLOCK] and LCKCR[LOCK] fields.

Some example sequences are defined in Example sequences. The reset sequence at LUT index 0 is shown in the following table.

Table 545. Reset sequence

Instruction	Pad	Operand	Comment
CMD	0h	3h	Read data byte command on one pad
ADDR	0h	18h	24 address bits to be sent on one pad
READ	0h	8h	Read 64 bits
JMP_ON_CS	0h	0h	Jump to instruction 0 (CMD)

74.4.2.6 Issuing SFM commands

Each access to the external device follows this sequence:

1. You must pre-populate the LUT with the serial flash memory command sequences that are required for the flash memory device being used.
2. The module executes the instructions in this sequence one by one. The transaction starts and the module configues the value of SR[BUSY].
3. Communication with the external serial flash memory device starts and the transaction executes.
4. After the transaction is complete (all transmit and receive operations with the external serial flash memory device are complete), the module resets SR[BUSY]. In case of an IP command, FR[TFF] is asserted.

For details, see Flash memory programming and Flash memory read.

You can trigger the processing of SFM commands in the QuadSPI module in one of the following ways:

Using IP commands

For IP commands, the required components need to be written into the following registers and in this sequence:

1. Write the serial flash memory address to be used as provided in the Serial Flash Address Register (SFAR). For IP commands not related to specific addresses, the base address of the related flash memory needs to be programmed.

For example, for an instruction which does not require an address (that is, write enable instruction), the SFAR should be programmed with the base address of the memory the command is to be sent to.

2. Write the sequence ID and data size details in the IP Configuration Register (IPCR).
3. Note that writing a value to IPCR[SEQID] must be the last step of the sequence. It is possible to combine all the fields of the IPCR into one single write. See IP Configuration Register (IPCR) for details.

Using AHB commands

Any AHB memory-mapped access is routed to one of the buffers depending on the master port number of the request. If the access is a "miss," a new serial flash memory transaction is initiated. The transaction is based on the sequence pointed to by BFGENCR[SEQID] as described in Flexible read xAHB buffers.

An AHB access is considered memory mapped when the access is to the memory-mapped serial flash memories, as described in Memory Mapped Serial Flash Data - Individual Flash mode on Flash memory A.

74.4.2.7 Flash memory programming

In all cases, the memory sector to be written needs to be erased first. The programming sequence is then initiated in the following way:

1. Check that SR[BUSY] is de-asserted or the value of the BUSY field is 0, also, check that the TX buffer is empty. If you need to discard the data present in the TX buffer (SR[TXNE]) then the TX buffer must be cleared by writing 1 to MCR[CLR_TXF].
2. Program the address related to the command in SFAR.
3. Provide initial data for the program command into the circular buffer through the TBDR. At least one words of data must be written into the TX buffer up to a maximum of 32 entries.
4. Program the IPCR to trigger the command. IPCR[SEQID] should point to an index of the LUT that has the flash memory program sequence pre-programmed. You must write 1 to IPCR[IDATSZ] to denote the size of the write.
5. Repeat step 3, depending on the amount of data required, until all of the required data is written to the TBDR. SR[TXFULL] can be used to check if the buffer is ready to receive more data. At any time, TBSR[TRCTR] can be read to check how many words have been written into the TX buffer.

After writing to IPCR[SEQID] (see step 4), the module starts executing the programmed sequence. The software ensures that the correct sequence is programmed into the LUT in accordance with the flash memory connected to the module. The data is fetched from the TX buffer. It consists of 32 entries of 32-bit sizes and is organized as a circular FIFO, the read pointer for which is incremented after each fetch. When all the data is transmitted, the QuadSPI module returns from the busy state to the idle state. However, this is not true for the external device because the internal programming is still ongoing. You may monitor the relevant status information available from the serial flash memory device and ensure that the programming is done appropriately.

74.4.2.8 Flash memory read

Host access to the data stored in the external serial flash memory device is performed in two steps. First, the data must be read into the internal buffers and in the second step, these internal buffers can be read by the host.

Reading serial flash memory data into the QuadSPImodule internal buffers

A read access to the external serial flash memory device can be triggered in two different ways:

- IP command read: For reading flash memory data into the RX buffer, you must provide the correct sequence ID in IPCR[SEQID]. The sequence ID points to a sequence in the LUT. The software needs to ensure that a correct read sequence is programmed in the LUT in accordance with the serial flash memory device connected on board. You must program the SFAR , and IPCRs. All available read commands supported by the external serial flash memory are possible.

  Optionally, it is possible to clear the RX buffer pointer prior to triggering the IP command by writing a 1 to MCR[CLR_RXF].

  Using these inputs, the complete transaction is built when IPCR[SEQID] is written to. The transaction related to the read access starts and the requested number of bytes is fetched from the external serial flash memory device into the RX buffer. As the read access is triggered by an IP command, the value of both SR[IP_ACC] and SR[BUSY] is set to 1.. A count of the number of entries currently in the Rx buffer can be obtained from RBSR[RDBFL].

Communication with the external serial flash memory stops if the specified number of bytes are read (on successful completion of the transaction).

- AHB command read: For reading flash memory data into the AHB buffer, you must:
  - Set up a read access by a master to the address range in the system memory map, which the external serial flash memory devices are mapped to.
  -
  - Program the buffer registers corresponding to the AHB master initiating the request, and this depends on the configuration of RBCT[RXBRD].
  - Provide the correct sequence ID in the BFGENCR. The software ensures that a correct read sequence is programmed in the LUT in accordance with the serial flash memory device connected on board. Flash memory device selection and access mode are determined by the address accessed in the AHB address space associated with the QuadSPI module (see Memory-mapped serial flash memory data—individual flash memory mode on flash memory A

  On each AHB read access to the memory mapped area, the valid data in the AHB buffer is checked against the address requested in the actual read. When the AHB read request cannot be served from the content of the AHB buffer, the buffer is flushed and the controller executes the sequence pointed to by the sequence ID. The requested number of buffer entries defined in BUFxCR[ADATSZ] is then fetched from the external serial flash memory device into the internal AHB buffer. As the read access is triggered through the AHB bus, the value of SR[AHB_ACC] is set, driving SR[BUSY] in turn, until the transaction is complete. Communication with the external serial flash memory stops when the specified number of entries is filled.

Data transfer from the QuadSPI module internal buffers

The data read out from the external serial flash memory device by the QuadSPI module is stored in the internal buffers. The means of accessing the data from the buffer differs depending on which buffer the data is loaded to. See Block diagram for details on the two available buffers, the RX buffer and the AHB buffer, in this module. The buffer appears transparent to you and is non-memory mapped. See the "Flexible AHB Buffer" section for details.

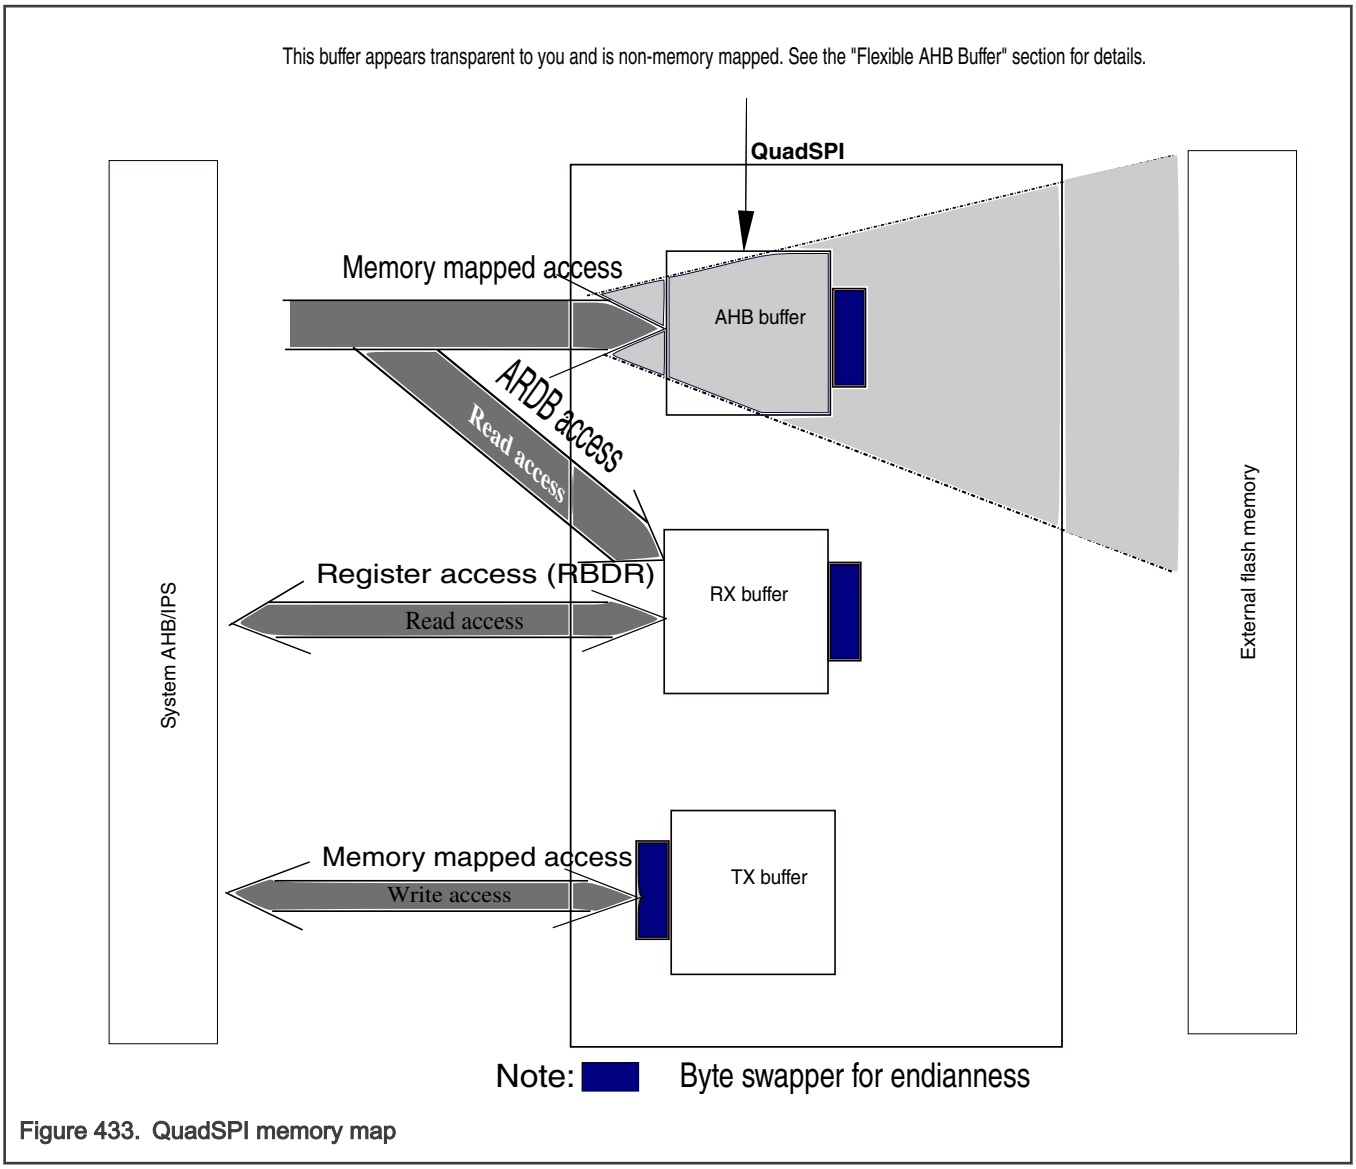

Figure 433. QuadSPI memory map

The RX buffer is implemented as FIFO of depth entries of 4 bytes. Its content is accessible in two different address areas, both referring to identical data and the same physical memory:

- In the IPS address space in the area associated with RX Buffer Data Register (RBDR0 - RBDR63).
- In the AHB address space in the area associated with AHB RX Data Buffer Register (ARDB0 - ARDB127).Two successive entries are accessed with one single 64-bit AHB read operation.

The RX buffer operation can be summarized as follows:

- RBCT[WMRK] determines at which fill level SR[RXWE] is asserted and how many entries are removed from the RX buffer on each buffer POP operation.
- SR[RXWE] indicates that the configured number of data entries is available in the RX buffer and RBSR[RDBFL] indicates how many valid entries are available in total.
- The first entry (RBDR0 or ARDB0) always corresponds to the first valid entry in the RX buffer.

For details, see RX Buffer Data Register (RBDR0 - RBDR63) and AHB RX Data Buffer Register (ARDB0 - ARDB127).

- Flag-based data read of the RX buffer is performed by polling SR[RXWE]. When it is asserted, the valid entries can be read either via the IPS address space (RBDRn) or the AHB address space (ARDBn). A buffer POP operation must be

triggered by the application by writing a 1 to FR[RBDF]. This automatically updates the FIFO to point to the next entry as defined by RBCT[WMRK]. For example, if WMRK is set to 3, then the buffer discards 16 bytes of data.

- DMA-controlled data read of the RX buffer is performed by using the DMA module. The application must ensure that the DMA controller of the related chip is programmed appropriately, as described in DMA usage.
- DMA-controlled read out is triggered fully automatically by the assertion of SR[RXWE]. The related buffer POP operation is also handled completely inside the QuadSPI module. As in the case explained here, accessing the RX buffer content either on RBDRn or ARDBn related addresses is equivalent.
- AHB buffer data read via memory-mapped access: This kind of access is performed by reading one of the addresses assigned to the external serial flash memory device(s) within the range specified in Table 567. If this is not the case, a memory-mapped AHB command read is triggered as described above. If the requested data is already available in the AHB buffer, it is provided directly to the host.

When an AHB access is made to the flash memory mapped address, the data is fetched and returned to the AHB interface. The AHB interface is stalled until the data is fetched. As soon as the data from the requested address is read by the QuadSPI module, the AHB read access is served. Therefore, it is possible to run sequential reads from the AHB buffer at arbitrary speed without the need to monitor any information about the availability of the data. Nevertheless, this access scheme stalls the AHB bus for the time required to read the data from the serial flash memory device. If you know that the access is sequential, a better way is to have a prefetch enabled by programming the value of BUFxCR[ADATSZ] so that the data is fetched into the buffer before the next sequential AHB access.

As long as the host restricts its accesses to the data present in the buffer and to the data currently fetched from the serial flash memory, it is possible to run the host read from the AHB buffer simultaneously with the serial flash memory read into the AHB buffer.

74.4.2.9 Byte ordering of serial flash memory read data

The basic scheme is that the first byte read out of the serial flash memory device, which is addressed by SFAR[SFADR], corresponds to RBDR0[31:24] for IP command read. In contrast to that for AHB command read, the bytes are always positioned according to the byte ordering of the AHB bus.

- Byte ordering in individual flash memory mode

  The following table provides the byte ordering scheme of how the byte oriented data space of the serial flash memory device is mapped into one single 32-bit entry of the RX buffer or the AHB buffer. The table is valid within the following context:

  — Flash memory A in individual flash memory mode

  — All AHB data read commands with 32-bit access size

Table 546. Byte ordering in individual flash memory mode

Serial flash memory byte numbering	3	2	1	0
Buffer entry bit position [31:0] (32-bit data width)	[31:24]	[23:16]	[15:8]	[7:0]

NOTE

For IP commands, the read size can be specified as number of bytes. If this number is not a multiple of four, then the last buffer entry is not completely filled with the missing higher numbered bytes at undefined values.

  For AHB commands and reads, starting from an address not aligned to 32-bit boundaries, the requested bytes are given at the appropriate positions according to the AMBA AHB specification.

- Buffer entry ordering for 64-bit read access

  For read access via the AHB interface, a 64-bit access is possible. Each 64-bit access reads two 32-bit entries, simultaneously. The ordering of these 32-bit entries within the 64-bit word is provided in the following table.

Table 547. 64-bit read access buffer entry ordering

AHB read data bit position [63:0]	[63:32]	[31:0]
Buffer entry #	Odd (1, 3, 5, ...)	Even (0, 2, 4, ...)

74.4.2.10 Normal mode interrupt and DMA requests

The QuadSPI module has different flags that can only generate interrupt requests and one flag that can generate an interrupt as well as DMA requests. The following table lists the eight conditions. Note that the flags mentioned in the table are associated with the Flag Register (FR).

Table 548. Interrupt and DMA request conditions

Condition	Flag (FR)	DMA
TX buffer fill	TBFF	-
TX buffer underrun	TBUF	-
Illegal instruction error	ILLINE	-
RX buffer drain	RBDF	X
RX buffer overflow	RBOF	-
AHB buffer overflow	ABOF	-
AHB sequence error	ABSEF	-
AHB illegal transaction error	AITEF	-
AHB illegal burst size error	AIBSEF	-
IP command trigger during AHB access error	IPAEF	-
IP command trigger could not be executed error	IPIEF	-
IP command related transaction finished	TFF	-

Each condition has a corresponsing field in the Flag Register (FR) and a request enable field in the DMA Request Select and Enable Register (RSER). The FR[RBDF] has separate enable fields for generating IRQ and DMA requests. Note that not all the fields have an individual IRQ line. See the chip's Interrupt Vector table for details.

- Transmit buffer fill interrupt request

  This indicates that the TX buffer can accept new data. The buffer is asserted if FR[TBFF] is asserted and if the value of the corresponding enable field, RSER[TBFIE], is 1. See TX buffer Operation for details on the assertion of FR[TBFF].

  Apart from IRQ, it is possible to handle the TX buffer fill by using the DMA. If the value of RSER[TBFDE] is 1, a DMA request is triggered when the number of available space in the TX buffer is more than the TBCT[WMRK] valid entries and the value of SR[TXWA] is set. The application must configure the environment appropriately (for example, the DMA controller) for the DMA transfer.

- Receive buffer drain interrupt or DMA request

  This is derived from FR[RBDF], indicating that the RX buffer of the QuadSPI module has data available from the serial flash memory device to be read by the host. It remains set as long as RBSR[RXWE] is configured. Also, RSER[RBDIE] enables the related IRQ.

Apart from the IRQ, it is possible to handle the RX buffer drain by using the DMA. If the value of RSER[RBDDE] is 1, a DMA request is triggered when the RX buffer contains more than RBCT[WMRK] valid entries. The application must set the environment appropriately (for example, the DMA controller) for the DMA transfers.

- Buffer overflow/underrun interrupt request

  This is a combination of the following fields (all located in the Flag Register (FR) with the related enable bits in the DMA Request Select and Enable Register (RSER)):

  — TBUF - TX buffer underrun, enabled by TBUIE

  — RBOF - RX buffer overflow, enabled by RBOIE

  — ABOF - AHB buffer overflow, enabled by ABOIE

  — The transmit buffer underrun indicates that an underrun condition in the TX buffer has occurred. It is generated when a write instruction is triggered whilst the TX buffer is empty and the the value of RSER[TBUIE] is 1.

  — The receive buffer overflow indicates that an overflow condition in the RX buffer has occurred. It is generated when the RX buffer is full, an additional read transfer attempts to write into the RX buffer, and the value of RSER[RBOIE] is 1.

  — The AHB buffer overflow indicates that an overflow condition in the AHB buffer has occurred. It is generated when the AHB buffer is full, an additional read transfer attempts to write into the AHB buffer and the value of RSER[ABOIE] is 1.

  — The data from the transfers that generated the individual overflow conditions is ignored.

- Serial flash memory command error interrupt request

  If the IPAEF, IPIEF fields in the FR are set, and the related interrupt enable bits in the RSER are also set, then an interrupt is requested.

- Transaction finished interrupt request

  The IP command transaction finished IRQ indicates the completion of the current IP command. It is triggered by FR[TFF] and is masked by RSER[TFIE].

74.4.2.11 TX buffer operation

The TX buffer provides the data used for page programming. For proper operation, it is required to provide at least one entry in the TX buffer prior to starting the execution of the page programming command. The application must ensure that the required number of data bytes is written into the TX buffer fast enough as long as the command is executed without a TX buffer overflow or underrun.

The QuadSPI module sets the FR[TBFF] field as long as the TX buffer is not full and can accept more data. At the end of write through TX buffer, you must clear FR[TBFF] to avoid unnecessary last TX buffer fill interrupt. However, there would always be a pending request asserted from QuadSPI controller at the end of any DMA transfer. When external DMA finishes transfer iteration, this request from QuadSPI is kept asserted for the next iteration loop.

NOTE

Even if the generation of DMA requests for filling the TX buffer is disabled by using RSER[TBFDE], the TX buffer still accepts a DMA transfer because of the last asserted pending request.

Disabling of DMA transfer should be controlled by an external DMA master.

When the QuadSPI module tries to pull data out of an empty TX buffer, FR[TBUB] signals the TX buffer underrun. The TX buffer underrun flag is also asserted when the TX buffer contains less than 32-bits of data and the QuadSPI module tries to pull out data from it. The current IP command leading to the underrun condition is continued until the specified number of bytes is sent to the serial flash memory device. Also, the data that is transferred is in the Fs format. This means, after the underrun flag is set under this condition, it returns Fs until the required number of bytes are not sent. This has been done to ensure that the software does not erase the whole sector after underrun and just reprogramming from failure point serves the purpose. When this sequence command is complete, FR[TBFF] is asserted, indicating that the TX buffer is ready to be written again.

The TX buffer overflow is not signaled explicitly, but TBSR[TRBFL] can monitor the TX buffer fill level.

For more information, see TX Buffer Status Register (TBSR) and Flag Register (FR).

74.4.2.12 Address scheme

Earlier, serial flash memories supported only a 24-bit address space, restricting the maximum memory size of the serial flash memory to 16 MB. The new memory specification supports two types of 32-bit addressing mode in addition to the legacy 24-bit address mode.

Extended address mode

In this mode, the legacy 24-bit commands are converted to accept 32-bit address commands. The flash memory needs to be configured for the 32-bit address mode. Also, while programming the LUT sequence in QuadSPI for 32-bit mode, the ADDR commands should be programmed with 32d as the operand value,. By default, QuadSPI is in 24-bit legacy address mode. Each of the memory vendors have a different way of enabling this mode (see the memory specification from memory vendors). For example, the command B7h sent to the Macronix flash memory enables it for the 32-bit address mode.

Extended address register

In this mode, the upper 8 bits of the 32-bit register are provided by the Extended address register in the memory, which provides a specific register that is updated according to the address to be accessed. This effectively converts the legacy 24-bit address command into 32-bit address commands. The memories greater in size than 16 MB consist of banks of 16 MB each. The 8 bits occupied in the extended address register effectively enable a bank. For example, in Spansion memory, when the extended address register is updated with a value of 1h, with the help of the 17h command, it opens Bank1 of the memory. The consequent 24-bit address commands lead to Bank1. The extended address register needs to be updated with the respective value for access to other banks. This effectively converts the legacy 24-bit address command into 32-bit address commands.

This mode has been introduced for flash memories that need addresses segregated into rows and columns. The value in SFACR[CAS] defines the width of the column address required by a flash memory. The actual address to be provided is derived from the incoming address in case of AHB-initiated transactions and the value of SFAR in case of IPS-initiated transactions, if the value of SFACR[CAS] is 0. Otherwise, the actual address takes CAS into consideration. If the value of SFACR[CAS] is 3, then bits 26-3 of the programmed address are sent to the flash memory as its page address. This is in case the flash memory is operating in a 24-bit mode and bits 2-0 are sent as its column address. If a flash memory requirement for column address is less than the number of pads in which address has to be sent, then QuadSPI appends the remaining bits by 0. You must program the operand value in CADDR and CADDR_DDR command accordingly. It must be ensured that the total number of address bits requested by flash memory as its page and column address must not be more than 32 bits.

This mode has been introduced for flash memories, which have a word-addressable memory. This means, each address of the flash memory contains one word (two bytes) of data. The value of SFACR [WA] is configured to 1 to enter this mode. QuadSPI internally divides the incoming address in the AHB bus or the address in the SFAR to map it to a valid flash memory location. For example, if the incoming address is 2004h, the controller re-maps this address to access the flash memory location 1002h. If not in this mode, the incoming address 2004h is mapped to flash memory location 2004h.

74.4.3 Module Disable mode

Module Disable mode is a block-specific mode that the QuadSPI can enter to disable serial flash memory clock and AHB command. This mode can be entered by:

- The host software: by writing a '1' to MCR[MDIS]

Below are the condition that must be fulfilled to enter the Module Disable mode:

- SR[BUSY] = 0
- SR[AHBTRN] = 0
- RBSR[RDBFL] = 0
- SR[RXDMA] = 0
- SR[TXDMA] = 0
- None of the flags in FR are enabled as interrupts is set

The conditions mentioned above ensures the following:

- There is no SFM command currently being executed.
- All the data read into the RX buffer from the serial flash memory have been fetched by the application.
- There is no current AHB access.
- There is no active DMA request.
- There is no enabled interrupt that is pending.

Certain read or write operations have a different effect when the QuadSPI is in the Module Disable mode. In the Module Disable mode, not all of the status and flag bits of the QuadSPI module are updated, and writing to them has no effect. Interrupt and DMA request signals cannot be cleared while in the Module Disable mode.

NOTE

It is illegal to issue a new SFM command starting two clock cycles prior to raising the request of entering the Module Disable mode until the QuadSPI stays in this mode.

74.4.4 Leaving Module Disable mode

In the Module Disable mode, the serial flash memory clock and AHB command to the QuadSPI module are switched off.

After the QuadSPI has left this mode and has returned to Normal mode, the execution of the first SFM command is deferred until the clock to drive that part of the module related to the serial flash memory device is available. Depending upon the point in time when the first SFM command is triggered, the actual execution of the command starts with a delay, respective with the re-enabling of the flash memory clock signal.

74.5 Initialization/application information

This section provides the initialization and application information of the QuadSPI module.

74.5.1 Power up and reset

The serial flash memory devices connected to the QuadSPI module might require special voltage characteristics of their inputs during power up or reset. The application must ensure this.

74.5.2 Available status/flag information

This section provides an overview of the different flags and statuses available, and their interdependencies for different use cases. The SR and FR are the related registers.

74.5.2.1 IP commands

See IP Configuration Register (IPCR) for additional details not explicitly covered in this paragraph.

- IP commands—normal operation

  Writing to IPCR[SEQID] triggers the execution of a new IP command. Given that this is a legal command, SR[IPACC] and SR[BUSY] are asserted simultaneously, immediately after the execution starts.

  After the instruction on the serial flash memory device is complete, these field deassert and FR[TFF] is configured.

- IP commands—error situations

  See Overview_of_Error_Flags for details.

74.5.2.2 AHB commands

See the "Reading serial flash memory data into the QuadSPI module internal buffers" topic in theFlash Memory Read section for details.

- AHB commands—normal operation

Memory-mapped read access to a serial flash memory address not contained in the AHB buffer triggers the execution of an AHB command. Given that this is a legal command, SR[AHB_ACC] and SR[BUSY] are asserted simultaneously, immediately after the execution starts. After the instruction on the serial flash memory device is complete, these fields are deasserted.

- IP commands—error situations

  See Overview of FR error flags for details.

74.5.2.3 SFM commands

An SFM command consists of an instruction code and all other parameters (for example, size or mode bytes) needed for that specific instruction code. Triggering a command either initiates a transaction on the external serial flash memory or results in an error. See Table 549 for details on errors.

74.5.2.4 Overview of error flags

The following table provides an overview of the different error flags in the FR and additional error-related details.

Table 549. Overview of FR error flags

Error category	Error flag in FR	Command execution on serial flash memory device TFF behavior (in case of IP commands only)	Description
AHB error flag	ABOF	Flash memory transaction continues until it finishes	Set when the module tries to push data into the AHB buffer that exceeds the size of the AHB buffer. Occurs only because of the wrong programming of BUFxCR[ADATSZ].
AHB error flag	AIBSEF	Flash memory transaction is aborted	Total burst size of the AHB transaction is greater than prefetch data size.
AHB error flag	AITEF	Flash memory transaction is aborted	No response is generated from QuadSPI to AHB bus in case of illegal transaction. Also, the watchdog timer expires.
Miscellaneous error flag	ILLINE	Flash memory transaction aborted	Illegal instruction error flag - set when an illegal instruction is encountered by the controller in any of the sequences.
Command arbitration error	IPIEF	TFF not asserted in conjunction with that command	IP command error - caused when IP access is currently in progress (IP_ACC is set) and during: • Write attempt to IPCR register • Write attempt to SFAR register • Write attempt to RBCT register
Command arbitration error	IPAEF	TFF not asserted in conjunction with that command	• AHB command already running, another IP command could not be executed

Table continues on the next page...

Table 549. Overview of FR error flags (continued)

Error category	Error flag in FR	Command execution on serial flash memory device TFF behavior (in case of IP commands only)	Description
			• AHB command already running, write attempt to IPCR[SEQID]
Buffer-related error	RBOF	TFF is asserted on completion	• RX buffer overrun
Buffer-related error	TBUF	TFF is asserted on completion	• TX buffer underrun

Note that only the buffer-related errors are associated with a transaction on the external serial flash memory. All the other errors do not trigger an actual transaction.

74.5.2.5 IP bus and AHB access command collisions

There are two flags related to this topic, FR[IPAEF] and FR[IPIEF]. See the "Reading serial flash memory data into the QuadSPI module internal buffers" topic of the Flash Memory read section for a description of the flags.

74.5.3 Flash memory device selection

Regardless of the SFM command (IP or AHB), the access mode is selected by specifying the 32-bit address value for the following SFM command.

For IP commands, the access mode is selected with the address programmed into the SFAR register. See Serial Flash Address Register (SFAR) for details.

For AHB commands, the access mode is determined by the memory-mapped address. See AMBA Bus Register Memory Map for details.

74.5.4 DMA usage

For a complete description of the DMA module, see the related DMA Controller chapter. This section only provides QuadSPI-specific DMA usage details.

74.5.4.1 DMA usage in normal mode

74.5.4.1.1 Bandwidth considerations

Careful consideration of the throughput rate of the entire chain (serial flash memory -> AHB bus / IP bus -> DMA controller) involved in the read/write data process is essential for a proper operation. Such analysis must take into account not only the data rate provided by the serial flash memory but also the data rate of the AHB bus and the performance of the DMA controller in reading/writing data from/to the RX/TX buffer.

Two figures must match for a proper operation, which means that the data rate provided by the serial flash memory device must not exceed the average RX buffer readout data rate. Otherwise, the longer this state persists, it results into an RX buffer overflow. Similarly, the data consumed by the serial flash memory device must not exceed the average TX buffer fill rate. If this persists, it leads to an underrun.

AHB bus side (data read)

The total number of bus cycles for each DMA minor loop completion is added from the following components:

The following table provides certain examples for typical use cases:

Case 1: DMA needs to read 4 bytes from SRAM and provide to QuadSPI. It costs total four bus clock cycles. Then, DMA handshake adds additional six bus clock cycles, resulting in a total of [6 + 4 * (32/4) = 38] bus clock cycles.

Table 550. Access duration examples for bus clock side

TBCT[WMRK]	Number of bytes per DMA loop	Number of bus clock cycles for DMA minor loop	Time duration of DMA minor loop for 60 MHz bus clock frequency
3	16	6+(16/4)*4 = 22	~366ns
7	32	6+(32/4)*4 = 38	~633ns
11	48	6+(48/4)*4 = 54	~900ns
15	64	6+(64/4)*4 = 70	~1166ns

Case 2: DMA needs to read 32 bytes from SRAM and provide to QuadSPI. DMA handshake takes an additional six bus cycles, with 32 bytes DMA read from SRAM costs (8 + 3) core clock cycles. DMA writes 32 bytes to QuadSPI, takes 2 * (32/4) = 16 bus cycles with one additional CPU access to QuadSPI, costing two bus clock cycles. This results in a total 6 + (8+3)/2 + 2 * (32/4) +2 = 30 bus clock cycles.

Table 551. Access duration examples for bus clock side

TBCT[WMRK]	Number of bytes per DMA loop >	Number of bus clock cycles for DMA minor loop	Time duration of DMA minor loop for 80 MHz bus clock frequency
3	16	6 + (4+3) /2 + (16/4)*2 + 2 = 20	~333ns
7	32	6 + (8+3) /2 + (32/4)*2 + 2 = 30	~500ns
11	48	6 + (4+3)/2*3 + (48/4)*2 + 2 = 44	~733ns
15	64	6 + (8+3) + (64/4)*2 + 2 = 51	~810ns

NOTE

This table figure represents an ideal scenario; actual performance depends on how the chip integrates DMA and QuadSPI modules.

Serial flash memory device side (data read)

The number of serial flash memory cycles can be determined in the following way:

- Number of serial flash memory clock cycles is required to read 4 bytes, corresponding to one RX buffer entry (setup of command and address not considered): , eight cycles for quad mode (SDR) instructions in individual flash memory mode, and so on.
- Overhead because of clock domain crossing: one cycle

The following table lists the number of clock cycles required to read the data from the serial flash memory corresponding to the different settings of RBCT[WMRK]:

Table 552. Access duration examples for serial flash memory side

RBCT[WMRK] setting	Num bytes per DMA loop [1]	Num SCKFx for 80 MHz SCKFx		Time duration of flash memory data readout for 80 MHz SCKFx (~12.5ns period)	
		IFM [2] quad	IFM quad DDR	IFM quad	IFM quad DDR
0	4	8	4	~100ns	~50ns
1	8	16	8	~200ns	~100ns
3	16	32	16	~400ns	~200ns
7	32	64	32	~800ns	~400ns

1. DMA loop refers to one minor loop completion that is equivalent to one major loop iteration.
2. Individual flash memory mode

NOTE

The table figure represents an ideal scenario; actual performance depends on how the chip integrates with DMA and QuadSPI modules.

A complementary example is when the watermark is set to be too high. In such a case, the time taken by the DMA to read out the RX buffer entries should be lesser than the time taken by the controller to push in the remaining entries in the buffer.

IPS bus side (data write)

The total number of bus cycles for each DMA minor loop completion are added from the following components:

- Overhead for each minor loop, given by DMA controller: assume 10 cycles
- Overhead because to clock domain crossing: assume two cycles
- Number of bus clock cycles required for 16 bytes (128-bit write size): assume four cycles (read/write sequence of DMA controller)

Note that the size of the minor loop is determined by the size of TBCT[WMRK]; therefore, the overhead specified above distributes among (TBCT[WMRK]+1) write accesses of 32-bit each.

The following table provides some examples for typical use cases:

Table 553. Access duration examples for bus clock side

TBCT[WMRK]	Number of bytes per DMA loop [1]	Number of bus clock cycles for DMA minor loop	Time duration of DMA minor loop for 80 MHz bus clock frequency
3	16	12+4 = 16	~200ns
7	32	12+8 = 20	~250ns
11	48	12+12 = 24	~300ns
15	64	12+16 = 28	~350ns
19	80	12+20 = 32	~400ns

1. DMA loop refers to one minor loop completion that is equivalent to one.

NOTE

The table figure represents an ideal scenario; actual performance depends on how the chip integrates with DMA and QuadSPI modules.

Serial flash memory device side (data write)

The number of serial flash memory cycles can be determined in the following way:

- Number of serial flash memory clock cycles required to write 16 bytes, corresponding to four TX buffer entry (setup of command and address not considered): 32 cycles for quad SDR writes in individual flash memory mode.
- Overhead due to clock domain crossing: one cycle

The following table lists the number of clock cycles required to read the data from the serial flash memory corresponding to the different settings of TBCT[WMRK]:

Table 554. Access duration examples for serial flash memory side

TBCT[WMRK] setting	Num bytes per DMA loop [1]	Num SCKFx		Time duration for consuming data at flash memory interface 100 MHz SCKFx (10 ns period)[2]		Time for FIFO to get empty[3]	
		IFM [4] quad	[5] single IO SDR mode	IFM quad	PFM single IO SDR	IFM quad	PFM single IO SDR
3	16	32	64	320ns	640ns	2240ns	4480ns
7	32	64	128	640ns	1280ns	1920ns	3840ns
15	64	128	256	1280ns	2560ns	1280ns	2560ns
23	96	192	384	1920ns	3840ns	640ns	1280ns

1. DMA loop refers to one minor loop completion that is equivalent to one major loop iteration.
2. Not all flash memory devices support writes at 100 MHz. See the flash memory data sheet for the actual page program frequency supported.
3. The assumption for these timings is that the TX Fifo is full when the transaction is initiated
4. Individual flash memory mode
5. Parallel flash memory mode

NOTE

The tables mentioned above are only examples which must be correlated with the DMA in the system.

Considering the examples provided in the two tables above for TX FIFO, it is evident that depending on the relationship between the bus clock and serial flash memory clock frequencies, there are settings possible where the serial flash memory consumes data faster than the IPS bus can write data in TX buffer. In these cases, a TX buffer underrun situation occurs. To avoid TX buffer underrun, the data transaction size should be large enough.

74.5.5 Flash memory devices address mapping

QuadSPI is configured in Single mode for the supported flash memory port A

The sizes of the flash memory devices are mapped with the system memory space based on the configurations of the following registers:

- SFA1AD
- SFA2AD
- SFB1AD
- SFB2AD

The total memory region for the flash memory devices is mapped between QuadSPI_AMBA_BASE and TOP_ADDR_MEMB2 such that the corresponding CS is asserted based on SFA1AD, SFA2AD and SFB1AD register configurations.

74.5.5.1 Single mode

For single mode configuration, you must write the same value to SFB1AD and SFB2AD registers that you write to the SFA2AD register.

For dual-die flash memories, the values you write to SFB1AD and SFB2AD registers corresponds to the mapped top addresses of each die.

For single-die flash memories, you must write the same value to SFA2AD register that you write to the SFA1AD register.

Following is a programming example for single mode single-die flash memory:

- QuadSPI_AMBA_BASE - 1000_0000h
- SFA1AD[TPADA1] - 2000_0000h
- SFA2AD[TPADA2] - 2000_0000h
- SFB1AD[TPADB1] - 2000_0000h
- SFB2AD[TPADB2] - 2000_0000h

The following figure illustrates the memory mapping for single mode QuadSPI configuration.

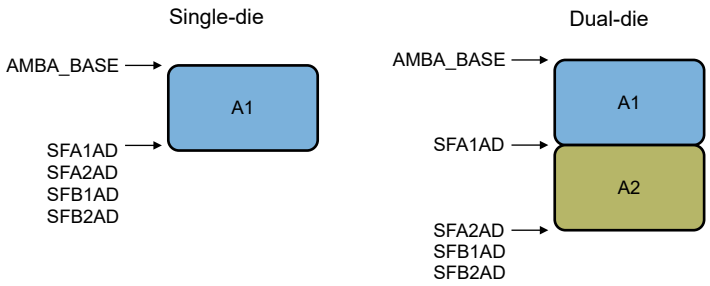

Figure 434. Memory map for Single mode

74.6 Byte ordering – endianness

The following topics show the byte ordering in 64-bit LE configuration for AHB buffer and 32-bit LE for TX/RX buffer.

74.6.1 Programming flash memory data

CPU writes instructions to the TBDR register, such as:

- Write TBDR: 4_03_02_01h
- Write TBDR: 8_07_06_05h

The following table shows the content against each TX buffer entry.

Table 555. Example of QuadSPI TX buffer

TX buffer entry	Content
0	4_03_02_01h
1	8_07_06_05h

Programming the TX buffer into the external serial flash memory device results in the following byte order to be sent to the serial flash memory:

- 01...02...03...04...05...06...07...08

74.6.2 Reading flash memory data into the RX buffer

Reading the content from the same address provides the following sequence of bytes, identical to the write case:

- 01...02...03...04...05...06...07...08

The following table shows the content against each TX buffer entry.

Table 556. Resulting RX buffer content

RX buffer entry	Content
0	4_03_02_01h
1	8_07_06_05h

74.6.2.1 Readout of the RX buffer through RBDRn

The RX buffer content appears at CPU read access through the peripheral bus interface in the following order:

- Read RBDR0: 4_03_02_01h
- Read RBDR1: 8_07_06_05h

74.6.2.2 Readout of the RX buffer through ARDBn

The RX buffer content appears at read access on the AMBA AHB interface at the QuadSPI module boundary:

- 32-bit access: Read ARDB0: 4_03_02_01h
- 32-bit access: Read ARDB1: 8_07_06_05h
- 64-bit access: Read ARDB0: 8_07_06_05_04_03_02_01h

74.6.3 Reading flash memory data into the AHB buffer

Reading the content from the same address as it was written to provides the following sequence of bytes, identical to the write case:

- 01...02...03...04...05...06...07...08

The following table shows the content against each TX buffer entry.

Table 557. Resulting AHB buffer content

AHB buffer entry	Content
0	8_07_06_05_04_03_02_01h

74.6.3.1 Readout of the AHB buffer through memory-mapped read

The AHB buffer content appears at read access on the AMBA AHB interface at the QuadSPI module boundary:

- 32-bit read access: 4_03_02_01h
- 32-bit read access: 8_07_06_05h
- 64-bit read access: 8_07_06_05_04_03_02_01h

74.7 Serial flash memory devices

Several different vendors make flash memory devices with a QuadSPI interface. At present, there is no set standard for the QuadSPI instruction set. The most common commands currently have the same instruction code for all vendors; however, some commands are unique to specific vendors. Some of the example sequences are provided in the following sections.

74.7.1 Example sequences

This section provides the example sequences of the QuadSPI module.

Table 558. Exit 4 x I/O read enhance performance mode (XIP) (Macronix) and read status

Instruction	Pad	Operand	Description
CMD	0h	EBh	4xIO read command
ADDR	2h	18h	24-bit address to be sent on four pads
MODE	2h	0h	2 mode cycles (exit XIP)
DUMMY	0h	4h	4 dummy cycles
READ	2h	8h	Read 64 bits
CMD	0h	5h	Read Status register
READ	0h	1h	Status register data
STOP	0h	0h	Stop, instruction over

74.7.1.1 Fast read sequence (Macronix/Numonyx/Spansion/Winbond)

The following table shows the fast read sequence for Macronix/Numonyx/Spansion/Winbond flash memories.

Table 559. Fast read sequence

Instruction	Pad	Operand	Description
CMD	0h	Bh	Fast read command = 0Bh
ADDR	0h	18h	24 address bits to be sent on one pad
DUMMY	0h	8h	Eight dummy cycles
READ	0h	4h	Read 32 bits on one pad
JMP_ON_CS	0h	0h	Jump to instruction 0 (CMD)

74.7.1.2 Fast read quad output (Winbond)

The following table shows the fast read quad output sequence for Winbond memories

Table 560. Fast read quad output sequence

Instruction	Pad	Operand	Description
CMD	0h	6Bh	Fast read quad output command = 6Bh
ADDR	0h	18h	24 address bits to be sent on one pad
DUMMY	0h	8h	Eight dummy cycles
READ	2h	4h	Read 32 bits on four pads
JMP_ON_CS	0h	0h	Jump to instruction 0 (CMD)

74.7.1.3 4 x I/O read enhance performance mode (XIP) (Macronix)

The following table shows the 4 x I/O read enhance performance mode for Macronix flash memories. The enhanced performance mode is also known as XIP mode.

Table 561. Fast read quad output sequence

Instruction	Pad	Operand	Description
CMD	0h	EBh	4xI/O read command = EBh
ADDR	2h	18h	24 address bits to be sent on four pads
MODE	2h	A5h	Two mode cycles
DUMMY	0h	4h	Four dummy cycles
READ	2h	4h	Read 32 bits on four pads
JMP_ON_CS	0h	1h	Jump to instruction 1 (ADDR)

When in XIP mode, the software must ensure that all the flash memories connected to the controller are in this mode. As a part of initializing the controller, all the flash memories might be enabled with XIP by carrying out dummy reads.

74.7.1.4 Dual command page program (Numonyx)

The following table shows the dual command page program sequence for Numonyx flash memories.

Table 562. Dual command page program sequence

Instruction	Pad	Operand	Description
CMD	1h	2h	Dual command page program = 02h on 2 pads
ADDR	1h	18h	24 address bits to be sent on two pads
WRITE	1h	20h	Write 32 bytes on two pads
STOP	0h	0h	Stop, instruction over

74.7.1.5 Sector erase (Macronix/Numonyx/Spansion)

The following table shows the Sector erase sequence for the Macronix/Numonyx/Spansion flash memories.

Table 563. Sector erase sequence

Instruction	Pad	Operand	Description
CMD	0h	20h	Sector erase command = 20h
ADDR	0h	18h	24 address bits to be sent on one pad
STOP	0h	0h	Stop, instruction over

74.7.1.6 Read status register (Macronix/Numonyx/Spansion/Winbond)

The following table shows the read status register sequence for Macronix/Numonyx/Spansion/Winbond flash memories.

Table 564. Read status register sequence

Instruction	Pad	Operand	Description
CMD	0h	0h5	Read status register command = 05h
READ	0h	0h1	Read status register data
STOP	0h	0h	Stop, instruction over

74.8 Sampling of serial flash memory input data

74.8.1 Basic description

QuadSPI is used to read data from the serial flash memory device. Depending on the actual implementation, there is a delay between the internal clocking in the QuadSPI module and the external serial flash memory device. See the following figure for an overview of this scheme.

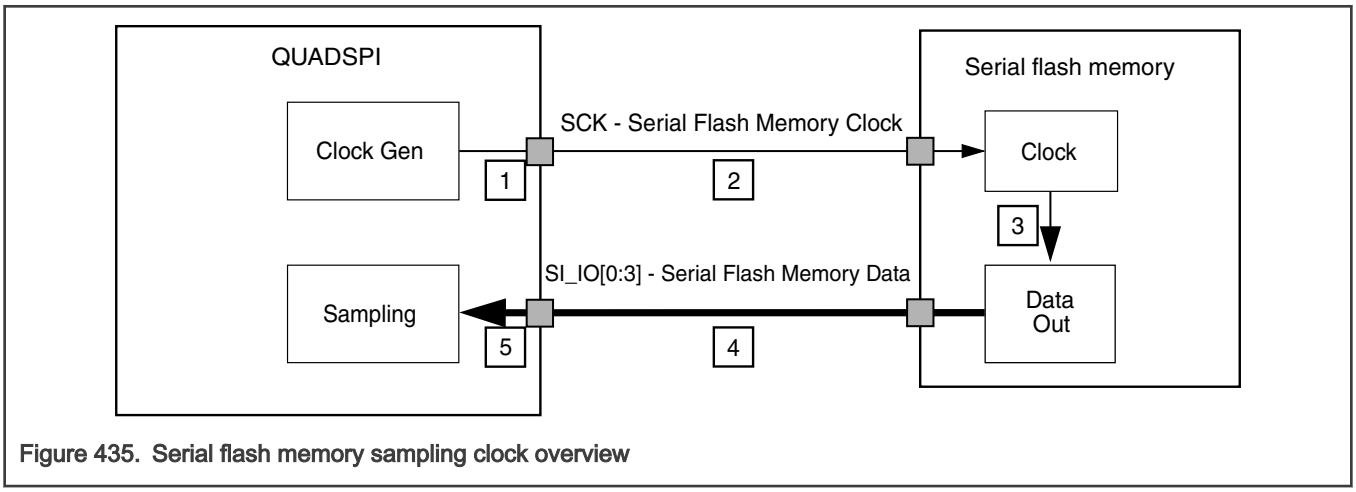

Figure 435. Serial flash memory sampling clock overview

The rising edge of the internal reference clock is taken as timing reference for the data output of the serial flash memory. After a time of $t_{Del,total}$ the data arrives at the internal sampling stage of the QuadSPI module. Considering the figure provided here, the following parts of the delay chain contribute to $t_{Del,total}$:

- Output delay of the serial flash memory clock output of the device containing the QuadSPI module
- Wire delay of application/PCB from the device containing the QuadSPI module to the external serial flash memory device
- Clock to data out delay of the external serial flash memory device, including input and output delays
- Wire delay of application/PCB from the external serial flash memory device to the device containing the QuadSPI module
- Device delay corresponding to the input data

NOTE

The $t_{Del,total}$ is specific to the characteristics of the actual implementation. Also, the serial flash memory device clock (SCK) is inverted with respect to the QuadSPI internal reference clock.

74.8.2 DQS sampling method

74.8.2.1 Basic description

In the DQS mode, the data strobe signal (DQS/RWDS) is used to sample the read data. Here, both DQS and the data sent by the flash memory move in the same direction; therefore, it is relatively easier to achieve at higher frequencies.

When using DQS for SDR reads, QuadSPI internally samples the incoming data on the rising edge of the strobe signal.

The next figure shows the sampling read data in the SDR mode using the DQS.

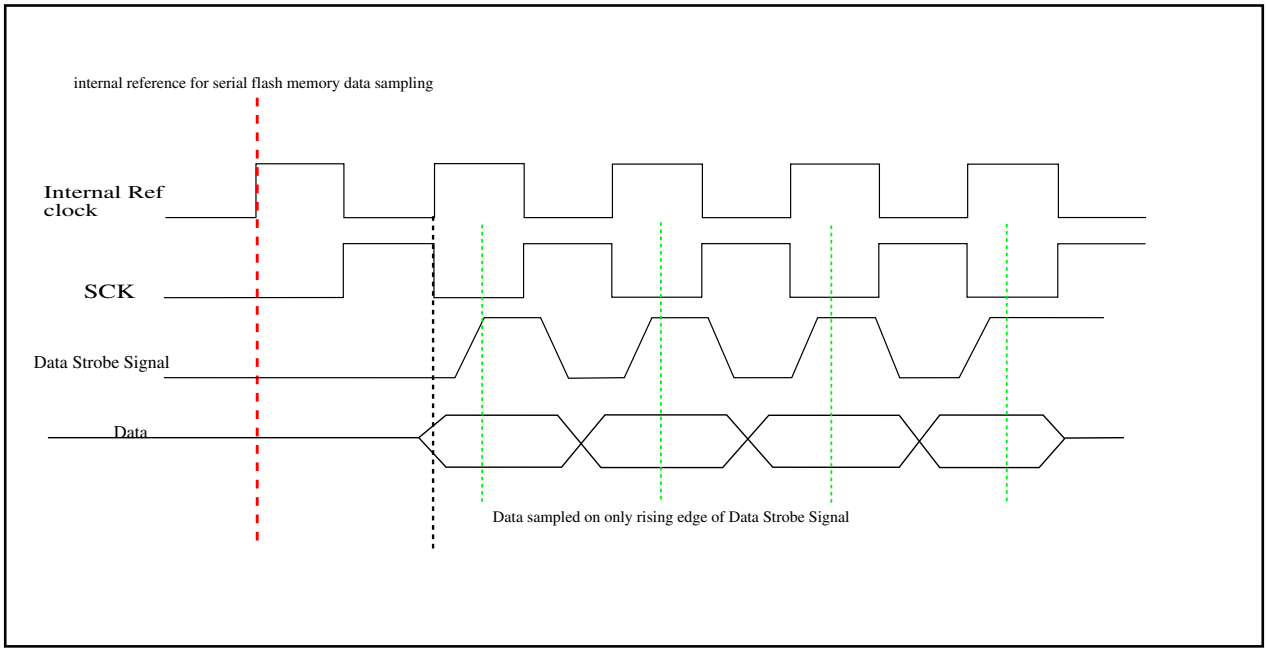

Figure 436. Data strobe functionality in SDR mode

74.8.2.2 Pad loopback

The internal clock is loop-backed from the dummy internal pad to compensate data pad delays. This can be enabled by configuring the value of MCR[DQS_FA_SEL] as "01" for flash memory A. This mode can be used with the following configuration:

- High/low frequency delay chain manual programming using DLLCRA[SLV_DLY_COARSE] or DLLCRB[SLV_DLY_COARSE]

NOTE

This mode may not be available on the chip. See the "Supported read modes" section in the chip-specific QuadSPI information for the read modes that this chip supports.

74.9 Delay chain usage

Slave delay chain programming sequence—

Following is the programming sequence for DLL bypass mode.

1. Program DLLCRA[SLV_EN]=1, DLLCRA[SLV_DLL_BYPASS]=1, and DLLCRA[SLAVE_AUTO_UPDT]=0.
2. Program the following fields to provide the desired DQS delay for sampling: DLLCRA[SLV_FINE_OFFSET], DLLCRA[SLV_DLY_COARSE], and DLLCR[FREQEN]. See the chip-specific QuadSPI information for the supported programming settings.
3. Program DLLCRA[SLV_UPD]=1 to load these values in the slave delay chain.
4. Check the slave delay chain update status by polling DLLSR[SLVA_LOCK]=1 and clear DLLCRA[SLV_UPD] after confirming the update state.

74.10 Memory map and register definition

This section provides the memory map and register definitions for the QuadSPI module.

74.10.1 Register write access

Following are the write access restriction terms that apply to all the registers:

- Register write access restriction

  For each register field, the write access conditions are specified in the detailed register description.

  The following table provides a description of the write access conditions. If, for a specific register bit or field, none of the given write access conditions is fulfilled, any write attempt to this register bit or field is ignored without any notification. The values of the bits or fields are not changed.

  The condition term [A or B] indicates that the register or field can be written to if at least one of the conditions is fulfilled.

Table 565. Register write access restrictions

Condition	Description
Anytime	No write access restriction
Disabled mode	Write access only if MCR[MDIS] = 1
Normal mode	Write access only if the module is in the normal mode

- Register write access requirements

  You can access all registers using 8-bit, 16-bit, and 32-bit wide operations. For some of the registers, at least a 16-bit or 32-bit wide write access is required to ensure correct operation. This write access requirement is stated in the detailed register description for each affected register.

74.10.2 QuadSPI register descriptions

This section provides the memory map and register definitions for the QuadSPI module.

Access to the following addresses does not result in a transfer error:

- 4h
- 50h
- 64h
- 104h
- 120h
- 138h
- 168h
- 188h
- 18Ch

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE The software resets need the clock to be running to propagate to the design. The value of MCR[MDIS] should be 0 when the software reset bits are asserted. Also, before they can be deasserted again (by setting MCR[SWRSTHD] to 0), it is recommended to set the value of MCR[MDIS] to 1. After the software resets have been deasserted, the normal operation can be started by setting MCR[MDIS] to 0. **NOTE** Software must wait for at least three system cycles and three flash cycles after changing the value of this field.
0 SWRSTSD	Software reset for serial flash memory domain 0b - No action 1b - Serial flash memory domain flops are reset. This field does not reset configuration registers. It is advisable to reset both the serial flash memory domain and AHB domain at the same time. Resetting only one domain might lead to side effects. **NOTE** The software resets need the clock to be running to propagate to the design. The value of MCR[MDIS] should therefore be 0 when the software reset bits are asserted. Also, before they can be deasserted again (by specifying 0 as the value for MCR[SWRSTSD]), it is recommended to specify 1 as the value for MCR[MDIS]. After the software resets are deasserted, the normal operation can be started by specifying 0 as the value for MCR[MDIS]. **NOTE** Software must wait for at least three system cycles and three flash cycles after changing the value of this field.

74.10.2.3 IP Configuration Register (IPCR)

Offset

Register	Offset
IPCR	8h

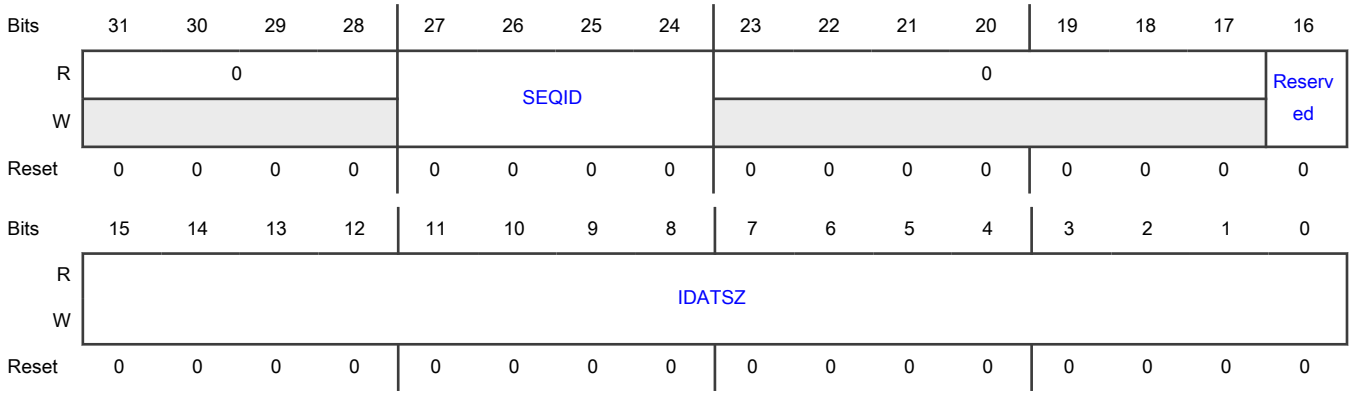
Function

This register provides all the configuration required for an IP-initiated command, which can be triggered by writing in the SEQID field of this register. If the SEQID field is written successfully, a new command to the external serial flash memory is initiated per the sequence pointed to by this field. See Normal mode for details on command triggering and command execution.

Special write-access is permitted if:

- SR[IP_ACC]=0

Diagram



Fields

Field	Function
31-28 —	Reserved
27-24 SEQID	Points to a sequence in the LUT This field defines bits [6:2] of the LUT index. The bits [1:0] are always assumed to be 0. See LUT for details. A write to this field triggers a transaction on the serial flash memory interface.
23-17 —	Reserved
16 —	Reserved
15-0 IDATSZ	IP data transfer size This field defines the data transfer size, in bytes, of the IP command.

74.10.2.4 Flash Memory Configuration Register (FLSHCR)

Offset

Register	Offset
FLSHCR	Ch

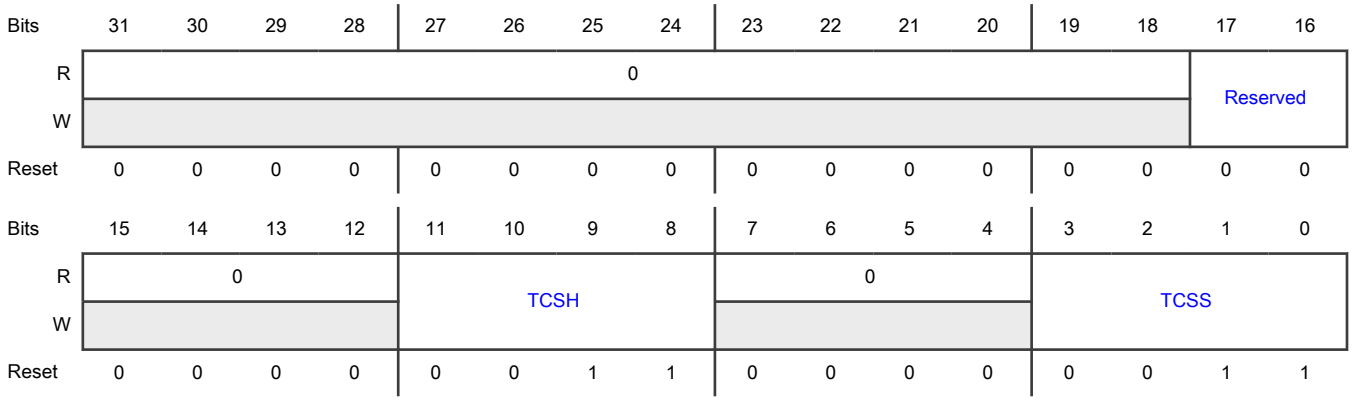
Function

This register contains the timings that are specific to the flash memory device. The QuadSPI controller must meet these timings for the device to function correctly.

Special write-access is permitted if:

- SR[AHB_ACC] = 0
- SR[IP_ACC] = 0

Diagram



Fields

Field	Function
31-18 —	Reserved
17-16 —	Reserved

11-8 TCSH	Serial flash memory CS hold time This hold time is in terms of serial flash memory clock cycles, and it must be greater than or equal to five flash memory clock cycles.
7-4 —	Reserved
3-0 TCSS	Serial flash memory CS setup time This setup time is in terms of serial flash memory clock cycles, and it must be greater than or equal to two flash memory clock cycles.

74.10.2.5 Buffer 0 Configuration Register (BUF0CR)

Offset

Register	Offset
BUF0CR	10h

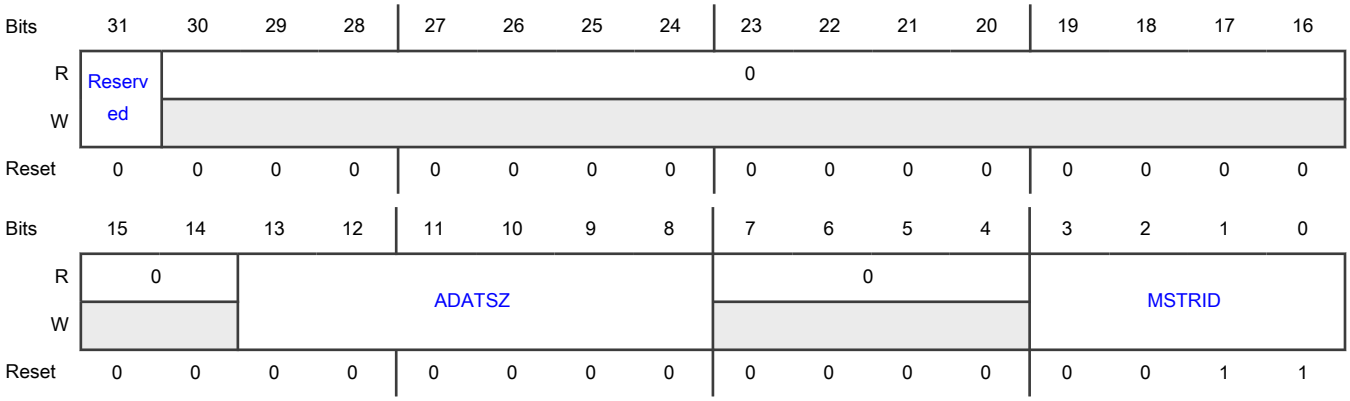
Function

This register provides the configuration for any read access routed to buffer0, which happens when the master port number of the incoming AHB request matches BUF0CR[MSTRID]. Any buffer "miss" leads to a serial flash memory transaction being triggered per the sequence pointed to by BFGENCR[SEQID].

Special write-access is permitted if:

- SR[AHB_ACC] = 0

Diagram



Fields

Field	Function
31 —	Reserved
30-14 —	Reserved
13-8 ADATSZ	AHB data transfer size Defines the read data transfer size in 8 bytes of an AHB triggered read access to serial flash memory. For example, a value of 0x2 sets transfer size to 16 bytes. When ADATSZ = 0, the data size mentioned in the sequence pointed to by the SEQID field overrides this value. The software should ensure that this transfer size is not greater than the size of the buffer.
7-4 —	Reserved
3-0 MSTRID	Master ID ID of the AHB master associated with BUFFER 0 Any AHB read access with this master port number is routed to this buffer. You must ensure that the master IDs associated with all buffers are different.

74.10.2.6 Buffer 1 Configuration Register (BUF1CR)

Offset

Register	Offset
BUF1CR	14h

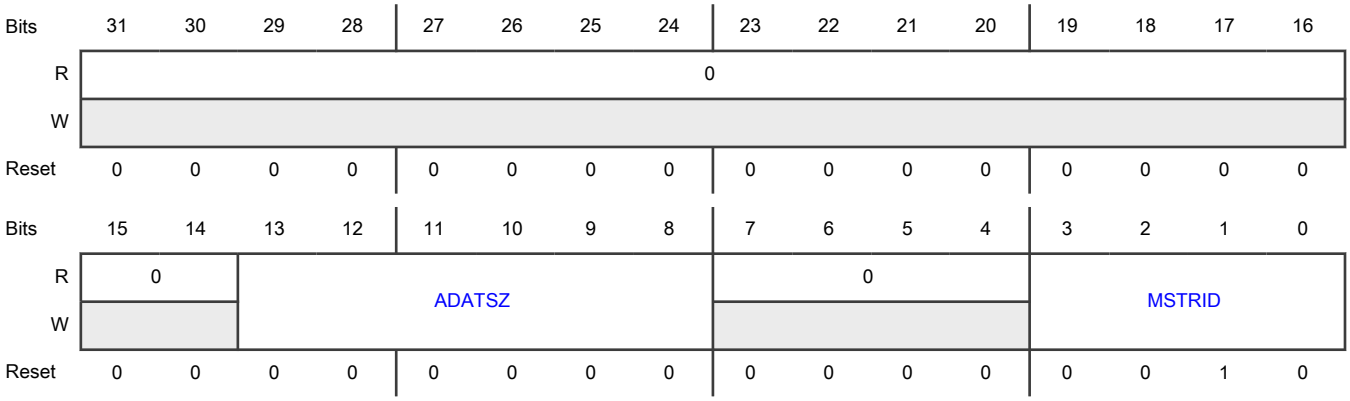
Function

This register provides the configuration for any access routed to buffer 1, which happens when the master port number of the incoming AHB request matches the MSTRID field of this register. Any buffer "miss" leads to the buffer being flushed and a serial flash memory transaction being triggered per the sequence pointed to by BFGENCR[SEQID].

Special write-access is permitted if:

- SR[AHB_ACC] = 0

Diagram



Fields

Field	Function
31-14 —	Reserved
13-8 ADATSZ	AHB data transfer size This field defines the read data transfer size in 8 bytes of an AHB triggered read access to serial flash memory. For example, a value of 0x2 sets the transfer size to 16 bytes. When ADATSZ = 0, the data size mentioned in the sequence pointed to by the SEQID field overrides this value. Software should ensure that this transfer size is not greater than the size of this buffer.
7-4 —	Reserved
3-0 MSTRID	Master ID ID of the AHB master associated with BUFFER 1

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Any AHB read access with this master port number is routed to this buffer. You must ensure that the master IDs associated with all buffers are different.

74.10.2.7 Buffer 2 Configuration Register (BUF2CR)

Offset

Register	Offset
BUF2CR	18h

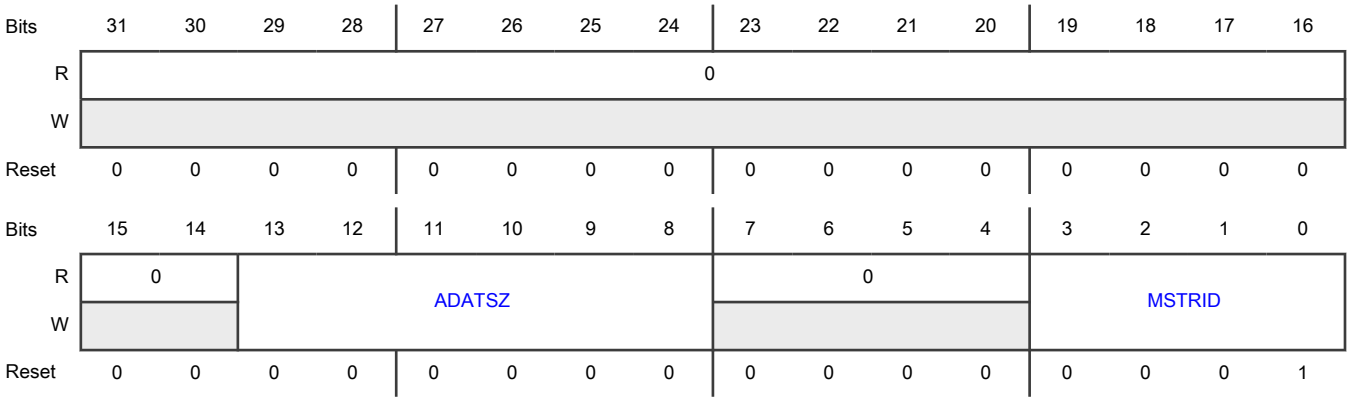
Function

This register provides the configuration for any access routed to buffer 2, which happens when the master port number of the incoming AHB request matches the MSTRID field of this register. Any buffer "miss" leads to the buffer being flushed and a serial flash memory transaction being triggered per the sequence pointed to by BFGENCR[SEQID].

Special write-access is permitted if:

- SR[AHB_ACC] = 0

Diagram



Fields

Field	Function
31-14 —	Reserved
13-8 ADATSZ	AHB data transfer size This field defines the read data transfer size in 8 bytes of an AHB triggered read access to the serial flash memory. For example, a value of 0x2 sets transfer size to 16 bytes. When ADATSZ = 0, the data size

Table continues on the next page...

Table continued from the previous page...

Field	Function
	mentioned in the sequence pointed to by the SEQID field overrides this value. The software should ensure that this transfer size is not greater than the size of this buffer.
7-4 —	Reserved
3-0 MSTRID	Master ID The ID of the AHB master associated with BUFFER2. Any AHB read access with this master port number is routed to this buffer. It must be ensured that the master IDs associated with all buffers are different.

74.10.2.8 Buffer 3 Configuration Register (BUF3CR)

Offset

Register	Offset
BUF3CR	1Ch

Function

This register provides the configuration for any access to buffer 3.

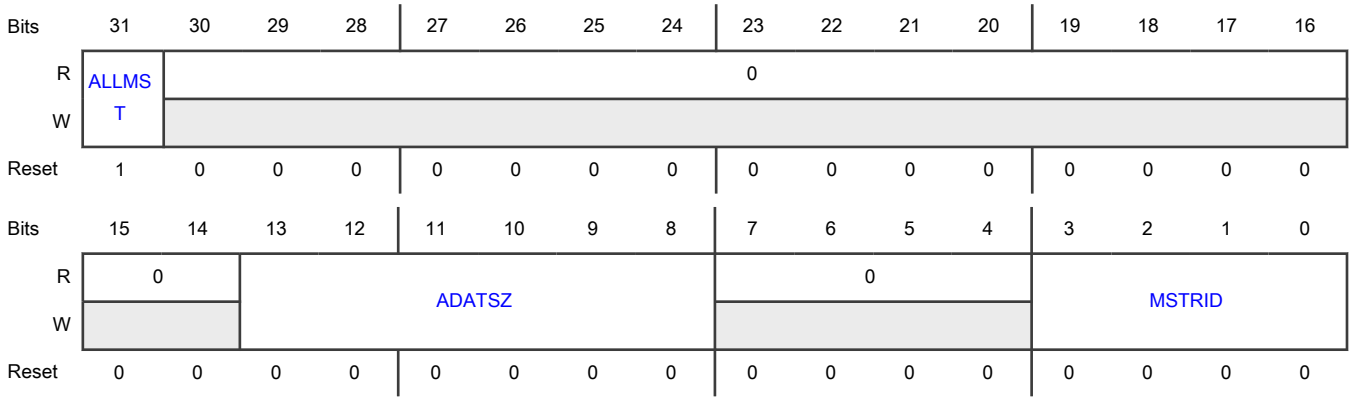
An access is routed to buffer 3 when the master port number of the incoming AHB request matches the MSTRID field of BUF3CR. Any buffer "miss" leads to the buffer being flushed and a serial flash memory transaction being triggered per the sequence pointed to by BFGENCR[SEQID].

In case the value of the ALLMST field is not 1, any such transaction (where master port number does not match any of the MSTRID fields) is returned with an ERROR response.

Special write-access is permitted if:

- SR[AHB_ACC] = 0

Diagram



Fields

Field	Function
31 ALLMST	All master enable When set, buffer3 acts as an all-master buffer. Any AHB access with a master port number not matching with the master ID of buffer0, buffer1, or buffer2 is routed to buffer3. When set, the MSTRID field of this register is ignored.
30-14 —	Reserved
13-8 ADATSZ	AHB data transfer size Defines the read data transfer size in 8 bytes of an AHB triggered read access to serial flash memory. When ADATSZ = 0, the data size mentioned in the sequence pointed to by the SEQID field overrides this value. The software should ensure that this transfer size is not greater than the size of this buffer.
7-4 —	Reserved
3-0 MSTRID	Master ID ID of the AHB master associated with BUFFER 3. Any AHB read access with this master port number is routed to this buffer. You must ensure that the master IDs associated with all buffers are different.

74.10.2.9 Buffer Generic Configuration Register (BFGENCR)

Offset

Register	Offset
BFGENCR	20h

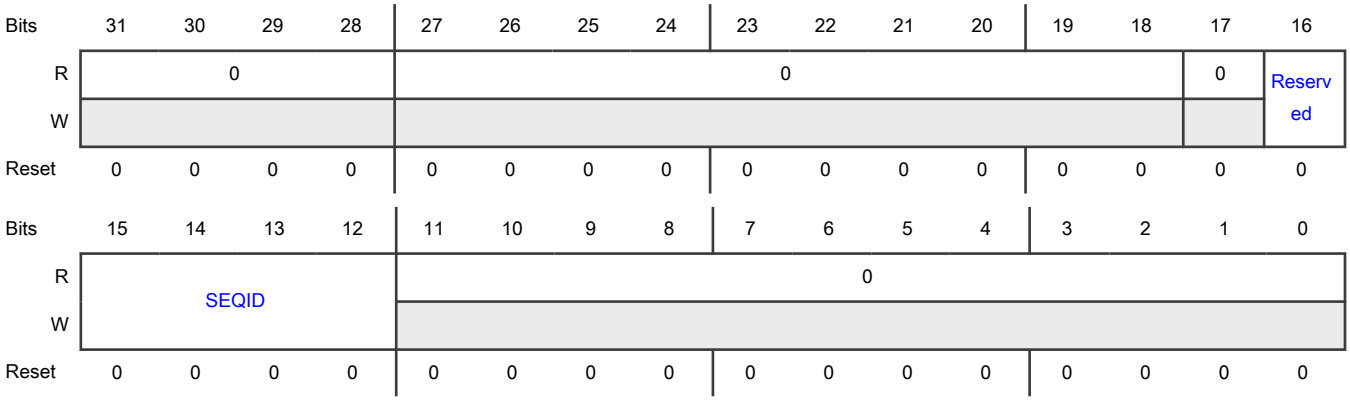
Function

This register provides generic configuration to any of the buffer accesses. Any buffer "miss" leads to the buffer being flushed and a serial flash memory transaction being triggered per the sequence pointed to by the SEQID field.

Special write-access is permitted if:

- SR[AHB_ACC] = 0

Diagram



Fields

Field	Function

27-18 —	Reserved
17 —	Reserved
16 —	Reserved
15-12 SEQID	Points to a sequence in the LUT This field defines the bits [6:2] of the LUT index. The bits [1:0] are always assumed to be 0. See LUT. **NOTE** If the sequence pointer differs in the new and the previous sequences, you should reset it. See sequence pointer clear register for more information.
11-0 —	Reserved

74.10.2.10 SOC Configuration Register (SOCCR)

Offset

Register	Offset
SOCCR	24h

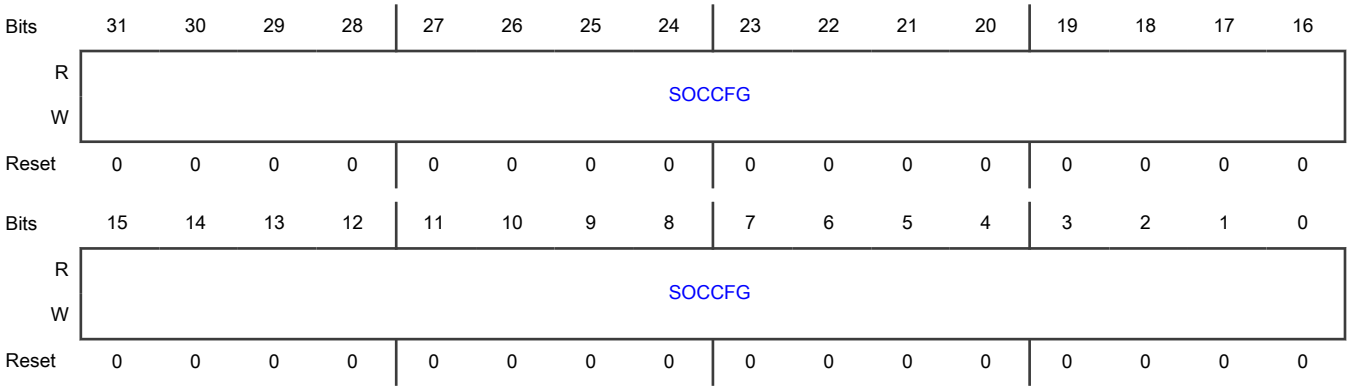
Function

This register is programmed at the chip level for QuadSPI delay chain configuration. For details, see chip-specific QuadSPI information.

Special write-access is permitted if:

- SR[AHB_ACC] = 0

Diagram



Fields

Field	Function
31-0 SOCCFG	SOC configuration This field configuration is specific to chip. For details, see chip-specific QuadSPI information.

74.10.2.11 Buffer 0 Top Index Register (BUF0IND)

Offset

Register	Offset
BUF0IND	30h

Function

This register specifies the top index for buffer 0, which defines its size. Note that the three LSBs of this register are set to 0. This ensures that the buffer is 64-bit aligned because each buffer entry is 64-bits long.

The register value should be set to the desired number of bytes. For example, setting BUF0IND[31:3] to 0 gives 0 bytes, setting the value to 1 gives 8 bytes, and so on.

The size of buffer 0 is the difference between BUF0IND and 0.

The software must ensure that the value of TPINDX0 is not greater than the size of buffer 0.

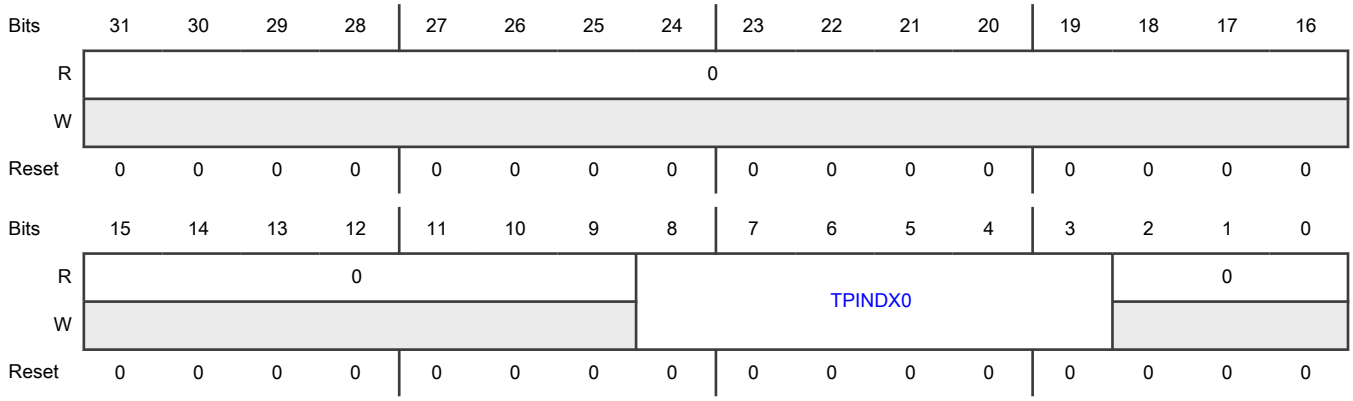
NOTE

The hardware does not provide any protection against illegal programming.

Special write-access is permitted if:

- SR[AHB_ACC] = 0

Diagram



Fields

Field	Function
31-9 —	Reserved
8-3 TPINDX0	Top index of buffer 0
2-0 —	Reserved

74.10.2.12 Buffer 1 Top Index Register (BUF1IND)

Offset

Register	Offset
BUF1IND	34h

Function

This register specifies the top index of buffer 1, which defines its size. Note that the three LSBs of this register are set to 0. This ensures that the buffer is 64-bit aligned because each buffer entry is 64-bits long.

The size of buffer 1 is the difference between BUF1IND and BUF0IND. The register value should be entered in bytes. For example, if BUF0IND = 0x100, then setting BUF1IND = 0x130 sets the size of buffer 1 to 0x30 bytes.

The software must ensure that the value of TPINDX1 is not greater than the size of buffer 1.

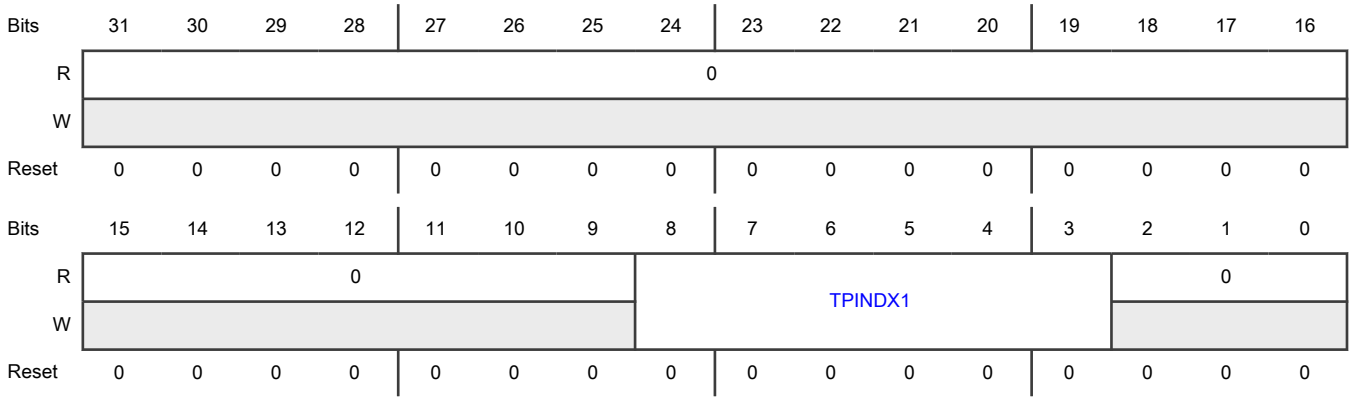
NOTE

The hardware does not provide any protection against illegal programming.

Special write-access is permitted if:

- SR[AHB_ACC] = 0

Diagram



Fields

Field	Function
31-9 —	Reserved
8-3 TPINDX1	Top index of buffer 1
2-0 —	Reserved

74.10.2.13 Buffer 2 Top Index Register (BUF2IND)

Offset

Register	Offset
BUF2IND	38h

Function

This register specifies the top index of buffer 2, which defines its size. Note that the three LSBs of this register are set to 0. This ensures that the buffer is 64-bit aligned because each buffer entry is 64-bits long.

The size of buffer 2 is the difference between BUF2IND and BUF1IND. The register value should be entered in bytes. For example, if BUF1IND = 0x130 then setting BUF2IND = 0x180 sets the size of buffer 2 to 0x50 bytes.

The software must ensure that the value of TPINDX2 is not greater than the size of buffer 2.

NOTE

The hardware does not provide any protection against illegal programming.

Special write-access is permitted if:

- SR[AHB_ACC] = 0

23-20 —	Reserved
19-16 SLV_FINE_OFFSET	Fine offset delay elements in incoming DQS This field sets the number of fine offset delay elements up to 16 in incoming DQS, and the default must be 1 element.
15 —	Reserved
14-12 SLV_DLY_OFFSET	T/16 offset delay elements in incoming DQS This field sets the number of T/16 offset delay elements in incoming DQS; default is 0.
11-8 SLV_DLY_COARSE	Delay elements in each delay tap This field sets the number of delay elements in each delay tap. The field is used to overwrite DLL-generated delay values and works when the value of SLV_DLL_BYPASS is 1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
7-5 —	Reserved
4 —	Reserved
3 —	Reserved
2 SLV_EN	Slave enable 0b - DLL slave logic remains in reset, and its value should be 0 for at least three flash memory clock cycles for reset. 1b - Enables DQS slave delay chain, and should be 1 before any slave configuration settings take place.
1 SLV_DLL_BYPASS	Slave DLL bypass This field enables selection of the number of delays in each slave delay tap. 0b - Disables manual selection of coarse delays in the slave delay chain. 1b - Enables selection of number of delays in each slave delay tap, based on DLLCRA[SLV_DLY_COARSE].
0 SLV_UPD	Slave update You must program this field only after slave delay chain configuration takes place. 0b - Disables any further update on DQS slave delay chain. 1b - Updates the DQS slave delay chain with either ref-delay or bypass slave delay value, and should be set in the absence of the DQS clock.

74.10.2.15 Serial Flash Memory Address Register (SFAR)

Offset

Register	Offset
SFAR	100h

Function

The module automatically translates this address on the memory map to the address on the flash memory. When operating in a 24-bit mode, only bits 23-0 are sent to the flash memory. In the 32-bit mode, bits 27-0 are used with bits 31-28 driven to 0 See Table 566 for the mapping between the access mode and the SFAR content and Normal mode for details on command triggering and command execution. The software must ensure that the serial flash memory address provided in the SFAR register lies in the valid flash memory address range, as defined in Table 566.

Special write-access is permitted if:

- SR[IP_ACC] = 0

74.10.2.16 Sampling Register (SMPR)

Offset

Register	Offset
SMPR	108h

Function

This register allows configuration of how the incoming data from the external serial flash memory devices is sampled in the QuadSPI module.

NOTE

See the chip data sheet for programming the register fields.

Special write-access is permitted in the disabled mode.

Diagram

R	0								RDBFL							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-16 RDCTR	Read counter Indicates the number of 4-byte entries removed from the RX buffer. For example, a value of 0x2 indicates that 8 bytes have been removed. It is incremented by the number (RBCT[WMRK] + 1) on RX buffer POP event. The RX buffer can be popped using DMA or FR[RBDF]. The RSER[RBDDE] defines which pop should be pursued. For details, see AHB RX Data Buffer Register (ARDB0 - ARDB127) and Data Transfer from the QuadSPI Module Internal Buffers.

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-8 —	Reserved
7-0 RDBFL	RX buffer fill level Indicates the number of 4-byte entries available in the RX buffer. For example, a value of 0x2 indicates 8 bytes are available.

74.10.2.18 RX Buffer Control Register (RBCT)

Offset

Register	Offset
RBCT	110h

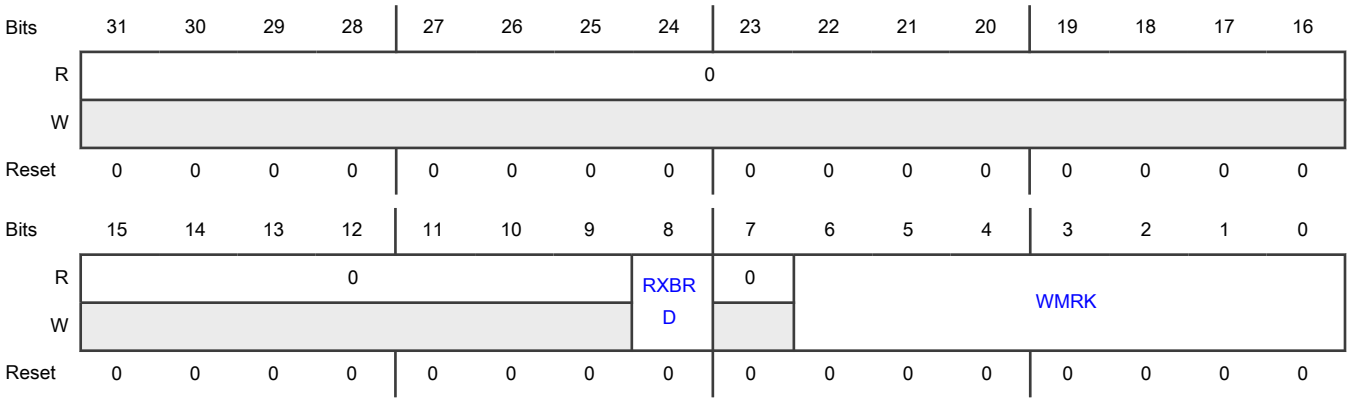
Function

This register contains control data related to the receive data buffer.

Special write-access is permitted if:

- SR[IP_ACC] = 0

Diagram



Fields

Field	Function
31-9 —	Reserved
8	RX buffer readout

Table continues on the next page...

Table continued from the previous page...

Field	Function
RXBRD	This field specifies the access scheme for the RX buffer readout. 0b — RX buffer content is read using the AHB bus registers. See AHB RX Data Buffer Register (ARDB0 - ARDB127). 1b — RX buffer content is read using the IP bus registers. See RX Buffer Data Register (RBDR0 - RBDR63).
7 —	Reserved
6-0 WMRK	RX buffer watermark This field determines when the readout action of the RX buffer is triggered. When the number of valid entries in the RX buffer is equal to or greater than the number given by (WMRK+1), the SR[RXWE] flag is asserted. The value should be entered as the number of 4-byte entries minus 1. For example, a value of 0x0 sets the watermark to 4 bytes, 1 to 8 bytes, 2 to 12 bytes, and so on. For details, see DMA usage.

74.10.2.19 Data Learning Status Flash Memory A Register (DLSR_FA)

Offset

Register	Offset
DLSR_FA	134h

Function

This register shows sampling point selected by data learning algorithm when the value of DLSR_FA[DLPFFA] is 0. Otherwise, it shows the pattern matching outline.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31 DLPFFA	Data learning pattern fail This field asserts when data learning fails at flash memory A.
30-16 —	Reserved
15-8 POS_EDGE	DLP positive edge match signature for flash memory A
7-0 NEG_EDGE	DLP negative edge match signature for flash memory A

74.10.2.20 TX Buffer Status Register (TBSR)

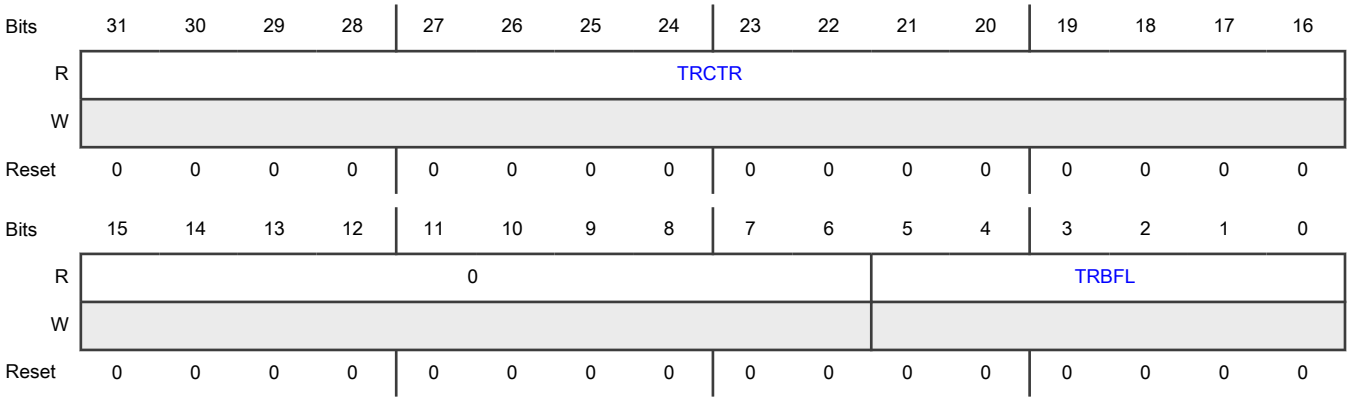
Offset

Register	Offset
TBSR	150h

Function

This register contains information related to the transmit data buffer.

Diagram



Fields

Field	Function
31-16	Transmit counter

Table continues on the next page...

Table continued from the previous page...

Field	Function
TRCTR	This field indicates how many entries of 4 bytes have been written into the TX buffer by host accesses. It is reset to 0 when a 1 is written to MCR[CLR_TXF]. It is incremented on each write access to the TBDR register when another word has been pushed onto the TX buffer. When it is not cleared, the TRCTR field wraps around to 0. See TX Buffer Data Register (TBDR) for details.
15-6 —	Reserved
5-0 TRBFL	TX buffer fill level This field contains the number of entries of 4 bytes each available in the TX buffer for the QuadSPI module to transmit to the serial flash memory device. The value of this field can reach maximum up to the total TX buffer size.

74.10.2.21 TX Buffer Data Register (TBDR)

Offset

Register	Offset
TBDR	154h

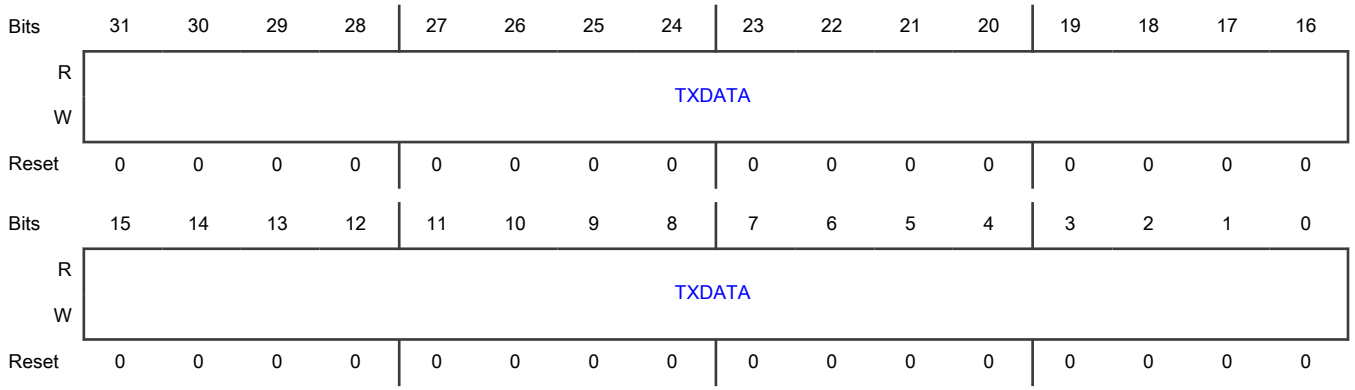
Function

This register provides access to the circular TX buffer of depth 32 , so the total size is 32 * 4 bytes. This buffer provides the data written into it as write data for the page programming commands to the serial flash memory device. See Table 546 for the byte ordering scheme. A write transaction on the flash memory with data size of less than 32 bits leads to the removal of one data entry from the TX buffer. The valid bits are used and the rest of the bits are discarded.

Special write-access is permitted if:

- SR[TXFULL] = 0

Diagram



Fields

Field	Function
31-0 TXDATA	TX data On write access, the data is written to the next available entry of the TX buffer and TBSR[TRBFL] is updated accordingly. On a read access, the last data written to the register is returned.

74.10.2.22 TX Buffer Control Register (TBCT)

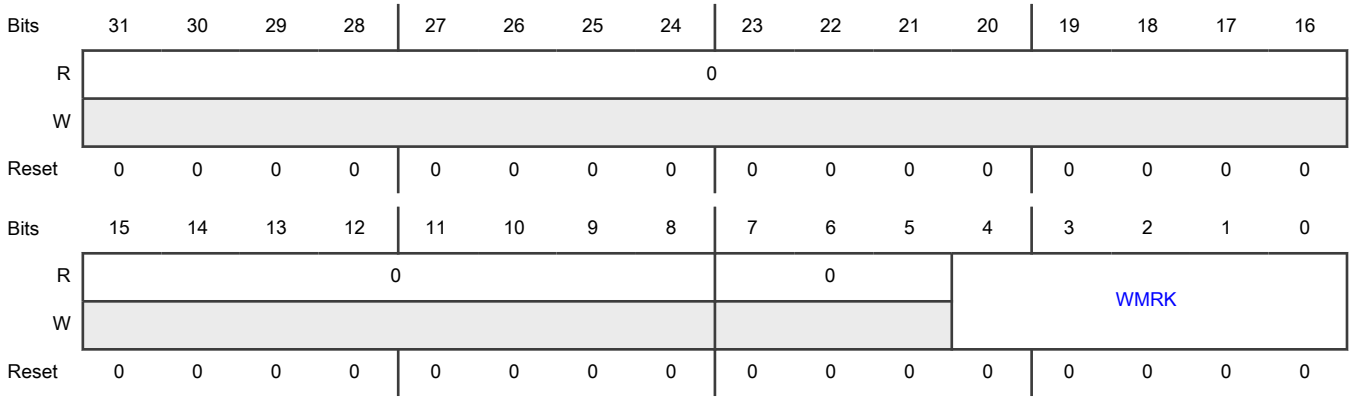
Offset

Register	Offset
TBCT	158h

Function

This register contains control information for transmit data buffer.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-5 —	Reserved
4-0 WMRK	Watermark for TX buffer Determines the watermark for the TX buffer

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When the number of available space in the TX buffer is greater than or equal to the number provided by WMRK (number of 4-byte entries), SR[TXWA] is asserted. For example, a value of 0x1 sets the watermark to 4 bytes, 0x2 sets it to 8 bytes, 0x3 sets it to 12 bytes, and so on. For details, see DMA usage. WMRK = 0 is invalid.

74.10.2.23 Status Register (SR)

Offset

Register	Offset
SR	15Ch

Function

This register provides all the available status information about SFM command execution and arbitration, the RX buffer, TX buffer, and the AHB buffer.

Diagram

26 TXDMA	TX DMA Asserted when the TXFIFO fill via DMA is active and DMA is requested or running
25 TXWA	TX buffer watermark available Asserted when the number of available spaces in the TX buffer is greater than or equal to the value provided by TBCT[WMRK]
24 TXNE	TX buffer not empty Asserted when TX buffer contains data
23 RXDMA	RX buffer DMA Asserted when RX buffer read out via DMA is active; that is, when DMA is requested or running
22-20 —	Reserved
19 RXFULL	RX buffer full Asserted when the RX buffer is full; that is, when RBSR[RDBFL] is equal to 32
18-17 —	Reserved
16 RXWE	RX buffer watermark exceeded Asserted when the number of valid entries in the RX buffer exceeds the number provided in RBCT[WMRK]
15 —	Reserved
14 AHB3FUL	AHB 3 buffer full Asserted when AHB 3 buffer is full
13 AHB2FUL	AHB 2 buffer full Asserted when AHB 2 buffer is full
12 AHB1FUL	AHB 1 buffer full Asserted when the AHB 1 buffer is full
11 AHB0FUL	AHB 0 buffer full Asserted when the AHB 0 buffer is full
10	AHB 3 buffer not empty

Table continues on the next page...

Table continued from the previous page...

Field	Function
AHB3NE	Asserted when the AHB 3 buffer contains data
9 AHB2NE	AHB 2 buffer not empty Asserted when the AHB 2 buffer contains data
8 AHB1NE	AHB 1 buffer not empty Asserted when the AHB 1 buffer contains data
7 AHB0NE	AHB 0 buffer not empty Asserted when the AHB 0 buffer contains data
6 AHBTRN	AHB access transaction pending Asserted when there is a pending request on the AHB interface. See Flash memory mapped AMBA bus.
5 —	Reserved
4 —	Reserved
3 —	Reserved
2 AHB_ACC	AHB read access Asserted when the currently executed transaction is initiated by the AHB bus
1 IP_ACC	IP access Asserted when transaction currently executed is initiated by the IP bus
0 BUSY	Module busy Asserted when module is currently busy handling a transaction to an external flash memory device

74.10.2.24 Flag Register (FR)

Offset

Register	Offset
FR	160h

Function

This register provides all available flags about SFM command execution and arbitration, which may serve as the source for the generation of interrupt service requests. Note that the error flags in this register do not relate directly to the execution of the transaction in the serial flash memory device itself but only to the behavior and conditions visible in the QuadSPI module.

Special write-access is permitted in the enabled mode.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W		W1C	W1C	W1C	W1C				W1C	W1C						W1C
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31 —	Reserved
30-29 —	Reserved
28 —	Reserved
27 TBFF	TX buffer fill flag Before writing to the TX buffer, this field should be cleared. Then, it should be read back. If it is set, the TX buffer can include more data. If the field remains cleared, the TX buffer can be considered as full. See TX buffer operation for details.
26 TBUF	TX buffer underrun flag This field is set if the module tries to pull data when the TX buffer is empty. The IP command leading to the TX buffer underrun is continued (data sent to the serial flash memory device is undefined). Here, a valid underrun means that it should have occurred during the transaction so that few bytes (that is, less than 4 bytes) are left in FIFO and the remaining are filled with "FFFFh". The software should initiate a TX transaction only when 128 bits are written in the TX buffer. This field does not set if transfer is less than 128 bits. The application must clear the TX buffer in response to this event by writing a 1 to MCR[CLR_TXF]. The application must clear the TX buffer in response to this event by writing a 1 to MCR[CLR_TXF].
25 —	Reserved
24 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
23 ILLINE	Illegal instruction error flag This field is set when an illegal instruction is encountered by the controller in any of the sequences. As soon as the field is set, you must assert MCR[SWRSTSD] and MCR[SWRSTHD]. That is, reset the flash memory and AHB domain after reconfiguring the correct sequence instruction. See Table 544 for a list of legal instructions.
22-21 —	Reserved
20 —	Reserved
19-18 —	Reserved
17 RBOF	RX buffer overflow flag This field is set when no more data can be pushed into the RX buffer from the serial flash memory device. The IP command leading to this condition is continued until the number of bytes in IPCR[IDATSZ] are read from the serial flash memory device. The content of the RX buffer remains unchanged.
16 RBDF	RX buffer drain flag This field is set if SR[RXWE] is asserted. Writing 1 to this field triggers one of the following actions: • If the RX buffer has up to RBCT[WMRK] valid entries, then the flag is cleared. • If the RX buffer has more than RBCT[WMRK] valid entries and the RSER[RBDDE] field is not set (flag driven mode), an RX buffer POP event is triggered. The flag remains set if the RX buffer contains more than RBCT[WMRK] valid entries after the RX buffer POP event is complete. The flag is cleared if the RX buffer contains less than or equal to RBCT[WMRK] valid entries after the RX buffer POP event is complete. See the "Receive Buffer Drain Interrupt or DMA Request" section in Normal mode interrupt and DMA requests for details.
15 —	Reserved
14 AITEF	AHB illegal transaction error flag This is set whenever there is no response generated from QuadSPI to AHB bus in case of an illegal transaction and the watchdog timer expires. The timer value is considered as a parameter.
13	AHB illegal burst size error flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
AIBSEF	This is set whenever the total burst size (size x beat) of an AHB transaction is greater than the prefetch data size, which is defined by BUFxCR[ADATSZ] or data size mentioned in the sequence pointed to by the SEQID field in case ADATSZ = 0. See HBURST support with AHB read details on HBURST feature.
12 ABOF	AHB buffer overflow flag This is set when the size of the AHB access exceeds the size of the AHB buffer. This condition can occur only if BUFxCR[ADATSZ] is programmed incorrectly. The AHB command leading to this condition is continued until the number of entries according to BUFxCR[ADATSZ] have been read from the serial flash memory device. The content of the AHB buffer is not changed.
11 —	Reserved
10 —	Reserved
9 —	Reserved
8 —	Reserved
7 IPAEF	IP command trigger during AHB access error flag This is set when the following condition occurs: • A write access occurs to IPCR[SEQID] and the SR[AHB_ACC] field is set. Any command leading to the assertion of the IPAEF field is ignored.
6 IPIEF	IP command trigger could not be executed error flag This is set when the SR[IP_ACC] and SR[AWRACC] fields are set (that is, an IP triggered command is currently executing) and any of the following conditions occurs: • Write access to the IPCR. Any command leading to the assertion of the IPIEF flag is ignored. • Write access to the SFAR • Write access to the RBCT
5 —	Reserved
4 —	Reserved
3-1	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
0 TFF	IP command transaction finished flag This field is set after the QuadSPI module completes a running IP command. If an error occurs, and the related error flags are valid in the same clock cycle, the TFF flag is asserted.

74.10.2.25 Interrupt and DMA Request Select and Enable Register (RSER)

Offset

Register	Offset
RSER	164h

Function

This register provides enables and selectors for the interrupts in the QuadSPI module.

NOTE

Each field of the FR enabled as source for an interrupt prevents the QuadSPI module from entering the Stop mode or Module Disable mode when this flag is set.

Special write-access is permitted in the "Anytime" mode.

74.10.2.26 Sequence Pointer Clear Register (SPTRCLR)

Offset

Register	Offset
SPTRCLR	16Ch

Function

This register provides fields to reset the IP and buffer sequence pointers. The sequence pointer contains the index of instructions within the LUT entry that is to be executed next. For example, if the LUT entry ends on a JMP_ON_CS value of 2, the index is stored as 2.

The software should reset the sequence pointers whenever the sequence ID is changed by updating the SEQID field in the IPCR or BFGENCR.

74.10.2.29 Serial Flash Memory B1 Top Address Register (SFB1AD)

Offset

Register	Offset
SFB1AD	188h

Function

This register provides the address mapping for serial flash memory B1. The difference between SFB1AD[TPADB1] and SFA2AD[TPADA2] defines the size of the memory map for serial flash memory B1.

Special write-access is permitted if:

- SR[IP_ACC] = 0
- SR[AHB_ACC] = 0

74.10.2.31 RX Buffer Data Register (RBDR0 - RBDR63)

Offset

For a = 0 to 63:

Register	Offset
RBDRa	200h + (a × 4h)

Function

These registers provide access to individual entries in the RX buffer. See Table 546 for the byte ordering scheme.

RBDR0 corresponds to the actual position of the read pointer within the RX buffer. The number of valid entries available depends on the number of RX buffer entries implemented and on the number of valid buffer entries available in the RX buffer.

Example 1 - RX buffer filled completely with 128 words: In this case, the address range for valid read access extends from RBDR0 to RBDR63.

Example 2 - RX buffer filled with five valid words: RX buffer fill level of RBSR[RDBFL] is 5. In this case, access to RBDR4 provides the last valid entry.

Any access beyond the range of valid RX buffer entries provides undefined results.

NOTE

To access data beyond RBDR[63], you must pop the data by using FR[RBDF]. See here for details.

74.10.2.32 LUT Key Register (LUTKEY)

Offset

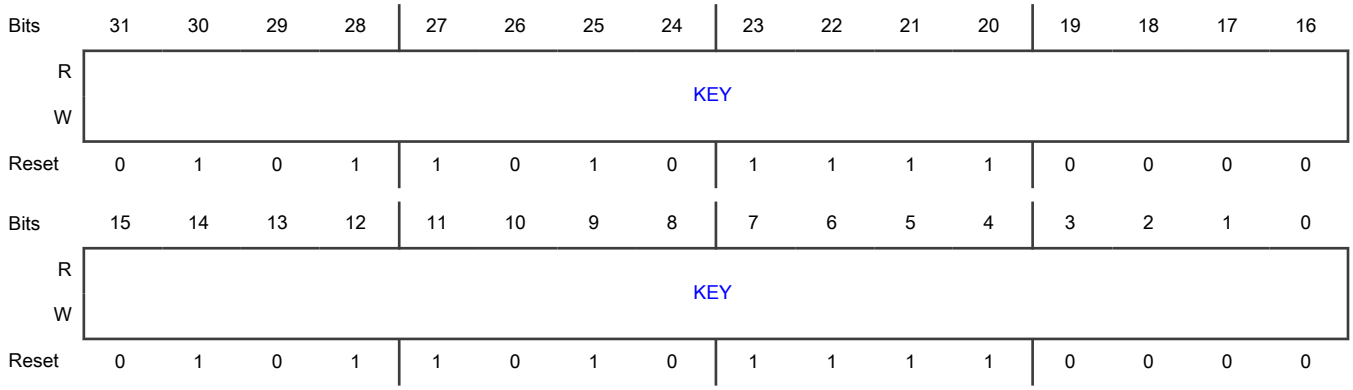
Register	Offset
LUTKEY	300h

Function

This register contains the key to lock and unlock the LUT. See LUT for details.

Special write-access is permitted in the "Anytime" mode.

Diagram



Fields

Field	Function
31-0 KEY	Key to lock or unlock the LUT The key is 0x5AF05AF0 and the read value is always 0x5AF05AF0.

74.10.2.33 LUT Lock Configuration Register (LCKCR)

Offset

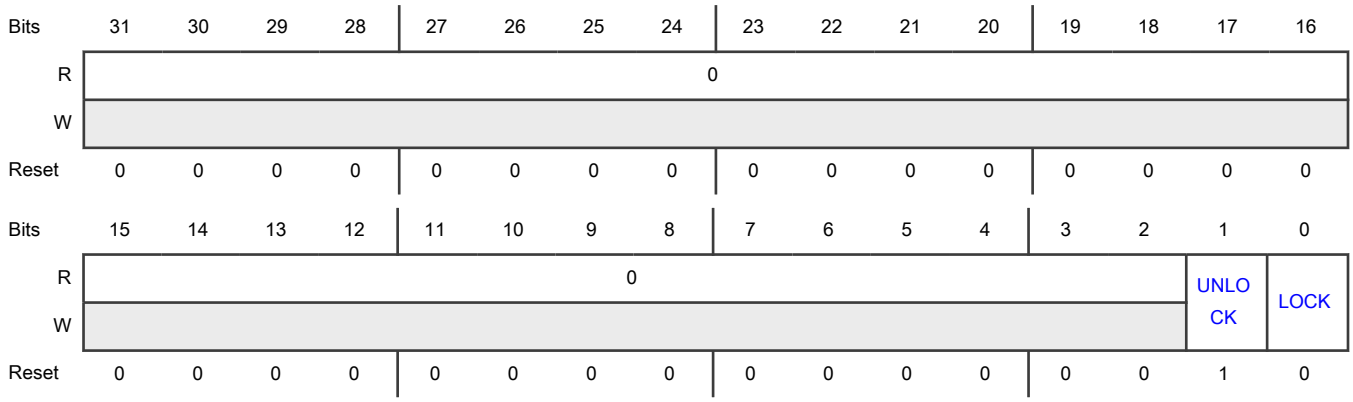
Register	Offset
LCKCR	304h

Function

This register is used along with the LUTKEY register to lock or unlock the LUT. This register should be written immediately after the LUTKEY register for the lock or unlock operation to be successful. See LUT for details. Setting both the LOCK and UNLOCK bits as "00" or "11" is not allowed.

Special write access is permitted after writing the LUT key register.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 UNLOCK	Unlock LUT Unlocks the LUT when the following two conditions are met: • This register is written just after the LUT Key Register (LUTKEY). • The LUT key register was written with the 0x5AF05AF0 key.
0 LOCK	Lock LUT Locks the LUT when the following conditions are met: • This register is written just after the LUT Key Register (LUTKEY). • The LUT key register is written with the 0x5AF05AF0 key.

74.10.2.34 LUT Register (LUT0)

Offset

Register	Offset
LUT0	310h

Function

A sequence of instruction-operand pairs may be pre-populated in the LUT according to the device connected on board. Each instruction-operand pair is of 16 bits (2 bytes) each. Every sequence preprogrammed by Program Sequence Engine in the LUT is referred to by its index. The LUT registers act as lookup tables for sequences of instructions. The programmable sequence engine executes the instructions in these sequences to generate a valid serial flash memory transaction. There are a total of 20 LUT registers. These 20 registers are divided into groups of 5 registers that make a valid sequence. Therefore, LUT[0], LUT[5], LUT[10] ..... LUT[15] are the starting registers of a valid sequence. Each of these sets of 5 registers can have a maximum of 10 instructions. Reset value of the register shown below is only applicable to LUT2 to LUT19. A maximum of 4 sequences can be defined at one time. See LUT that describes the LUT registers in detail.

Special write-access is permitted if the LUT is unlocked.

74.10.3 Serial flash memory address assignment

The serial flash memory address assignment can be modified by writing into Serial Flash Memory A1 Top Address Register (SFA1AD) and Serial Flash Memory A2 Top Address Register (SFA2AD) for device A

Table 566. Serial flash memory address assignment

Parameter	Function	Access mode
QuadSPI_AMBA_BASE ((31:10) - 22 bits)	QuadSPI AHB base address First address of the serial flash memory device as presented to the QuadSPI controller. This might be the base of the serial flash memory in the system address map or it may be a remapping, for instance to 0h, performed by the system. (See the system address map file attached to this document)	
QuadSPI_ARDB_BASE	First address of the QuadSPI Rx buffer on system memory map	
TOP_ADDR_MEMA1(TPADA1)	Top address for the external flash memory A1 (the first of the two independent flash memories sharing the IOFA)	Any access to the address space between TOP_ADDR_MEMA1 and QuadSPI_AMBA_BASE is routed to serial flash memory A1.
TOP_ADDR_MEMA2(TPADA2)	Top address for the external flash memory A2 (the second of the two independent flash memories sharing the IOFA)	Any access to the address space between TOP_ADDR_MEMA2 and TOP_ADDR_MEMA1 is routed to serial flash memory A2.

74.11 Flash memory mapped AMBA bus

QuadSPI_AMBA_BASE defines the address to be used as the start address of the serial flash memory device, as defined by the system memory map. Note that this may be a remapping of the physical address of the serial flash memory in the system. See the system address map for details.

Table 567. QuadSPI AMBA bus memory map

Address	Register name
QuadSPI_AMBA_BASE to (TOP_ADDR_MEMA2 - 1h)	• See Memory-mapped serial flash memory data—individual flash memory mode on flash memory A. • For information about byte ordering, see Table 546 and Table 547.
QuadSPI_ARDB_BASE to... (32 * 4 Byte) QuadSPI_ARDB_BASE + 1FFh	• See AHB RX Data Buffer Register (ARDB0 - ARDB127). • For information about the byte ordering, see Table 546.

NOTE

Any read access to non-implemented addresses provides undefined results.

In individual flash memory modes, the 3/4 address bytes (as programmed in the instruction/operand in the sequence) available for the flash memory address are determined by SFADR[23:0] or SFADR[31:0] as provided in the table shown above.

74.11.1 AHB bus access read considerations

Note that all logic in the QuadSPI module implementing the AHB bus access is designed to read the content of an external serial flash memory device. Therefore, the following restrictions apply to the QuadSPI module with respect to accesses to the AHB bus:

- Any AHB command resulting in the assertion of the FR[ABSEF] flag is answered with the ERROR condition according to the AMBA_AHB specification. The resulting AHB command is ignored.
- AHB bus read access types—NONSEQ and BUSY—are fully supported.
- AHB read access type—SEQ—is treated in the same way as NONSEQ. See Flash memory mapped AMBA bus for details.
- Early burst termination is not supported for AHB transactions.

74.11.2 Memory-mapped serial flash memory data—individual flash memory mode on flash memory A

Starting with address QuadSPI_AMBA_BASE, the content of the first external serial flash memory device is mapped into the address space of the device containing the QuadSPI module. Serial flash memory byte address 0h corresponds to bus address, QuadSPI_AMBA_BASE, in an increasing order. . See the following table for the address mapping. The byte ordering for 32-bit access is provided in Table 546 and for 64-bit read access, the byte ordering is provided in Table 547.

Table 568. Memory-mapped individual flash memory mode—flash memory A address scheme

Memory-mapped address 32-bit access	Memory-mapped address 64-bit access	Serial flash memory byte address	Flash memory device
QuadSPI_AMBA_BASE + 0h	QuadSPI_AMBA_BASE + 0h	0h to 3h	A1
QuadSPI_AMBA_BASE + 4h		4h to 7h	
...	...	...	
TOP_ADDR_MEMA1 - 8h	TOP_ADDR_MEMA1 - 8h	(TOP_ADDR_MEMA1- 8h) to (TOP_ADDR_MEMA1 - 0h4 -0h1)	
TOP_ADDR_MEMA1 - 4h		(TOP_ADDR_MEMA1 - 4h) to (TOP_ADDR_MEMA1 - 0h1)	
TOP_ADDR_MEMA1 + 4h	TOP_ADDR_MEMA1 + 0h	0h to 3h	A2
TOP_ADDR_MEMA1 + 0h4		4h to 7h	
...	...	...	
TOP_ADDR_MEMA2 - 8h	TOP_ADDR_MEMA2 - 8h	(TOP_ADDR_MEMA2 - 8h) to (TOP_ADDR_MEMA2 - 4h - 1h)	
TOP_ADDR_MEMA2 - 4h		(TOP_ADDR_MEMA2 - 4h) to (TOP_ADDR_MEMA2 - 1h)	

The available address range depends on the size of the external serial flash memory device. Any access beyond the size of the external serial flash memory provides undefined results.

For details concerning the read process, see Flash memory read.

74.11.3 ARDB register descriptions

NOTE

See the system memory map in this document for the base address of the QuadSPI AHB RX data buffer.

74.11.3.1 ARDB memory map

QuadSPI_ARDB base address: 6800_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h - 1FCh	AHB RX Data Buffer Register (ARDB0 - ARDB127)	32	RO	0000_0000h

74.11.3.2 AHB RX Data Buffer Register (ARDB0 - ARDB127)

Offset

For a = 0 to 127:

Register	Offset
ARDBa	0h + (a × 4h)

Function

This register is used to read the buffer content of the RX buffer from successive addresses. ARDB0 corresponds to the RX buffer register entry corresponding to the current value of the read pointer in an increasing order.

The increment of the read pointer depends on the access scheme (DMA or flag-driven). See Flash memory read, RX buffer, data read through register interface, and AHB read for the description of successive accesses to the RX buffer content. See Byte Ordering of Serial Flash Memory Read Data for the byte ordering scheme.

Valid address range accessible in the ARDB*n* range depends on the number of RX buffer entries implemented and on the number of valid buffer entries available in the RX buffer.

- Example 1 - RX buffer filled completely with 128 words: In this case, the address range for valid read access extends from ARDB0 to ARDB127.
- Example 2 - RX buffer filled with five valid words; RX buffer fill level RBSR[RDBFL] is 5. In this case, an access to ARDB4 provides the last valid entry.

Chapter 75
Debug Subsystem

75.1 Introduction

This chapter discusses the debug and trace architecture of the chip that is based on the specifications provided in the *Arm® CoreSight™ SoC-400 Technical Reference Manual*. See References for a link to this document and to other related documentation available on the Arm website.

The chip architecture includes debug and trace modules. See Features for details on the debug and trace features that Cortex-M7 core clusters support.

The debug components that the Cortex-M7 core supports are accessible via the Arm DAP controller-based architecture. The DAP controller works in parallel with the system JTAGC. Both these controllers share the JTAG port and JTAG instruction set.

The system components are similar for different chips in the same family and include the primary core debug interfaces, the chip-level debug interfaces, and chip-level trace interfaces. The accelerator components include debug and trace circuits. These circuits are necessary for any application-specific accelerators required for the different application spaces that a chip supports. They vary from one chip to another and could include only trace components.

75.2 Interfaces supported in MWCT2S family

Table 569. Interfaces supported in MWCT2S family

MWCT2D17S	MWCT2D16S	MWCT2016S / MWCT2015S / MWCT2014S
Cortex-M7_0 (CTI, DWT, BPU, ETM, ITM)	Cortex-M7_0 (CTI, DWT, BPU, ITM)	Cortex-M7_0 (CTI, DWT, BPU, ITM)

75.3 Block diagram

This figure illustrates the DAP architecture of the MWCT2xxxS family.

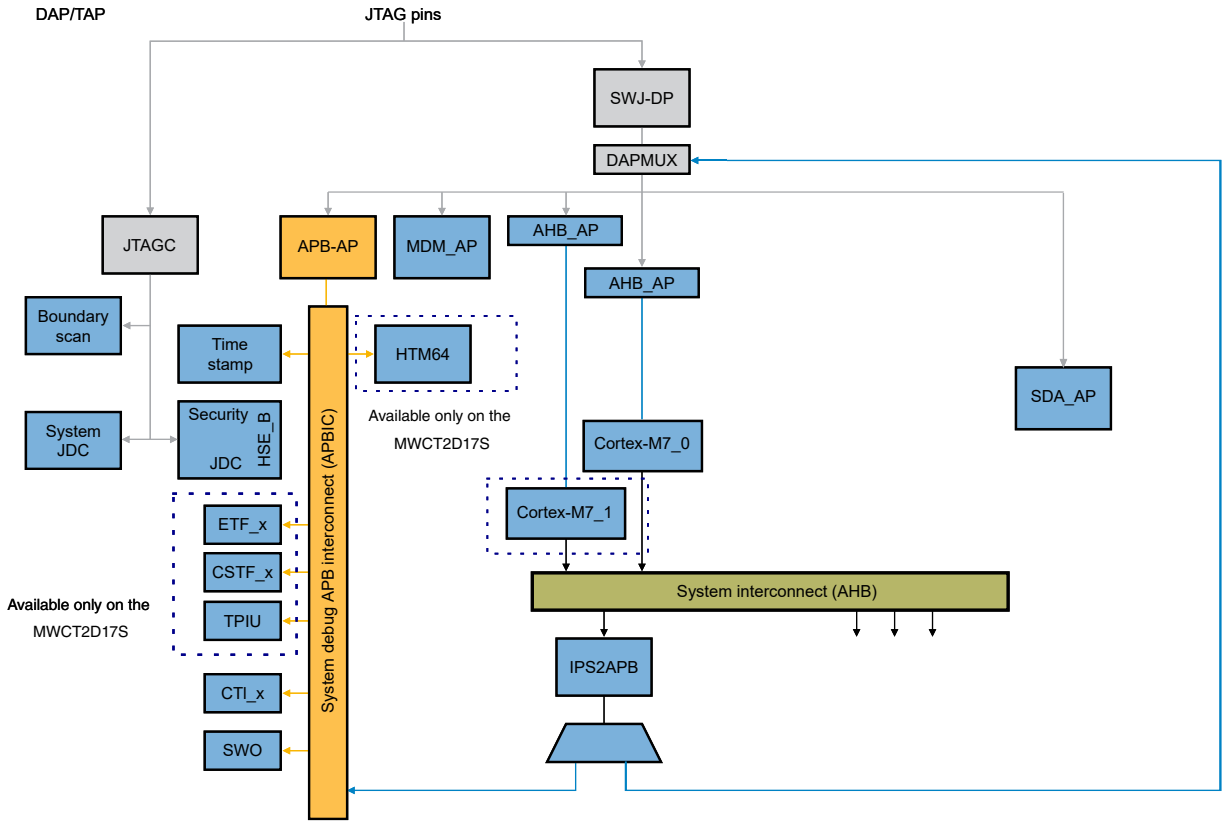

Figure 437. DAP architecture

NOTE

Debug components other than the Cortex-M0+ core are accessible through software path (CORE > AXBS > AIPS > DAPMUX > APs), that is, by directly specifying the memory mapped addresses without doing challenge response.

75.4 Features

This chip includes these features that support the functions listed under each feature type:

- Debug control
  - Is implemented via IEEE 1149.1-compliant JTAG
- Test control
  - Is implemented via IEEE 1149.1-compliant JTAG
  - Uses IEEE 1149.6 extension to IEEE 1149.1
- Trace interface
  - Includes four high-speed data pads and one clock pad up to 125 MHz (125 MB/s throughput per pad)
  - Includes 16 low-speed data pads and one clock pad @25 MHz (100 MB/s throughput per pad)
- Debug security
  - Includes a DAP/TAP interface that controls all debug features and is gated by Cortex M0+ JDC module
  - Includes security modes as described in the "Security" chapter
- Debugging and run control

  - Is implemented through stopping points, starting points, breakpoints, and watchpoints
  - Each Cortex-M7 core supports eight instruction comparators and a watchpoint unit having four watchpoints
- Trace source
  - Includes Cortex-M7:
    - ETM that provides instruction and data trace
    - ITM that provides DWT, time-stamping, and diagnostic information
- Cross-triggering support
  - Controls run-control options of cores based on other cores
  - Provides a matrix having connections to:
    - HTM via system CTI
    - All Cortex-M7 CPUs
- Ability to view and modify all memory-mapped areas that are not otherwise blocked—includes a system bus debug access port
- Performance monitoring of cores—implements a performance monitoring unit (PMU) on each Cortex core
- Safety
  - Supports monitoring of debug signals to avoid common mode faults
  - Allows checking of erroneous activation of debugging, especially if intrusive (for example, a CPU entering Debug state)
- Timestamps
  - Generates a timestamp bus for distribution to the trace sources
  - Includes a 48-bit binary timestamp bus
  - Clocks timestamp generator by a frequency given in Table 577

75.5 Debug

75.5.1 TAP connectivity

This figure shows a detailed view of TAP connectivity. JTAG select, SWJ-DP, and JTAG-DP are parts of DAP.

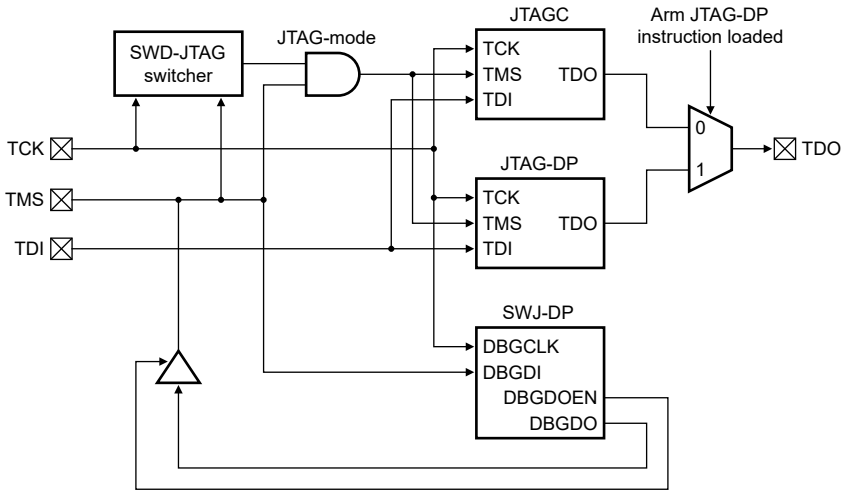

Figure 438. TAP connectivity

The debug port comes out of reset in a standard JTAG mode. It switches to another mode by using the change sequences. After the mode changes, unused debug pins can be reassigned to any of their alternative muxed functions.

JTAG-DP and JTAGC are connected in an overlay scheme and both have an Instruction Register (IR) length of 8 bits.

75.5.2 DAP TAP

DAP is an Arm component that provides multiple-master driving ports. A single external interface port accesses and controls these ports to provide system-wide debug.

The DAP Instruction Register (DAP IR) overlays with the system JTAG Instruction Register (JTAGC IR). Table 570 presents DAP instructions. In addition to the four codes listed in the table, DAP uses BYPASS, which is identical to JTAGC BYPASS and is therefore not shown in the table.

Table 570. DAP IR codes

Code	DAP IR
1111_1000b	ABORT
1111_1010b	DPACC
1111_1011b	APACC
1111_1110b	IDCODE

DAP offers an AHB master interface to access system buses. It also exports the internal DAP bus to extend the access ports. For more information on DAP TAP, see the *Arm Debug Interface Architecture Specification* document available in References.

In this chip:

- The AHB slave ports of all Cortex-M*x* cores provide debugger access to all memory units and registers in the system.
- The new pass-through approach allows the debugger to see a cache coherent view of the memory map for that core.
- The debugger must access the corresponding AHB_AP port to access the AHB-S port of that subsystem.
- XRDC controls system access.
- A core can access the debug components of another core through a DAPMUX to the bus interconnect.
- The exported DAP bus hosts AHB_AP and MDM_AP.
  - MDM_AP hosts system-level JTAG status and control registers (see MDM_AP register descriptions). These registers can be used for cross triggering, synchronized debug, and other miscellaneous control and status functions.
  - APB_AP uses an APSEL value of 1h to access any APB-mapped debug modules.

Table 574 describes the access addresses of APB-mapped debug modules. The value of the DAP select signal in the APSEL field of SWJ-DP's Select register selects the access ports in the DAP. Table 571 shows APSEL decoding.

Table 571. DAP master address mapping

DAP master #	DAP component	DAPBUS base address (access from debugger) [1]	System memory map address (access from cores)		Selected port or master	Applicability
			Page number	Base address		
0h	Reserved	0000_0000h	0	4025_0000h	Reserved	-

Table continues on the next page...

Table 571. DAP master address mapping (continued)

DAP master #	DAP component	DAPBUS base address (access from debugger) [1]	System memory map address (access from cores)		Selected port or master	Applicability
			Page number	Base address		
1h	APB_AP to all APB-mapped debug modules (for example, ETFs, HTM, and trace funnels)	0100_0000h	0	4025_0100h	APB_AP to all APB-mapped debug modules (for example, ETFs, HTM, CSTF, and so on)	MWCT2D17S (for ETF, HTM, and CSTF see Table 569)
2h	Reserved	0200_0000h	0	4025_0200h	Reserved	-
4h	AHB_AP to Cortex-M7_0 debug modules and chip system memory map	0400_0000h	0	4025_0400h	AHB_AP to Cortex-M7_0 debug modules and chip system memory map	All
5h	AHB_AP to Cortex-M7_1 debug modules and chip system memory map	0500_0000h	0	4025_0500h	AHB_AP to Cortex-M7_1 debug modules and chip system memory map	MWCT2D17S, MWCT2x16S
6h	MDM_AP	0600_0000h	0	4025_0600h	MDM_AP	All
7h	SDA_AP	0700_0000h	0	4025_4700h	SDA_AP used for challenge-response (CR) in SWJ-DP mode	All
9h—FFh	Reserved (default AP response)	—	—	—	—	—

1. For example, 4025_XXYYh address is provided when accessing access ports (APs) via the debugger. Here, XX shows the AP select number and YY shows the address to be accessed. If you access MDM_AP via the cores on 4h, you must provide the address 4025_0604h

NOTE

Accessing SDA_AP simultaneously from the core and the debugger is prohibited. If you try to do so, you may receive unpredictable responses to core-initiated transactions (for example, incorrect data read, a failed attempt to write to the register, or a transfer error). Debugger-initiated transactions proceed correctly.

75.5.3 System JTAGC

JTAGC connects in parallel with the TAP controller (JTAG-DP of DAP), which has an IR length of 8 bits. The JTAGC IR codes overlay the ones of the DAP controller. DAP uses four instructions and JTAGC uses the remaining ones. The TAP outputs (TPOs) are multiplexed based on the selected IR code. This chip is fully JTAG-compliant and appears as a single TAP to the JTAG chain.

This table shows the JTAGC IR codes. The instructions that are used by Arm DAP TAP are shown in Table 570.

Table 572. JTAG instructions for JTAGC

Code	JTAGC IR

75.5.3.1 Chip JTAG/Target ID

Each chip in the MWCT2xxxS family includes a unique JTAG ID, which must be changed when instantiated with a different die in an SiP. The next table shows the JTAGC ID for this chip.

Table 573. JTAG/Target ID

Chip	PRN	DC	PIN	MIC	IDCODE ID	JTAG ID	Target ID
MWCT2D17S	0	26h (38d)	160h (352d)	Eh (14d)	1	0996_001Dh	0996_001Dh
MWCT2015S	0	26h (38d)	16Ch (364d)	Eh (14d)	1	0996_C01Dh	0996_C01Dh
MWCT2016S	0	26h (38d)	168h (360d)	Eh (14d)	1	0996_801Dh	0996_801Dh
MWCT2D16S	0	26h (38d)	164h (356d)	Eh (14d)	1	0996_401Dh	0996_401Dh

75.5.3.2 JDC

JDC allows you to access two 32-bit data registers by using the JTAG interface and by software running on one of the CPUs in the chip. These registers exchange data between an internal CPU and an external debug tool.

75.5.4 Peripheral IPG debug implementation

Any core can control a peripheral instance individually. You define the core's control over a peripheral during application development.

For peripheral halt, all individual cores have the same capability and are gated by a dedicated MDM_AP core halt register field. For more information, see the configurations defined in MDM_AP register descriptions.

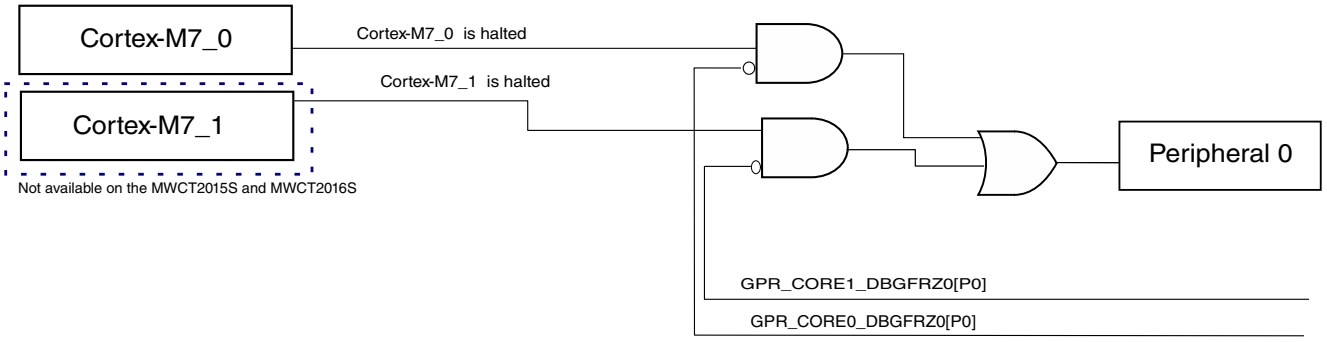

Figure 439. Peripheral IPG debug implementation

75.5.5 Application debugging

This section covers the following two cases:

- Case 1: Debugger connected—application debugging from the first instruction
- Case 2: Debugger not connected

75.5.5.1 Application debugging from first instruction

This chip supports debugging from the first instruction on system power-up, destructive reset, functional reset, and standby exit. However, by default, debugging from the first instruction is disabled.

The next figure shows the timing diagram of application debug implementation from first instruction on system power-up or destructive reset.

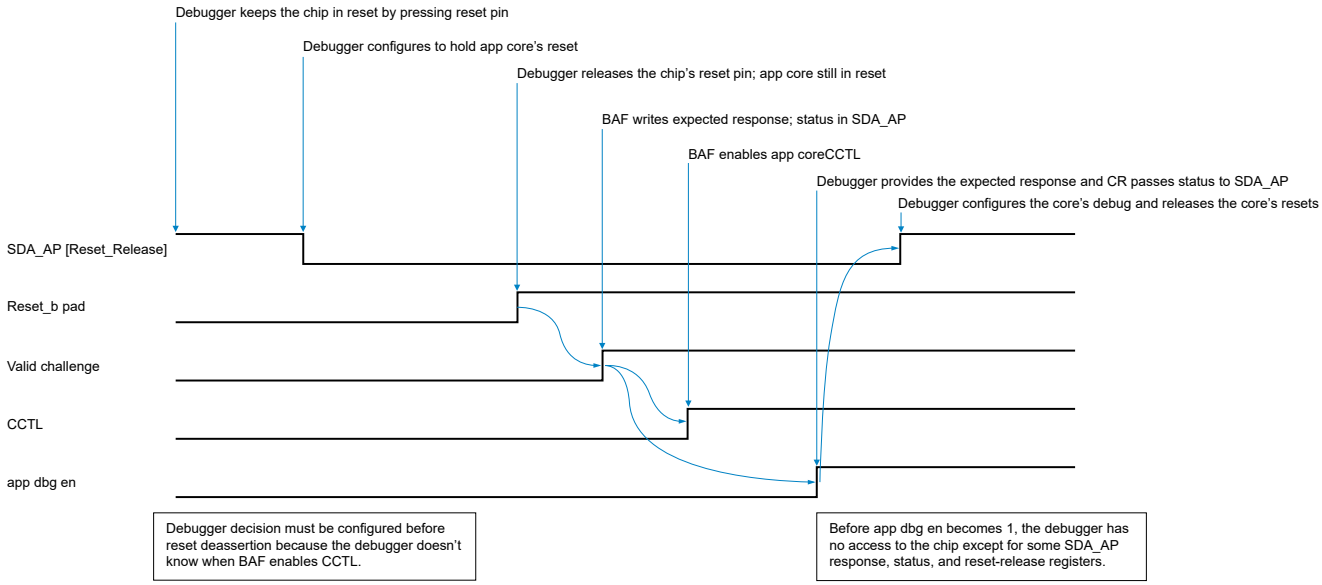

Figure 440. Application debug implementation from first instruction

These are the steps involved in enabling application debug from the first instruction on system power-up or destructive reset:

1. After the reset is applied, the debugger provides an option to debug from the first instruction. To do this:
   a. Write 1 to SDAAPRSTCTRL[RSTRELTLCM70].
   b. Set the reset value of Reset Control (SDAAPRSTCTRL).
2. Cortex M0+ starts after the reset pin is released.
3. Debugger challenge-response (CR) starts.
4. Cortex-M7_0 and Cortex-M7_1 remain in reset until MC_ME's PRTN0_CORE0_PCONF[CCE] field becomes 1 for Cortex-M7_0 and PRTN0_CORE1_PCONF[CCE] field becomes 1 for Cortex-M7_1.
5. When BAF or FW writes 1 to MC_ME's PRTN0_CORE0_PCONF[CCE] field for Cortex-M7_0 and to PRTN0_CORE1_PCONF[CCE] field for Cortex-M7_1, and the debugger CR has passed:
   - If the value of SDAAPRSTCTRL[RSTRELTLCM70] is 0 for the core, the debugger configures the core debug registers and then enables these fields that start the code execution.
   - If the value of SDAAPRSTCTRL[RSTRELTLCM70] is 1 for the core, the debugger configures the core debug registers and then enables these fields that start the code execution.

To debug from the first instruction during the low-power debug protocol, the debugger:

1. Writes 0 to SDAAPRSTCTRL[RSTRELTLCM70] for the cores.
2. Writes 1 to MDMAPWIRREL[WTRSTRGM].

75.5.5.2 Debugger not connected

If the debugger is not connected, the value of the DBGPWRUP_ACK signal is 0 as there is no DBGPWRUP_REQ. This results in the following scenario:

1. The booting core writes 1 to MC_ME's PRTN0_CORE0_PCONF[CCE] field for Cortex-M7_0 and to PRTN0_CORE1_PCONF[CCE] field for Cortex-M7_1.
2. The application core starts running. In case of Lock-step mode, the checker core executes the same code after a delay of two cycles.

75.5.6 Debugger considerations while flash program/erase

The flash programming can be done by application cores as well as debugger. The debugger can program/erase flash using either of the following two options:

1. Loading the program/erase code to SRAM from the debugger and then executing the program/erase sequence by application code from SRAM.
   - Debugger is connected and authenticated.
   - The debugger loads the code in the form of application binary image into the on-chip SRAM.
   - The debugger then initiates the application core to execute the binary from SRAM.
2. Debugger executing the program/erase sequence.
   - Debugger is connected and authenticated.
   - The debugger then initiates the flash programming by reading/writing the registers involved and following the program/erase sequence.

First option is the recommended because of less execution time. In second option, the debugger is the master and since the debug interface is serial, the execution takes more time.

In some cases, you might experience flash program/erase failure due to flash watchdog timeout when debugger executes the flash program/erase sequence due to the serial interface. Therefore, it is recommended to use the first option. In case second option is required, it should be performed in reduced clocking options (Option E and E2 only. For details, refer to the **Clocking details** section in the **Clocking** chapter).

75.5.7 SWJ-DP sequence for debug authentication

To perform the SWJ-DP sequence for debug authentication, the debugger:

1. Polls the AUTHSTTS[CHALRDY] field until it indicates the challenge status.
2. Reads Key Challenge (KEYCHAL0 - KEYCHAL7) if the challenge is valid and creates an authenticated 256-bit response key.
3. Writes a 256-bit response key to Key Response (KEYRESP0 - KEYRESP7).
4. Indicates that the response is ready by configuring AUTHCTL[HSEAUTHREQ].
5. Checks the status of Authentication Status (AUTHSTTS) to evaluate if the operation is successful.

   If the authentication process is successful and the debugger has write access to Debug Enable Control (DBGENCTRL), the challenge or response is considered successful too.

NOTE

SDA_AP supports challenge and response based on both JTAG and SWJ-DP modes. See SDAAPGENCTRL0[JTAG_CR_EN] for details.

75.6 APB memory map

You can access the debug registers via the APB_AP bus. The next table shows all the addresses for the CoreSight APB components and the addressing used for accessing the DAP components via the memory interface. You can also access all APB registers from the processing cores.

Table 574. APB components mapping

Debug APB component	APBIC base address (access from debugger)	System memory map address (access from cores)		Memory allocation (KB)	APB-AP0 slot number	Applicability
		Page number	Base address			
APB_AP ROM table	F8h	0	4024_00F8h	4	APBIC base	All
Funnel 0	1000h	0	4024_1000h	4	0	ETM/ ITM:MWCT2D17S ITM: MWCT2016S, MWCT2014S, MWCT2D16S
Funnel 1	2000h	0	4024_2000h	4	1	MWCT2D17S
Funnel 2	3000h	0	4024_3000h	4	2	MWCT2D17S
CM7_cluster_ETF_ETMI	4000h	1	4024_4000h	4	3	MWCT2D17S
CM7_cluster_ETF_ETMD	5000h	1	4024_5000h	4	4	MWCT2D17S
HTM ETF	6000h	1	4024_6000h	4	5	MWCT2D17S
Shared_system_ETF	7000h	1	4024_7000h	4	6	MWCT2D17S
HTM 0	8000h	2	4024_8000h	4	7	MWCT2D17S
HTM 0 CTI	9000h	2	4024_9000h	4	8	MWCT2D17S
TPIU	A000h	2	4024_A000h	4	9	MWCT2D17S
System SWO	B000h	2	4024_B000h	4	10	All
Timestamp CTL	C000h	3	4024_C000h	4	11	All

Funnel 0 should be configure to buffer the data coming from the different sources, to avoid padding data with null packets that affect the bandwidth.

75.7 Trace

75.7.1 Trace modules and connectivity

The Trace subsystem:

- Combines trace data from all internal clients that generate trace information
- Includes a 32-bit TPIU
- Includes these components:
  - ATB
  - ATBR

— CSTF

— Debug APB

— ETF

— TPIU

Multiple options for trace output allow parallel tracing. Trace information can be read from the trace interface or the DAP interface, and traces can be alternatively read out from ETF at a slow speed via APB_AP. Table 575 shows EFT sizes.

Table 575. ETF sizes

FIFO	Memory interface data width (in bits)
Cortex-M7 ETM/ITM cluster ETF	64
Cortex-M7 ETMD cluster ETF	128
HTM ETF	64
Shared system ETF	64

NOTE

- The DMA-HTM trace supports four words at 80 MHz. For HTM trace, both DBGENCTRL[GSPNIDEN] and DBGENCTRL[GSPIDEN] must be 1.
- Enabling any one of data trace causes overflow inside ETM and trace packets get dropped. Enabling instruction trace of both the core simultaneously does not cause any overflow.

Control (MDMAPCTL) provides fields to override the speed control (see Table 576 for details) from some of the trace sinks (and TPIU). The complete trace pipeline bandwidth is limited by the slowest sink component. The default settings of these fields allow maximum bandwidth for the TPIU to trace. When tracing to memory (if supported), the fields may need to be changed.

Table 576. Trace output overrides

Trace destination	SWO_override	TPIU_override
TPIU	1	0

The trace sources of the chip are the cores and their related modules. Trace funnels exist for all possible trace clients. For more information on the various components in the trace bus connectivity, see the *CoreSight Components Technical Reference Manual* (available in References). See Table 577 for details on funnel assignments.

The ATBR is integrated to send a shared funnel output across TPIU. This figure illustrates the chip's detailed trace architecture.

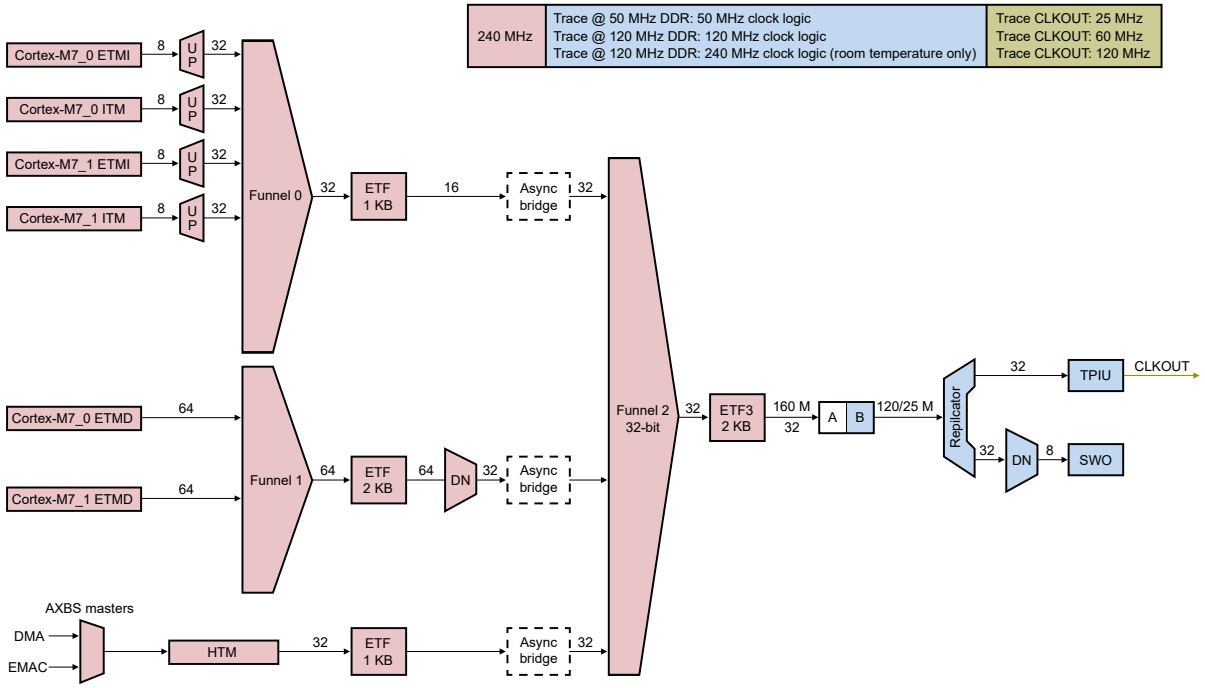

Figure 441. MWCT2D17S detailed trace architecture

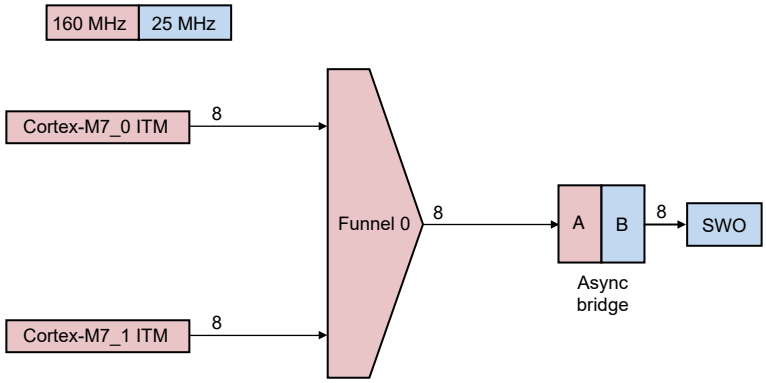

Figure 442. MWCT2D16S detailed trace architecture

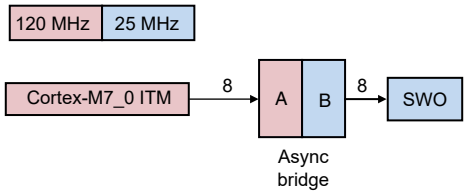

Figure 443. MWCT2016S/MWCT2015S detailed trace architecture

Table 577. Funnel assignments

Funnel	Port	Input	Frequency (MHz)	Applicability
			MWCT2015S/ MWCT2016S	
0	0	Cortex-M7_0 ETMI		MWCT2D17S
0	2	Cortex-M7_1 ETMI		MWCT2D17S
0	3	Cortex-M7_1 ITM		MWCT2D17S
1	0	Cortex-M7_0 ETMD		MWCT2D17S
1	1	Cortex-M7_1 ETMD		MWCT2D17S
1	4-7	Reserved		-
2	0	Cortex-M7 instruction ETF through an asynchronous bridge		MWCT2D17S
2	1	Cortex-M7 data ETF through an asynchronous bridge		MWCT2D17S
2	2	HTM ETF through an asynchronous bridge		MWCT2D17S
2	3-7	Reserved		-

75.7.1.1 Chip's bus trace client

Chips in the MWCT2xxxS family include a bus trace client.

HTM provides the address and data trace information about AXBS buses. The information from an HTM can be used with the debugger to enable easy, accurate debugging on AXBS-based embedded systems. The chip implements an HTM64 configuration to trace 64-bit AXBS masters in the system. To simplify the implementation, instead of tracing the individual ports of various AXBS masters and slaves, which may be running at different frequencies, HTM64 snoops the AXBS crossbar master ports that are all synchronous with a 160 MHz system clock. This table provides details related to the HTM input connectivity.

Table 578. HTM connections

HTM64 port	AHB crossbar port
HTMBUSSELECT0	M0 AXBS_Lite XBIC (DMA)
HTMBUSSELECT1	M3 AXBS (Ethernet)
HTMBUSSELECT2	M6 AXBS (Ethernet 2)

75.7.1.2 TPIU interface

A standard 16-bit parallel TPIU is integrated into the debug subsystem. Chips in the MWCT2xxxS family generate the trace via the trace port.

To prevent instruction trace from being dropped in a multi-core environment, a TPIU throughput of 55.2 MB/s or higher must be maintained. You could use these pin and frequency combinations:

- Four high-speed data + one clock pads @120 MHz (240 Mbit/s throughput per pad) totaling 120 MB/s
- 16 low-speed data + one clock pads @25 MHz (50 Mbit/s throughput per pad) totaling 100 MB/s

High-end chips from the MWCT2xxxS family support at least 56 MB/s of trace throughput on the TPIU interface.

Table 579. Throughput

Core	Throughput value	Applicability
Cortex-M7_0	27.6 MB/s	MWCT2D17S
Cortex-M7_1	27.6 MB/s	MWCT2D17S, MWCT2D16S
Total	82.8 MB/s	

75.7.1.3 TPIU flush

To allow the chip to enter Standby mode, software executes an WFI instruction indicating Standby entry. When the chip enters this mode, MC_RGM asserts a trace flush request to the TPIU and waits for a trace flush done signal from the TPIU before requesting MC_PCU to proceed. The TPIU and debug infrastructure clocks can be gated after this. Because the TPIU is sourced from system clock, the clock must not be gated until this point.

75.7.1.4 Trace through reset

All debug and trace components (HTM, ETM, ETF, and so on) are on destructive reset. When tracing through reset, the clock switches from PLL to FIRC. It is recommended to preserve the following pad configurations across reset, which are performed through MDMAPCTL[DBGRSTFASTPAD] and MDMAPCTL[DBGRSTSLOWPAD]:

- Four high-speed data + one clock pads @120 MHz (240 Mbits/s throughput per pad) totaling 120 MB/s
- 16 low-speed data + one clock pads @25 MHz (50 Mbits/s throughput per pad) totaling 100 MB/s

The implementation involves writing 1 to MDMAPCTL[DBGRSTFASTPAD] or MDMAPCTL[DBGRSTSLOWPAD], depending on which set of trace pads you need to enable. These fields also control:

- The trace pad mux.
- The "obe" of the trace pads, which, if configured, is retained over functional reset because the reset is controlled using the above-mentioned corresponding fields.

75.8 Embedded cross trigger (ECT)

ECT allows multi-core run control and trace cross-triggering, such as synchronous stop-start for all cores or trigger trace on a trigger event from another core or module. See the *CoreSight Components Technical Reference Manual* (available in References) for detailed information on ECT.

ECT architecture involves CTMs and CTIs. The CTIs provide a cross-triggering interface between the cores and other debug and trace modules. The channels of these CTIs are interconnected using CTMs, as shown in this figure.

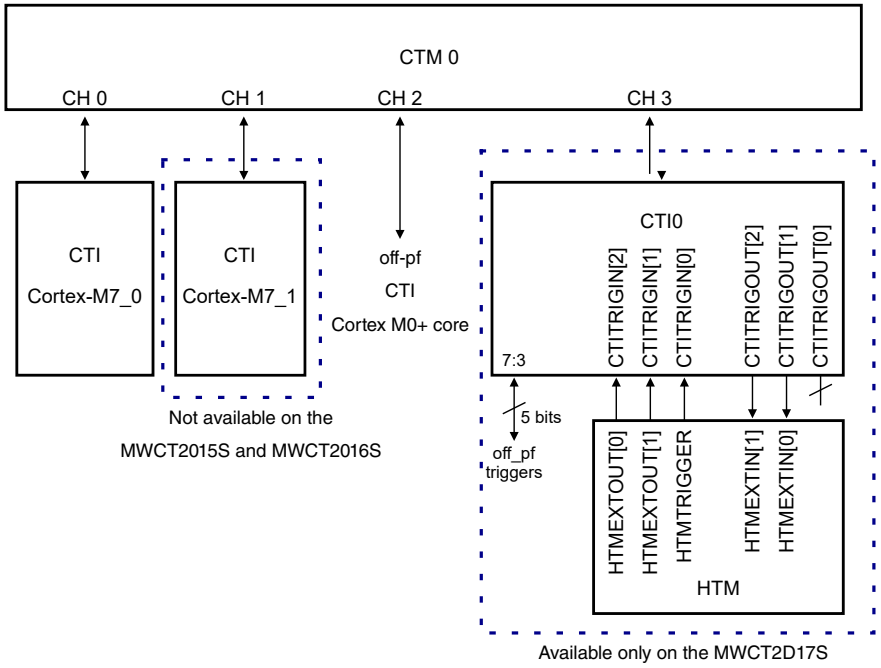

Figure 444. ECT

75.8.1 CTI assignments

Table 580. CTI assignments

CTI instance	Trigger number	Trigger in	Trigger out
CTI_Cortex-M7_0	7	ETM event output 3	Processor restart
	6	ETM event output 2	ETM event input 3
	5	ETM event output 1	ETM event input 2
	4	ETM event output 0	ETM event input 1
	3	DWT comparator output 2	ETM event input 0
	2	DWT comparator output 1	Interrupt request 1
	1	DWT comparator output 0	Interrupt request 0
	0	Processor halted	Processor debug request
CTI_Cortex-M7_1	7	ETM event output 3	Processor restart
	6	ETM event output 2	ETM event input 3
	5	ETM event output 1	ETM event input 2
	4	ETM event output 0	ETM event input 1
	3	DWT comparator output 2	ETM event input 0
	2	DWT comparator output 1	Interrupt request 1

Table continues on the next page...

Table 580. CTI assignments (continued)

CTI instance	Trigger number	Trigger in	Trigger out
	1	DWT comparator output 0	Interrupt request 0
	0	Processor halted	Processor debug request
CTI_Cortex-M7_2	7	ETM event output 3	Processor restart
	6	ETM event output 2	ETM event input 3
	5	ETM event output 1	ETM event input 2
	4	ETM event output 0	ETM event input 1
	3	DWT comparator output 2	ETM event input 0
	2	DWT comparator output 1	Interrupt request 1
	1	DWT comparator output 0	Interrupt request 0
	0	Processor halted	Processor debug request
CTI_Cortex-M7_3	7	ETM event output 3	Processor restart
	6	ETM event output 2	ETM event input 3
	5	ETM event output 1	ETM event input 2
	4	ETM event output 0	ETM event input 1
	3	DWT comparator output 2	ETM event input 0
	1	DWT comparator output 0	Interrupt request 0
	0	Processor halted	Processor debug request
	2	DWT comparator output 1	Interrupt request 1
CTI_0	7	Reserved (grounded)	Reserved (no connection)
	6	ETF_3 full	ETF_3 trigger input
	5	ETF_2 full	ETF_2 trigger input
	4	ETF_1 full	ETF_1 trigger input
	3	ETF_0 full	ETF_0 trigger input
	2	HTM trigger out 2	HTM trigger in 2
	1	HTM trigger out 1	HTM trigger in 1
	0	Reserved	HTM trigger in 0

75.9 Low-power debug handshake protocol

The debugger must perform this sequence to enter or exit Standby mode, if the debugger handshake is enabled:

1. Power on DAP.

   The debugger connection is established.

2. Configure the Debug subsystem for the relevant operations.

3. Write 1 to MDMAPWIREN[LWPWREN] to gate entry into Standby mode with the debugger handshake. If TPIU is disabled, write 1 to MDMAPWIREN[LWPRSTPRVT] too.

4. Disable POR_WDG for monitoring the entry to or exit from Standby mode by writing 1 to DCM's DCMRWP1[8] field. This is required for low-power debug handshake because debugger configurations can be more time consuming than the POR_WDG threshold levels and can raise a false POR_WDG event.
5. Write 1 to DCMRWF1[STANDBY_IO_CONFIG] in the Device Configuration Module (DCM). This causes padkeeping to be disabled on standby entry itself without any software dependency. This is needed in case of low-power debug since otherwise the padkeeping on TDO would result in no debugger communication. In other cases, DCMRWF1[STANDBY_IO_CONFIG] should be configured as 0 before standby entry.
6. Initiate entry into Standby mode. See the "Power Management" chapter for the Standby mode entry sequence and configurations.
7. Identify whether the low-power debug is enabled on the low-power entry.
   - If low-power debug is enabled and TPIU is enabled too, trace flush starts, and the debugger acknowledges the following:
     — Low-power debug traces
     — DAP-related configuration reception and context saving

     After this, the chip enters Standby mode.
   - If TPIU is disabled:
     — The debugger acknowledges DAP-related configuration reception and context saving by writing 1 to MDMAPWIRREL[PRVNTRSTRGM].

     After this, the chip enters Standby mode.
   - If low-power debug is disabled, the chip enters Standby mode without waiting for debugger acknowledgment.

   On any wakeup event, the chip starts the Standby mode exit sequence described in the "Power Management" chapter. After the chip exits Standby mode, the debugger connection is restored. By this time, the debugger is already aware that it has enabled the low-power debug handshake. In this case, the debugger must poll MDMAPSTTS[DESTRST] to check whether:
   - The debug infrastructure is out of reset.
   - The DAP connection can be established.

   After DAP is powered on (the debugger connection is established), the debugger:
   a. Reconfigures the debug and trace attributes using the fields in DBGENCTRL
   b. Writes 1 to MDMAPWIRREL[WTRSTRGM] after the debugger trace context is restored

      The chip exits Standby mode.

      If low-power debug is not configured, the chip exits Standby mode without waiting for the debugger to write to MDMAPWIRREL[WTRSTRGM].
8. Reconfigure the debug and trace configuration in SDA_AP register descriptions after the chip exits Standby mode.

NOTE

If the chip wakes up from Standby mode through pad reset, the debugger must perform a CR again.

75.10 Debug resets

The debug subsystem follows this sequence on the source of reset:

1. POR resets the complete debug logic.
2. The destructive reset resets all types of debug logic except JTAGC.

Conversely, the debug subsystem can generate a system reset using these mechanisms:

- System destructive reset defined in Control (MDMAPCTL) that allows the debugger to provide the destructive reset to the system. The debugger loses connection to the system with this reset.

- System functional reset defined in Control (MDMAPCTL) that allows the debugger to hold the system in functional reset.

To program various debug registers, the functional clocks must be enabled. All debug and trace components must be on destructive reset.

75.11 Debug across device LifeCycles

The debug access to the system is available in early lifecycles and subsequently based on NVM configuration settings.

After the debug is set to 'Trusted', the system access is allowed after a successful authorization step between the debugger and the system.

The authorization provides provisions to allow debug for Cortex M0+ core and Cortex M7 cores.

Following table shows the debug access based on various configuration bits.

Table 581. Debug access based on LifeCycle and bit configurations

LifeCycle	Configuration bits				Debug access
	DBG_EN_OEM	APP_DIS_OEM	DBG_EN_FLD	APP_DIS_FLD	Appl Core Debug
MCU_PROD	-	-	-	-	Open
	-	-	-	-	Open
CUST_DEL	-	-	-	-	Open
	-	-	-	-	Open
OEM_PROD	0	-	-	-	Closed
	1	0	-	-	Trusted
	1	0	-	-	Trusted
	1	1	-	-	Disabled
IN_FIELD	-	-	0	-	Closed
	-	-	1	0	Trusted
	-	-	1	0	Trusted
	-	-	1	1	Disabled
PRE_FA	-	-	-	-	Trusted
	-	-	-	-	Trusted
FA	-	-	-	-	Open

NOTE

1. **Closed:** Debug is not possible in this state (not even if keys are known - no authentication is possible)
2. **Open:** Debug is always possible
3. **Trusted:** Debug is possible after successful authentication (Challenge/Response handshake with correct credentials)
4. **Disabled:** Debug has been explicitly disabled via burning of a fuse in that LC, otherwise behaves as Closed
5. During functional reset, the debug-enable will retain its last status, while DCM scans NVM for lifecycle and DCF values. Debug status will be re-evaluated once dcm_done gets 1.
6. During temporary advancement of lifecycle, debug-en will immediately reflect the status based on updated lifecycle/DCF bits.

75.12 Pin interface

This table presents a summary of functional and power pins that are used for debugging purposes.

Table 582. Pin interface

Pin type	Pins	Number of pins (balls)[1]	Nominal voltage
Functional JTAG	JCOMP, TCK, TMS, TDI, TDO	Five (only TDI and TDO can be multiplexed with GPIO or other functions)	3.3 V, 5 V
Functional trace pins (parallel trace)	TRACE_CLK	One	3.3 V, 5 V
	TRACE_D[15:0]	16	3.3 V, 5 V
Ground	VSS	See the IOMUX file attached to this document for information on the number of VSS pins in various packages.	0 V

1. The terms pins and balls are used interchangeably. Some chip packages include pins and others include balls.

75.12.1 Debug port and pin descriptions

The pads to which the debug signals are mapped operate using the JTAG functionality out of reset but can later be reassigned to their alternate functionalities. TDI and TDO can operate as alternate GPIO functions. See this table for pin assignments in different modes.

Table 583. Debug port pins

Pin name	JTAG debug port		Internal pullup or pulldown logic
	Type	Description	
TMS	I/O	JTAG test mode selection (TMS)	Pullup
TCK/SWCLK	I	JTAG test clock (TCK)	Pulldown
TDI	I	JTAG test data input (TDI)	Pullup
TDO/TRACESWO	O	JTAG test data output (TDO)	Not connected

75.12.2 Trace port pin descriptions

This chip generates trace via TPIU that transmits the trace data out of the chip over a parallel trace port. The trace port consists of an ETM trace clock and 16 parallel trace data outputs. The Arm optional trace port control (TRACECTRL), debug request (DBGRQ), and debug acknowledge (DBGACK) signals are not implemented.

Table 584. Trace output port pins

Pin name	Description
TRACE_DATA00	ETM parallel trace data output 01
TRACE_DATA01	ETM parallel trace data output 01
TRACE_DATA02	ETM parallel trace data output 02
TRACE_DATA03	ETM parallel trace data output 03
TRACE_DATA04	ETM parallel trace data output 04
TRACE_DATA05	ETM parallel trace data output 05
TRACE_DATA06	ETM parallel trace data output 06
TRACE_DATA07	ETM parallel trace data output 07
TRACE_DATA08	ETM parallel trace data output 08
TRACE_DATA09	ETM parallel trace data output 09
TRACE_DATA10	ETM parallel trace data output 10
TRACE_DATA11	ETM parallel trace data output 11
TRACE_DATA12	ETM parallel trace data output 12
TRACE_DATA13	ETM parallel trace data output 13
TRACE_DATA14	ETM parallel trace data output 14
TRACE_DATA15	ETM parallel trace data output 15
TRACE_CLK	ETM parallel trace clock output

NOTE

By default, Rx pins float and are not pulled inside. An internal active pulldown logic exists only when you enable Rx via software (IBE).

75.13 Timestamp distribution network

The timestamp distribution network uses CoreSight timestamp components to generate a 48-bit timestamp value for the trace sources, as shown in the next figure. The CoreSight timestamp generator generates a 64-bit counter value, but only the least significant 48 bits are distributed to the trace sources. A 7-bit narrow timestamp is derived from the 48-bit timestamp and distributed to the trace client, where a decoder regenerates the 48-bit timestamp. The generator must be programmed, and you could find the related programming information in the *CoreSight Components Technical Reference Manual* (available in References).

This chip supports 48-bit timestamping. The generator operates at a frequency of up to 320 MHz and gives a 64-bit timestamp value..

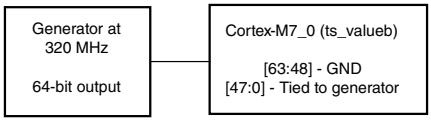

Figure 445. Timestamp distribution network

75.14 Peripheral debug freeze register descriptions

Implement the logic provided in this section for each peripheral instance supporting the debug operation.

NOTE

Debug freeze is enabled for all the peripherals so that as soon as the core halts, peripherals can be frozen to support debugging from the first instruction.

For register details, refer to the following registers in the Device Configuration Module (DCM):

- Read Write GPR On Destructive Reset Register (DCMRWD6)
- Read Write GPR On Destructive Reset Register (DCMRWD7)
- Read Write GPR On Destructive Reset Register (DCMRWD8)
- Read Write GPR On Destructive Reset Register (DCMRWD9)

75.15 MDM_AP register descriptions

The debugger has access to the status and control elements implemented as registers in MDM_AP, which is selected by APSEL (6h) on the DAP bus. These registers provide additional control and status information for typical debug, cross-triggering, and run-control scenarios. Also, the register fields provide a way for the debugger to get the updated status of the core without initiating a bus transaction across the crossbar switch, thus remaining less intrusive during a debug session.

MDM_AP is accessible as DAP (see DAP TAP for details).

75.15.1 MDM_AP memory map

MDM_AP base address: 4025_0600h

Offset	Register	Width (In bits)	Access	Reset value
0h	Status (MDMAPSTTS)	32	RO	7000_0000h

0 —	Reserved

75.15.3 Control (MDMAPCTL)

Offset

Register	Offset
MDMAPCTL	4h

Function

Allows the debugger:

- To give the destructive reset to the system. A system destructive reset enables this. The debugger also loses connection to the system with this reset.
- To hold the system in functional reset. A system functional reset enables this.

NOTE

The trace functionality on trace pins is selected with this register and is retained across the functional reset.

Chapter 76
JTAG Controller (JTAGC)

76.1 Chip-specific JTAGC information

The following figure shows the detailed TAP connectivity. SWD/JTAG SELECT, SWDP and JTAG-DP are part of ARM DAP

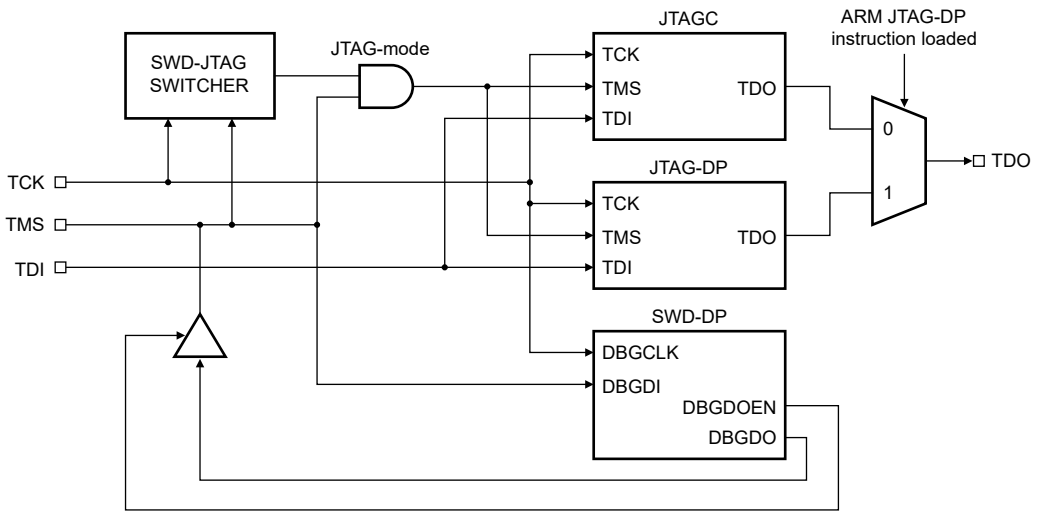

Figure 446. Test and Debug Access Port (TAP) connectivity

The debug port comes out of reset in a standard JTAG mode. It is switched to SWD mode by the change sequences described in JTAG to SWD change sequence . Once the mode has been changed, unused debug pins can be reassigned to any of their alternative muxed functions

JTAG-to-SWD change sequence:

1. Send more than 50 TCK cycles with TMS (SWDIO) =1
2. Send the 16-bit sequence on TMS (SWDIO) = 0111_1001_1110_0111 (MSB transmitted first)
3. Send more than 50 TCK cycles with TMS (SWDIO) =1

NOTE

In case of any reset event, JTAGC is moved to Test Logic Reset (TLR) state first and then JTAGC should be used.

NOTE

If JTAG pins are used for alternative functionality and reset event arrives, then these pins need to be reconfigured to required functionality before using it, in order to avoid unintentional entry in JTAG mode.

76.2 Overview

The JTAGC block provides the means to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE 1149.1-2001 standard. All data input to and output from the JTAGC block is communicated in serial format.

76.2.1 Block diagram

The following is a simplified block diagram of the JTAG Controller (JTAGC) block. See the chip-specific configuration information within this chapter as well as Register description for more information about the JTAGC registers.

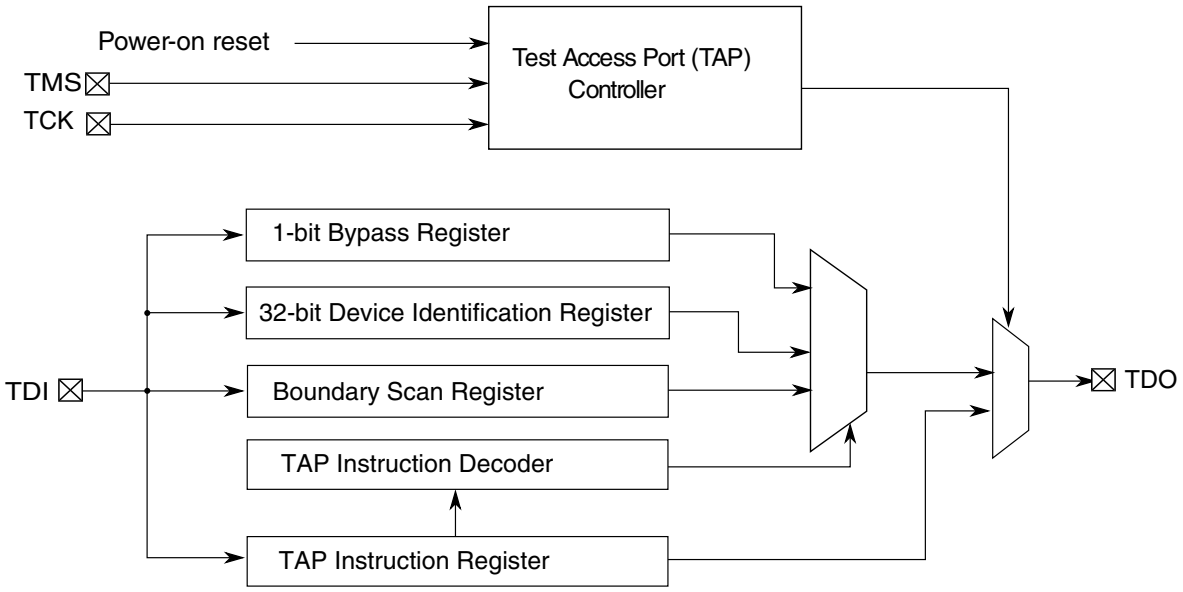

Figure 447. JTAG (IEEE 1149.1) block diagram

76.2.2 Features

The JTAGC block is compliant with the IEEE 1149.1-2001 standard, and supports the following features:

- IEEE 1149.1-2001 TAP interface
  - Four pins (TDI, TMS, TCK, and TDO)
- Instruction register that supports several IEEE 1149.1–2001 defined instructions as well as several public and private device-specific instructions (see JTAGC block instructions for a list of supported instructions).
- Sharing of the TAP with other TAP controllers via ACCESS_AUX_x instructions
- Bypass register, boundary scan register, and device identification register
- TAP controller state machine that controls the operation of the data registers, instruction register, and associated circuitry

76.3 Functional description

This section explains the JTAGC functional description.

76.3.1 Modes of operation

The JTAGC block uses a power-on reset indication as its primary reset signals. Several IEEE 1149.1–2001 defined test modes are supported, as well as a bypass mode.

76.3.1.1 Reset

The JTAGC block is placed in reset when:

- Power-on reset is asserted
- TMS input is held high for enough consecutive rising edges of TCK to sequence the TAP controller state machine into the Test-Logic-Reset state

Holding TMS high for five consecutive rising edges of TCK guarantees entry into the Test-Logic-Reset state regardless of the current TAP controller state. Asserting power-on reset results in asynchronous entry into the reset state.

When in reset, the following actions occur:

- The TAP controller is forced into the Test-Logic-Reset state, thereby disabling the test logic and allowing normal operation of the on-chip system logic to continue unhindered.
- The instruction register is loaded with the IDCODE instruction.

76.3.1.2 IEEE 1149.1–2001 defined test modes

The JTAGC block supports several IEEE 1149.1–2001 defined test modes. A test mode is selected by loading the appropriate instruction into the instruction register when the JTAGC is enabled. Supported test instructions include EXTEST, HIGHZ, CLAMP, SAMPLE, and SAMPLE/PRELOAD.

Each instruction defines the set of data register(s) that may operate and interact with the on-chip system logic when the instruction is current. Only one test data register path is enabled to shift data between TDI and TDO for each instruction.

The boundary scan register is enabled for serial access between TDI and TDO when the EXTEST, SAMPLE, or SAMPLE/PRELOAD instructions are active. The single-bit bypass register shift stage is enabled for serial access between TDI and TDO when the following instructions are active:

- BYPASS
- HIGHZ
- CLAMP

The functionality of each test mode is explained in more detail in JTAGC block instructions.

76.3.1.3 Bypass mode

When no test operation is required, the BYPASS instruction can be loaded to place the JTAGC block into bypass mode. When in bypass mode, the single-bit bypass shift register is used to provide a minimum-length serial path to shift data between TDI and TDO.

76.3.2 JTAGC reset configuration

When in reset, the TAP controller is forced into the Test-Logic-Reset state, thus disabling the test logic and allowing normal operation of the on-chip system logic. In addition, the instruction register is loaded with the IDCODE instruction.

76.3.3 IEEE 1149.1-2001 (JTAG) TAP

The JTAGC block uses the IEEE 1149.1-2001 TAP for accessing registers. This port can be shared with other TAP controllers on the MCU. Ownership of the port is determined by the value of the currently loaded instruction. For more detail on TAP sharing via JTAGC instructions, see ACCESS_AUX_x instructions .

Data is shifted between TDI and TDO through the selected register starting with the least significant bit, as illustrated in the following figure. This applies for the instruction register, test data registers, and the bypass register.

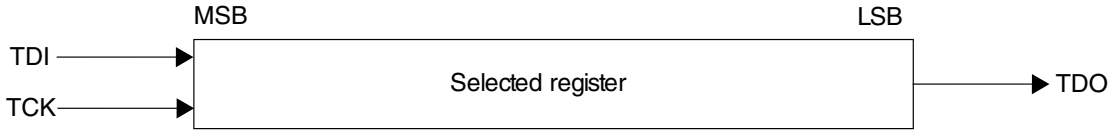

Figure 448. Shifting data through a register

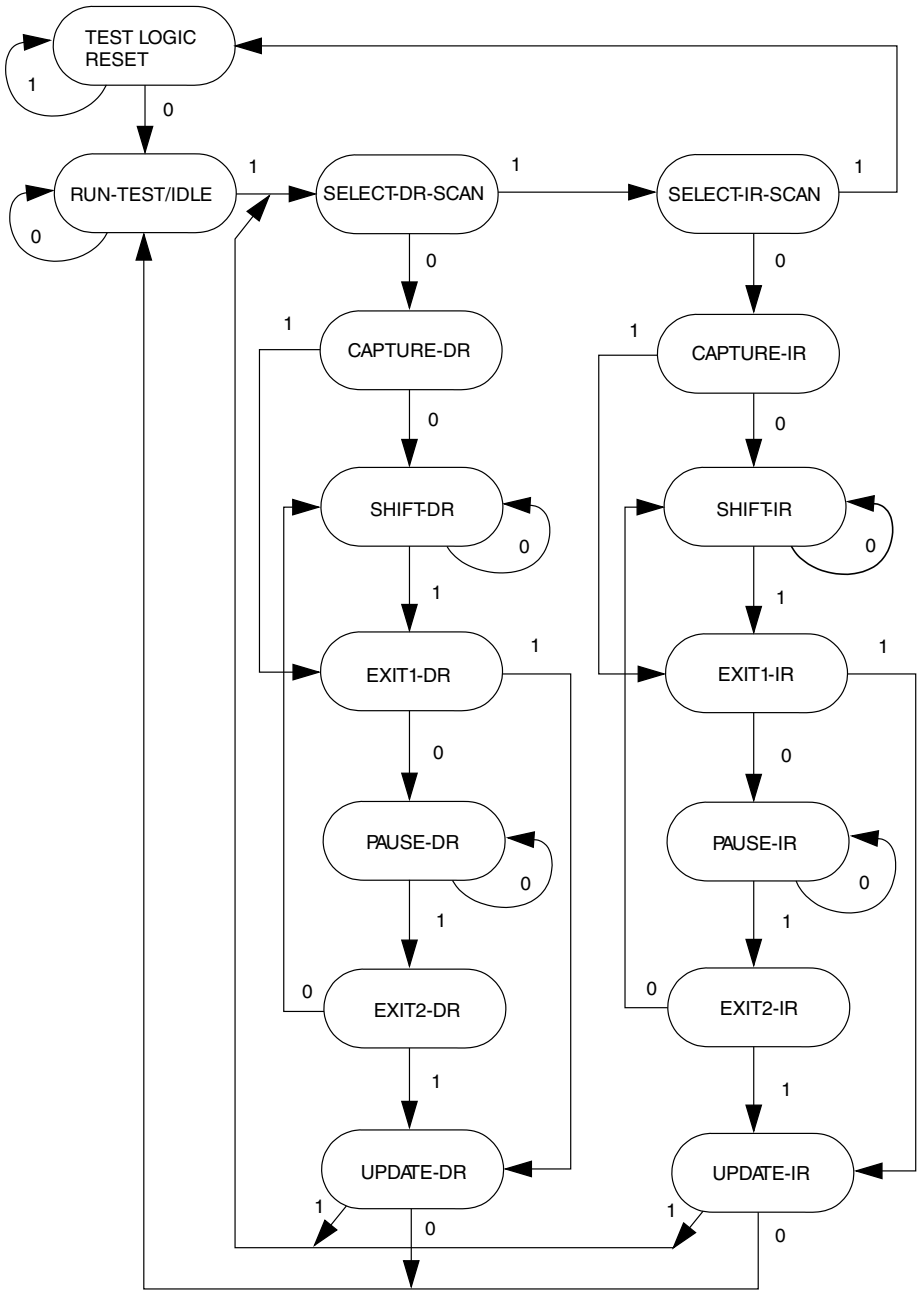
76.3.4 TAP controller state machine

The TAP controller is a synchronous state machine that interprets the sequence of logical values on the TMS pin.

The following figure shows the machine's states. The value shown next to each state is the value of the TMS signal sampled on the rising edge of the TCK signal. As the figure shows, holding TMS at logic 1 when clocking TCK through a sufficient number of rising edges also causes the state machine to enter the Test-Logic-Reset state.



The value shown adjacent to each state transition in this figure represents the value of TMS at the time of a rising edge of TCK.

Figure 449. IEEE 1149.1-2001 TAP controller finite state machine

76.3.4.1 Enabling the TAP controller

The JTAGC TAP controller is enabled by setting the JTAGC enable to a logic 1 value.

76.3.4.2 Selecting an IEEE 1149.1-2001 register

Access to the JTAGC data registers is achieved by loading the instruction register with any of the JTAGC block instructions when the JTAGC is enabled. Instructions are shifted in via the Select-IR-Scan path and loaded in the Update-IR state. At this point, all data register access is performed via the Select-DR-Scan path.

The Select-DR-Scan path is used to read or write the register data by shifting in the data (LSB first) during the Shift-DR state. When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the Capture-DR state. When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the Update-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated after the required number of bits have been acquired.

76.3.5 JTAGC block instructions

The JTAGC implements instructions defined in IEEE 1149.1-2001. See the chip-specific JTAGC information for the JTAGC instructions implemented on this chip. See the IEEE 1149.1-2001 standard for additional information. All undefined opcodes are reserved.

76.3.5.1 IDCODE instruction

IDCODE selects the 32-bit device identification register as the shift path between TDI and TDO. This instruction allows interrogation of the MCU to determine its version number and other part identification data. IDCODE is the instruction placed into the instruction register when the JTAGC block is reset.

76.3.5.2 SAMPLE/PRELOAD instruction

The SAMPLE/PRELOAD instruction has two functions:

- The SAMPLE portion of the instruction obtains a sample of the system data and control signals present at the MCU input pins, and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE/PRELOAD instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. Both the data capture and the shift operation are transparent to system operation.
- The PRELOAD portion of the instruction initializes the boundary scan register cells before selecting the EXTEST or CLAMP instructions to perform boundary scan tests. This is achieved by shifting in initialization data to the boundary scan register during the Shift-DR state. The initialization data is transferred to the parallel outputs of the boundary scan register cells on the falling edge of TCK in the Update-DR state. The data is applied to the external output pins by the EXTEST or CLAMP instruction. System operation is not affected.

76.3.5.3 SAMPLE instruction

The SAMPLE instruction obtains a sample of the system data and control signals present at the MCU input pins, and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. There is no defined action in the Update-DR state. Both the data capture and the shift operation are transparent to system operation.

76.3.5.4 EXTEST external test instruction

EXTEST selects the boundary scan register as the shift path between TDI and TDO. It allows testing of off-chip circuitry and board-level interconnections by driving preloaded data contained in the boundary scan register onto the system output pins. Typically, the preloaded data is loaded into the boundary scan register using the SAMPLE/PRELOAD instruction before the selection of EXTEST. EXTEST asserts the internal system reset for the MCU to force a predictable internal state when performing external boundary scan operations.

76.3.5.5 TEST_LEAKAGE instruction

The TEST_LEAKAGE instruction forces the jtag_leakage output signal to high. It is intended to tristate all output pad buffers and disable all of the part's pad input buffers except JCOMP and TEST. The jtag_leakage signal is asserted at the falling edge of TCK following the TAP controller state machine transition from the Update-IR state to the Run-Test-Idle state. When asserted, the part disables TCK, TMS, and TDI inputs and forces them to a logic 1. The TAP controller state machine remains in the Run-Test-Idle state until the JCOMP input is set to a value other than the JTAGC enable encoding. TEST_LEAKAGE also asserts the internal system reset for the MCU to force a predictable internal state.

76.3.5.6 HIGHZ instruction

HIGHZ selects the bypass register as the shift path between TDI and TDO. When HIGHZ is active all output drivers are placed in an inactive drive state (for example, high impedance). HIGHZ also asserts the internal system reset for the MCU to force a predictable internal state.

76.3.5.7 CLAMP instruction

CLAMP allows the state of signals driven from MCU pins to be determined from the boundary scan register when the bypass register is selected as the serial path between TDI and TDO. CLAMP enhances test efficiency by reducing the overall shift path to a single bit (the bypass register) when conducting an EXTEST type of instruction through the boundary scan register. CLAMP also asserts the internal system reset for the MCU to force a predictable internal state.

76.3.5.8 ACCESS_AUX_x instructions

The JTAGC is configurable to allow other TAP controllers on the device to share the port with it. This is done by providing ACCESS_AUX_x instructions for each of these TAP controllers.

When this instruction is loaded, control of the JTAG pins is transferred to the selected TAP controller. Any data input via TDI and TMS is passed to the selected TAP controller, and any TDO output from the selected TAP controller is sent back to the JTAGC to be output on the pins.

The JTAGC regains control of the JTAG port during the UPDATE-DR state if the PAUSE-DR state was entered. Auxiliary TAP controllers are held in RUN-TEST/IDLE when they are inactive. Instructions not used to access an auxiliary TAP controller on a device are treated like the BYPASS instruction.

76.3.5.9 BYPASS instruction

BYPASS selects the bypass register, creating a single-bit shift register path between TDI and TDO. BYPASS enhances test efficiency by reducing the overall shift path when no test operation of the MCU is required. This allows more rapid movement of test data to and from other components on a board that are required to perform test functions. When the BYPASS instruction is active the system logic operates normally.

76.3.6 Boundary scan

The boundary scan technique allows signals at component boundaries to be controlled and observed through the shift-register stage associated with each pad. Each stage is part of a larger boundary scan register cell, and cells for each pad are interconnected serially to form a shift-register chain around the border of the design. The boundary scan register consists of this shift-register chain, and is connected between TDI and TDO when the EXTEST, SAMPLE, or SAMPLE/PRELOAD instructions are loaded. The shift-register chain contains a serial input and serial output, as well as clock and control signals.

76.4 External signal description

The JTAGC consists of a set of signals that connect to off-chip development tools and allow access to test support functions. The JTAGC signals are outlined in the following table and described in the following sections.

Table 585. JTAG signal properties

Name	I/O	Function	Reset state
TCK	Input	Test clock	Weak pulldown
TDI	Input	Test data in	Weak pullup
TDO	Output	Test data out	High Z[1]
TMS	Input	Test mode select	Weak pullup

1. TDO output buffer enable is negated when the JTAGC is not in the Shift-IR or Shift-DR states. A weak pull may be implemented at the TDO pad for use when JTAGC is inactive.

76.4.1 Test clock input (TCK)

Test Clock Input (TCK) is an input pin used to synchronize the test logic and control register access through the TAP.

76.4.2 Test data input (TDI)

Test Data Input (TDI) is an input pin that receives serial test instructions and data. TDI is sampled on the rising edge of TCK.

76.4.3 Test data output (TDO)

Test Data Output (TDO) is an output pin that transmits serial output for test instructions and data. TDO is tristateable and is actively driven only in the Shift-IR and Shift-DR states of the TAP controller state machine, which is described in TAP controller state machine.

76.4.4 Test mode select (TMS)

Test Mode Select (TMS) is an input pin used to sequence the IEEE 1149.1-2001 test control state machine. TMS is sampled on the rising edge of TCK.

76.5 Initialization/application information

The test logic is a static logic design, and TCK can be stopped in either a high or low state without loss of data. However, the system clock is not synchronized to TCK internally. Any mixed operation using both the test logic and the system functional logic requires external synchronization.

To initialize the JTAGC block and enable access to registers, the following sequence is required:

1. Place the JTAGC in reset through TAP controller state machine transitions controlled by TMS.
2. Load the appropriate instruction for the test or action to be performed.

76.6 Register description

This section provides a detailed description of the JTAGC block registers accessible through the TAP interface, including data registers and the instruction register. Individual bit-level descriptions and reset states of each register are included. These registers are not memory-mapped and can only be accessed through the TAP.

76.6.1 Instruction register

The JTAGC block uses a 8-bit instruction register as shown in the following figure.

The instruction register allows instructions to be loaded into the block to select the test to be performed, or the test data register to be accessed, or both. Instructions are shifted in through TDI when the TAP controller is in the Shift-IR state, and latched on the falling edge of TCK in the Update-IR state. The latched instruction value can only be changed in the Update-IR and Test-Logic-Reset TAP controller states.

Synchronous entry into the Test-Logic-Reset state results in the IDCODE instruction being loaded on the falling edge of TCK. Asynchronous entry into the Test-Logic-Reset state results in asynchronous loading of the IDCODE instruction. During the Capture-IR TAP controller state, the instruction shift register is loaded with the value 0b1, making this value the register's read value when the TAP controller is sequenced into the Shift-IR state.

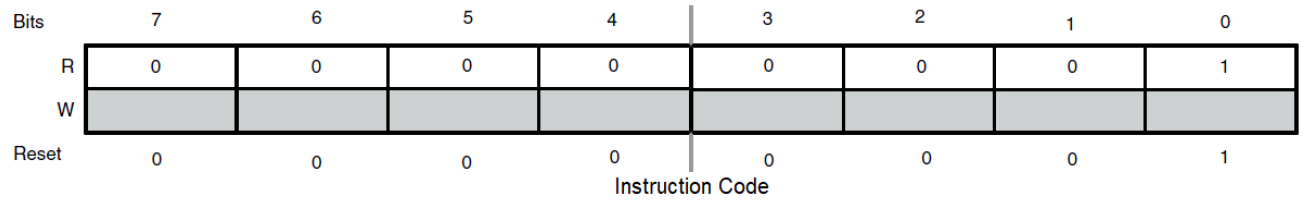


Figure 450. Instruction register

76.6.2 Bypass register

The bypass register is a single-bit shift register path selected for serial data transfer between TDI and TDO when the following instructions are active:

- BYPASS
- HIGHZ
- CLAMP

After entry into the Capture-DR state, the single-bit shift register is set to a logic 0. Therefore, the first bit shifted out after selecting the bypass register is always a logic 0.

76.6.3 Device identification register

The device identification (JTAG ID) register, shown in the following figure, allows the revision number, part number, manufacturer, and design center responsible for the design of the part to be determined through the TAP.

The device identification register is selected for serial data transfer between TDI and TDO when the IDCODE instruction is active. Entry into the Capture-DR state when the device identification register is selected loads the IDCODE into the shift register to be shifted out on TDO in the Shift-DR state. No action occurs in the Update-DR state.

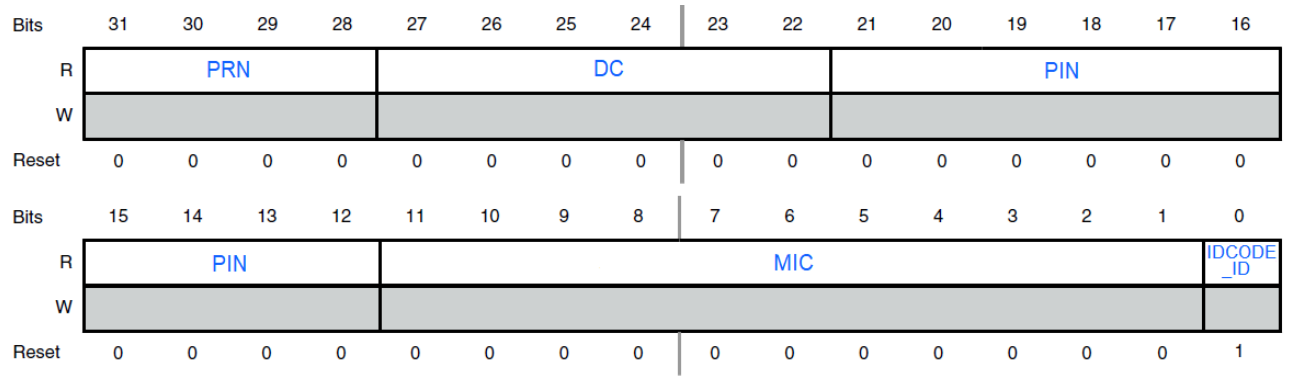

Figure 451. Device identification register

The following table describes the device identification register functions. The device identification register values are described in the chip-specific JTAGC information.

Table 586. Device identification register field descriptions

Field	Function
PRN	Part revision number

Table continues on the next page...

Table 586. Device identification register field descriptions (continued)

Field	Function
	Contains the revision number of the part.
DC	Design center Indicates the design center.
PIN	Part identification number Contains the part number of the device.
MIC	Manufacturer identity code Contains the reduced Joint Electron Device Engineering Council (JEDEC) ID .
IDCODE ID	IDCODE register ID Identifies this register as the device identification register and not the bypass register. Always set to 1.

76.6.4 Boundary scan register

The boundary scan register is connected between TDI and TDO when the EXTEST, SAMPLE, or SAMPLE/PRELOAD instructions are active. It is used to:

- Capture input pin data
- Force fixed values on output pins
- Select a logic value and direction for bidirectional pins

Each bit of the boundary scan register represents a separate boundary scan register cell, as described in the IEEE 1149.1-2001 standard and discussed in Boundary scan. The size of the boundary scan register and bit ordering is device-dependent and can be found in the device BSDL file.

Chapter 77
JTAG Data Communication (JDC)

77.1 Introduction

The JTAG Data Communication (JDC) module provides the capability to move register data between the IPS and JTAG domains. This facilitates communication between internal resources that access memory-mapped register space and an external tool that accesses the JTAG port.

77.2 Overview

The JDC module consists of:

- IPS-accessible registers
- JTAG-accessible registers
- Associated logic to coordinate movement of data from one register domain to another

The JDC implements the following IPS data registers, occupying separate memory space:

- 1 32-bit memory mapped register that can be read or written via IPS (JTAG Output Data Register (JOUT_IPS)), and whose contents are ported out for capture into a JTAG register (JOUT) to be read via the JTAG port.
- 1 32-bit memory mapped register that can only be read via IPS (JTAG Input Data Register (JIN_IPS)), and whose contents are loaded from a JTAG register (JIN).

JDC indicates when:

- New data has been shifted in via the JTAG port and is ready to be read from the JTAG Input Data Register (JIN_IPS) register
- New data has been written to the JTAG Output Data Register (JOUT_IPS) register and is ready to be read via the JTAG port

A Module Status Register (MSR) captures the state of these flags and also provides the flags to a JTAG register (JOUT) for tool visibility.

There is a single bus interface to port register data out to the JTAGC, and a single bus interface to port data in from the JTAGC. The architecture is shown in the following figure.

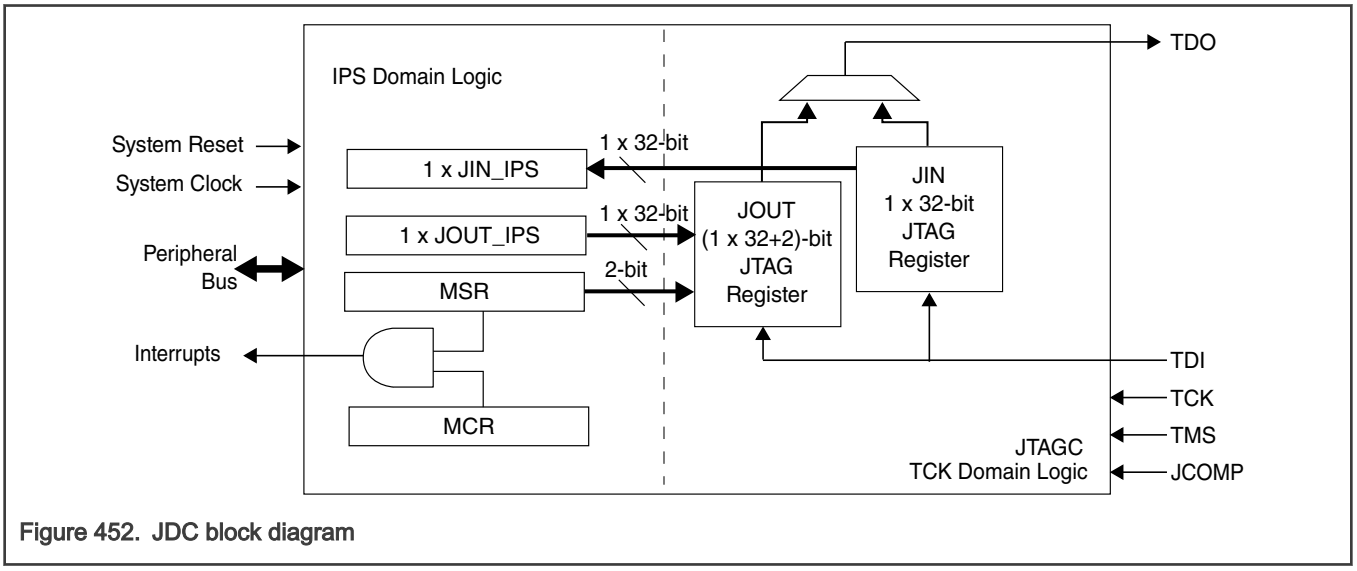

Figure 452. JDC block diagram

77.3 Signal description

JDC signals are listed in the following table.

Table 587. Signal properties

Name	Function	I/O	Reset
TCK	Test clock input	I	—
TMS	Test mode select	I	0
TDI	Test data in	I	0
JCOMP	JTAG compliance pin	I	0
TDO	Test data out	O	HiZ

77.4 Functional description

The JDC module provides the ability to shift in data via the JTAG port and capture that data in memory-mapped register that can be accessed via IPS. It also provides the ability to capture data written to memory-mapped register into a JTAG shift register for output via the JTAG port. An overview of the module functionality is described here.

- Software write to the JOUT_IPS register:
  1. The JDC sets the JOUT_RDY flag bit, indicating new data is available to be read from the JOUT register via the JTAG port.
  2. The MSR reflects the state of the JOUT_RDY bit.
  3. The JDC also captures the state of the JOUT_RDY bit in the JOUT register.
  4. A JTAG read of the JOUT register via execution of the JOUT_READ instruction with a JOUT_RDY bit whose value is logic 1 indicates the register contains new data.
  5. The JDC clears the JOUT_RDY flag bit upon exit of the Capture-DR JTAG state during execution of the JOUT_READ instruction.
  6. Clearing the JOUT_RDY bit indicates to software that a new data value can be written to the JOUT_IPS register.
- JTAG write to the JIN register via execution of the JIN_WRITE JTAG instruction:
  1. The JDC updates the contents of the JIN_IPS register upon exit of the Update-DR state.
  2. An update of the JIN_IPS register sets the JIN_RDY flag bit, indicating new data is available to be read via IPS.
  3. The MSR register reflects the state of the JIN_RDY bit.
  4. The JDC also captures the state of the JIN_RDY bit in the JOUT register.
  5. The JDC clears the JIN_RDY flag bit upon software read of the JIN_IPS register.
  6. A JTAG read of the JOUT register with a JIN_RDY value of logic 0 indicates new data can be written to the JIN register.

77.4.1 JTAG register access

See the JTAGC documentation for information on how to access the JTAG registers.

77.4.1.1 JDC block instructions

The JDC block implements the instructions listed in Table 588. This section gives an overview of each instruction. All undefined opcodes are reserved.

Table 588. JTAG instructions

Instruction	Code[4:0]	Instruction summary
Reserved	00001	Factory debug reserved.
JOUT_READ	00010	Selects JOUT data register. The JDC captures data from JOUT_IPS into JOUT data register upon entry to Capture-DR state when JOUT_READ is active.
JIN_WRITE	01110	Selects JIN data register. The JDC captures data from JIN into JIN_IPS upon exit of Update-DR state when JIN_WRITE is active.
BYPASS[1]	11111	Selects bypass register for data operations.
Reserved	All other opcodes	Decoded to select bypass register.

1. This is an IEEE 1149.1-2001 defined instruction. See the IEEE 1149.1-2001 standard for more details.

77.5 Secure challenge/response connection procedure

A summary of how the JDC can be used to interact with a security module to perform challenge/response password authorization is as follows:

1. After exit of reset, all registers are at their reset values. JIN_RDY bit value of 0 indicates the tool may write data to the JIN register. JOUT_RDY bit value of 0 indicates that software may write data to the JOUT_IPS register.
2. The MCR register is programmed to enable JOUT and JIN interrupts, or not.
3. Once the tool is ready to start the authorization process, it writes a value to the JIN register via execution of the JTAGC JIN_WRITE instruction.
4. Software monitors the state of the JIN_RDY bit or enables the JIN interrupt and uses the interrupt assertion as a trigger to start the authorization process.
5. Once the authorization process is started, software writes the first JOUT value to the JOUT_IPS register. This sets the JOUT_RDY bit value to 1.
6. Following the initial tool write to the JIN register, the tool polls the JOUT register to determine when software has provided a challenge word. Upon reading the JOUT register with JOUT_RDY bit set, the tool records the data value to be used to generate the appropriate response. The read of the JOUT register clears the JOUT_RDY bit. The clearing of the JOUT_RDY bit also sets the JOUT_INT bit and asserts the JOUT interrupt if the MCR[JOUT_IEN] is set.
7. With the JOUT_RDY bit cleared, software may now provide the next challenge word.
8. Once the tool has generated a response word, it uses the value of the JIN_RDY bit from the JOUT register read to determine when it can perform a write to the JIN register to provide the response.
9. The security module can provide additional challenge words and read back the corresponding response words as needed, repeating the process.

Simply providing a password without using the challenge/response protocol can be done in a similar way. The tool provides 32-bits of the password at a time with each write to the JIN register, and monitors the JIN_RDY bit value of the JOUT register to determine when the next JIN register value can be written. There is no need for software to write the JOUT_IPS register in this case.

For details related to the lifecycle stage at which this process is performed, see the "Hardware Security Engine" chapter.

77.6 JDC register descriptions

The following sections describe the implemented 32-bit registers. Only 32-bit accesses are valid. The effects of access that are not 32 bits are not defined.

77.6.1 JDC memory map

JDC base address: 4039_4000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Module Configuration Register (MCR)	32	RW	0000_0000h
4h	Module Status Register (MSR)	32	W1C	0000_0000h
8h	JTAG Output Data Register (JOUT_IPS)	32	RW	0000_0000h
Ch	JTAG Input Data Register (JIN_IPS)	32	RO	0000_0000h

77.6.2 Module Configuration Register (MCR)

Offset

Register	Offset
MCR	0h

Function

The MCR enables the interrupt outputs of the JDC. This register is reset by system destructive reset.

77.7 Non-memory-mapped register definition

The JDC also implements two JTAG accessible registers that are not memory-mapped. One JTAG register shifts in data to be placed in the JIN_IPS register. The other JTAG register captures data from the JOUT_IPS register plus ready status from the MSR, to be shifted out via the JTAG port.

77.7.1 JTAG output data register (JOUT)

The JOUT register captures data from the JOUT_IPS register upon execution of the JOUT_READ JTAG instruction. It also holds the JIN_RDY and JOUT_RDY status bits. This register is reset by system destructive reset and JTAG reset. The reset value of the JOUT register is 0. The following figure shows the format of the JOUT register.

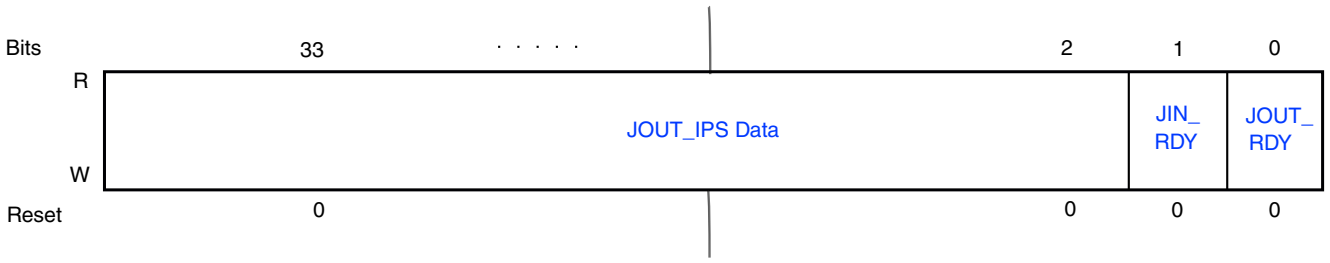

Figure 453. JOUT

The JOUT register is described in the following table.

Table 589. JOUT JTAG register field descriptions

Field	Function
JOUT_IPS Data	JOUT_IPS Data Data value from JOUT_IPS register
JIN_RDY	JIN_RDY State of JIN_RDY bit from MSR
JOUT_RDY	JOUT_RDY State of JOUT_RDY bit from MSR

77.7.2 JTAG input data register (JIN)

The external tool writes data to the JIN register via JTAG during execution of the JIN_WRITE JTAG instruction. The JDC later captures JIN data in the JIN_IPS register to be read via IPS. This register is reset by system destructive reset and JTAG reset. The reset value of the JIN register is 0. The following figure shows the format of the JIN register.

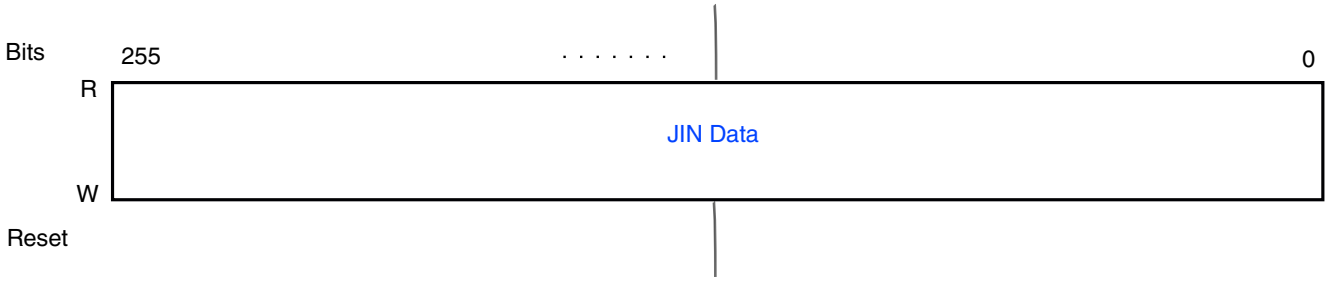

Figure 454. JIN

The JIN register is described in the following table.

XBAR	Crossbar bus interface

Chapter 78
Temperature Sensor (TempSense)

78.1 Introduction

The TEMPSENSE module contains control registers for use with the Temperature Sensor hard block. These registers use a peripheral bus interface to communicate with the chip.

78.1.1 Overview

TEMPSENSE is used to measure the temperature on the chip through an ADC.

78.1.2 Block diagram

The functional structure of the TEMPSENSE can be seen in the block diagram in Figure 455.

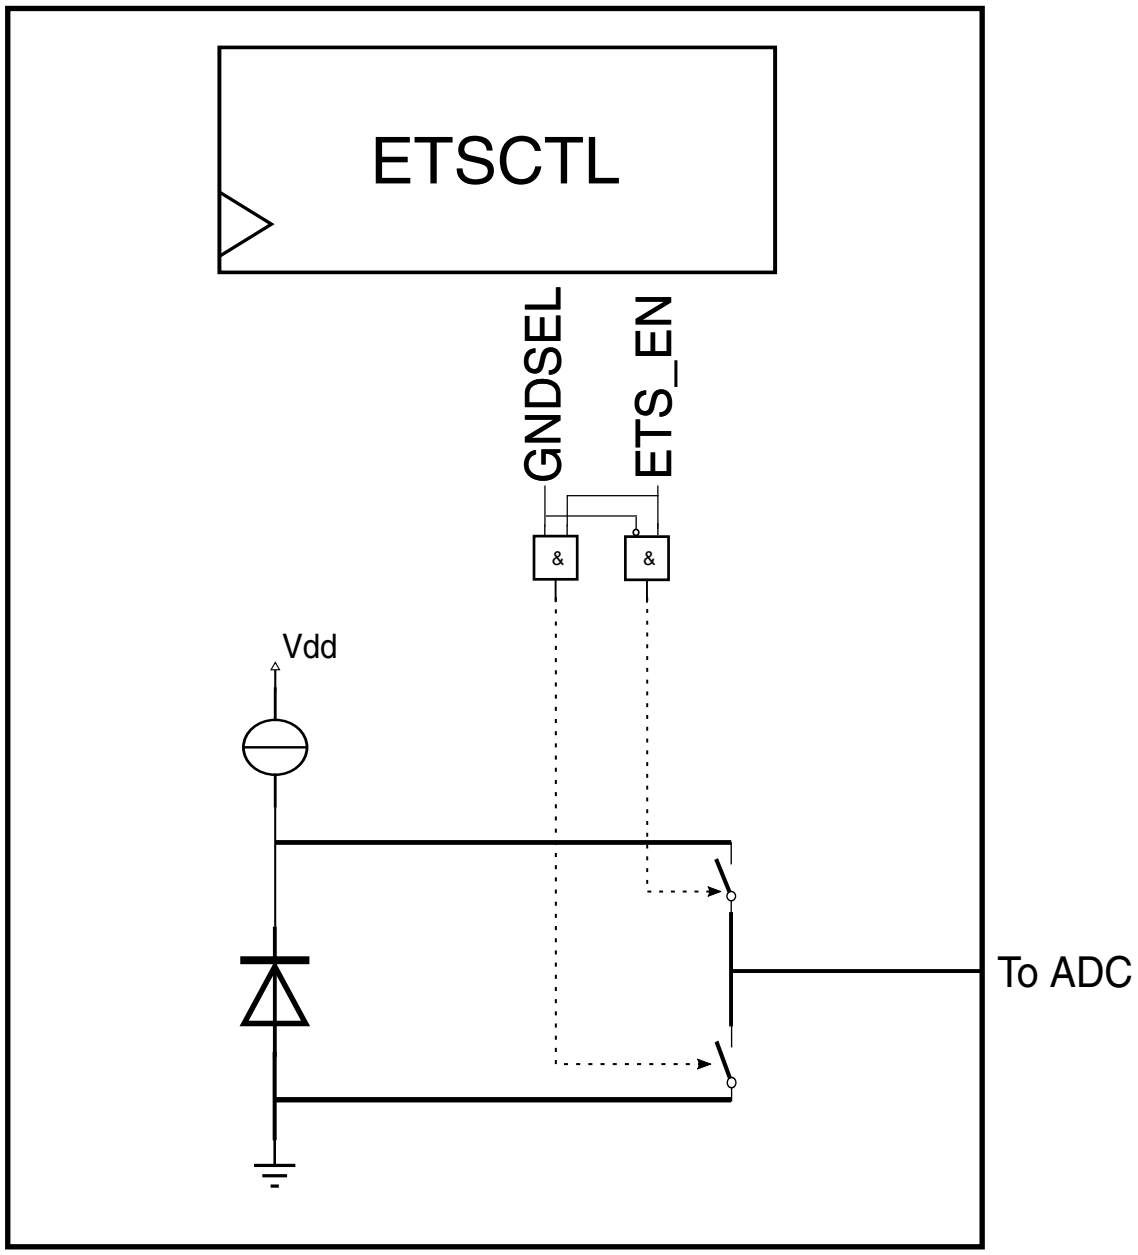

Figure 455. TEMPSENSE block diagram

78.1.3 Features

The TEMPSENSE includes the following features:

- Provide a voltage proportional to the temperature which will be read out by ADC
- Ground selection for improved precision in the ETS. The ETS ground could be different from the ADC ground. By exposing it to the ADC, the temperature calculation could be improved as the voltage value will be more precise.

78.2 Functional description

78.2.1 General

The TEMPSENSE module is designed to measure the temperature on the chip. The TEMPSENSE output can be read by an ADC on demand so that the software can determine the current die temperature. The software should enable the TEMPSENSE by setting ETSCTL[ETS_EN].

Coefficients are used to allow a simple and accurate calculation of linearized temperature directly from the ADC. The increase of the sampling time of the ADC from the minimum sampling value is increasing the temperature accuracy.

78.2.2 Conversion voltage Temperature

Solve the equation for the conversion from voltage to temperature. where V_{ETS} is the difference of V_{be} and V_{GND}. V_{GND} is expose on the ADC output when ETSCTL[GNDSEL] is set.

$$T_{ETS} = TCA_0 + TCA_1 \cdot V_{ETS} + TCA_2 \cdot V_{ETS}^2$$

The coefficients TCA0, TCA1 and TCA2 are read from the corresponding registers. They are stored in a signed fixed-point format as the folowing TCAx(11,4) (1 bit for the sign, 11 bits for the integer part and 4 bits for the decimal part).

The calculation of the temperature should be done with the actual coefficient values provided in the TCAx fields. See the example below for an ambient temperature of 25C, and an ADC reference voltage of 5V.

$$TCA0 = (000110100100.1110)_2 = (000110100100)_2 + (1110)_2 \times \frac{1}{2^4} = +((420)_{10} + (14)_{10} \times \frac{1}{2^4}) = +420.8750\ C$$

$$TCA1 = (100010101111.1110)_2 = (100010101111)_2 + (1110)_2 \times \frac{1}{2^4} = -((175)_{10} + (14)_{10} \times \frac{1}{2^4}) = -175.8750\ C/V$$

$$TCA2 = (100000011101.1110)_2 = (100000011101)_2 + (1110)_2 \times \frac{1}{2^4} = -((29)_{10} + (14)_{10} \times \frac{1}{2^4}) = -29.8750\ C^2/V^2$$

$$V_{ETS} = (010110001011)_2 = (1419)_{10} \times \frac{Vref}{2^{12}} = 1.7322\ V$$

By using the formula the junction temperature calculated is 26.5838 C.

The maximal calculation error is 0.0313 Degrees

If the supply of the ETS module is 3.3V, a conversion is necessary to calculate the accurate temperature.

$$V_{ETS} = (100001100110)_2 = (2150)_{10} \times \frac{Vrefadc}{2^{12}} \times \frac{Vsupply}{Vrefadc} = (2150)_{10} \times \frac{Vsupply}{2^{12}} = 1.7322\ V$$

78.3 Memory map and register definition

78.3.1 Transfer error description

The following actions will cause a transfer error and will not change the register content:

- Any access to an unused register address
- Write access to a read-only register (TCAx)

78.3.2 TempSense register descriptions

78.3.2.1 TempSense memory map

TEMPSENSE base address: 4037_C000h

Offset	Register	Width (In bits)	Access	Reset value
0h	ETS Control (ETSCTL)	32	RW	0000_0000h
8h	Temperature Coefficient (TCA0)	32	RO	See description
Ch	Temperature Coefficient (TCA1)	32	RO	See description
10h	Temperature Coefficient (TCA2)	32	RO	See description

78.3.2.2 ETS Control (ETSCTL)

Offset

Register	Offset
ETSCTL	0h

Diagram

Legal information

Definitions

Draft — A draft status on a document indicates that the content is still under internal review and subject to formal approval, which may result in modifications or additions. NXP Semiconductors does not give any representations or warranties as to the accuracy or completeness of information included in a draft version of a document and shall have no liability for the consequences of use of such information.

Disclaimers

Limited warranty and liability — Information in this document is believed to be accurate and reliable. However, NXP Semiconductors does not give any representations or warranties, expressed or implied, as to the accuracy or completeness of such information and shall have no liability for the consequences of use of such information. NXP Semiconductors takes no responsibility for the content in this document if provided by an information source outside of NXP Semiconductors.

In no event shall NXP Semiconductors be liable for any indirect, incidental, punitive, special or consequential damages (including - without limitation - lost profits, lost savings, business interruption, costs related to the removal or replacement of any products or rework charges) whether or not such damages are based on tort (including negligence), warranty, breach of contract or any other legal theory.

Notwithstanding any damages that customer might incur for any reason whatsoever, NXP Semiconductors' aggregate and cumulative liability towards customer for the products described herein shall be limited in accordance with the Terms and conditions of commercial sale of NXP Semiconductors.

Right to make changes — NXP Semiconductors reserves the right to make changes to information published in this document, including without limitation specifications and product descriptions, at any time and without notice. This document supersedes and replaces all information supplied prior to the publication hereof.

Suitability for use — NXP Semiconductors products are not designed, authorized or warranted to be suitable for use in life support, life-critical or safety-critical systems or equipment, nor in applications where failure or malfunction of an NXP Semiconductors product can reasonably be expected to result in personal injury, death or severe property or environmental damage. NXP Semiconductors and its suppliers accept no liability for inclusion and/or use of NXP Semiconductors products in such equipment or applications and therefore such inclusion and/or use is at the customer's own risk.

Applications — Applications that are described herein for any of these products are for illustrative purposes only. NXP Semiconductors makes no representation or warranty that such applications will be suitable for the specified use without further testing or modification.

Customers are responsible for the design and operation of their applications and products using NXP Semiconductors products, and NXP Semiconductors accepts no liability for any assistance with applications or customer product design. It is customer's sole responsibility to determine whether the NXP Semiconductors product is suitable and fit for the customer's applications and products planned, as well as for the planned application and use of customer's third party customer(s). Customers should provide appropriate design and operating safeguards to minimize the risks associated with their applications and products.

NXP Semiconductors does not accept any liability related to any default, damage, costs or problem which is based on any weakness or default in the customer's applications or products, or the application or use by customer's third party customer(s). Customer is responsible for doing all necessary testing for the customer's applications and products using NXP Semiconductors products in order to avoid a default of the applications and the products or of the application or use by customer's third party customer(s). NXP does not accept any liability in this respect.

Terms and conditions of commercial sale — NXP Semiconductors products are sold subject to the general terms and conditions of commercial sale, as published at http://www.nxp.com/profile/terms, unless otherwise agreed in a valid written individual agreement. In case an individual agreement is concluded only the terms and conditions of the respective agreement shall apply. NXP Semiconductors hereby expressly objects to applying the customer's general terms and conditions with regard to the purchase of NXP Semiconductors products by customer.

Export control — This document as well as the item(s) described herein may be subject to export control regulations. Export might require a prior authorization from competent authorities.

Suitability for use in non-automotive qualified products — Unless this data sheet expressly states that this specific NXP Semiconductors product is automotive qualified, the product is not suitable for automotive use. It is neither qualified nor tested in accordance with automotive testing or application requirements. NXP Semiconductors accepts no liability for inclusion and/or use of non-automotive qualified products in automotive equipment or applications.

In the event that customer uses the product for design-in and use in automotive applications to automotive specifications and standards, customer (a) shall use the product without NXP Semiconductors' warranty of the product for such automotive applications, use and specifications, and (b) whenever customer uses the product for automotive applications beyond NXP Semiconductors' specifications such use shall be solely at customer's own risk, and (c) customer fully indemnifies NXP Semiconductors for any liability, damages or failed product claims resulting from customer design and use of the product for automotive applications beyond NXP Semiconductors' standard warranty and NXP Semiconductors' product specifications.

Translations — A non-English (translated) version of a document, including the legal information in that document, is for reference only. The English version shall prevail in case of any discrepancy between the translated and English versions.

Security — Customer understands that all NXP products may be subject to unidentified vulnerabilities or may support established security standards or specifications with known limitations. Customer is responsible for the design and operation of its applications and products throughout their lifecycles to reduce the effect of these vulnerabilities on customer's applications and products. Customer's responsibility also extends to other open and/or proprietary technologies supported by NXP products for use in customer's applications. NXP accepts no liability for any vulnerability. Customer should regularly check security updates from NXP and follow up appropriately.

Customer shall select products with security features that best meet rules, regulations, and standards of the intended application and make the ultimate design decisions regarding its products and is solely responsible for compliance with all legal, regulatory, and security related requirements concerning its products, regardless of any information or support that may be provided by NXP.

NXP has a Product Security Incident Response Team (PSIRT) (reachable at PSIRT@nxp.com) that manages the investigation, reporting, and solution release to security vulnerabilities of NXP products.
